and 90 days (2 hours/day, 5 days/week) to investigate the development of myocardial hypertrophy (heart/body weight ratio, mRNA expression of hypertrophy markers via real-time RT-PCR, and protein expression via immunoblots). Basal heart function was determined *in vitro* by Langendorff-perfusion. Blood pressure and heart rate were monitored *in vivo* via telemetric analysis. Due to a reduced increase in body weight, the MS groups had an approximately 20% larger increase in heart/body weight ratio after just 30 days ( $5.83 \pm 0.29$  versus  $4.94 \pm 0.35$  mg/g;  $p < 0.01$ ) accompanied by elevated basal heart function (left ventricular developed pressure:  $103.9 \pm 5.9$  vs.  $83.3 \pm 6.5$  mm Hg,  $p < 0.01$ ). The mRNA expression of myocardial hypertrophy markers, i.e., atrial natriuretic factor, ornithine decarboxylase, and TGF- $\beta$ , increased in both ventricles (more pronounced at 90 days than at 30 days). In the sham groups these markers were less increased in the left ventricle and did not change over time in the right ventricle. Increases in ANF and TGF- $\beta$  were confirmed on the protein level in the 90-day MS group. There were no measurable differences for blood pressure or heart rate between MS and sham groups. The mRNA expression for calcium-handling proteins (SERCA2A and NCX) did not change. At the same time, there was less  $\beta$ -adrenergic response in heart function to isoproterenol (100 nM). SHR exposed to MS showed a faster progression of myocardial hypertrophy with a reduction in  $\beta$ -adrenergic response. This effect is independent of hypertension and occurs in both ventricles. The data suggest the acceleration of cardiac dysfunction development by sub-chronic MS exposure in rats.

## CIGARETTE SMOKE ENHANCES ENDOTOXIN-INDUCED PULMONARY INFLAMMATION.

G. Kulkarni, P. Nadkarni, J. M. Cerreta and J. O. Cantor. Department of Pharmaceutical Sciences, Saint John's University, Jamaica, NY. Sponsor: L. Trombetta.

Long-term cigarette smoke exposure induces chronic pulmonary inflammation, leading to asthma, bronchitis, and emphysema. However, the short-term effects of smoke inhalation are less clear, since they are not generally associated with significant changes in lung morphology. Indeed, acute smoke exposure may adversely affect the lung only if underlying disease is present. To test this hypothesis, Syrian hamsters pretreated with 0.2 mg E. coli endotoxin were passively exposed to cigarette smoke for 2 hrs per day over a period of 3-5 days. Controls were also given endotoxin, but continuously exposed to room air instead. All the animals were euthanized 24 hr after the last smoking session. Bronchoalveolar lavage (BAL) was then performed to measure the pulmonary inflammatory response. Compared to controls, animals receiving both endotoxin and cigarette smoke showed a 155% increase in lavaged neutrophils at 3 days (19.6% vs 7.70%;  $p < 0.05$ ) and a 203% increase at 5 days (16.47% vs 6.33%;  $p < 0.05$ ). Elevations in lymphocyte counts were also seen in the smoke-exposed group at both time points (67% and 57%, respectively). Such results indicate that short-term inhalation of cigarette smoke can enhance pre-existing lung inflammation. More importantly, these findings provide further evidence that persons with underlying lung disease may be adversely affected by even limited amounts of second-hand smoke.

TETRAHYDROCANNABINOL CAUSES PULMONARY CELL MITOCHONDRIAL INJURY *IN VITRO* AND *IN VIVO*.

T. A. Sarafian<sup>1</sup>, N. Habib<sup>1</sup>, M. J. Oldham<sup>2</sup>, N. Seeram<sup>1</sup>, R. Lee<sup>1</sup>, D. P. Tashkin<sup>1</sup> and M. D. Roth<sup>1</sup>. <sup>1</sup>Medicine, UCLA, Los Angeles, CA and <sup>2</sup>Community and Environmental Medicine, UC Irvine, Irvine, CA.

Habitual marijuana smoking is associated with chronic bronchitis and inflammation of the upper bronchial airways. We have demonstrated previously that *in vitro* exposure of lung epithelial cells to whole marijuana smoke or to tetrahydrocannabinol (THC), the primary psychoactive component of marijuana, results in decreased cellular ATP levels. Examination of mitochondria in these cells using the fluorescent potentiometric probe, JC-1, revealed THC-induced loss of mitochondrial membrane potential. This loss was only partially reversible following THC removal and was attenuated by cyclosporin A, suggesting a role for the permeability transition pore. Particulate smoke extracts from marijuana cigarettes also impaired mitochondrial membrane potential whereas tobacco or placebo (0% THC) marijuana smoke extracts produced minimal effects. We have established an *in vivo* smoke inhalation model using the rat. Using a cross-flow nose-only inhalation model system, 20 min exposure to marijuana smoke produced blood THC levels ranging from 2-15 ng/ml and lung levels of 46-76 ng/g wet wt tissue. Values varied as a function of total smoke consumed. Following *in situ* JC-1 staining of lungs by intratracheal infusion, red JC-1 fluorescence, characteristic of mitochondrial staining, was greatly diminished throughout the lungs of rats exposed to marijuana smoke. These results suggest that inhalation of marijuana smoke may have deleterious effects on lung cell energetics and may contribute to adverse health effects observed in humans. (Supported by NIH Grant R37 DA03018).

SPONTANEOUSLY HYPERTENSIVE RATS ARE SUSCEPTIBLE TO AIRWAY DISEASE INDUCED BY SULFUR DIOXIDE.

M. C. Schladweiler<sup>1</sup>, A. D. Ledbetter<sup>1</sup>, D. L. Costa<sup>1</sup>, K. E. Pinkerton<sup>2</sup>, J. H. Richards<sup>1</sup>, P. Evansky<sup>1</sup> and U. P. Kodavanti<sup>1</sup>. <sup>1</sup>NHEERL/ETD/PTB, USEPA, Durham, NC and <sup>2</sup>UC Davis, Davis, CA.

Rodent models of chronic pulmonary diseases induced by sulfur dioxide (SO<sub>2</sub>), elastase or tobacco smoke have limited utility because of their lack of chronicity of inflammation, and they demonstrate limited sensitivity to a given experimental manipulation. We hypothesized that disease susceptibility from experimental exposures require unique genetic predisposition. Spontaneously hypertensive (SH) rats, with genetic susceptibility to cardiovascular disease, and Sprague Dawley (SD) rats were exposed: 1) nose-only to SO<sub>2</sub> at 0, 250 or 350 ppmx5h/dx4d; 2) to porcine pancreatic elastase (PPE), intratracheal (IT) at 0, 400, 800 or 1200 U/kg; or 3) to SO<sub>2</sub> (only SH rats pre-exposed to PPE at 0 or 800 U/Kg, IT, 1 week prior) at 0 or 350 ppm, 5h/dx4d. Pulmonary functional and biological impairments were evaluated. PPE caused severe pulmonary injury and inflammation in SD rats. The severity of acute injury was less in SH rats but inflammation persisted for a longer time following exposure. In contrast to PPE, SO<sub>2</sub>-induced neutrophilic inflammation was 30-40 fold higher in SH than in SD rats, and was associated with an increase in alveolar macrophages. These changes in SH rats persisted for up to 7 days. Although the inflammatory response was higher in SH rats, SO<sub>2</sub>-induced changes in breathing parameters were not significantly different between SH and SD rats. We then hypothesized that SO<sub>2</sub>-induced inflammation would be more severe in PPE-pretreated SH rats. Neither pulmonary injury nor inflammation was greater in PPE-pretreated SH rats, except for a slightly greater increase in alveolar macrophages. Similarly, the plethysmographic measurement of breathing parameters indicated marginally greater PenH values following the PPE+SO<sub>2</sub> exposure. In conclusion, SH rats demonstrated several fold greater inflammatory response to SO<sub>2</sub> than SD rats, but the strain differences were not marked in regards to effects on breathing parameters. Also, PPE-induced injury is not exacerbated by subsequent SO<sub>2</sub> exposure. (Does not reflect USEPA policy).

HOST-DEPENDENT INCREASE IN LUNG EPITHELIAL MEMBRANE PERMEABILITY AFTER O<sub>3</sub>.

E. McElvania TeKippe, K. G. Berman, J. W. Hollingsworth II, D. A. Schwartz and W. Foster. *Pulmonary, Allergy, and Critical Care, Duke University, Durham, NC*.

Ozone (O<sub>3</sub>), an ambient air pollutant and strong oxidant, when inhaled can lead to an inflammatory response characterized by polymorphonuclear (PMN) cell infiltration of lung tissue and PMN recruitment into the airspaces. To better understand the role of host defense in O<sub>3</sub>-induced inflammation we investigated the lung response of 9 genetically diverse inbred strains of mice (129/Svlm, A/J, BALB/cJ, BTBR, C3H/Hej, C57Bl/6J, DBA/2J, FVB/NJ, and CAST/EI) to a 3 h exposure to 2 ppm O<sub>3</sub>. Age-matched male controls were exposed to filtered air (FA). Based upon the number of PMNs in bronchoalveolar lavage (BAL) fluid collected at sacrifice, 6 or 24 h post-exposure, we selected resistant, C3H/Hej (CHJ), and a susceptible, 129/Svlm (129S), strains for further evaluation to determine if epithelial membrane integrity, was a co-determinant of host vulnerability to O<sub>3</sub>. Additional CHJ and 129S mice were exposed to FA or O<sub>3</sub> and evaluated 24 h post-exposure. BAL results replicated the differential inflammatory cell responses observed previously. Mice, not undergoing BAL, were anesthetized and were studied *in vivo* with a non-invasive radio-isotopic marker (Tc99m-DTPA) to assess epithelial membrane integrity. Transference of the permeable marker (MW = 490 dalt, molec radius = 0.57 nm) from the lung to the vasculature was monitored by scintigraphy and recorded dynamically. In O<sub>3</sub>-susceptible 129S mice, Tc99m transference half-times were decreased on average by 43% (n=6, epithelium more permeable) as compared to half-times of FA controls (n=6); whereas for O<sub>3</sub>-resistant CHJ mice, transference half-times were equivalent between FA and O<sub>3</sub> exposed mice (n=6 each). If O<sub>3</sub>-treated 129S mice were permitted to recover, Tc99m transference half-times returned to normal values within 7 days. These data suggest that O<sub>3</sub>-induced inflammatory cell responses are strain dependent, and that airway recruitment of PMNs following an acute exposure to O<sub>3</sub> may co-depend upon the integrity of the epithelial membrane. Research sponsored by NIH awards: HL62641, ES012496, ES011961.

EVALUATION OF THE SENSITIVITY TO INHALED OXIDANTS IN CSB MICE.

I. M. Kooter<sup>1</sup>, P. H. Fokkens<sup>1</sup>, D. L. Leseman<sup>1</sup>, J. F. Boere<sup>1</sup>, M. E. Gerlofs Nijland<sup>1</sup>, H. van Steeg<sup>2</sup> and F. R. Cassee<sup>1</sup>. <sup>1</sup>MGO, RIVM, Bilthoven, Netherlands and <sup>2</sup>TOX, RIVM, Bilthoven, Netherlands. Sponsor: H. van Loveren.

To study oxidative stress as a mechanism for the health effects caused by air pollution, Cockayne syndrome B (CSB) mice were exposed to the model oxidant, ozone. CSB-/- mice are deficient in their transcription coupled repair. CSB-/- and +/- mice

were either exposed for 8 hours to 0.8 ppm ozone or clean air. Clear pathological changes in the lung due to ozone, as well an increase of neutrophils were observed in both CSB-/- and CSB+/- mice. The ozone exposed CSB-/- mice show a stronger increase in antioxidant levels (total glutathione and uric acid) and a significant increase in TNFa in broncho alveolar lavage fluid compared to their +/- wild types. These results are compared with the gene expression profile in whole lung tissue using the micro-array technique. We concluded that ozone, as a model oxidant, affects the CSB-/- mice more than its wild type counterpart. The data provide support to use this model in future studies to investigate the role of oxidative stress in health effects due to air pollution.

ZINC DEFICIENCY ENHANCES PRO-INFLAMMATORY RESPONSES AFTER OZONE EXPOSURE.

I. Jaspers<sup>1,3</sup>, K. A. Bridge<sup>2</sup>, M. Doyle<sup>2</sup>, K. Sexton<sup>2</sup>, E. Ho<sup>4</sup>, M. Styblo<sup>3</sup> and H. Jeffries<sup>2</sup>. <sup>1</sup>CEMALB, University of North Carolina, Chapel Hill, NC, <sup>2</sup>ESE, University of North Carolina, Chapel Hill, NC, <sup>3</sup>Pediatrics, University of North Carolina, Chapel Hill, NC and <sup>4</sup>Nutrition, Oregon State University, Corvallis, OR.

Previous studies have demonstrated that humans are differentially susceptible to adverse health effects induced by exposure to ozone. Serum analysis have shown that the elderly (people >65 years) are deficient in several key vitamins and trace elements, including zinc (Zn). The trace element Zn is essential for the function of several key signaling molecules and antioxidant enzymes, meaning insufficient dietary Zn intake and consequently low intracellular Zn levels could potentially alter the susceptibility to air pollution. We have established an *in vitro* model of human respiratory epithelial cells (A549 cells) grown under Zn-deficient (Zn-DF) or Zn-inadequate (Zn-AD) conditions. Culturing these cells under Zn-DF conditions significantly reduces their intracellular Zn levels and the activity of key Zn-dependent enzymes, such as Cu, Zn-SOD, while the activity Zn-independent antioxidant enzymes, such as catalase and glutathione peroxidase, remain unchanged. Zn-AD and Zn-DF cells grown on membranes were exposed to 0.2 ppm ozone for 5 hours and subsequently analyzed for LDH release and the release of pro-inflammatory cytokines, such as IL-8, MCP-1, and IL-6. Ozone exposure caused similar LDH release in both Zn-AD and Zn-DF cells. Interestingly, ozone induced greater release of IL-8, MCP-1, and IL-6 into the apical compartment of Zn-DF cells as compared to Zn-AD cells, while ozone-induced cytokine release into the basolateral compartment was similar in Zn-DF and Zn-AD cells. These data suggest that Zn-DF respiratory epithelial cells are more susceptible to adverse inflammatory effects induced by ozone exposure and that ozone-induced cytokine release is greater towards the apical side than the basolateral side. Overall, these results suggest that the nutritional status of individuals could influence their susceptibility to air pollutant-induced health effects.

MECHANISMS REGULATING ACTIVATION OF MACROPHAGES IN THE LUNG FOLLOWING OZONE INHALATION.

A. Conner<sup>1,3</sup>, J. D. Laskin<sup>2,3</sup> and D. L. Laskin<sup>1,3</sup>. <sup>1</sup>Pharmacology and Toxicology, Rutgers University, Piscataway, NJ, <sup>2</sup>Environmental and Occupational Medicine, UMDNJ-Robert W Johnson Med. Sch, Piscataway, NJ and <sup>3</sup>Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ.

Studies from our laboratory have demonstrated that the toxicity of inhaled ozone is due, in part, to cytotoxic inflammatory mediators released from activated alveolar macrophages. Thus following ozone inhalation, alveolar macrophage production of nitric oxide, generated from inducible nitric oxide synthase (NOSII), tumor necrosis factor- $\alpha$  (TNF $\alpha$ ), and prostaglandin E2 (PGE2) produced via cyclooxygenase-2 (COX-2) are increased. Moreover, blocking macrophages or inflammatory mediators abrogates ozone-induced toxicity. In the present studies we analyzed mechanisms regulating macrophage activation in the lung following ozone inhalation. Triggering receptor on myeloid cells (TREM-1) is a newly identified receptor thought to be involved in amplifying the inflammatory response by stimulating the release of proinflammatory mediators from phagocytic cells. Treatment of C3H/OuJ mice with ozone (0.8 ppm, 3 hr) caused a time-dependent induction of expression of TREM-1 mRNA in alveolar macrophages which was evident 12-24 hr after exposure. Similar activity was observed in C3H/HeJ mice which possess a mutated non-functional Toll-like receptor 4 (TLR-4), making them insensitive to bacterially derived endotoxin. These mutant mice were found to be resistant to ozone-induced toxicity, as measured by protein accumulation in bronchoalveolar lavage fluid. This was correlated with reduced expression of NOSII and COX-2 protein in the lung and delayed expression of the anti-inflammatory cytokine, IL-10, demonstrating the importance of TLR-4 in the pathogenesis of inflammation and tissue injury induced by ozone. Our findings that mutations in TLR-4 do not affect ozone-induced expression of TREM-1 suggest that there are multiple independent pathways mediating macrophage activation in the lung following ozone inhalation. Supported by NIH grants ES04738, GM34310, ES05022 and ES007148.

3 $\beta$ -HYDROXY-5-OXO-5, 6-SECOCHOLESTAN-6-AL, A MAJOR OZONATION PRODUCT OF CHOLESTEROL, INDUCES APOPTOSIS IN CARDIOMYOCYTES.

M. Haque<sup>1</sup>, I. Sehgal<sup>1</sup>, S. Murthy<sup>2</sup>, J. Francis<sup>1</sup> and R. Uppu<sup>3</sup>. <sup>1</sup>LSU School of Veterinary Medicine, Baton Rouge, LA, <sup>2</sup>Tulane University Health Sciences Center, New Orleans, LA and <sup>3</sup>Southern University, Baton Rouge, LA.

Ozone toxicity induces pulmonary dysfunction in humans and animals. Since ozone does not penetrate far ( $<2\text{ }\mu\text{m}$ ) into the lung parenchyma, the adverse effects of ozone are thought to be mediated via the ozonation products formed at the air/lung interface. Thus, phospholipids, cholesterol, and cholesterol esters present in the epithelial lining fluids and in the alveolar cell membranes are among the primary targets for the reaction of ozone. The interaction of ozone with these lipids results in the formation of a number of toxic metabolites including 3 $\beta$ -hydroxy-5-oxo-5, 6-secocholestan-6-al (Chol-Seco), the major ozonation product of cholesterol. Most studies to date have concentrated on the effects of ozone and the ozonation products on the lung parenchyma. The present study was undertaken with the purpose of determining the extra-pulmonary effects of ozone mediated via cholesterol ozonation using cardiomyocytes derived from the embryonic rat myocardium (H9C2 cells). The H9C2 cells were treated with varying low concentrations (0-10  $\mu\text{M}$ ) of Chol-Seco for 12-24 h at 37 $\pm$ 0.5 °C. After incubation, the cells were fixed and analyzed using flow cytometry and immunocytochemistry. It was observed that Chol-Seco induces a time and dose dependent increases in cardiomyocyte apoptosis. The lowest dose of 2  $\mu\text{M}$  Chol-Seco for instance, was found to cause 14 $\pm$ 1.1% apoptosis against DMSO controls that only showed 3 $\pm$ 0.1% apoptosis. At 5 and 10  $\mu\text{M}$  Chol-Seco, the percent apoptotic cells at 24 h were 45 $\pm$ 3.8 and 52 $\pm$ 2.0, respectively. Apoptosis was also seen at 12 h and 18 h, with the highest dose inducing greater cell death. Anexin staining showed a similar pattern. These results suggest that cholesterol ozonation product(s) is/are potent inducers of apoptosis in cardiomyocytes and might play a role in ozone induced myocardial injury. (Funding support from NIEHS ES10018 and LBRN is acknowledged.

INCREASED SUSCEPTIBILITY OF HYPERTHYROID RATS TO OZONE: EARLY EVENTS AND MECHANISMS.

L. Huffman<sup>1,2</sup>, C. Beighley<sup>3</sup>, D. Frazer<sup>1,2</sup>, W. McKinney<sup>1</sup> and D. Porter<sup>1,2</sup>. <sup>1</sup>PPRB, NIOSH, Morgantown, WV, <sup>2</sup>Physiology and Pharmacology, West Virginia University, Morgantown, WV and <sup>3</sup>Biostatistics, NIOSH, Morgantown, WV.

Previous studies have determined that ozone-induced lung damage and inflammation are much greater in hyperthyroid vs. normal rats at 18 hours following exposure. The purpose of the present investigation was to study early events and mechanisms underlying the increased sensitivity to ozone in a hyperthyroid state. Specifically, the degree of lung epithelial cell barrier disruption, extracellular lining fluid antioxidant status, and the release of inflammatory mediators were examined. To create a hyperthyroid condition, mature male Sprague-Dawley rats were implanted with time-release pellets containing thyroxine; control rats received placebo pellets. After 7 days, the animals were exposed to air or ozone (2 ppm, 3 h). Immediately following the end of the exposure, bronchoalveolar lavage (BAL) fluid and cells were harvested. BAL fluid albumin levels and total antioxidant status were examined. In addition, levels of PGE2, MIP-2, MCP-1, and TNF- $\alpha$  were determined in BAL fluid and following *ex vivo* culture of BAL cells. The results of this study are consistent with the following hypotheses: 1) a marked increase in the permeability of the alveolar-capillary barrier is an early event underlying the increased susceptibility of hyperthyroid rats to ozone, however this does not appear to be due to overall changes in BAL fluid antioxidant potential; 2) early increases in MIP-2, but not PGE2, are involved in the enhanced lung response to ozone in a hyperthyroid state; 3) inflammatory mediator production (i.e., PGE2, MIP-2, MCP-1, and TNF- $\alpha$ ) by alveolar macrophages plays a minimal role in the initial responses to ozone in a hyperthyroid state.

INHIBITION OF TRANSFORMING GROWTH FACTOR BETA MNRA TRANSCRIPTION BY ANTISENSE OLIGONUCLEOTIDES IN AMIODARONE TREATED HAMSTERS.

H. conway, U. Doshi and J. M. Cerreta. Department of Pharmaceutical Sciences, St. John's University, Jamaica, NY.

Pulmonary fibrosis is an often fatal disease characterized by cellular hyperplasia and excessive accumulation of extracellular matrix components with remodeling of the lung. The precise series of events leading to such scarring are not well understood. Amiodarone is an antiarrhythmic drug that is known to cause pulmonary fibrosis. Amiodarone induces an increase in transforming growth factor beta (TGF $\beta$ ) and such increase plays a significant role in the fibrotic process. The hypothesis of the current study is that blocking TGF $\beta$  mRNA transcription will modulate amiodarone induced pulmonary fibrosis in hamsters. Golden Syrian hamsters were

treated with TGF $\beta$  antisense oligonucleotides by aerosolization. Following such treatment animals were exposed to amiodarone by intratracheal insufflation. The hamsters were euthanized 24 hours after treatment, bronchoalveolar lavage (BAL) samples obtained and the lung tissue either frozen in liquid nitrogen or fixed in formalin and embedded in paraffin. TGF $\beta$  levels were measured in BAL samples by Western blot analysis. TGF $\beta$  levels were significantly decreased in animals treated with the antisense oligonucleotides as compared to control. BAL samples from treated and control animals were analyzed by light microscopy to determine the level of inflammatory cells present in the lung. A significant decrease was observed in the number of inflammatory cells present in the BAL fluid from antisense treated animals as compared to controls. Immunohistochemical analysis of frozen tissue sections from animals treated with antisense oligonucleotides prior to toxicant exposure exhibited a decrease in TGF $\beta$  levels as compared to controls. Morphologic study revealed reduction in areas of interstitial thickening in animals treated with TGF $\beta$  antisense oligonucleotides as compared to the controls. Antisense oligonucleotides to TGF $\beta$  mRNA inhibited, but did not completely prevent cytokine production in animals exposed to amiodarone and reduced alterations in lung architecture.

INVESTIGATION OF PREVENTION OF AMIODARONE- AND DESETHYLMIODARONE-INDUCED TOXICITY IN HUMAN PERIPHERAL LUNG EPITHELIAL CELLS HPL1A.

A. C. Nicolescu, J. F. Brien, W. J. Racz and T. E. Massey. Pharmacology & Toxicology, Queen's University, Kingston, ON, Canada.

Amiodarone (AM) is a highly effective antidysrhythmic used in the treatment of serious ventricular and supraventricular dysrhythmias. The mechanisms underlying AM-induced pulmonary toxicity (AIPT) have not been elucidated. Evidence suggests an important role for N-desethylamiodarone (DEA), a major AM metabolite, in AIPT. The immortalized, non-transformed human peripheral lung epithelial cell line (HPL1A) is morphologically and biochemically very similar to normal human peripheral lung epithelial cells. HPL1A cells have many characteristics that make them excellent candidates for assessing the mechanisms of toxicant action in human peripheral lung epithelial cells. In this study, HPL1A cells were grown to approximately 80% monolayer confluence, transferred to 96-well plates and incubated with AM or DEA concentrations varying from 0 to 1 mM. At 2, 4, 8, 12, 24, and 36 hours, viability was assessed using the 3-[4, 5-dimethylthiazol-2-yl]-2, 5-diphenyltetrazolium bromide (MTT) assay. Time- and concentration-dependent losses of cell viability were observed, with DEA being more cytotoxic than AM at shorter incubation times. AM toxicity, expressed as the concentration that produces a 50% loss of cell viability, drastically increased with the incubation time. In contrast, DEA toxicity showed little variation over the incubation time period. Prior incubation with the spin trap a-phenyl-N-t-butylnitron (PBN, 10  $\mu\text{M}$ ) for 30 minutes provided only slight protection against AM/DEA-induced toxicity. These results support that long-term rather than acute exposure of HPL1A cells to AM is associated with an increased loss in cell viability. The observed cytoprotective effect of the spin trap suggest that AIPT may be in part mediated by a free-radical process. HPL1A cells represent a potentially competent model for elucidating the mechanisms of the AM-induced adverse pulmonary effects in humans. (Supported by Canadian Institutes of Health Research grant number MOP-13257).

GENE MICROARRAY ANALYSIS IN A RAT MODEL OF SMOKE INHALATION-INDUCED ACUTE LUNG INJURY.

S. S. Wong<sup>1</sup>, N. N. Sun<sup>1</sup>, C. D. Fastje<sup>1</sup>, R. Lantz<sup>2</sup> and M. L. Witten<sup>1</sup>. <sup>1</sup>Center for Toxicology & Department of Pediatrics, The University of Arizona, Tucson, AZ and <sup>2</sup>Center for Toxicology & Department of Cell Biology/Anatomy, The University of Arizona, Tucson, AZ.

In a rat model of acute lung injury (ALI)/acute respiratory distress syndrome (ARDS)-like injury, we examined 28, 757 genes cDNA microarrays for early transcriptome alterations in the homologized lung tissue at 24 hours post-smoke insult. Data indicated that genes responsible for membrane enzyme, transporter, hemoglobin, signal transducer, binding activity, and transcription regulation were dysregulated. Smoke inhalation-mediated alterations in the identified genes were largely sorted into many signaling transduction pathways, including chemokine/cytokine, hormone, DNA binding, transcription factor, and G-protein receptor. Moreover, genes encoding different oxidoreductase, transferase, and isomerase were affected. Among them, the rapid inductions of sulfotransferase (Sult-n) and inositol/phosphatidylinositol kinase (Pik3cb) suggest that the metabolism of smoke toxins were prominent in the acute phase of smoke inhalation-induced ALI/ARDS. These findings reveal that there are complex molecular cascades involving disturbances in different subcellular compartments, influencing thereafter the normal cellular functions, leading to ALI/ARDS (Supported by ALA).

## EXPRESSION AND CHARACTERIZATION OF TRPM8 RECEPTORS IN THE LUNG EPITHELIUM.

A. S. Sabnis, M. E. Johansen, G. S. Yost and C. A. Reilly. *Pharmacology & Toxicology, University of Utah, Salt Lake City, UT.*

Several members of the Transient Receptor Potential (TRP) family of ion channels have been identified as physiological temperature sensors. These receptors respond to changes in temperatures, ranging from hot to cold, as well as chemical agonists such as menthol, capsaicin etc. Transient Receptor Potential Cation Channel, Melastatin subfamily, member 8 (TRPM8) has been shown to function as a cold sensing channel within the mammalian somatosensory system and acts by converting thermal stimuli into bio-chemical and electrical signals. Although much emphasis has been placed on the expression of TRPM8 in cold-sensitive sensory neurons, it is currently unknown whether functional TRPM8 receptors are expressed in the human respiratory tract. Preliminary studies in our lab have demonstrated the expression of TRPM8 mRNA in the bronchiolar epithelial (BEAS-2B), alveolar epithelial (A549), and normal human bronchiolar epithelial (NHBE) cells using RT-PCR. Additional studies aimed to assess the expression of functional TRPM8 channels in these cells demonstrated that menthol, the prototypical agonist of TRPM8, produced significant increases in the intracellular calcium concentrations that ranged from 1.4-fold for A549 cells to 5.6- and 5.8-fold for BEAS-2B and NHBE cells, respectively. The EC<sub>50</sub> values for induction of calcium flux were 2 ± 1 mM, 0.02 ± 0.009 mM and 1.5 ± 0.8 mM in BEAS2B, A549 and NHBE cells, respectively. Furthermore, the influx of calcium was inhibited by capsazepine, an antagonist of TRPM8 receptors. These data were consistent with the expression of functional TRPM8 channels in respiratory epithelial cells. Expression of these receptors in the respiratory tract may represent a significant finding with respect to adverse respiratory responses to cold air (e.g. asthma, cough). Support was provided by Grant # HL069813.

## AEROSOLIZED HYALURONAN MODIFIES ENDOTOXIN-INDUCED LUNG INJURY IN A TIME-DEPENDENT MANNER.

P. Nadkarni, G. Kulkarni and J. Cantor. *Pharmacy and Allied Health Professions, St John's University, New York, NY. Sponsor: L. Trombetta.*

Inhalation of an aerosolized preparation of low-molecular weight (150 kDa) hyaluronan (HA) was previously shown by this laboratory to prevent experimentally induced pulmonary emphysema without causing additional lung inflammation. As a result, aerosolized HA has been proposed as a potential treatment for human emphysema. However, other investigators have found that low-molecular weight HA may be proinflammatory, prompting us to determine whether aerosolized HA could possibly enhance inflammation in a model of pulmonary disease other than emphysema. Using endotoxin-induced lung injury, we tested the effects of aerosolized HA on the acute inflammatory response. Syrian hamsters were exposed via nebulization to a 0.1% solution of 150 kDa HA in water for 2 hrs, either immediately before or after intratracheal instillation of 0.1 mg E.coli endotoxin (controls received endotoxin alone). All animals revealed a rapid influx of inflammatory cells into the lung which peaked within the first 24 hrs. While microscopic examination did not show any significant differences between HA-treated and untreated lungs with regard to the magnitude of the inflammatory response, a marked elevation in the percentage of lavaged neutrophils (69% vs 5.4%; p<0.05) was seen at 4 hrs post-endotoxin in animals receiving HA after endotoxin administration. In contrast, administration of HA prior to endotoxin resulted in a decline in the proportion of lavaged neutrophils at 4 hrs (2.1% vs 5.0%; p<0.05). These results indicate that HA modifies endotoxin-induced lung injury in a time-dependent manner. The fact that HA stimulates a neutrophil influx only when given after induction of pulmonary inflammation suggests that it may specifically interact with activated inflammatory cells (e.g. macrophages) that recruit neutrophils to the lung. How these findings might affect the therapeutic potential of HA remains to be determined.

## IMMUNE RESPONSE TO ZYMOSEN-INDUCED PULMONARY INFLAMMATION IN RATS.

S. Young, J. R. Roberts and J. M. Antonini. *NIOSH, Morgantown, WV.*

1→3-β-Glucans have been associated with increased pulmonary inflammation in mold-related indoor air problems. The objective of the present investigation was to determine the immune response to zymosan-induced pulmonary inflammation in SD rats. Rats received a single dose of zymosan A (2.5 mg/kg body weight) via intratracheal instillation (IT) and were euthanized on days 1, 4, 6, and 8 post IT. Inflammation and lung injury were assessed by measuring (1) neutrophil (PMN) infiltration into bronchoalveolar lavage fluid (BALF) and (2) albumin, total protein and lactate dehydrogenase levels in BALF. Alveolar macrophage activation was determined by chemiluminescence (CL). Immune response was investigated via im-

munophenotyping of lymphocytes and lymphokine production. Immunophenotyping was performed on BAL cells and lung-associated lymph node cells. Lymphokine production was measured from lymph node cells with or without concanavalin A stimulation by an enzyme-linked immunosorbent assay. Upon challenge with zymosan, rats exhibited increased inflammation and injury at the early time points post-IT exposure. Although elevations in PMN infiltration and CL had returned to control levels on day 4, lung-associated lymphocytes continued to proliferate and reached a maximum on day 6. The ratio of CD4 to CD8 T cells in the lymph node and BAL was lower in zymosan-treated rats than in control rats, indicating a greater increase in CD8 T cells as compare to CD4 T cells. Zymosan also increased the number of infiltrating NK cells, B cells, and T cells in BAL at all time points. B cells in BALF were found to be highest in number on day 1 for zymosan-treated rats. The ratio of T/B cells in BALF increased significantly on day 6 and 8. Zymosan treatment increased IL-2, IL-10 and IFNγ but not IL-4 production in lymphocytes. These data along with immunophenotyping of lymphocytes suggests that helper CD4 T and cytotoxic CD8 T cells are involved in the immune activation caused by zymosan treatment. In summary, rats exposed to zymosan had increased inflammation and altered lymphocyte profile, indicating an activation of innate and/or adaptive immune response in rats.

## HYDROGEN SULFIDE EXPOSURE CAUSES INTRACELLULAR ACIDIFICATION OF RAT NASAL RESPIRATORY EPITHELIAL CELLS.

E. S. Roberts, V. A. Wong, B. E. McManus and D. C. Dorman. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Hydrogen sulfide (H<sub>2</sub>S) is a naturally occurring gas that is also generated by several industries. The potential for widespread human inhalation exposure to this toxic gas is recognized as a public health concern. Human epidemiological investigations and experimental laboratory animal studies have confirmed that the nasal epithelium is a sensitive site for H<sub>2</sub>S-induced pathology. Cytochrome oxidase (Co) inhibition has been postulated as one mechanism of H<sub>2</sub>S toxicity. Inhibition of Co disrupts the electron transport chain and impairs oxidative metabolism, leading to decreased ATP production and the build-up of lactic acid. While Co is a sensitive marker of H<sub>2</sub>S exposure, there is an incomplete correlation between H<sub>2</sub>S-induced nasal lesions and Co inhibition. Another mechanism by which H<sub>2</sub>S (a weak organic acid) could cause nasal injury is intracellular acidification and cytotoxicity. Literature reports show that changes in intracellular pH due to exposure to organic acids such as vinyl acetate can lead to cell death. To further understand the mechanism by which H<sub>2</sub>S damages the nasal epithelium, nasal respiratory epithelial cells were isolated from naive rats; loaded with the pH-sensitive dye, SNARF-1; and exposed to air or 400 ppm H<sub>2</sub>S for 90 min. Vinyl acetate (1000 μM) was used as a positive control. Intracellular pH was measured by flow cytometry and cell lysates were used to quantify total protein and Co activity. Flow cytometric analysis showed that nasal respiratory epithelial cells exposed to air maintained a pH of 7.6 ± 0.05. A significant decrease in intracellular pH occurred following exposure to either vinyl acetate (15% decrease from control) or H<sub>2</sub>S (5% decrease from control). Co activity in air-exposed cells was 1.39 ± 0.01 Δabs/min/mg protein, while Co activity in cells exposed to H<sub>2</sub>S was not detectable. The intracellular acidification of nasal respiratory epithelial cells by H<sub>2</sub>S demonstrates a novel mechanism of H<sub>2</sub>S-induced nasal respiratory cellular toxicity.

## PERTURBATION OF COPPER HOMEOSTASIS AND EXPRESSION OF COPPER-BINDING PROTEINS IN CADMIUM-RESISTANT LUNG FIBROBLASTS.

D. K. Chou<sup>1</sup>, Y. Zhao<sup>1</sup>, S. Gao<sup>1</sup>, L. Chen<sup>1</sup>, I. Chou<sup>2</sup>, P. Toselli<sup>1</sup>, P. Stone<sup>1</sup> and W. Li<sup>1</sup>. <sup>1</sup>*Biochemistry, Boston University School of Medicine, Boston, MA* and <sup>2</sup>*Microbiology, Boston University School of Medicine, Boston, MA.*

To probe molecular mechanisms of cadmium (Cd) damage to the lung extracellular matrix (ECM) we developed Cd-resistant (CdR) cells derived from rat fetal lung fibroblasts (RFL6) by incubation with graded doses of Cd. CdR cells have been shown to display upregulation of metallothionein (MT) and glutathione (GSH), two metal scavenging agents, coupled with downregulation of lysyl oxidase (LO), a copper (Cu)-dependent enzyme necessary for crosslinking collagen and elastin in the ECM. Here we examined cellular uptake and distribution of Cu and compared expression of LO with other Cu-binding proteins in CdR cells. A <sup>64</sup>Cu 1-h pulse assay revealed that the amount of radioactivity associated with CdR cells was 2.1-fold of the parental Cd-sensitive (CdS) control. Thus, LO deficiency in CdR cells is not due to a reduced cell uptake of Cu, a cofactor of LO. Antibody affinity chromatography assays indicated a low level of <sup>64</sup>Cu bound to the LO fraction amounting to 9% of the CdS control as compared to 1, 400% of the control of <sup>64</sup>Cu associated with the MT fraction in CdR cells pulsed with isotope for 4 h. This suggests that the high level of cellular Cu in CdR cells at least in part resulted from elevated levels of cellular MT. Steady-state protein levels as determined by Western blot

showed that there were > 8-fold increases in MT, 1.0-1.6-fold in Cu/Zn-superoxide dismutase (SOD), 1.5-2.5-fold in CCS which delivers Cu to SOD, 1.0-1.5- fold in Mn-SOD and 1.0-1.5-fold in  $\gamma$ -glutamylcysteine synthetase, a GSH synthetic enzyme, in CdR cells resistant to 10-80  $\mu$ M Cd compared to the CdS control. In contrast, all LO species, i.e., the 46 kDa preproenzyme, the 50 kDa proenzyme and the 32 kDa mature enzyme were reduced by 84%, 70% and 98%, respectively. These results point out that downregulation of LO is linked with upregulation of other Cu-binding proteins and alteration in Cu homeostasis in CdR cells (Supported by NIH grant R01-ES11340 & Philip Morris ERP).

PHOTOCHEMICAL REACTIONS ENHANCE INFLAMMATORY RESPONSES IN HUMAN LUNG CELLS.

M. Doyle<sup>1</sup>, K. G. Sexton<sup>1</sup>, H. Jeffries<sup>1</sup>, K. Lichtveld<sup>1</sup> and I. Jaspers<sup>2,1</sup>. <sup>1</sup>*ESE, UNC-CH, Chapel Hill, NC* and <sup>2</sup>*CEMALB, UNC-CH, Chapel Hill, NC*.

The chemistry of hazardous air pollutants has been studied for many years, yet little is known about how these chemicals, once interacted with urban atmospheres, affect healthy and susceptible individuals. During this study, environmental irradiation chambers (also called smog chambers) use natural sunlight to induce the natural photochemically stimulated transformations of environmental pollutants. These smog chambers have been used for more than 30 years to investigate and develop chemical mechanisms of species found in the atmosphere and used in regulatory air quality models. Smog chambers, coupled with an *in vitro* system, using A549 cells, were used to investigate methanol, toluene, and 1, 3-butadiene in combination with a synthetic urban smog mixture. Once released into the atmosphere, these air pollutants interact with hydroxyl radicals and ozone, which are created by photochemical processes, to produce many identified and unidentified products. Once these chemical reactions occur, the toxic potential of these atmospheric pollutants is currently unclear. In this study, A549 cells were exposed simultaneously to irradiated and non-irradiated chamber mixtures for five hours. Post exposure, adverse health effects were determined by measures of increased cellular stress (cytokine release) and cytotoxicity. Exposure to the photochemically generated products of 1, 3-butadiene, toluene, and methanol induced increases in both cytotoxicity and IL-8 gene expression compared to 1, 3-butadiene, toluene, or methanol alone. The smog chamber/*in vitro* exposure design was used to investigate the toxicity of chemicals after photochemical reactions and interactions with the urban atmosphere on healthy and susceptible individuals using representative *in vitro* samples. This research helps connect the gaps in the literature to explain the toxicity found from exposures to multiple environmental pollutants found in an urban atmospheric setting, and provides a way to obtain a more truthful estimate of toxicity of ambient releases of pollutants.

**943**

INHALATION EXPOSURE TO TERTIARY AMYL METHYL ETHER (TAME) ALTERS THE ACTIVITIES OF CYTOCHROME P450 ISOZYMES IN HEPATIC AND RESPIRATORY TISSUES OF SPRAGUE DAWLEY RATS.

J. L. Weissert and R. A. Schatz. *Toxicology, Northeastern University, Boston, MA*.

Fuel oxygenates, as mandated by amendments to the Clean Air Act of 1990, are blended with gasoline to help reduce harmful vehicle exhaust emissions. To date, methyl-tert butyl ether (MTBE) is the most common oxygenate employed to produce cleaner burning fuels. TAME, as well as ethyl-tert butyl ether and diisopropyl ether, are less commonly used oxygenates; but with the recent launch of the MTBE phase-out program due to health concerns, the demand for TAME may increase. The full impact of TAME on human health, however, is yet to be determined. The aim of this study was to examine the alterations in CYP450 activities in rat nasal mucosa, lung and liver immediately following, and 24 h after, an acute 6 h inhalation exposure to TAME. CYP450 activity was measured in microsomes using specific enzyme probes. TAME (100ppm, 0 h or 24 h) exposure resulted in inhibition of CYP1A1 (69% & 53%), CYP1A2 (96% & 65%), CYP2A3 (89% & 41%), CYP2B1 (44% & 79%), CYP3A (28% & 21%) and CYP4B1 (36% & 23%) in nasal mucosa. Exposure to 300ppm (0 h or 24 h) inhibited nasal mucosal CYP1A1 (79% & 45%), CYP1A2 (80% & 61%), CYP2A3 (84% & 49%), and CYP2B1 (83% & 70%). CYP4B1 was inhibited 27% at 24 h only. In lung, TAME (100ppm or 300ppm) inhibited CYP2A3 (31% & 88%) and CYP2B1 (36% & 22%) at 0 h with recovery to control levels at 24 h. Lung CYP4B1 activity increased 23% immediately following the 300ppm exposure but was subsequently inhibited by 26% at 24 h post-exposure. Hepatic CYP2B1 activity increased at 0 h (87%) and 24 h (207%) following the 300ppm exposure. CYP1A1 activity increased (44%) 24 h following 300ppm only. TAME (100ppm) inhibited CYP3A (16%) at 0 h whereas inhibition of CYP2A3 (27%) and an increase in CYP2E1 activity (19%) occurred 24 h post-exposure in liver. These alterations in CYP450 activity following TAME exposure may lead to adverse human health outcomes upon co-exposure with other agents, such as other solvents in gasoline, by increasing bioactivation and/or delaying detoxication via this system.

BIOPERSISTENCE OF ROCK WOOL (RW) IN THE RAT LUNG AFTER SHORT-TERM INHALATION VIA NOSE.

Y. Kudo, Y. Sugiura, M. Tsunoda, T. Satoh and Y. Aizawa. *Department of Preventive Medicine and Public Health, Kitasato University School of Medicine, Sagamihara, Japan*.

Rock wool (RW), a man-made vitreous fiber, has been used as residential and commercial thermal and acoustic insulation. IARC classified RW as a Group III carcinogen. For the evaluation of the safety of RW, data on the biopersistence of RW in the lung are required. We evaluated the biopersistence of RW in the rat lung after short-term inhalation via the nose, by determination of the length and diameter of each fiber and the total number of fibers. Male Fischer 344 rats (n=24) were exposed to 30 mg/m<sup>3</sup> RW (Nittobou) for 3 hours/day for 5 consecutive days in nose-only inhalation chambers. The rats were divided into four groups, and six rats each were euthanized at 1 hour, and 7, 14, and 28 days after the inhalation exposure. The lungs were removed, and prepared using a freeze-drying method. The dry tissue was ashed by low-temperature ashing. RW was collected after filtration. The size of each fiber and the total numbers of fibers were determined by phase contrast microscopy and WINROOF software. The geometric mean values of the length of the fibers were 8.49 mm at 1 hour, 9.57 mm at 7 days, 7.68 mm at 14 days, and 8.36 mm at 24 days. The geometric mean values of the diameter of fibers were 1.48 mm at 1 hour, 1.51 mm at 7 days, 1.31 mm at 14 days, and 1.41 mm at 24 days. The total numbers of fibers in the lung expressed as percentages of that at 1 hour were 94.1% at 7 days, 76.9% at 14 days and 59.3% at 28 days. The time in which the number of total fibers was halved was 38 days. The time in which the number of long fibers (>20 mm) was halved was 29 days. Although the length and diameter of the fibers in the lung did not change dramatically during the experiment, the total number of fibers decreased. The decrease in the total number of fibers may have been due to excretion by mucociliary movement, or phagocytosis of macrophages at bronchus and trachea. For the further evaluation of the safety of RW, the effects of long-term exposure should be evaluated for a longer observation time.

TWO-WEEK INHALATION STUDIES WITH DISK-SHAPED PARTICLES OF POTASSIUM TITANATE COMPOUNDS: TERRACESS PS AND TERRACESS LS.

S. Sakai<sup>1</sup>, K. Inada<sup>1</sup>, A. K. Tanaka<sup>1</sup>, D. P. Kelly<sup>3</sup>, G. Sykes<sup>3</sup> and K. P. Lee<sup>4</sup>.

<sup>1</sup>*Osuka Chemical Co. Ltd., Osaka, Japan*, <sup>2</sup>*DuPont Haskell Laboratory, Newark, DE*, <sup>3</sup>*Veterinary Pathology Services, West Grove, PA* and <sup>4</sup>*Pathology Consulting, Newark, DE*.

Inhaled fibrous particles are known to have potential fibrogenic and carcinogenic activities that are related to fiber dimensions and physicochemical characteristics. Terracess PS (MgK<sub>2</sub>TiO) and Terracess LS (LiK<sub>2</sub>TiO) are manufactured as disk-shaped particles to avoid potential fiber toxicity. Groups of 10 male rats were exposed whole-body to Terracess PS (TPS) or Terracess LS (TLS) aerosols at concentrations of 0, 5, 25, or 100 mg/m<sup>3</sup> for 6 hrs/day for 9 days over a two-week period. The mass median aerodynamic equivalent diameter of the aerosols was 3.6 to 4.3  $\mu$ m for TPS and 2.9 to 3.3  $\mu$ m for TLS. No adverse effects were observed in exposed rats in clinical observations, body weights, and clinical pathology including urine, hematology, and blood chemistry parameters. Lung and lung/brain weight ratio were not affected. No adverse histopathological effects were observed in the respiratory tract including nose, larynx/pharynx, trachea, and lungs. Inhaled Terracess particles were mostly phagocytized by free alveolar macrophages (AMs) in the alveolar airspaces. The adjacent alveolar walls enclosing dust-laden AMs showed normal structure. Some inhaled test particles were detected in thoracic lymph nodes via lung clearance processes. The absence of adverse effects in the alveolar walls was likely due to the test material's low reactivity and disk shape. Based on the lack of adverse effects in the respiratory tract, the no-observed-adverse-effect-level for Terracess PS and Terracess LS was 100 mg/m<sup>3</sup> and the lung responses were considered similar to "nuisance" type dusts.

**946**

CHRONIC LUNG TOXICITY IN RATS DUE TO EXPOSURE TO DIFFERENT CONCENTRATIONS OF THE MINERAL OIL.

F. S. Abouzakhar<sup>1, 2, 3</sup>. <sup>1</sup>*Electrical Eng., Al-Tabadi University, Sirt, Libya*, <sup>2</sup>*Forensic Med. & Toxicology, El Minia University, El Minia, Egypt*, <sup>3</sup>*Pharmacology & Therapeutics, Ain Shams University, Ain Shams, Egypt* and <sup>4</sup>*Internal Medicine, Al-Tabadi University, Sirt, Libya*. Sponsor: F. Abouzakhar.

This work was done to study the histopathological effect of chronic exposure to mineral oil (BS148) on the lung of rats. The study was done on 80 rats divided into 4 groups (20 rats each). The first group (used as control) was exposed to atmospheric air. The second group to mineral oil at 100 mg/m<sup>3</sup> concentration, the third group was exposed to 200 mg/m<sup>3</sup> and the fourth one to 400 mg/m<sup>3</sup> concentration (the inhalation done for 3.5 h/d, 4 d/w for 12 weeks). By the end of 12th week the

animals were sacrificed and their lungs were taken for histopathological study. The histopathological results revealed that all lungs of the control group were normal. Of the 2nd group, lungs of 8 rats(40%) showed mild affection in the form of mild alveolar macrophage infiltration. 75% of rats of the 3rd group showed mild to moderate alveolar macrophage infiltration while, 100% of the lungs of the 4th group were affected, 40 % of which showed severe alveolar macrophage infiltration. From this work, it can be concluded that inhalation exposure of rats to mineral oil (BS148) resulted in concentration dependent lung affection.

**SENSORY IRRITATION RESPONSE TO ATP,  $\alpha$ ,  $\beta$ -METHYLENE-ATP AND ADENOSINE AEROSOLS.**

W. S. Wilkie and J. B. Morris. *Toxicology Program, University of Connecticut, Storrs, CT.*

In many organs, including the lungs, sensory nerves may be activated via purinergic signaling pathways. The current experiments were aimed at examining the potential role of purinergic activation of the nasal sensory irritation response. This response is mediated by trigeminal sensory nerves and is characterized by a decreased breathing frequency due to a pause at the start of each expiration. Female B6C3F1 mice were exposed for 15 minutes to aerosolized ATP,  $\alpha$ ,  $\beta$ -methyleneATP (a P2X receptor agonist) or adenosine (an A receptor agonist) in a double plethysmograph and expiratory pause duration was measured. Aerosolized ATP (10 mg/ml) acted a sensory irritant, inducing an expiratory pause of 150-200 msec duration within 2 minute of the start of exposure. The response diminished to approximately 20 msec within 5 minutes of the onset of exposure. The response to ATP aerosol was significantly lower in capsaicin-pretreated mice, providing evidence for the participation of TRPV1 (capsaicin)-receptor expressing C fibers. Airways resistance (sRaw) was not increased over control (saline) aerosol levels by ATP aerosol suggesting that nasal sensory nerve C fiber activation does not necessarily induce an obstructive response in the mouse. The P2X agonist  $\alpha$ ,  $\beta$ -methyleneATP also produced a rapid response (within 2 minute of the onset of exposure) that diminished as the exposure progressed. In contrast, adenosine aerosol produced a biphasic response with an early response (pause duration 150-200 msec, within 2 minute of the onset of exposure) followed by a decline and then a delayed response (pause duration ~80 msec) from 10-15 minutes of exposure. This response pattern is similar to that caused by exposure to acetic acid or ethyl acetate vapor. These results suggest purinergic signaling pathways may play a role in initiating the sensory irritation response and both A and P2X receptor families may be involved.

**948**

**EFFECTS OF GROUP HOUSING ON REPRODUCTIVE PARAMETERS IN THE SEXUALLY MATURE CYNOMOLGUS MONKEY.**

G. Weinbauer<sup>1</sup>, M. Niehoff<sup>1</sup>, M. Bergmann<sup>2</sup> and W. Mueller<sup>1</sup>. <sup>1</sup>*Covance Laboratories GmbH, 48163 Muenster, Germany* and <sup>2</sup>*Institute of Veterinary Anatomy, University of Giessen, 35392 Giessen, Germany.*

Cynomolgus monkeys represent the most commonly used nonhuman primate species in toxicology. During reproductive and developmental toxicity studies, animals are housed singly in order to avoid interference with reproductive/developmental parameters imposed by social rank and associated behaviour. Current recommendations and anticipated European guidelines will enforce group housing for primates in order to provide improved social interactions and more enriched environments. Whilst potential effects on reproductive functions are not relevant for group-housed juvenile and immature primates, this aspect becomes critical for group housing of mature animals. The current project evaluates the effects on reproductive parameters of single housing into isosexual group housing of female monkeys (maturity proven by vaginal bleedings) and male monkeys (maturity proven by sperm in the ejaculate). A group of seven males was studied for a period of 26 weeks and a group of eight females was studied for a period of 9-10 months. Semen samples and testicular volumes were assessed in 3-4 week intervals. Vaginal smears were collected daily throughout the study period. Social rank was determined using a food challenge test. Among group-housed males, testicular volumes declined by 30-40 % within 6 weeks in three animals with lowest social rank and remained lower until week 13. Unexpectedly, thereafter testis size increased in these animals. Sperm motility and sperm numbers were not consistently altered in these subordinate animals. For females that had regular menstrual cycles when housed singly, menstrual cycles became more irregular during group housing. The social rank of females was difficult to ascertain. In conclusion, group housing of sexually mature animals is currently not recommended for reproductive toxicity studies. Further research (different group sizes, duration of group formation, etc.) is needed to clarify whether circumstances permitting group housing for reproductive toxicity studies can be identified.

**949**

**28-DAY INHALATION AND REPRODUCTIVE/DEVELOPMENTAL SCREENING TOXICITY STUDIES OF TETRAMETHYLSILANE IN SPRAGUE-DAWLEY RATS.**

W. Siddiqui<sup>1</sup>, L. Meeker<sup>1</sup>, J. Tobin<sup>1</sup>, J. Crissman<sup>1</sup>, J. Knochel<sup>1</sup>, S. Crofoot<sup>1</sup>, G. Burin<sup>2</sup> and K. Plotzke<sup>1</sup>. <sup>1</sup>*Health and Environmental Sciences, Dow Corning Corporation, Midland, MI* and <sup>2</sup>*Toxicology Division, Technology Sciences Group, Washington, DC.*

Tetramethylsilane (TMS) is a volatile, highly flammable liquid used as an industrial solvent. The potential toxicity of TMS, a High Production Volume chemical (HPV), was evaluated in a combined repeated exposure toxicity study with a reproductive/developmental toxicity screening test. The study design utilized an enhanced version of the protocol in accordance with the OECD and EPA test guidelines Nos. 422 and 870.3650, respectively. Developmental neurotoxicity endpoints including Functional Observational Battery (FOB) and Motor Activity were performed on male and female rats. The test substance was administered six hours a day, seven days a week by inhalation to 10 rats/sex/group at 0, 200, 1000, and 5000 ppm. All animals survived to the scheduled necropsy. There were no clinical signs or effects on body weights and food consumption among the groups. No treatment-related changes were observed in any FOB or motor activity parameters. There were no alterations in hematology, serum chemistry, organ weights, organ to body weight ratios or macroscopic examination of organs/tissues among the groups. Histopathologic examination of tissues and organs for control and high exposure animals demonstrated no significant microscopic findings. No effects were observed in any of the reproductive parameters evaluated. One female in 200 ppm group was found non-gravid but the remaining females produced litters that were similar in all respects to control litters. Based on the results of this study, the NOAEL for tetramethylsilane in rats via inhalation route was considered to be 5000 ppm. (Sponsored by the Silicones Environmental, Health and Safety Council).

**950**

**GLYCIDEOXYPROPYLTRIMETHOXYSILANE (TMSPGE): ONE-GENERATION REPRODUCTION STUDY IN THE RAT.**

W. H. Koch<sup>1</sup> and H. Becker<sup>2</sup>. <sup>1</sup>*Epona Associates, LLC, Willington, CT* and <sup>2</sup>*Toxicology/Safety Assessment 1, RCC Ltd, Fullinsdorf, Switzerland.*

The potential effect of TMSPGE, an HPV chemical, was evaluated in a one-generation reproductive toxicity study. The study investigated the effects of TMSPGE to the rat on reproductive performance. The test substance was administered by gavage, once daily to males for a 70-day pre-pairing period, during the pairing period and until the last litter reached day 7 post partum. Females received the test substance during a 14-day pre-pairing period, and during pairing, gestation and lactation periods. Doses were 0, 250, 500 or 1000 mg/kg bw/day. Signs of discomfort after dosing were noted in all treated female animals; clinical signs were not observed in any male animal. Mean food consumption was not affected by treatment with TMSPGE. At 1000 mg/kg bw/d, mean body weight gain of males during pre-pairing was slightly decreased, resulting in a slightly lower mean body weight at the end of pre-pairing. This reduction was considered to be test substance related. During and after pairing, lower absolute body weights at 1000 mg/kg bw/d persisted, while body weight gain was similar to that of the control. Body weights of females was not affected by treatment. There were no test substance related macroscopic or microscopic findings. At 1000 mg/kg bw/d, statistically significant increased mean relative liver and kidney weights were noted for males and females. No effects were observed in any of the reproductive parameters evaluated. In the liver of high dose males, the severity of glycogen deposition was slightly increased; this finding was not considered to be test substance related. A slightly increased severity of tubular hyaline change occurred in the kidneys of high dose males; this change reflects an increased accumulation of alpha-2-microglobulin which is a male rat specific phenomenon. No test substance related findings, clinical signs or macroscopic findings were noted for any litter. The NOAEL (parental) is 500 mg/kg bw/d; the NOAEL (reproductive effects) is 1000 mg/kg bw/d. (Sponsored by the Silicones Environmental, Health and Safety Council).

**951**

**DEVELOPMENTAL TOXICITY AND COMBINED MALE AND FEMALE FERTILITY STUDIES IN RATS EXPOSED TO 2, 3-DICHLORO-1, 3-BUTADIENE (DCBD) BY INHALATION.**

L. A. Malley, E. Mylchreest, A. O. O'Neill, T. A. Kegelman, G. P. Sykes and R. Valentine. *DuPont Haskell Laboratory, Newark, DE.*

In a fertility study, Crl:CD(SD)IGS BR rats (24/sex/group) were exposed by inhalation to 0, 1, 5, or 50 ppm DCBD (6 hr/day) during prematting (8 wks; 5 days/wk), cohabitation of mating pairs (up to 2 wks, 7 days/wk), postcohabitation for males (-7 days) and from conception to implantation (days 0-7 of gestation [G]). Estrous cyclicity was evaluated during prematting (last 3 wks) and cohabita-

tion. Reproductive and potential target organs, sperm parameters, and day 21G fetuses (viability, weight, external alterations) were evaluated. In a developmental study, pregnant Crl:CD(SD)IGS BR rats (22/group) were exposed to 0, 1, 10, or 50 ppm DCBD (6 hr/day) on days 6-20G; dams were necropsied on day 21G and fetuses were evaluated (viability, weight, and external, visceral and skeletal exams). During the in-life portion of the studies, body weight, food consumption, and clinical observation data were collected. Gasping and labored breathing occurred during the first exposure in both studies at 50 ppm. Fetal weight was decreased at 50 ppm in the developmental toxicity study. In the fertility study, decreased parental body weight, weight gain, food consumption and food efficiency and degeneration of the nasal olfactory epithelium were observed at 50 ppm. There were no effects on reproductive function, fetal viability or malformations in either study. The NOEL for reproductive toxicity was 50 ppm. The NOEL for effects in parental rats was 5 ppm based on adverse effects on body weight and food consumption parameters, and nasal olfactory epithelial toxicity at 50 ppm. The NOEL for maternal and developmental toxicity was 10 ppm based on reduced maternal weight gain and food consumption and fetal weight at 50 ppm in the developmental toxicity study.

**952**

LACK OF FERTILITY OR ESTROUS CYCLE EFFECTS OF A FLUORINATED ORGANIC ETHOXYLATE SURFACTANT IN RATS.

J. M. Lewis<sup>1</sup>, E. Mylchreest<sup>1</sup>, S. R. Frame<sup>1</sup>, R. C. Buck<sup>2</sup> and J. C. Stadler<sup>1</sup>.  
*DuPont Haskell Laboratory, Newark, DE and <sup>2</sup>DuPont, Wilmington, DE.*

The purpose of this study was to determine the repeatability of fertility and estrous cycle effects observed at doses of 25 mg/kg/day and above, with no dose-response, in a previously conducted reproduction study and to establish a NOEL for reproductive parameters. Crl:CD(SD)IGS BR rats were dosed once daily by gavage at 0, 1, 10, or 25 mg/kg/day. Following 72 days of dosing (pre mating), the P1 males and females were cohoused within their respective treatment groups to produce F1 litters. Clinical observations, body weight, and food consumption in P1 rats were recorded weekly throughout the study; estrous cyclicity was evaluated during pre mating (last 3 wks) and during cohabitation. F1 litter viability, weights, and clinical observations were determined at birth and on day 4. After litter production, all P1 rats were given a gross pathological examination, the liver (target organ) was weighed, the liver and reproductive organs saved, and uterine implantation sites and ovarian corpora lutea counted. Liver and gross lesions from randomly selected P1 rats in the control and 25 mg/kg/day groups were examined microscopically. Treatment related effects were limited to increased liver weight in P1 rats at 25 mg/kg/day, which was not accompanied by gross or histological changes. This effect was considered a non-adverse physiological adaptive response. The NOEL for P1 rats, F1 litters, and reproductive parameters, including fertility, was 25 mg/kg/day, the highest dose tested. These results support the conclusion that the apparent increase in estrous cycle length and decreased fertility reported in the first study are unlikely to be test substance-related. Thus, the overall LOEL for reproductive parameters is 100 mg/kg/day, based on reduced pup survival and weight during lactation observed in the first study. The overall NOEL for reproductive parameters is 25 mg/kg/day, which is the same as the NOEL for subchronic toxicity observed in both studies.

**953**

DEVELOPMENTAL IMMUNOTOXICITY OF DEXAMETHASONE AND CYCLOSPORIN A.

I. D. Waalkens-Berendsen, A. P. Wolterbeek, A. Dijkstra, F. C. Kuper, A. H. Penninks, M. Zijverden van, E. I. Klein Koerkamp, P. T. Berg van den and M. M. Tegelenbosch. *Toxicology and Applied Pharmacology, TNO Nutrition and Food Research, Zeist, Netherlands.* Sponsor: V. Feron.

Introduction. As pre and postnatal exposure can result in various types of immunotoxic effects in the offspring, incorporation of immunotoxicological determinations is considered in reproductive toxicology studies. The impact of maternal treatment and direct dosing of pre-weaning rats with dexamethasone and cyclosporin A on development of the immune system was investigated. Materials and Methods. Two developmental toxicity studies were performed in Wistar rats. In the first study rats were treated subcutaneously with 20 or 100 µg dexamethasone/kg from gestation day (GD) 0 to postnatal day (PND) 21. In the second study dams were treated orally with 5 or 15 mg cyclosporin A/kg from GD 6 to PND 21 and a selection of pups was dosed directly with 12.5 mg cyclosporin A /kg from PND 14-21. Enhanced immunopathology was performed. Immune function was studied by flow cytometric lymphocyte subset analysis in blood and by T cell-dependent antibody response to Keyhole Limpet Hemocyanine. Results. Dexamethasone induced maternal toxicity, decreased pup weights and immunopathological effects on thymus, spleen, bone marrow and mesenteric lymph nodes. The KLH-specific IgM and IgG antibody titers were not affected. Cyclosporin A induced a dose related increased post-implantation loss. The KLH-specific IgM and IgG antibody titers were not affected. The KLH-specific IgM antibody titer measured in pups dosed directly with cyclosporin A was increased (as compared to non-treated pups). The increase was similar in dosed pups derived from cyclosporin-treated dams and control dams. Conclusion. These data suggest that maternal dexamethasone and cy-

closporin A treatment up to dose levels of 100µg/kg and 15 mg/kg, respectively, influences postnatal immune system-related parameters in the offspring to a low extent. The pre-weaning rat (directly dosed) seems to be a more appropriate model for investigating possible effects on the development of the immune system than the adult rat.

BEHAVIORAL ABNORMALITY ASSOCIATED WITH ATTENTION DEFICIT HYPERACTIVE DISORDER IN RAT OFFSPRING PRENATALLY EXPOSED TO 5-BROMO-2'-DEOXYURIDINE.

K. Orito<sup>1</sup>, M. Kuwagata<sup>2</sup>, T. Ogawa<sup>3</sup>, K. Muneoka<sup>3</sup>, M. Shirai<sup>1</sup>, F. Akahori<sup>1</sup>, K. Mishima<sup>4</sup> and M. Fujiwara<sup>4</sup>.  
*Pharmacology, Azabu University School of Veterinary Medicine, Sagamihara, Japan, <sup>2</sup>Hatano Research Institute, FDSC, Hadano, Japan, <sup>3</sup>Anatomy I, Showa University School of Medicine, Tokyo, Japan and <sup>4</sup>Neuropharmacology, Faculty of Pharmaceutical Sciences, Fukuoka University, Fukuoka, Japan.*

Our previous study revealed that rat offspring prenatally exposed to 5-bromo-2'-deoxyuridine (BrdU) exhibited hyperactivity. In the present study, the behavioral abnormalities induced by prenatal exposure to BrdU were further examined and a possible association with problematic behaviors of attention deficit hyperactive disorder (ADHD) was evaluated. Sprague-Dawley rats were treated with BrdU 50 mg/kg, IP or carboxymethylcellulose (CMC), its vehicle, on gestational days nine through 15, and their offspring (BrdU rats and CMC rats, respectively) were subjected to behavioral tests at five to six weeks of age. A continuous locomotor activity monitoring system revealed that locomotor activity increased when lights were out and gradually decreased during the night cycle in CMC rats. In BrdU rats, locomotor activity was kept increased throughout the night cycle. In elevated plus maze task, the number of open arm entries and time spent per one open arm entry, both of which are indices of impulsivity, were significantly increased in BrdU rats when compared with those of CMC rats. In the Y-maze test, spontaneous alternation behavior was significantly lower in BrdU rats. Long-term potentiation, a cellular mechanism of memory, was not different between BrdU and CMC rats. Thus, lowered spontaneous alternation behavior in BrdU rats was not caused by a deficiency of short-term memory but by attention deficit. These data suggest that BrdU rats showed ADHD-like behavior abnormalities including hyperactivity, impulsivity, and attention deficit.

MATERNAL DETOXICATION VIA CYP1A1 PREVENTS METABOLIC ACTIVATION AND EMBRYO TOXICITY FOLLOWING ORAL EXPOSURE TO BENZO(A)PYRENE.

C. P. Curran<sup>1</sup>, M. L. Miller<sup>1</sup>, N. Dragin<sup>1</sup>, T. P. Dalton<sup>1</sup>, D. W. Nebert<sup>1</sup> and S. Uno<sup>2</sup>.  
*<sup>1</sup>University of Cincinnati Medical Center, Cincinnati, OH and <sup>2</sup>Nihon University School of Medicine, Tokyo, Japan.*

Maternal smoking can produce numerous adverse outcomes in pregnancy, including lower birthweights. Recently, CYP1A1 polymorphisms were associated with an increased risk of low birthweight in infants born to mothers who smoked during pregnancy. Benzo[a]pyrene (BaP), a known carcinogen and mutagen in cigarette smoke, also causes fetal toxicity. BaP must be metabolically activated to produce its toxic effects. CYP1A1 plays a paradoxical role in the metabolism of BaP. It oxidizes BaP to DNA-reactive carcinogenic species, but this oxidation is required for conjugation and elimination. Thus, the role of CYP1A1 in eliminating or potentiating BaP toxicity must be evaluated in the context of the animal. To explore the role of CYP1A1 on BaP toxicity during gestation, we exposed *Cyp1a1(+/-)* and *Cyp1a1(-/-)* dams to 12.5 mg/kg/day oral BaP from gestational day(GD)4 to 10. There was nearly 100 percent *in utero* lethality and fewer implantation sites in *Cyp1a1(-/-)* dams. In contrast, there was little BaP-mediated toxicity to fetuses of *Cyp1a1(+/-)* dams, even at 125 mg/kg/day. To determine whether the lethality was due to a maternal or fetal effect of CYP1A1, we mated *Cyp1a1(+/-)* females with *Cyp1a1(-/-)* males and *Cyp1a1(-/-)* females with *Cyp1a1(+/-)* males. Dams were treated with 12.5 mg/kg/day BaP from GD4-10. Weight gain during gestation was significantly less in *Cyp1a1(-/-)* dams compared with *Cyp1a1(+/-)* dams ( $0.8 \pm 0.4$ g v.  $14.6 \pm 0.5$ g). DNA adducts in maternal liver, placenta and fetal tissues were dramatically higher in *Cyp1a1(-/-)* dams compared with *Cyp1a1(+/-)* dams. The genotype of the fetuses made no difference in terms of lethality or DNA adduct formation. We conclude that the presence of CYP1A1 in the mother is an important determinant in protection against oral BaP-induced teratogenesis and embryo toxicity. Supported in part by NIH grants P30 ES06096 and R01 ES08147.

MATURATION OF HEPATIC CYTOCHROME P450 ISOZYMES IN DEVELOPING SPRAGUE-DAWLEY RATS.

B. McPhail, S. Muralidhara, S. Anand and J. Bruckner. *Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.*

Cytochrome P450s (CYP450s) play a key role in the metabolic activation and inactivation of a wide range of xenobiotics. The ontogeny of a number of CYP450 isozymes has recently been delineated in human liver. There is relatively little such

information about immature rats, a primary animal model for infants and children. Our study was designed to characterize the ontogeny of several toxicologically-relevant CYP450 isozymes (CYP1A1/2, CYP2B1/2, and CYP2E1) as well as total CYP450 in Sprague-Dawley rats. Liver microsomes were prepared from unsexed naive rats at days 5, 10, 15, 21, 30, 40, 50 and 60 post-birth. On days 5, 10, and 15, samples were pooled and analyzed as a single sample. CYP1A1/2, CYP2B1/2 and CYP2E1 activities were measured using the substrates 7-Ethoxresorufin, 7-Pentoxyresorufin and para-Nitrophenol, respectively. CYP1A1/2 and CYP2B1/2 activities were measured using a spectrofluorimeter; CYP2E1 and total CYP450 were measured with a spectrophotometer. CYP1A1/2 activity was very low on day 5 and 10, but near-maximal by day 30. CYP2B1/2 displayed a similar pattern, with low activity on day 5, a 2-fold increase on days 10 and 15, peak activity days 30 and 40, followed by somewhat lower values on days 50 and 60. In contrast, CYP2E1 activity was relatively high by day 5 and exhibited moderately higher, but stable values the remainder of the developmental period. Total CYP450 levels were quite low on days 5, 10 and 15, with an abrupt increase to maximal levels by day 30. The differential expression of CYP450 isozymes during development may be an important factor in age-dependent susceptibility to pesticides, solvents and other toxicants metabolized by CYP450s.

957

RESISTANCE TO PCB INDUCTION OF P450 1A (CYP1A) ACTIVITY AND REACTIVE OXYGEN SPECIES (ROS) PRODUCTION IN A POLLUTED KILLIFISH (*FUNDULUS HETEROCLITUS*) POPULATIONS.

X. Arzuaga<sup>1</sup> and A. A. Elskus<sup>2</sup>. <sup>1</sup>Toxicology, University of Kentucky, Lexington, KY and <sup>2</sup>Department of Biological Sciences, USGS, Orono, ME. Sponsor: B. Hennig.

New Bedford Harbor MA and Newark Bay NJ are highly contaminated with polychlorinated biphenyls (PCBs). During early fish development, exposure to PCBs results in activation of the aryl hydrocarbon receptor (AHR), induction of cytochrome P450 1A (CYP1A) and increased production of Reactive Oxygen Species (ROS). Previous studies have demonstrated that first generation killifish (*Fundulus heteroclitus*) embryos from Newark Bay and New Bedford Harbor are resistant to PCB induction of CYP1A expression and mortality. We hypothesized that PCB induced P450 activity is associated with increased ROS production and that contaminated site killifish are resistant to PCB induction of ROS production. Killifish embryos from contaminated sites and a reference site were exposed to vehicle (acetone) or the potent CYP1A inducer, PCB126 (0.3nM), from day two to day seven post fertilization (pf). Superoxide production (detected with dihydroethidium) was measured on day 7 pf and *in ovo* CYP1A activity (ethoxresorufin-o-deethylase, EROD) was measured on day 9 pf. Treatment with PCB126 induced CYP1A activity and reactive oxygen species (ROS) production in reference site, but not polluted site embryos. To determine if PCB induced ROS production is dependent on AHR activation and induction of responsive P450s, reference site embryos were treated with the AHR/CYP1A inhibitor a-naphthoflavone (ANF) alone (367 nM), or the P450 inhibitor piperonyl butoxide (PBO) alone or in combination with PCB126. ANF blocked PCB126 induction of CYP1A activity, but did not affect ROS production. PBO treatment inhibited PCB induction of CYP1A activity and ROS production. Our results suggest that chronic contaminated killifish populations are resistant to PCB induction of CYP1A activity and ROS production and that PCB induced P450 activity plays an important role in ROS production.

SUB-CHRONIC SODIUM ARSENATE EXPOSURE AFFECTS FERTILITY AND EARLY DEVELOPMENT IN HOMING PIGEONS: A MODEL FOR MIGRATORY BIRDS.

J. Brasel<sup>1</sup>, A. C. Collier<sup>2</sup> and C. A. Pritsos<sup>2,1</sup>. <sup>1</sup>Environmental Sciences and Health Program, University of Nevada, Reno, NV and <sup>2</sup>Nutrition, University of Nevada, Reno, NV.

Arsenic is found in high levels in surface waters near mine sites and in organoarsenic pesticide manufacturing plants where migratory birds are exposed and could result in fertility or developmental toxicities as shown for some mammalian species. These studies investigate the effect of repeated low doses of sodium arsenate on fertility, embryonic and neonatal development in homing pigeons as a model for migratory birds. Homing pigeons received doses of 0.5, 1.0, or 2.0 mg/kg of sodium arsenate a total of four times. Dosed birds were allowed to randomly mate and breed. Fertility and neonatal growth rates were recorded over four breeding cycles. Eggs were collected for embryo extraction at 2 days, 6 days, 8 days, and 12 days. Bone development was observed utilizing the Von Kossa staining method on sagittal sections of 8-day embryos. RT-PCR was performed on 2-day, 6-day and 12-day embryos for several developmental markers. Significantly lower fertility rates and 24-hour birth weights were observed for the treated birds as compared to the control birds. Morphological studies indicated no difference in bone development between the two groups. Skeletal Alpha-Actin was expressed consistently in 2-day, 6-day, and 12-day embryos and Cardiac Alpha Actin was expressed

consistently in 6-day and 12 day embryos with no difference between treated and control groups. Embryonic Heart Myomesin was expressed in all 12-day embryos and a single 6-day treated embryo. Sub chronic sodium arsenate exposure in pigeons corresponded with significantly lower fertility and birth weights and may cause the disruption of developmental gene expression, particularly embryonic heart myomesin. These data indicate that exposure to arsenate through mining contaminants and/or pesticide production may cause population-level effects in migratory bird species through decreased reproductive capacity. This study was funded in part by USDA Hatch Grant NEV 00727 and the Nevada Agricultural Experiment Station.

TRUE HERMAPHRODITISM IN A CD-1 MOUSE.

A. Moran. Covance Laboratories Ltd., Harrogate, United Kingdom. Sponsor: D. Everett.

True hermaphroditism was diagnosed in a 20 week old female CD-1 mouse. Although no macroscopic abnormalities were recorded in the gonads, the uterus was dilated and the cervix thickened. Microscopically, bilateral ovaries were present. The right ovary was composed of several large central corpora lutea and variable amounts of ovarian stroma. Surrounding this were small numbers of seminiferous tubules, lined by Sertoli cells and lacking spermatogonia. In the adjacent connective tissue, a well defined section of epididymis was present. The left ovary was composed of variably atrophic seminiferous tubules lined by frequently vacuolated Sertoli cells. Small amounts of ovarian stromal tissue was also identified. Immunohistochemical analysis using Testosterone, 3 beta-hydroxy steroid dehydrogenase, p450c17, Vimentin and alpha-Smooth muscle actin was performed. In addition, chromosomal analysis was carried out to determine the presence of numeric or structural defects of the sex chromosomes

CIGARETTE SMOKE INHALATION IN JUVENILE RATS: A POTENTIAL ANIMAL MODEL OF ADOLESCENT NICOTINE ADDICTION.

T. F. Murray<sup>1</sup>, J. M. Benson<sup>2</sup>, E. B. Barr<sup>2</sup>, J. McDonald<sup>2</sup>, M. D. Campen<sup>2</sup>, X. Yan<sup>1</sup> and C. S. Hale<sup>1</sup>. <sup>1</sup>Physiology and Pharmacology, University of Georgia, Athens, GA and <sup>2</sup>Lovelace Biomedical and Environmental Institute, Albuquerque, NM.

Chronic administration of nicotine increases the density of nicotinic receptors in human and rodent brain. An increased susceptibility of juvenile rats to this receptor upregulation has been reported using continuous nicotine exposure with osmotic minipumps. The purpose of this study was to validate a model of nicotine addiction in juvenile rats inhaling cigarette smoke for 7 days. Rats were exposed in whole-body inhalation chambers to mainstream cigarette smoke generated from 2R4F cigarettes or filtered air (controls). Exposures were to 100 mg total particulate material/m<sup>3</sup> for 4 hours/day for 7 days. Subgroups were sacrificed immediately after the seventh exposure and after a 3-day hold period. Endpoints included evaluations of behavioral changes, body weight, and concentrations of nicotine and cotinine in blood and brain. Acetylcholine nicotinic receptor (nAChR) upregulation in the brain was determined by quantifying the extent of [<sup>125</sup>I]epibatidine binding in brain sections by receptor autoradiography. Concentrations (mean, n = 4) of nicotine in brains of juvenile (733 ng/g) and adult brains (985 ng/g) were not significantly different immediately following the seventh exposure. Nicotinic receptor upregulation was observed in brains of both juvenile and adult rats; however, the responses in the n. accumbens, cerebral cortex, thalamus and hippocampus were more profound in the juvenile as compared to adult rats. Exposure resulted in significant depression of heart rate and heart rate variability. These data confirm that nicotine inhaled as a component of cigarette smoke for only 7 days during adolescence produces robust increases in nAChR density, a hallmark of nicotine addiction. The effects in specific brain regions were more pronounced in juveniles than in adults despite similar nicotine and cotinine concentrations in whole brain. This animal model may be useful for studies investigating the mechanisms underlying nicotine addiction in juveniles.

"SENSORIMOTOR PERFORMANCE DEFICITS, NEURONAL CELL LOSS, AND ELEVATED GLIAL ACIDIC PROTEIN EXPRESSION IN PURKINJE CELLS AND CA1 OF THE HIPPOCAMPUS IN ADULT OFFSPRING FOLLOWING MATERNAL EXPOSURE TO NICOTINE".

W. A. Khan, A. M. Dechkovskaia, A. A. Rahman, X. Guan and M. B. Abou-Donia. Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.

The present studies were carried out in the offspring at adulthood following maternal exposure to nicotine via osmotic pump. Timed pregnant female Sprague-Dawley rats (300-350 gm) were treated with nicotine (3.3mg/kg, in bacteriostatic

water via s.c. implantation of the pump) from gestational days (GD) 4-20. Control animals were treated with saline via s.c. implantation of the pump. Male and female offspring on postnatal day (PND 90) were evaluated for sensorimotor functions, changes in the ligand binding for various types of nicotinic acetylcholine receptors in the cortex, and pathological alterations in the cerebellum and hippocampus. Neurobehavioral evaluations included, beam-walk-score, beam-walk time, incline plane and grip time response. Only male offspring from nicotine treated mothers showed significant deficits in beam-walk time and incline plane whereas both male and female offspring from nicotine treated mothers showed significant impairments in forepaw grip time. Ligand binding densities for [<sup>3</sup>H]epibatidine, [<sup>3</sup>H]cytisine and [<sup>3</sup>H] $\alpha$ -bungarotoxin did not show any significant changes in the cortex. Histopathological evaluation using cresyl violet staining showed a significant decrease in Purkinje cells in the cerebellum, and an increase in glial fibrillary acidic protein (GFAP) immunostaining in the white matter in both male and female offspring from nicotine treated mothers. CA1 subfield of the hippocampus from the female offspring of nicotine treated mothers showed a decrease in surviving neurons and an increase of GFAP immunostaining. These data suggest that maternal exposure to nicotine produces significant neurobehavioral deficits and pathological alterations in the cerebellum and CA1 subfield of the hippocampus in adult offspring. Supported by a grant from the External Research Program of Philip Morris, USA.

**"INCREASED EXPRESSION OF GLIAL FIBRILLARY ACIDIC PROTEIN IN THE MOTOR CORTEX AND HIPPOCAMPUS, AND NEUROBEHAVIORAL DEFICITS IN THE OFFSPRING FOLLOWING GESTATIONAL EXPOSURE TO IMIDACLOPRID".**

A. A. Abdel-Rahman, A. M. Dechkovskaia, J. M. Sutton, T. Tu, W. A. Khan and M. B. Abou-Donia. *Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

Imidacloprid belongs to a new generation of insecticides known as neonicotinoids. It has one of the fastest growing sales of any insecticide worldwide due to its selectivity for insects and its safety to human population. However, its neurotoxicity due to developmental exposure is not known. In the present studies, timed pregnant Sprague-Dawley rats (300-350 gm) were treated with a single intraperitoneal injection of imidacloprid (337 mg/kg, 0.75XLD<sub>50</sub> in corn oil) on gestational day 9. Control rats were treated with corn oil. On postnatal day 30, the offspring were evaluated for changes in the ligand binding for nicotinic acetylcholine receptors (nAChR) and muscarinic acetylcholine receptors (m2 mAChR), neurobehavioral performance and pathological alteration in brain regions. Beam-walk time, incline plane and forepaw grip time showed significant impairments in the offspring from imidacloprid treated mothers. Ligand binding densities for [<sup>3</sup>H]cytisine for  $\alpha 4\beta 2$  type nAChR did not show any significant change, whereas [<sup>3</sup>H]AFDX 384, a ligand for m2mAChR showed significant increase in the cortex of the offspring from imidacloprid treated mothers. Histopathological evaluation using cresyl violet staining did not show any alterations in surviving neurons in different brain regions. A significant increase in glial fibrillary acidic protein (GFAP) immunostaining in the motor cortex and hippocampus CA1 and dentate gyrus of the offspring from imidacloprid treated mothers was observed. These data suggest that gestational exposure to a large toxic dose of imidacloprid produces significant neurobehavioral deficits, and an increased expression of GFAP in different brain regions of the offspring on PND 30. These changes may have long-term adverse health effects later in life.

**963**

**NONCHOLINESTERASE MECHANISM(S) OF CHLORPYRIFOS NEUROTOXICITY INDICATED BY GENE EXPRESSION PROFILES OF RAT BRAIN TISSUE.**

A. R. Stapleton<sup>1</sup>, N. DelRaso<sup>2</sup> and V. Chan<sup>1</sup>. <sup>1</sup>*ManTech Environmental Technology, Inc., Wright-Patterson AFB, Dayton, OH* and <sup>2</sup>*Applied Biotechnology Branch, Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson AFB, Dayton, OH.* Sponsor: J. Gearhart.

Chlorpyrifos (CPF) is a widely used organophosphate insecticide that affects the nervous system by reversibly inhibiting the activity of cholinesterase (ChE). Recent studies have suggested that low doses of CPF disrupt brain development and cognitive function by mechanisms that do not involve the inhibition of acetylcholinesterase (AChE). Few reports in the literature have addressed the effect of CPF on the nervous system using transcriptomic profiling. In this study brain tissues isolated from rats 4 days after treatment with 1.0mg/kg, 10 mg/kg and 50mg/kg of CPF were processed for Affymetrix RAE230A Genechip analysis. Statistical analysis showed that the expression level of 151 genes changed in the brain isolated from CPF-treated animals. Genes playing a role in the G-protein pathways and sodium, potassium and cation transport showed down-regulation. Also down-regulated were responders to hypoxia and oxidative stress, as were the

genes involved in the regulation of synapse proteins and membranes. Transcripts for the genes involved in membrane synapse transmission and brain development showed up-regulation as well as those genes connected to transcription factors, protein phosphorylation and intracellular protein transport. Interestingly, the gene for the precursor of beta amyloid and the putative rat homolog of the human gamma synuclein gene, which have been implicated in neurodegenerative pathogenesis including Alzheimer's disease, were up-regulated after CPF treatment. This finding is consistent with the reports that CPF neurotoxicity involves pathways other than cholinesterase. Further analysis of the molecular and biological functions of these genes will likely provide a better understanding as to the mechanism(s) of CPF neurotoxicity.

**964**

**OXIDATIVE MECHANISMS CONTRIBUTING TO THE DEVELOPMENTAL NEUROTOXICITY OF NICOTINE AND CHLORPYRIFOS.**

D. Qiao, F. J. Seidler and T. A. Slotkin. *Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC.*

Nicotine and chlorpyrifos are developmental neurotoxicants that, despite their differences in structure and mechanism of action, share many aspects for damage to the developing brain. Both are thought to generate oxidative radicals; in the current study, we evaluated their ability to produce lipid peroxidation in two *in vitro* models of neural cell development (PC12 and SH-SY5Y cells) and for nicotine, with treatment of adolescent rats *in vivo*. Nicotine and chlorpyrifos, in concentrations relevant to human exposures, elicited an increase in thiobarbituric acid-reactive species (TBARS) in undifferentiated cells, an effect that was prevented by addition of the antioxidant, Vitamin E. Initiating differentiation with nerve growth factor, which enhances nicotinic acetylcholine receptor expression, increased the TBARS response to nicotine but not chlorpyrifos, suggesting that the two agents act by different originating mechanisms to converge on the endpoint of oxidative damage. Furthermore, nicotine protected the cells from oxidative damage evoked by chlorpyrifos and similarly blocked the antimitotic effect of chlorpyrifos. Treatment of adolescent rats with nicotine elicited increases in TBARS in multiple brain regions when given in doses that simulate plasma nicotine concentrations found in smokers or at one-tenth the dose. Our results indicate that nicotine and chlorpyrifos elicit oxidative damage to developing neural cells both *in vitro* and *in vivo*, a mechanism that explains some of the neurodevelopmental endpoints that are common to the two agents. The balance between neuroprotectant and neurotoxicant actions of nicotine may be particularly important in situations where exposure to tobacco smoke is combined with other prooxidant insults. Support: NIH ES10387 and ES10356, and Philip Morris USA.

**DEVELOPMENTAL CHLORPYRIFOS EXPOSURE TARGETS SEROTONIN FUNCTION AND RELATED BEHAVIORS.**

J. E. Aldridge, E. D. Levin, F. J. Seidler and T. A. Slotkin. *Pharmacol/Cancer Biol, Duke U Med. Ctr, Durham, NC.*

Developmental exposure to chlorpyrifos (CPF) causes persistent changes in serotonergic (5HT) systems. We administered 1 mg/kg/day of CPF to rats on postnatal days 1-4, a regimen below the threshold for systemic toxicity. When tested in adulthood, CPF-exposed animals showed abnormalities in 5HT synaptic transmission and in behavioral tests that depend on 5HT. Both 5HT1A and 5HT2 receptor subtypes were upregulated in multiple brain regions, suggestive of reduced 5HT synaptic activity. In agreement, the ability of 5HT to stimulate adenylyl cyclase showed a distinct switch from stimulatory to inhibitory actions in females. For behavioral testing, we adopted two tests from standard procedures utilized in evaluations of 5HT systems in anxiety and depression. In the elevated plus maze, animals treated with CPF spent more time in the open arms, indicative of increased risk-taking behavior. In a test for anhedonia, the CPF-exposed group showed a decreased preference for chocolate milk versus water, indicative of decreased importance of rewarding stimuli. Both these findings are characteristic of a deficit in 5HT synaptic activity. Developmental CPF exposure also has lasting effects on cognitive function. We replicated our earlier finding, that developmental CPF exposure impairs the normal sex differences in 16-arm radial maze spatial learning and memory. During acquisition training control male rats performed more accurately than control females. CPF treatment eliminated this sex difference. Females exposed to CPF showed a reduction in working and reference memory errors, reducing their error rate to that equivalent of control males. Conversely, CPF-exposed males exhibited an increase in working and reference memory errors. To measure the CPF-induced functional impairment of 5HT function a dose-effect function of the 5HT2 antagonist ketanserin is used. Our results indicate that otherwise subtoxic neonatal CPF exposure produces lasting changes in 5HT synaptic activity and related behavioral performance. NIH ES10387, ES10356, ES07031.

YOUNG ANIMALS ARE DEFICIENT IN BOTH HEPATIC P450 AND CARBOXYLESTERASE DETOXIFICATION OF DELTAMETHRIN, A PYRETHROID PESTICIDE.

W. T. Haines<sup>1,2</sup>, R. S. Marshall<sup>2</sup>, D. L. Hunter<sup>2</sup> and S. Padilla<sup>2</sup>. <sup>1</sup>*Curriculum in Toxicology, University of NC at Chapel Hill, Chapel Hill, NC* and <sup>2</sup>*Neurotoxicology Division, USEPA, Research Triangle Park, NC*.

It is known that young rats are markedly more sensitive to the acute toxicity of deltamethrin, a pyrethroid pesticide. To determine the underlying mechanism for that increased sensitivity, the deltamethrin detoxification capability of liver from postnatal day 21 (PND21) rats was compared to the detoxification capability of liver from adult (PND90) rats. All animals were male, Long-Evans rats; n=4 per age. Two primary detoxification routes were examined: carboxylesterase (CaE) activity in liver homogenates and P450 detoxification in liver microsomes. Deltamethrin detoxification was assessed by measuring the disappearance of deltamethrin over time using an HPLC method. It was found that hepatic P450s metabolized deltamethrin much more efficiently than CaEs, and that adult liver (either enzyme) metabolized deltamethrin more rapidly than PND21 liver (adult P450 =  $197.8 \pm 18.8$ ; PND21 P450 =  $97.3 \pm 6.8$ ; adult CaE =  $15.4 \pm 1.2$ ; PND21 CaE =  $4.8 \pm 1.4$ ) (ng deltamethrin metabolized/min/mg protein). Adult liver P450s metabolized deltamethrin twice as fast as the PND21 liver P450s, and adult liver CaEs metabolized deltamethrin 3.2 times faster than PND 21 hepatic CaEs. In a related investigation to determine which P450s are responsible for deltamethrin detoxification, various rat Supersomes® were assessed for deltamethrin detoxification potential. It was found that both 1A1 and 2B1 metabolized deltamethrin. In sum, young animals are deficient in enzymes which detoxify deltamethrin; this lack of detoxification capability may explain the marked age-related sensitivity to deltamethrin. *This is an abstract of a proposed presentation and does not reflect Agency policy.*

EFFECT OF ORGANOPHOSPHORUS INSECTICIDES AND THEIR METABOLITES ON DNA SYNTHESIS IN ASTROGLIAL CELLS.

M. Guizzetti, S. Pathak, G. Giordano and L. G. Costa. *EOHS, University of Washington, Seattle, WA*.

Though little attention has been given to the possibility that glial cells may represent a target for the developmental neurotoxicity of organophosphorus (OP) insecticides, recent evidence, obtained in particular with chlorpyrifos (CP), suggests that developmental exposure to this compound may indeed target astrocytes. To substantiate and expand these observations, we carried out a series of *in vitro* studies utilizing fetal rat astrocytes and a human astrocytoma cell line, 1321N1 cells, to investigate the effect of the OPs CP, diazinon (DZ) and parathion (P), their oxygen analogs chlorpyrifos oxon (CPO), diaxonon (DZO) and paraxon (PO), and their metabolites 3, 5, 6-trichloro-2-pyridinol (TCP), 2-isopropyl-6-methyl-4-pyrimidol (IMP) and para-nitrophenol (PNP), on cell proliferation. In fetal rat astrocytes and astrocytoma cells maintained in serum CP, DZ, P, CPO, DZO, and PO induced a concentration-dependent inhibition in [<sup>3</sup>H]thymidine incorporation with a very similar potency (IC<sub>50</sub>s between 45 and 57  $\mu$ M). Among the other metabolites, PNP was the most potent (IC<sub>50</sub>s = 81 and 70  $\mu$ M for rat astrocytes and astrocytoma cells, respectively), while TCP and IMP were much less effective (IC<sub>50</sub>s > 100  $\mu$ M). Cytotoxicity appears to account only for a small part of the effect on DNA synthesis. OP insecticides and their oxons were 3-6 fold more potent in inhibiting [<sup>3</sup>H]thymidine incorporation when cells were synchronized in the G0 phase of the cell cycle and re-stimulated by carbachol or EGF. These results suggest that OP insecticides and their oxons affect astroglial cell proliferation and that the transition from the G0 to the G1/S phase of the cell cycle may be particularly sensitive to the action of these compounds. (Supported in part by ES09601/EPA-R826886, ES07033).

PON1 MODULATES OP TOXICITY DURING DEVELOPMENT.

C. Pettan-Brewer<sup>1</sup>, T. B. Cole<sup>1,2,3</sup>, J. Fisher<sup>3</sup>, B. Walter<sup>3</sup>, A. Forbes<sup>3</sup>, N. Yee<sup>1</sup>, L. G. Costa<sup>3</sup> and C. E. Furlong<sup>1,2</sup>. <sup>1</sup>*Medical Genetics, University of Washington, Seattle, WA*, <sup>2</sup>*Genome Sciences, University of Washington, Seattle, WA* and <sup>3</sup>*Environmental and Occupational Health Sciences, University of Washington, Seattle, WA*.

Paraoxonase (PON1) is an HDL-associated enzyme that hydrolyzes multiple substrates, including organophosphorous compounds such as the nerve agents sarin and soman, and the highly toxic oxon forms of diazinon and chlorpyrifos. PON1 activity is determined in part by a Q192R coding region polymorphism that affects its catalytic efficiency and in part by differences in PON1 expression levels, which vary widely (>13 fold). Young children represent a particularly susceptible population for OP exposure due to low abundance of PON1. To address the involvement of PON1 in protecting against OP-related neurotoxicity during development,

PON1 knockout (PON1<sup>-/-</sup>) mice, or mice expressing PON1 (human or mouse), were exposed chronically (PN4 to PN21) to low levels of chlorpyrifos oxon (CPO). Endpoints included cholinesterase activity, histopathology, behavior, and gene expression. As early as PN4, PON1<sup>-/-</sup> mice were more sensitive than wild-type mice to inhibition of brain cholinesterase by CPO. At PN22 and persisting as long as 4 months, chronic developmental exposure of PON1<sup>-/-</sup> mice to 0.18 or 0.25 mg/kg/d CPO resulted consistently in perinuclear vacuolization of cells and abnormal distribution of neurons in the neocortex, with an increase in the number of affected cells at 0.25 mg/kg/d. In mice expressing PON1, this pathology was less severe and was only observed at 0.25 mg/kg/d. The neurobehavioral test battery did not reveal any effects on the specific behaviors chosen for assessment. However, from PN16-19, PON1<sup>-/-</sup> mice exposed chronically to 0.18 or 0.25 mg/kg/d exhibited striking hyperactivity immediately following CPO administration. These studies used multiple endpoints to reveal toxicity associated with low level OP exposure, and indicate that PON1 modulates OP toxicity during development. REPEATED EARLY POSTNATAL EXPOSURE TO CHLORPYRIFOS AFFECTS WORKING MEMORY PERFORMANCE IN THE 12-ARM RADIAL MAZE.

F. O. Johnson, J. E. Chambers and R. L. Carr. *Center For Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Starkville, MS*.

Developmental exposure to chlorpyrifos (CPS) is thought to be associated with cognitive deficits in children. The current study investigated the effects of repeated early postnatal CPS exposure on spatial memory. Using an incremental dosing regimen, Sprague-Dawley rats were orally gavaged daily with either corn oil or a low CPS dosage of 1mg/kg from postnatal day (PND) 1-21; a medium dosage of 1 mg/kg from PND1-7, 2 mg/kg from PND8-14, and 4 mg/kg from PND15-21; or a high dosage of 1.5 mg/kg from PND1-7, 3 mg/kg from PND7-14, and 6 mg/kg from PND15-21. Rats were then tested beginning on PND36 for 4 weeks on a working memory task using a 12-arm radial maze paradigm. Developmental CPS exposure elicited significant reduction in cholinesterase activity that persisted up to 19 days after the cessation of exposure. Behavioral testing indicated significant treatment effects as demonstrated by decreased arm accuracy within and between training blocks. The number of total accurate choices made during the first eight arm visits was significantly decreased by CPS in both sexes. CPS treated rats also made significantly fewer correct choices prior to making their first error. However, as the animals became more familiar with the radial arm maze, performances in both control and CPS treated rats improved with respect to both total arm accuracy within first eight visits and accurate choices before first arm error. In the fourth week of testing, control males were significantly more accurate than control females, committing fewer errors and visited more arms before first error. Repeated exposure to CPS reversed this effect. These data suggest that repeated early postnatal exposure to CPS can alter spatial working memory in a gender specific manner that may persist beyond the period of exposure. (Supported by NIH R01 ES 10386).

DISRUPTION OF PERFORMANCE IN THE 12-ARM RADIAL MAZE IN RATS EXPOSED TO METHYL PARATHION DURING THE EARLY POSTNATAL PERIOD.

R. L. Carr, J. E. Chambers and F. Johnson. *Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS*.

Developmental exposure to methyl parathion (MPS) is suspected to contribute to cognitive deficits in children. The current study investigated the effects of repeated early postnatal exposure to MPS on spatial memory. Using an incremental dosing regimen, Sprague-Dawley rats were orally gavaged daily with either corn oil or methyl parathion at a low dose of 0.2 mg/kg from postnatal day (PND) 1-21; a medium dose of 0.2 mg/kg from PND1-7, 0.4 mg/kg from PND 8-14, and 0.6 mg/kg from PND15-21; or a high dose of 0.3 mg/kg from PND1-7, 0.6 mg/kg from PND8-14, and 0.9 mg/kg from PND15-21. These dosages are known to produce no overt signs of toxicity. Rats were then tested beginning on PND36 for 4 weeks (4 sessions per week for 16 total sessions) on a spatial working/reference memory task using a 12-arm radial maze paradigm. MPS exposure elicited significant ( $p < 0.05$ ) reduction in cholinesterase (ChE) activity that persisted up to 19 days after the cessation of exposure. Assessment of spatial working memory was made using two criteria; total number of correct choices in the first eight arm visits and the number of accurate arm choices before making the first error. The total number of correct arm choices in first eight arm visits was significantly reduced ( $p < 0.05$ ) in both MPS treated males and females as compared to controls. However, there were no treatment effects on the number of correct arm choices before making the first error. As the animals gained more experience became more fa-

miliar with the maze, the total number of accurate arm choices increased with decreasing latency over successive four-day training blocks in all groups. These data suggest that early postnatal exposure to MPS alters spatial working memory but to a lesser degree and is less persistent than CPS. (Supported by NIH R01 ES 10386).

#### NGF GENE EXPRESSION AND PROTEIN LEVELS IN THE JUVENILE HIPPOCAMPUS AFTER REPEATED EXPOSURE TO CHLORPYRIFOS AND METHYL PARATHION.

A. M. Betancourt, S. C. Burgess and R. L. Carr. *Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS.*

Phosphorothionates are the largest subclass of the organophosphate (OP) insecticides and are considered to be more toxic than the other subclasses. Two of the most commonly used phosphorothionates are the diethyl OP chlorpyrifos (CPS), and the dimethyl OP methyl parathion (MPS). The toxic effects of these compounds are attributed to the ability of their reactive metabolites to inhibit acetylcholinesterase (AChE) but there are differences in the patterns of AChE inhibition between the two insecticides. In the developing rat, the most dynamic aspects of cholinergic innervation take place during the first postnatal weeks. Neurotrophins, such as nerve growth factor (NGF), play an important role in this development and are regulated, in part, by neuronal activity. Given the excitatory signaling associated with OP exposure, it is possible that exposure to these two insecticides during that period could differentially disrupt the regulation of NGF levels and alter normal cholinergic development. The purpose of this project was to investigate the effects of CPS and MPS on gene expression and protein levels of the neurotrophin NGF in the hippocampus after repeated exposure (postnatal day 10-20) to CPS and MPS in rats. Using quantitative real-time RT-PCR, decreased NGF mRNA levels were observed in the hippocampus of both male and female rats exposed to the high dosage of CPS (6 mg/kg) but exposure to the high dosage of MPS (0.9 mg/ml) decreased hippocampal NGF mRNA levels in females only. However, there were no effects on NGF protein levels after either CPS or MPS treatment. The effect observed in NGF mRNA but not protein levels could be due to several factors such as the presence of multiple NGF transcripts in the hippocampus with only a select few controlling the level of NGF protein in the hippocampus or possible stabilization of the NGF protein as a result of OP exposure (Supported by NIH 1 P20 RR17661-01).

#### EFFECTS OF POSTNATAL TREATMENT WITH CHLORPYRIFOS AND METHYL PARATHION ON CHOLINERGIC PARAMETERS IN RAT BRAIN REGIONS.

S. Guo-Ross, J. A. Dobbs, M. B. Dail and J. E. Chambers. *Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.*

The effects of early postnatal exposure to the commonly used organophosphorus insecticides chlorpyrifos (CPS) and methyl parathion (MPS) were investigated. Cholinesterase (ChE) activity, choline acetyltransferase (ChAT) activity, and muscarinic acetylcholine receptor (mAChR) densities were examined in several brain regions, which include cerebral cortex, corpus striatum, hippocampus, medulla/pons, and cerebellum. Using an incremental dosing regimen, pups were orally gavaged daily with one of seven treatments. 1) corn oil (control) 2) CPS low dose of 1 mg/kg from postnatal day (PND) 1 to 21; 3) CPS medium dose of 1 mg/kg from PND 1-5, 2 mg/kg from PND 6-13, and 4 mg/kg from PND 14-21; 4) CPS high dose of 1.5 mg/kg from PND 1-5, 3 mg/kg from PND 6-13, and 6 mg/kg from PND 14-21; 5) MPS low dose of 0.2 mg/kg from PND 1-21; 6) MPS medium dose of 0.2 mg/kg from PND 1-5, 0.4 mg/kg from PND 6-13, and 0.6 mg/kg from PND 14-21; 7) MPS high dose of 0.3 mg/kg from PND 1-5, 0.6 mg/kg from PND 6-13, and 0.9 mg/kg from PND 14-21. ChE activity, assayed spectrophotometrically, was inhibited in a dose related manner on PND 20 (4-62%), 25 (11-26%) and 30 (1-26%). PND 40 showed no inhibition. ChAT activity was determined by radioenzymatic microdetermination on PNDs 20, 25, 30 and 40. Males exposed to MPS exhibited statistical decreases in ChAT activity in the cerebral cortex and hippocampus on PND 20 and 25. The only change in female ChAT activity was an increase seen in the medulla/pons on PND 20 and 30. No statistical differences were seen at PND 40 suggesting recovery has occurred. Total and sub-types of mAChR densities were investigated on PNDs 12 and 20 by radioligand receptor binding assay. Several changes were noted. For example, the levels of total mAChR in male and female hippocampus were found to decrease by 17-31% at PND 20 in the high dose of CPS and MPS treated pups. These results indicate that pups exposed postnatally to CPS and MPS exhibited alterations in cholinergic biochemistry. (Supported by NIH R01 ES 10386).

#### DEVELOPMENTAL PYRETHRIN EXPOSURE ALTERS DOPAMINERGIC NEUROCHEMISTRY RESULTING IN HYPERACTIVITY AND ENHANCED TOXICITY OF MPTP.

J. R. Richardson, T. S. Guillot, M. Caudle, M. Z. Wang and G. W. Miller.

*Center for Neurodegenerative Disease and Department of Environmental and Occupational Health, Rollins School of Public Health, Emory University, Atlanta, GA.*

The dopamine transporter (DAT) plays an integral role in control of locomotor activity and serves as the gateway for the parkinsonism-inducing toxin MPTP. Previously, we have observed that perinatal exposure of mice to 3 mg/kg of the pyrethroid pesticide deltamethrin increases DAT levels in their offspring at 28 days. In this study, we sought to determine the dose-related effects of low level deltamethrin exposure (0.3, 1, or 3 mg/kg every 3 days throughout gestation and lactation) on dopaminergic neurochemistry and locomotor activity in developing mice. We also determined whether deltamethrin exposure affects the dopaminergic toxicity of MPTP. At 5 weeks of age, striatal DAT levels were significantly increased by 21, 35, and 70% in offspring of the 0.3, 1, and 3 mg/kg groups, respectively. At these same doses, total locomotor activity was significantly increased by 98, 231, and 285%. The increased locomotor activity in deltamethrin treated offspring was attenuated by the dopamine receptor antagonist haloperidol, suggesting a primary role of the dopamine system in the locomotor promoting effects of deltamethrin. Finally, MPTP exposure (2 x 10 mg/kg s.c.) at 12 weeks of age resulted in a greater reduction of striatal dopamine in deltamethrin mice (77% in the 3 mg/kg group) compared to controls (66%). These data suggest that the developing dopaminergic system is particularly sensitive to deltamethrin exposure during the perinatal period even though there is no direct treatment of the offspring. The effects observed here are particularly notable since the dosage levels employed are 4-40-fold below the developmental NOAEL of 12 mg/kg and suggest that low-level deltamethrin exposure results in hyperactivity and increased risk of dopaminergic damage. (Supported by NIH R21ES012315 and F32ES013457).

#### NEONATAL EXPOSURE TO NICOTINE INDUCES INCREASED SUSCEPTIBILITY TO PARAOXON EXPOSURE AT ADULT AGE.

E. Ankarberg, A. Fredriksson and P. Eriksson. *Department of Environmental Toxicology, Uppsala University, Uppsala, Sweden.*

Low dose exposure of neonatal mice to nicotine has earlier been shown to induce an altered behavioral response to nicotine in adulthood. Organophosphorus insecticides are known to affect the cholinergic system by inhibition of acetylcholinesterase. This study was undertaken to investigate whether neonatal exposure to nicotine makes mice more susceptible to a known cholinergic agent, paraoxon. Neonatal, 10-day-old, male mice were exposed to nicotine-base (33 mg/kg b.wt.) or saline s.c. twice daily on 5 consecutive days. At five months of age the animals were exposed to paraoxon (0.17 or 0.25 mg/kg b.wt. (29% and 37% inhibition of cholinesterase, respectively)) or saline s.c. every second day for 7 days (total of 4 injections/mouse). Before the first paraoxon injection, the animals were observed for spontaneous motor behavior. The spontaneous behavior test did not reveal any differences in behavior between the treatment groups. Immediately after the spontaneous behavior test the animals received the first injection of paraoxon and were observed for acute effects of paraoxon on spontaneous behavior. The acute response to paraoxon in the spontaneous behavior test was a decreased level of activity in mice neonatally exposed to nicotine. Control animals showed no change in activity in response to the paraoxon injection. Two months after termination of the paraoxon treatment, the animals were again tested for spontaneous motor behavior. Animals neonatally exposed to nicotine and exposed to paraoxon as adults showed a deranged spontaneous behavior, including hyperactivity and lack of habituation. In conclusion, neonatal nicotine exposure makes adult mice more susceptible to a low-dose paraoxon exposure, resulting in a persistent change in spontaneous motor behavior.

975

#### NEONATAL EXPOSURE TO A SINGLE LOW DOSE OF A TYPE I PYRETHRIN (BIOALLETHRIN) AFFECTS SPONTANEOUS BEHAVIOR AND LEARNING IN ADULT MICE OF DIFFERENT STRAINS.

C. Fischer, A. Fredriksson and P. Eriksson. *Department of Environmental Toxicology, Uppsala University, Uppsala, Sweden.*

In earlier studies we have reported on developmental neurotoxic effects after neonatal exposure to pyrethrins. Neonatal NMRI mice exposed to a single oral dose of bioallethrin once daily during postnatal day 10 through 16 displayed deranged spontaneous behavior, changes in muscarinic cholinergic receptors in the cerebral cortex in adult mice. These effects were dose-response related. The task of this study was to determine whether neonatally exposed mice were affected by just a single low dose of bioallethrin. Two mice strains were used, NMRI and C57bl. NMRI

mice were orally given bioallethrin at two doses, 0.01mg/kg b.wt. and 0.7mg/kg b.wt. on postnatal day 10. C57bl mice were orally given bioallethrin, 0.07mg/kg b.wt. and 0.7mg/kg b.wt. Control mice for both strains orally received the 20% fat emulsion vehicle. Spontaneous behavior was observed in two-month-old mice and then again at four-months of age (C57bl only). Swim maze test was conducted at three months of age for NMRI and four months of age for C57bl mice. The results of the spontaneous behavior testing showed persistent and a significantly higher activity level in locomotion, rearing and total activity for the mice exposed to a single oral dose of bioallethrin (0.7mg/kg b.wt.) for both mouse strains. In C57bl mice the spontaneous behavior was even altered after the low dose of bioallethrin, 0.07mg/kg b.wt. The swim maze test revealed that C57bl mice exposed to bioallethrin at a dose of 0.7mg/kg b.wt. performed significantly worse than the control groups and the mice exposed to bioallethrin 0.07mg/kg b.wt., this was seen as their ability to relearn was impaired. The major findings of the present study show that just a single low dose of bioallethrin can cause the same developmental neurotoxic effect on spontaneous behavior as repetitive doses over one week of the neonatal period. This indicates the presence of a greater defined critical window during development when persistent effects can be induced by the pyrethroid bioallethrin.

Cholinesterases are classically known for their role in hydrolyzing neurotransmitters. Recent studies also suggest that they may have a broader role, particularly in the development of nervous system. Sequence similarities to lipases, esterases, and cell adhesion molecules appear to reflect their structural role in neurite outgrowth. Deviations in normal levels of acetylcholinesterase at specific times in nervous system development appear to contribute to observed neuroanatomic abnormalities such as altered neurite outgrowth. In this study, we explored the influence of diazinon and molinate on the normal outgrowth of neurites of the neuroblastoma cell line N1E-115. Diazinon, an organophosphorous insecticide and acetylcholinesterase inhibitor, and molinate, a thiocarbamate herbicide, were both evaluated for their ability to alter neurite outgrowth and inhibit acetylcholinesterase activity in N1E-115 cells. Three concentrations of each pesticide (1, 10, and 100 $\mu$ M) were used to assess cell viability, acetylcholinesterase activity, and neurite outgrowth. Based on the concentrations tested significant inhibition of acetylcholinesterase was not observed for both diazinon and molinate; however, we observed changes in neurite outgrowth. Using a probe line method to produce unbiased parameter estimates, we examined the number and size of cells and neurites following exposure to both pesticides. Preliminary results indicate a decrease in neurite outgrowth in N1E-115 cells following treatments with diazinon and molinate, suggesting broader modes of action for both pesticides.

#### NEUROPATHOLOGICAL FINDINGS IN DEVELOPMENTAL NEUROTOXICITY TESTING: COMPARISON OF QUALITATIVE AND QUANTITATIVE EVALUATIONS.

K. Raffaele<sup>1</sup>, W. Sette<sup>2</sup>, J. Doherty<sup>1</sup>, S. Makris<sup>1</sup> and K. Crofton<sup>3</sup>. <sup>1</sup>OPP, USEPA, Washington, DC, <sup>2</sup>OSA, USEPA, Washington, DC and <sup>3</sup>NHEERL, ORD, USEPA, Research Triangle Park, NC.

The USEPA Developmental Neurotoxicity Test (DNT) Guideline (OPPTS 870.6300) includes both qualitative histopathological evaluation and quantitative (morphometric) analysis. Quantitative assessments involve brain weight and linear measurements of several brain regions (minimally the neocortex, hippocampus, and cerebellum) in immature and adult offspring. OECD has released draft guidelines for DNT studies in which quantitative assessments are not required, but are recommended to assist in interpretation of brain weight or qualitative changes. The ability of qualitative and quantitative assessments to detect changes in the brain following developmental exposure was compared by examining the results of 31 guideline DNT studies. Qualitative neuropathological assessments were performed in pups on post-natal day 11 or 21 in all 31 studies; assessments in adults were performed in 28 studies. Morphometric evaluations were performed for pups in 21 studies and for adults in 19 studies. Qualitative neuropathologic effects were seen in only 2 studies (once in pups, once in adults); neither finding involved effects in the brain. Morphometric changes were seen in 12/21 evaluations for pups, 10/19 evaluations for adults. In 18 studies evaluating both ages, 11 found changes at both ages, 2 in adults only, and 1 in pups only. Changes in brain weight were not predictive of morphometric changes. Brain weight changes were seen in 12/30 studies in pups and 6/28 studies in adults; in 7 cases each for pups and adults, morphometric effects were found in the absence of brain weight changes. These results indicate that

morphometric evaluations detect changes not detected by qualitative histopathological evaluations or changes in brain weight, and vice versa. These data suggest all three procedures may uniquely contribute to neuropathological assessment in the DNT study. This abstract does not necessarily reflect the policy of the USEPA.

#### A SIMPLE METHOD TO ESTIMATE RAT PUP EXPOSURE IN DIETARY DEVELOPMENTAL NEUROTOXICITY STUDIES.

M. L. Weiner<sup>1</sup>, J. D. McCarty<sup>1</sup>, A. Chen<sup>1</sup>, M. Neme<sup>2</sup>, G. Schaefer<sup>2</sup> and J. Buelke-Sam<sup>3</sup>. <sup>1</sup>Toxicology, FMC Corporation, Princeton, NJ, <sup>2</sup>WIL Research Laboratories, Ashland, OH and <sup>3</sup>Toxicology Services, Greenfield, IN.

Verification of pup exposure during lactation is a major concern in developmental neurotoxicity studies, especially via dietary exposure. An accurate, sensitive method was developed to estimate rat pup compound consumption (CC) during lactation using levels of compound assayed in milk. Milk concentrations were determined and pup CC was estimated for two compounds in 3 range-finding studies for lactation days (LD) 4/5, 11 and 17/18 over a maternal dietary range of 50-350 ppm. Dams were fed treated diets from gestation day 6 to LD 21 (LD 17 in one study). Milk from at least 5 dams/group was collected, following SC injection with oxytocin (20 U/ml, 0.05 ml), manually by Pasteur pipettes on LD 4/5 (dams were lightly anesthetized for this sample) and by pump on LDs 11 and 17/18. Plasma was collected on the same dams on LDs 4/5 & 21 and for culled pups on postnatal day (PND) 4/5 and for weanlings on PND 21 in two studies. Milk and plasma were analyzed for levels of test compound by solvent extraction, liquid-liquid partition and Gas Chromatographic quantitation (LOD/LOQ = 0.01/0.05 ppm). Pup body weights (BW) on PNDs 4, 11 and 17, and pup BW gain for PNDs 0-4, 7-11 and 14-17 for the litters of dams sampled were used to estimate milk consumption (MC) by the method of Sampson and Jansen (J.Pediatric Gastroenterology and Nutrition, 3: 613; 1984). MC (g) was determined for each time interval by the formula: MC = 0.0332 + 0.0677 (BW) + 0.8775 (BW gain/24 hr). Pup CC was calculated for each time interval as CC (mg/kg BW) = (MC) (% compound in milk)(1000 mg/g) / BW in kg. Estimated pup doses positively correlated with plasma levels of each compound, determined for pups and dams from the same litters

#### THALIDOMIDE-INDUCED OXIDATIVE STRESS IN RAT DORSAL ROOT GANGLIA (DRG) CELL CULTURES.

R. Roman Gomez<sup>1</sup>, C. A. Flynn<sup>1</sup>, T. L. Buile<sup>1</sup>, P. A. Paximadis<sup>1</sup>, J. M. Hansen<sup>2</sup>, M. A. Philbert<sup>1</sup> and C. Harris<sup>1</sup>. <sup>1</sup>Environmental Health Sciences, University of Michigan, Ann Arbor, MI and <sup>2</sup>Biochemistry, Emory University, Atlanta, GA.

Thalidomide has beneficial effects in treating inflammatory, malignant and infectious diseases. Its potential therapeutic use is often limited by the onset of peripheral sensory neuropathies, the mechanisms for which are unknown. Studies suggest that thalidomide-induced free radicals may have a mechanistic role in its activity and lead to present efforts to determine whether thalidomide is causing oxidative stress and redox misregulation in the peripheral nervous system. DRGs, isolated as mixed neuronal and glial cell populations from GD 17 rat embryos, were grown under conditions that favor neuronal proliferation. HPLC analysis showed that glutathione (GSH) concentrations were not significantly altered following 50 and 100 mM thalidomide treatment for 2, 6, 24 and 48 hr. In contrast, glutathione disulfide (GSSG) concentrations increased significantly by 2.7 fold after 48 hr of 100 mM thalidomide exposure. After 24 hr and 48 hr, respectively, thalidomide shifted the intracellular redox potential towards the positive by +32.7 mV and +30.4 mV for 100 mM and +26.0 mV and +22.5 mV for 50 mM thalidomide treatments. These results show that thalidomide is causing oxidative stress sufficient to alter the redox potential of cultured cells and could be affecting essential cell activities that depend on a reduced cell environment. Further analysis attempted to determine whether differential responses to the drug occurred in neuronal and glial cells of the mixed culture. Qualitative analysis using confocal microscopy and CMFDA fluorescence showed a prolonged decrease in neuronal fluorescence after thalidomide treatment while glial cell fluorescence decreased only marginally and recovered soon after treatment, possibly, compensating for neuronal losses. These results show that thalidomide causes oxidative stress in DRG mixed neuronal and glial cell cultures and that differences exist in the response of associated cell types as they cope with changes related to oxidative stress.

#### EFFECTS OF DEVELOPMENTAL HYPOTHYROIDISM INDUCED BY PTU ON BRAIN FUNCTION IN RATS.

R. Tsuji, K. Kobayashi, T. Yoshioka, M. Sasaki, M. kushida, S. Yabushita, T. Mino and T. Seki. Sumitomo Chemical Co., Ltd., Environmental Health Science Laboratory, Osaka, Japan. Sponsor: T. Yamada.

It has been known that lack of thyroid hormone during development leads to structural, mental and behavioral changes in human and animals. In recent years, social concerns have increased about developmental neurotoxicity induced by environ-

mental chemicals, especially substances that affect the level of thyroid hormone. Hypothyroid rat experimentally induced by propylthiouracil (PTU) is considered to be a useful animal model for the developmental neurotoxicity. In the present study, we examined the effects on brain function in PTU-induced hypothyroidism rats in accordance with EPA DNT guideline. PTU was administered to dams orally at dosages of 0, 0.4, 1.0 and 2.5 mg/kg from Gestation Day 18 until postnatal day (PND) 21, and the effects on their offspring were evaluated. Although reduced concentration of triiodothyronine (T3) in 1.0 and 2.5 mg/kg groups, and thyroxin (T4) in all treated groups were detected on PND 22, these changes did not persist into adulthood. Reduced body and brain weight, and delay of eye opening were observed in 1.0 and 2.5 mg/kg groups. In the measurement of motor activity, tendency of reduction on PND 16, and increase on PND 21 and after, were detected. In the E-maze learning test, decreased ability was observed in infant and adults. In addition, decreased response in infant and increased response in adults were observed in acoustic startle response test. As a result, the changes in motor activity, learning ability and startle response were detected in PTU-induced hypothyroidism rat, and some of their responses varied by measurement time points that DNT guideline requires.

**981** EFFECT OF HYPOTHYROIDISM INDUCED BY PERINATAL EXPOSURE TO PTU ON CEREBELLAR GENE EXPRESSION.

K. kobayashi, R. Tsuji, T. Yoshioka, M. Kushida, T. Mino and T. Seki. *Sumitomo Chemical Co., Ltd., Osaka, Japan.* Sponsor: T. Yamada.

Certain kinds of developmental neurotoxicants are considered to work by affecting the level of thyroid hormone, which is essential for the brain development of both human and experimental animals. Hypothyroid rat experimentally induced by propylthiouracil (PTU) is now a useful animal model for the developmental neurotoxicity. The purpose of this study is to clarify the developmental alterations in gene expression caused by the decrease of thyroid hormones using this model. We quantified a series of genes in the cerebellum of rat exposed perinatally to various doses of PTU by quantitative RT-PCR on postnatal day (PND) 22 and after maturation. We especially focused on the genes implicated in the formation of neuronal network or synaptic function, including growth associated protein-43, brain-derived neurotrophic factor (BDNF), L1, neuronal cell adhesion molecule, synaptophysin, post synaptic density-95 and NMDA receptor 2A/2B (NR2A/NR2B), and also examined the control developmental profile of these genes mRNA. PTU-induced hypothyroidism in rats resulted in up-regulation of NR2B mRNA and down-regulation of NR2A and BDNF mRNAs in the cerebellum on PND 22, but no PTU-treatment-related alteration of these gene expressions were observed after maturation. Our additional examinations of NR2A and NR2B gene expression in cerebellum during earlier period demonstrated that PTU-treatment-related changes of NR2A and NR2B gene expression were evident on PND14, but not on PND4. There were no changes in other genes on PND22 and after maturation. These results suggested that PTU-induced hypothyroidism could delay switching from NR2B to NR2A subunits in the maturation of NMDA receptor. Developmental alteration of NMDA receptor, as changes in proportion of NR2A and NR2B subunits may provide a novel mechanism of developmental neurotoxicity underlying hypothyroidism.

**982** GABERIC FUNCTION IS ALTERED FOLLOWING DEVELOPMENTAL HYPOTHYROIDISM: NEUROANATOMICAL AND NEUROPHYSIOLOGICAL EVIDENCE.

M. E. Gilbert<sup>1</sup>, L. Sui<sup>1,2</sup>, S. Thomas<sup>3</sup>, S. Smoller<sup>3</sup>, J. Schon<sup>3</sup> and J. Goodman<sup>3</sup>. *<sup>1</sup>Neurotoxicology, USEPA, Research Triangle Park, NC, <sup>2</sup>NRC, Washington, DC and <sup>3</sup>CNRR, Helen Hayes Hosp, W Haverstraw, NY.*

Thyroid hormone deficiency during development produces changes in the structure of neurons and glial cells and alters synaptic function in the hippocampus. GABAergic interneurons comprise the bulk of local inhibitory neuronal circuitry and a subpopulation of these interneurons contain the calcium binding protein, parvalbumin (PV). A previous report indicated that severe hypothyroidism reduced PV staining in the neocortex (Berbel et al., 1996). The present study examined GABA-mediated inhibition and immunocytochemistry of PV-containing interneurons in the dentate gyrus of the hippocampal formation. Animals were deprived of thyroid hormone *in utero* and throughout lactation by exposing pregnant dams to propylthiouracil (PTU) via the drinking water (0, 3, 10 ppm) from GD 6 to weaning of the offspring. This regimen reduced maternal serum T4, increased TSH and had no effect on T3 at the low dose. Both T3 and T4 were reduced in the offspring at weaning but returned to control levels in adulthood. Synaptic inhibition of the perforant path-dentate gyrus synapse was evaluated using *in vivo* field potentials and paired pulse techniques in adult offspring. PTU-induced reduction in paired pulse depression and augmentation in facilitation were observed, indicating a suppression of GABA-mediated inhibition. Immunocytochemical staining for PV was reduced in the dentate gyrus and the neocortex. A cross-fostering study revealed

that postnatal hormone deficiency was required for an alteration in PV staining. Altered staining persisted to adulthood despite return of thyroid hormones to control levels. These data indicate that thyroid hormone insufficiency during the early postnatal period alters interneuron expression of PV and compromises GABA-mediated synaptic transmission. (Funded by USEPA, does not reflect USEPA policy).

**983** VITAMIN E PROTECTS AGAINST THE BEHAVIORAL DEFICITS PRODUCED BY NEONATAL SODIUM VALPROATE EXPOSURE IN MICE.

A. K. Halladay<sup>1,3</sup>, G. C. Wagner<sup>2,3</sup>, X. Ming<sup>3</sup> and K. R. Reuhl<sup>1,3</sup>. *<sup>1</sup>Pharmacology & Toxicology, Rutgers University, Piscataway, NJ, <sup>2</sup>Psychology, Rutgers University, Piscataway, NJ and <sup>3</sup>Center for Childhood Neurotoxicology & Exposure Assessment, UMDNJ, New Brunswick, NJ.*

We have previously reported that pre- and/or postnatal exposure to sodium valproate (VPA) produces delays and regressions in neurobehavioral development which resembles behavioral features of autism. Recently, we observed an elevation of a marker of lipid peroxidation, urinary 8-isoprostane, in children with autism. As generation of oxidative metabolites contributes to toxicity induced by VPA, the current studies examined whether antioxidant pretreatment would protect mice against VPA-induced behavioral disruptions. Male BALB/c mice were treated with alpha-tocopherol (250 mg/kg s.c.) diluted in corn oil from PND 11-15 followed by VPA (400 mg/kg s.c.) on PND 14. Mice treated with VPA and pretreated with the corn oil vehicle showed a reproducible delay in the development of the negative geotactic response on PND 15-17, loss of the established mid-air righting response on PND 15, as well as hyperactivity on PND 16-19. These behavioral disruptions were eliminated or partially ameliorated by pretreatment with vitamin E. Administration of VPA produced an elevation in hippocampal, but not cerebellar GFAP levels. The increase in hippocampal GFAP was not ameliorated by vitamin E pretreatment. Together, these results suggest that oxidative stress may play a role in the functional deficits produced by VPA, and that GFAP does not serve as a sentinel biomarker for the behavioral effects of VPA. (Supported by NIH ES05022, NIH/EPA ES011256 and NIH ES11279)

**984** CAMPTOTHECIN-INDUCED APOPTOSIS IN NEURAL STEM CELLS AND DIFFERENTIATED CULTURES THROUGH TWO DIFFERENT MECHANISMS.

J. Li, M. L. Spletter and J. A. Johnson. *University of Wisconsin at Madison, Madison, WI.*

We use both human and mouse neural stem cells (NSCs) as a model to evaluate the mechanism(s) involved in camptothecin (CA) induced cytotoxicity. Results from ultrastructural damage, TUNEL staining and Caspase 3 activation indicated that CA, a topoisomerase I inhibitor, induced apoptotic cell death in both stem cells and their differentiated cultures. CA (2.5 - 5  $\mu$ M) induced cleavable complex formation *in vitro* in pBR322 plasmid DNA. Cell cycle analysis showed that CA induced 50% and 95% cell loss in S and G2/M phases, respectively, and a 17% increase in G0/G1 phase during the undifferentiated stage. After CA treatment, there was a significant decrease in the rate of BrdU pre-incorporation (25% to 0.5%), suggesting that these S-phase stem cells are more susceptible to CA-induced cell death. In differentiated (post-mitotic) cultures, neurons were more vulnerable to CA-induced cytotoxicity than astrocytes. The same dose of CA induced a significant increase in ROS production, an extensive mitochondrial membrane potential change and calcium influx. CA-induced apoptosis could be suppressed by the G1/S phase blocker desferoxamine and adenovirus-mediated p53 siRNA only in stem cells but not the differentiated cultures. However, the differentiated cells showed increased susceptibility to glutamate-induced cytotoxicity compared to their progenitors. NMDA receptor antagonism, MK801, could significantly attenuate CA-induced apoptosis in differentiated cultures but not their progenitors. Since previous studies already showed a significant increase in the expression of certain NMDA receptors after stem cell differentiation, glutamate-induced toxicity may be involved in CA-induced apoptosis in differentiated cultures. Therefore, CA induces apoptosis in neural stem cells and their differentiated cells through two different mechanisms. (Supported by ES08089 (JAJ) and ES10042 (JAJ) from the NIEHS)

**985** THE ROLE OF AMYLOID- $\beta$  AND  $\alpha$ -SECRETASE CLEAVED AMYLOID PRECURSOR PROTEIN ON NEUROGENESIS IN ADULT HUMAN NEOCORTICAL SLICE CULTURES.

J. Kim<sup>1</sup>, T. D. Stein<sup>2</sup>, N. J. Anders<sup>1</sup> and J. A. Johnson<sup>1,2,3</sup>. *<sup>1</sup>School of Pharmacy, University of Wisconsin-Madison, Madison, WI, <sup>2</sup>Neuroscience Training Program, University of Wisconsin-Madison, Madison, WI and <sup>3</sup>Waisman Center, University of Wisconsin-Madison, Madison, WI.*

Neurogenesis in the adult brain is increased in certain pathological states and may provide a basis for neuronal replacement therapy in neurodegenerative diseases like Alzheimer's disease. Alzheimer's disease may be caused by the abnormal processing

of the amyloid precursor protein (APP) and the accumulation of amyloid- $\beta$ . The amyloid precursor protein can be proteolytically cleaved into multiple fragments, many of which have distinct biological actions. For instance, a high level of amyloid- $\beta$  is toxic and the  $\alpha$ -secretase cleaved APP (sAPP $\alpha$ ) is neuroprotective. While studies have shown evidence of enhanced neurogenesis in Alzheimer's disease, the fragments derived from amyloid precursor protein that may be responsible for this and the possible mechanisms for neurogenesis are unknown. A novel *ex vivo* model of Alzheimer's disease was established by culturing fresh adult human neocortical tissue. Histologically normal tissue removed from the temporal cortices of patients undergoing surgery for temporal lobe epilepsy was used for all experiments. The tissue was rapidly processed to generate 400-micron slices that were cultured in defined medium for up to three weeks. Slices were treated with aggregated and non-aggregated forms of amyloid- $\beta_{1-42}$  or sAPP $\alpha$ . Amyloid- $\beta$  increased levels of overall cell death as well as neuron cell death. We tested the neuroprotective potential of sAPP $\alpha$  and a peptide derived from it in tissue exposed to amyloid- $\beta$ . We examined the incorporation of BrdU and expression of immature neuronal markers in order to elucidate the role of amyloid- $\beta$  and sAPP $\alpha$  in neurogenesis. BISPHENOL-A, AN ENVIRONMENTAL CONTAMINANT THAT ACTS AS A THYROID HORMONE RECEPTOR ANTAGONIST *IN VITRO*, INCREASES SERUM THYROXINE AND ALTERS RC3/NEUROGRANIN EXPRESSION IN THE DEVELOPING RAT BRAIN.

R. Bansal and C. Parris. *Biology, University of Massachusetts, Amherst, MA.*  
Sponsor: R. Zoeller.

Bisphenol A (BPA, 4, 4 isopropylidenediphenol) is an industrial chemical used as a monomer in the production of polycarbonate plastics and epoxy resins. It is found in a number of products including food can linings, plastic water and milk bottles, adhesives and dental fillings and sealants, indicating potentially high human exposure. BPA has been found in human urine as well as in amniotic fluid and fetal serum, showing that it can pass through the placenta. BPA can competitively bind to the thyroid hormone receptor (TR) and acts as an antagonist of TR *in vitro*. To determine the *in vivo* effects of BPA exposure, we treated pregnant Sprague-Dawley rats with either 0, 1, 10 or 50 mg/kg/body weight BPA dosed onto wafers daily, from gestational day 6 through weaning and 1 male and 1 female pup were sacrificed on postnatal days 4, 8, 15, and 35. Serum total T4 was elevated by maternal exposure to 10 and 50mg/kg and there was no difference in male and female pups. Serum TSH was unaffected. RC3/Neurogranin, a known TH-responsive gene, was up-regulated by BPA exposure in the dentate gyrus of P15 males. These results indicate that BPA may act as an antagonist on TR beta regulation of TSH, but not on TR alpha regulation of RC3. To determine if BPA binds with the same affinity to both receptors, competitive binding assays with isolated recombinant TR alpha and TR beta were performed. BPA bound to both receptors with the same affinity, a Ki of  $1.44 \times 10^{-5}$  M. These studies show that BPA exerts an effect on thyroid hormone action during development and that these effects may be TR isoform specific.

**987**

EXPOSURE OF RHESUS MONKEYS TO COCAINE THROUGHOUT GESTATION RESULTS IN DECREASED SENSITIVITY TO COCAINE IN ADULTHOOD: EFFECTS OF COCAINE ON TIMING BEHAVIOR.

M. G. Paule<sup>1,3</sup>, M. P. Gillam<sup>1</sup>, S. A. Graham<sup>3</sup> and J. J. Chelonis<sup>2,3,1</sup>. <sup>1</sup>*Division of Neurotoxicology, National Center for Toxicological Research, Jefferson, AR,*  
<sup>2</sup>*Graduate School, University of Arkansas at Little Rock, Little Rock, AR and*  
<sup>3</sup>*Pediatrics, Arkansas Children's Hospital, Little Rock, AR.*

These studies examined whether animals exposed to cocaine prenatally would respond differently than control animals when challenged with several doses of cocaine as adults. Treatment groups consisted of untreated controls (n = 7) and animals that received total gestational exposure (TGE) to cocaine (n = 5). For the TGE group, nonpregnant females were treated IM with cocaine for up to several months prior to mating with doses of 1.0 to 3.0 mg/kg/injection, 3 times per day, 5 days per week. After pregnancies were detected (ca. gestational day 30-40) doses were escalated until birth as animals became tolerant to cocaine-induced appetite suppression: the dose was escalated by 0.5 to 1.0 mg/kg/injection up to maximums ranging from 3.5 to 7.5 mg/kg/injection at term (ca. 3/4 to 1 1/2 gram per day, human equivalent). At birth, TGE offspring weighed significantly less and had smaller head circumferences than controls, a finding also reported in human studies. At 6 years of age, cocaine dose-response curves were obtained: 15 min after the iv injection of 0.3, 1.0 or 1.75 mg/kg, subjects performed a timing task for food treats. The task required that subjects hold a response lever in the depressed position for at least 10 sec but no more than 14 sec. Endpoints included total lever holds and percent

correct holds. 2 way ANOVA (dose, treatment group) showed significant dose effects and that while there was no group effect on percent correct holds, there was a significant effect of group on total holds (p = .017), with the controls being significantly more sensitive to the disruptive effects of cocaine. These data demonstrate that gestational exposure to cocaine can cause long-lasting (permanent?) alterations in sensitivity to subsequent exposure to cocaine as evidenced by disruption of complex brain functions in primates.

**988**

OBSERVATION OF CATECHOLAMINERGIC NEURONS IN THE FETAL RAT BRAIN EXPOSED TO THE GENOTOXIC COMPOUND, 5-BROMO-2'-DEOXYURIDINE (BrdU).

T. Ogawa<sup>1</sup>, M. Kuwagata<sup>1,2</sup>, K. T. Muneoka<sup>1</sup> and S. Shioda<sup>1</sup>. <sup>1</sup>*Anatomy, Showa University School of Medicine, Tokyo, Japan and*<sup>2</sup>*Hatano Research Institute, Kanagawa, Japan.*

5-Bromo-2'-deoxyuridine (BrdU), a thymidine analogue, is incorporated into DNA as 5-bromouracil during the synthesis phase of the cell cycle, and has been used extensively as a tool for labeling proliferating cells in cancer research and developmental neuroscience. Doses ranging from 10 to 100 mg/kg are commonly injected into animals. However, BrdU has genotoxicity. It was reported that mutagenesis occurred when BrdU triphosphate was incorporated into DNA, and when the BrdU-containing DNA replicated. We earlier reported that prenatal exposure to BrdU at a dose generally administered to adult rodents (50 mg/kg) induces locomotor hyperactivity in rats, suggesting that fetal brain is very sensitive to BrdU-induced genotoxicity. We also demonstrated that BrdU induced cortical dysgenesis (lower cellularity and disrupted arrangement of immature cells in the cortical plate) in the fetal rat brain. Since the dopaminergic nervous system is often implicated in hyperactivity (e.g. neonatal 6-hydroxydopamine lesioning rat and dopamine transporter knockout mouse models), we evaluated catecholaminergic neurons in the fetal rat brain after BrdU treatment. Pregnant rats were administered 50 mg/kg of BrdU on gestation days 9.5-15.5. The fetal brains were collected at gestation day 16.5, serially sectioned by vibratome and processed for immunohistochemistry using anti tyrosine hydroxylase (TH) antibody. The TH immunoreactivities were observed in a wide variety of areas including frontal neocortex, caudate putamen, substantia nigra, ventral tegmental area, and locus caeruleus. There were no dramatic differences between the control and the BrdU-treated brains. As noted above, the BrdU-induced abnormality involved the cortical plate. Our data support the view that while the neurons differentiating in cortical plate are principally involved in the BrdU-induced developmental neurotoxicity, catecholaminergic cells are not among them.

**989**

HETEROGENEOUS SENSITIVITY OF THE EMBRYONIC NERVOUS SYSTEM TO THE GENOTOXIC AGENT BrdU IN MICE.

M. Kuwagata<sup>1,2</sup>, T. Ogawa<sup>2</sup>, K. T. Muneoka<sup>2</sup>, H. Ono<sup>1</sup> and S. Shioda<sup>2</sup>.

<sup>1</sup>*Toxicology, Hatano Research Institute, Food and Drug Safety Center, Kanagawa, Japan and*<sup>2</sup>*Anatomy, Showa University School of Medicine, Tokyo, Japan.*

In embryogenesis, the development of the neural system starts at an early stage and continues to develop after the postnatal period. Therefore, the fetal nervous system is a potential target for exogenous chemical insults. However, few research efforts focus on the examination of fetal brain relative to the adult. 5-Bromo-2'-deoxyuridine (BrdU), a thymidine analogue, is incorporated into any mitotic cell, and has been used as a marker of proliferating cells. BrdU is also considered a genotoxic agent. Previously, our studies demonstrated that prenatal BrdU exposure (50 mg/kg, intraperitoneally) on gestational day (GD) 9 to 15 induced abnormal behaviors and disrupted the monoaminergic nervous system in rat offspring. The fetal brain, after BrdU exposure, showed the induction of cell death in specific areas and abnormal structure of cortical plate. In this study, to examine more detailed effects of BrdU exposure on the fetal brain, C57BL/6 mice were exposed to 100 mg/kg BrdU intraperitoneally on GD9 or 11. Fetal brains were obtained 24 hours after the treatment, and examined in histopathological observations. BrdU did not induce cell death in fetal brains treated on GD9. However, treatment on GD11 increased cell death in specific areas such as the neocortex and striatum. No induction of cell death was observed in the substantia nigra, raphe and pons, which are nuclei of monoaminergic systems, even though BrdU was incorporated into these areas. The results suggest that the 1) sensitivity of the fetal brain to genotoxicity is different among fetal brain areas and developmental stages, 2) substantia nigra, raphe and pons seem to be tolerant to the genotoxic agent, indicating that monoaminergic neurons are more likely to carry mutations after prenatal exposure to genotoxic agents.

## 990 THE AHR IN CELL GROWTH AND DEATH.

D. H. Sherr<sup>1</sup> and P. Nagarkatti<sup>2</sup>. <sup>1</sup>*Environmental Health, Boston University School of Public Health, Boston, MA* and <sup>2</sup>*Department of Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA*.

Since its first description as a dioxin-binding protein in the 1980s, the aryl hydrocarbon receptor (AhR) has been studied primarily for its control of biologic responses to environmental agonists. However, in the last few years it has become apparent that the AhR, which clearly did not evolve to recognize environmental pollutants, likely plays an important physiologic function. Indeed, the ability of the AhR to directly regulate important cellular genes and factors such as Bax, the estrogen receptor, Rb, and NF- $\kappa$ B hints at a critical role for the AhR in cell growth and death. The presence of constitutively active AhR in cells that exhibit aberrant growth and apoptosis regulation, i.e. neoplastic cells, further supports this hypothesis. In this symposium we will present several examples of AhR-mediated control of cell growth and death and will begin to detail the molecular mechanisms through which this control is manifest. In some studies presented herein, AhR function is revealed with exogenous agonists such as TCDD or PAH. In other cases, constitutive AhR function is demonstrated by modulation of AhR expression and activity in the absence of exogenous ligands. In all cases, the roles that the AhR may play in normal cellular physiology and the consequences of disrupting these functions with environmental agonists are discussed.

## 991 LIGATION OF AHR LEADS TO UP-REGULATION OF APOPTOTIC GENES THROUGH DRE-DEPENDENT AND -INDEPENDENT PATHWAYS INVOLVING NF- $\kappa$ B AND CONSEQUENT INDUCTION OF APOPTOSIS IN THYMOCYTES.

P. S. Nagarkatti. *Pharmacology and Toxicology, Medical College of Virginia Campus, Virginia Commonwealth University, Richmond, VA*.

Previous studies from our laboratory have shown that TCDD triggers apoptosis in thymocytes mediated through Fas-Fas ligand (FasL) interactions. However, the precise role of AhR in regulating apoptosis or the expression of Fas and FasL in thymocytes is not clear. In the current study, we noted that TCDD induced/enhanced the expression of several apoptotic genes in the thymus, including Fas and Fas ligand (FasL) in AhR wild-type but not AhR KO mice. TCDD-mediated upregulation of FasL expression was seen only in thymic stromal but not T cells. Fas but not FasL gene promoter was found to contain a functional DRE. In contrast, in FasL gene promoter region, potential NF- $\kappa$ B binding sites were detected. When activation of NF- $\kappa$ B was further investigated, it was noted that TCDD treatment led to AhR-dependent nuclear translocation and co-localization of p50 and p65 subunits in thymic stromal cells. When TCDD-exposed thymic stromal cells were mixed with untreated thymic T cells, increased apoptosis was detected in T cells that involved Fas-FasL interactions. TCDD, at higher doses, also triggered the mitochondrial pathway of apoptosis. However, cross-talk between death receptor and mitochondrial pathways was not necessary for apoptosis inasmuch as, TCDD-treated Bid knock-out mice showed thymic atrophy and increased apoptosis, similar to the wild-type mice. Together, these findings demonstrate that activation through AhR leads to DRE-dependent induction of several apoptotic genes including Fas in thymocytes, and furthermore, also leads to activation of NF- $\kappa$ B that regulates FasL expression on thymic stromal cells. Thus, TCDD disrupts normal T cell-stromal cell interactions that play a critical role in T cell differentiation, leading to induction of apoptosis in T cells.

## 992 AHR CONTROL OF B LYMPHOCYTE DEATH AND GROWTH.

S. H. David, H. Ryu, J. K. Emberley, L. L. Allan and J. J. Schlezinger. *Environmental Health, Boston University School of Public Health, Boston, MA*.

Environmental agonists of the aryl hydrocarbon receptor (AhR) compromise a variety of immunologic functions including antigen presentation and B and T cell effector responses. Here, we discuss how the AhR mediates both direct and indirect effects on immature and mature B lymphocytes. With regard to indirect effects, we will present studies demonstrating that AhR agonists, such as the prototypic PAH, DMBA, induce AhR bearing bone marrow stromal cells to deliver an apoptosis signal to neighboring AhR- B cells. The intricate signaling pathway activated within the B cells that results in their demise involves caspases 2, 3, 8, and 9, Bid, Bax and other elements of the mitochondrial signaling pathway. Stress activated kinases (e.g. JNK) are also involved. Regarding direct effects on the B cell compartment, we demonstrate that stimulation of human peripheral B cells with signals mimicking activation of the innate and adaptive immune responses (i.e. signaling through toll-

like receptor 9 and CD40 respectively) induces high levels of constitutively active AhR. Possible roles that this constitutively active AhR may play in human lymphocytes will be discussed.

## 993 REGULATION OF MAMMARY TUMOR GROWTH THROUGH THE ARYL HYDROCARBON RECEPTOR.

S. H. Safe. *Veterinary Physiology, Texas A & M University, College Station, TX*.

The aryl hydrocarbon receptor (AhR) is widely expressed in cancer cell lines and tumors, and AhR ligands inhibit growth of some cancers. Research in this laboratory has focused on development of selective AhR modulators (SAhRMs) for cancer chemotherapy, and on understanding the growth inhibitory mechanisms of AhR action in breast and other cancer cell lines. The antiestrogenic activity of AhR agonists in estrogen receptor (ER)-positive breast cancer cells is complex and involves multiple pathways that are dependent, in part, on individual genes/gene promoters. Inhibitory AhR-ER crosstalk is associated with AhR ligand-induced proteasome-dependent degradation of ER, increased metabolism of 17 $\beta$ -estradiol (E2), AhR interaction with cis-acting dioxin responsive elements, AhR displacement of ER from some promoters, and induction of transcription factors. These multiple inhibitory pathways in ER-positive cells primarily target E2-responsive genes that are involved in cell cycle progression and DNA synthesis. However, results of ongoing studies also show that AhR agonists inhibit growth of ER-negative breast cancer cells and other ER-independent cell lines, and the mechanisms of these responses will also be discussed. (Supported by NIH ES09106 and ES04176)

## 994 CURRENT INSIGHTS INTO AHR-MEDIATED LIVER CELL CYCLE CONTROL.

C. J. Elferink. *Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX*. Sponsor: D. Sherr.

Liver homeostasis in response to pathogen infection or drug toxicity is achieved by the removal of damaged hepatocytes and their replacement to maintain a constant liver cell mass. The AhR is a ligand-activated transcription factor known to regulate both apoptotic and proliferative processes. Our goal is to understand mechanistically how the AhR contributes to tissue homeostasis by regulating cell growth and cell death. The AhR ligand 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) is the prototype for a class of compounds responsible for a range of toxic or adaptive endpoints. A notable response to TCDD is the AhR-mediated G1 cell cycle arrest detected in certain liver-derived cells in culture, and in the regenerating liver *in vivo*. Studies exploring the molecular basis for the AhR-dependent growth arrest have identified multiple mechanisms contributing to the arrest response, including direct and indirect transcriptional regulation, and processes influencing growth factor signaling.

## 995 AHR CONTROL OF APOPTOSIS INDUCED BY AGENTS CAUSING LYSOSOMAL DAMAGE.

J. J. Reiners. *Institute of Environmental Health Sciences, Wayne State University, Detroit, MI*. Sponsor: D. Sherr.

Agents which damage lysosomes can activate the intrinsic apoptotic pathway. This occurs as a consequence of lysosomal protease cleavage of Bid, and tBid-mediated cytochrome c release. Photodynamic therapy with the lysosomal sensitizer NP6, ceramides, and TNF all induce the release of lysosomal proteases into the cytosol of murine hepatoma 1c1c7 cells. Apoptosis induced by these agents is Bid-dependent, and can be suppressed by a sphingomyelin derivative that stabilizes lysosomes. In contrast, variants of the parental line deficient in the aryl hydrocarbon receptor (AhR) are resistant to the pro-apoptotic effects of the three agents. However, the variants are comparable to the parental line in terms of their susceptibilities to pro-apoptotic agents that do not damage lysosomes. Surprisingly, the relative sensitivities of AhR-deficient cells to different classes of apoptotic inducers are similar to that seen in several human disorders collectively referred to as lysosomal storage diseases. Analyses of lysosomes from AhR-deficient cells indicated that they were markedly more resistant to breakage induced by reactive oxygen species, and deficient in proteases, including those involved in Bid cleavage. The latter property appears to reflect a global defect in the processing/trafficking of proteases to the lysosomes. Introduction of the AhR into deficient cells corrected the defect and restored sensitivity to lysosomal disrupters. These studies suggest that the AhR, in the absence of exogenous ligands, influences the stabilities and contents of lysosomes.

## ORGANOPHOSPHATES & CARBAMATES: CHOLINERGIC & NONCHOLINERGIC MECHANISMS.

R. C. Gupta. *Toxicology, Murray State University, Hopkinsville, KY.*

Organophosphates (OPs) and carbamates (CMs) are commonly used as pesticides in agriculture, industry, and around the home/garden. Some OPs have also been used in chemical warfare and terrorism, while some CMs have been used to treat diseases such as myasthenia gravis and dementia. Interestingly, the CM pyridostigmine is used prophylactically to protect soldiers from possible OP nerve agent exposure. Many compounds of both classes are extremely toxic and lack selectivity, thus their inadvertent/accidental use continues to pose a threat to human and animal health, aquatic systems and wildlife. While these compounds have a wide variety of toxic effects, neurotoxicity elicited by inhibition of acetylcholinesterase (AChE) is generally of primary concern. In recent years, a variety of novel mechanisms for OPs and CMs have been proposed which may modulate cholinergic neurotoxicity or lead to non-cholinergic effects. Molecular studies of AChE and its interaction with inhibitors has allowed a more thorough characterization of the structure, function, and regulation of this enzyme. *In vitro* studies indicate that NGF-differentiated SY5Y cells may distinguish between OPs that produce OPIDN and those that do not, and may therefore be a suitable mechanistic model for exploring the effects of different classes of OPs. Evidence suggests that while cholinergic mechanisms play a critical role in the initial stage of cholinergic toxicity, neuronal damage/death may occur through non-cholinergic mechanisms including oxidative stress. The Food Quality Protection Act of 1996 requires EPA to consider the cumulative risk to pesticides with a common mechanism of action. In the case of OPs and CMs, this common mechanism is initiated by inhibition of AChE (via phosphorylation or carbamylation, respectively). However, noncholinergic mechanisms are not currently considered in risk assessment. This symposium will review the latest developments in understanding of molecular mechanisms (cholinergic and non-cholinergic) for these toxicants, as well as discuss current strategies of cumulative risk assessment for pesticides acting through a common mechanism.

**997**

## CONTEMPORARY PROTEOMICS IN ACETYLCHOLINESTERASE AND RELATED $\alpha$ , $\beta$ HYDROLASE-FOLD PROTEINS AS TARGETS OF TOXICOLOGICAL MANIFESTATIONS AND GENETIC DISORDERS.

P. Taylor, Z. Radic, L. Jennings and S. Camp. *Pharmacology, University of California, San Diego, La Jolla, CA.* Sponsor: R. Gupta.

Knowledge of sequence and structures of acetylcholinesterase (AChE) as a target of nerve agents enables one to design sensitive fluorescence sensors for remote detection of OP modified enzymes, develop means by which the nerve agent may be scavenged by derivatives of the target and analyze the target for structural differences that may be determinants of susceptibility among individuals. We describe how we might employ a fluorescent derivative of AChE itself for remote or field sensing of nerve agents or insecticides. Since the sensor is a conjugate of AChE itself, false positives are minimized. Perturbations of the active center gorge give rise to distinctive spectra, this allows one to distinguish types of inhibitor. In turn, the conjugates that give rise to the fluorescence changes can be analyzed by digestion with proteases, the active center peptide isolated and the offending OP identified by mass spectrometry. Analysis is sufficiently sensitive that it can be conducted with enzyme from brains of OP exposed mice. Moreover, precise kinetics of alkylphosphorylation, aging and reactivation can be followed by the respective masses of the active center peptide. Application of genomics and proteomics comes through the analysis of naturally occurring mutations in the AChE gene to ascertain whether any of these mutations confer an unusual susceptibility to alkylphosphates. Several synonymous and non-synonymous single nucleotide polymorphisms have been found in the open reading frame and others in potential regulatory regions in the human gene. Whether they play a role in affecting enzyme expression, catalytic activity or stability of the enzyme has yet to be determined. Mutations in related  $\alpha$ ,  $\beta$  hydrolase-fold proteins, such as neuroligin, govern expression and processing in their biosynthesis. In selected cases, disorders such as autism appear to be related to altered expression of proteins forming heterophilic adhesion interactions in synapses. Supported by R37GM8360 and DAMD170220025.

## ORGANOPHOSPHORUS AND CARBAMATE CHOLINESTERASE INHIBITORS: USES AND MISUSES OF A COMMON MECHANISM.

C. N. Pope. *Physiological Sciences, Oklahoma State University, Stillwater, OK.*

Cholinesterase inhibitors (anticholinesterases) have been used in the treatment of human and animal disease, to control insect vectors and parasites, and as weapons in chemical warfare and terrorism. Their uses and misuses are based on a common

mechanism of action initiated by inhibiting acetylcholinesterase (AChE). AChE is pivotally important in the dynamic regulation of cholinergic neurotransmission in the central and peripheral nervous systems where it rapidly and efficiently degrades the neurotransmitter, acetylcholine. Marked inhibition of AChE leads to accumulation of acetylcholine, with consequent over-stimulation of cholinergic receptors and resulting alteration of cellular functions. The wide distribution of cholinergic terminals within the central and peripheral nervous systems is the basis for an array of functional alterations possible following AChE inhibition. Although the molecular modification (e.g., carbamylation vs. phosphorylation) of AChE with different inhibitors can be an important determinant of effect (e.g., duration of action) leading to differential actions, a number of reports suggest that additional sites of action may be important in their pharmacologic or toxicologic effects. A number of enzymes (esterase and non-esterase), neurotransmitter receptors (cholinergic and non-cholinergic) and cell signaling components are sensitive to direct interaction with some anticholinesterases. In many cases, the toxicologic relevance of these additional sites is unclear. Recent studies of the interactive toxicity of binary mixtures of the organophosphorus insecticides chlorpyrifos, parathion and methylparathion indicate, however, that non-cholinesterase targets may be important in cumulative toxicity under some conditions. Interaction between anticholinesterases and other macromolecules may contribute to differences in acute toxicity among different inhibitors, to neurodevelopmental toxicity, and to more subtle, long-term sequelae sometimes reported in patients following anticholinesterase poisoning. (Supported by STAR grant 825811 from USEPA and R01 ES009119-05 from NIEHS).

## IN VITRO MODELS FOR TESTING NEUROTOXICITY OF ORGANOPHOSPHORUS COMPOUNDS AND PROTECTIVE EFFECTS OF OP HYDROLASE.

E. Tiffany-Castiglioni. *Veterinary Anatomy and Public Health, Texas A&M University, College Station, TX.*

OPs produce potent neurotoxic effects in humans, including OP-induced delayed neuropathy (OPIDN). The human neuroblastoma cell line SY5Y at various stages of differentiation can distinguish between OPs having different toxic effects on the nervous system. We have examined the potential for the 200 kD neurofilament protein (NF200) and other neuronal proteins to serve as indicators for neurite damage in a differentiated SY5Y cells. Mipafox, which induces OPIDN, increases NF200 protein expression in SY5Y cells differentiated with human beta-nerve growth factor (NGF, 20 ng/ml) when SY5Y cells are exposed to 0.3 or 30 microM mipafox during the last 5 days of neurite extension. However, mipafox produces little change in NF200 protein levels in SY5Y cells exposed continuously throughout neurite elongation. In contrast, paraoxon (up to 30 microM), which does not produce OPIDN, does not produce any change in NF200 levels. The upregulation of NF200 by mipafox may represent a compensatory response to neurite degeneration. Two other neuronal proteins, growth associated protein 43 (GAP43) and microtubule associated protein 2ab (MAP2ab) show no changes in response to OP treatment in NGF-treated cells. Protein expression of NF200 may therefore be an indicator by which the sensitivities of SY5Y cells to mipafox and paraoxon are distinguishable at the molecular level. This cell culture system has been further used to test the ability of an OP hydrolase enzyme from genetically engineered *E. coli* to degrade OP compounds and eliminate or reduce their neurotoxicity. We found that anti-AChE activity of paraoxon (maximum 3 microM) and anti-NTB activity of mipafox (250 microM) in SY5Y cells were completely prevented by degradation with OPH. Furthermore, biodegradation of mipafox with OPH significantly reduced modulation of these neuroskeletal protein biomarkers by OPs. These results indicate an alternative approach and test system for investigating structure-activity relationships of OPs and their bioremediation by OP hydrolase.

## OXIDATIVE STRESS INVOLVEMENT IN NEUROTOXICITY OF ORGANOPHOSPHATES AND CARBAMATES.

R. C. Gupta<sup>1</sup>, S. Milatovic<sup>2</sup>, T. J. Montine<sup>2</sup>, W. D. Dettbarn<sup>3</sup> and D. Milatovic<sup>2</sup>.  
<sup>1</sup>Toxicology, Murray State University, Hopkinsville, KY, <sup>2</sup>University of Washington, Seattle, WA and <sup>3</sup>Vanderbilt University, Nashville, TN.

Acute administration of organophosphates or carbamates results in a rapid increase of acetylcholine producing a rapid onset of seizures, convulsions, and subsequent neuropathology. The mechanisms involved in the pathogenesis of neuronal damage appear to be linked to free radical-mediated injury. This hypothesis-based investigation was undertaken to determine whether a causal relationship exists between oxidative stress and neurotoxicity induced by an organophosphate diisopropylfluorophosphate (DFP) or the carbamate carbofuran. Male rats exposed to an acute dose of DFP (1.5 mg/kg, sc) or carbofuran (1.5 mg/kg, sc) developed convulsions, seizure, and muscle fasciculations within 15-20 min, with maximal severity at 1 h, lasting for >2 h. At the time of peak severity, when AChE was markedly depressed

(> 75%), maximal increases in F2-isoprostanes and F4-neuroprostanes (markers of lipid peroxidation and ROS, 2-6-fold increase), citrulline (marker of NO/NOS and RNS, 4-8-fold increase), as well as depletion of high-energy phosphates (ATP, 36-60% and PCr, 28-52%) occurred in selected brain regions (cortex, amygdala, and hippocampus). Total adenine nucleotides and total creatine compounds were significantly reduced (36-58% and 28-48%, respectively). Pretreatment of rats with an antioxidant vitamin E (100 mg/kg, ip/day for 3 days) or the spin trapping agent PBN (200 mg/kg, ip) prevented significantly the increases in citrulline and the declines in high-energy phosphates. Detailed analysis of pyramidal neurons of CA1 region of hippocampus revealed that DFP or carbofuran caused marked decreases in total dendritic length (60-70%) and spine density (40%). These neuropathological and biochemical changes were completely prevented when rats were pretreated with a NMDA receptor antagonist memantine (18 mg/kg, sc). From these data, it is concluded that a causal relationship exists between AChE inhibitor- induced oxidative stress and neuropathology.

 **1001** EPA PERSPECTIVE: SCIENTIFIC APPROACHES FOR ASSESSING THE CUMULATIVE RISK OF ORGANOPHOSPHORUS AND N-METHYL CARBAMATE CHOLINESTERASE INHIBITING PESTICIDES.

A. Lowit. *Office of Pesticide Programs, USEPA, Washington, DC.* Sponsor: R. Gupta.

The Food Quality Protection Act of 1996 requires EPA to consider the cumulative risk to pesticides with a common mechanism of action. Under FQPA, cumulative risk is estimated for the common mechanism toxic effect used to establish that common mechanism group. In the case of the organophosphate (OP) and N-methyl carbamate pesticides, this effect is inhibition of acetylcholinesterase either through phosphorylation or carbamylation of the active site. The OP and the N-methyl carbamates were established as common mechanism groups by EPA in 1999 and 2001, respectively. The revised cumulative risk assessment (CRA) for the OPs was released to the public in June 2002; the preliminary CRA for the N-methyl carbamate is expected to be released to the public in the summer of 2005. This talk will discuss relative potency factor and pharmacokinetic approaches to estimating cumulative risk in addition to a discussion of key challenges in developing cumulative risk assessments. The development of physiologically-based pharmacokinetic/dynamic (PBPK/PD) models has increased rapidly in the last few years. However, the typical database of toxicology studies submitted for purposes of pesticide registration do not contain the appropriate types of pharmacokinetic and metabolism data needed to develop complex PBPK/PD models. This talk will also discuss a case study where targeted PK and metabolism experiments were conducted on carbaryl specifically for developing PBPK/PD models.

 **1002** PROTEOMICS AND ANTIBODY MICROARRAYS: APPLICATIONS IN TOXICOLOGY.

R. C. Zangar. *Pacific Northwest National Laboratory, Richland, WA.*

It is now possible to sequence a whole genome and predict the complete proteome of an organism. This information, when used in combination with sophisticated techniques for protein analysis such as tandem mass spectrometry (MS), allows for the rapid analysis of hundreds or thousands of proteins in a single biological sample. These proteomic technologies offer the ability to rapidly determine which of the identified proteins are altered in response to toxicity, xenobiotic exposure or various disease states. One specialized application of proteomics technology is the analysis of protein modifications. Since many of the toxic effects of xenobiotic exposure and oxidative stress are associated with covalent protein modifications, this area of research is expected to result in significant advances in our understanding of the molecular basis for toxicity. Another rapidly developing technology is protein arrays, which can be used for broad comparisons of protein-protein interactions or quantitative analyses. In comparison to MS-based analyses, protein microarrays generally have greater throughput but are limited to a select group of proteins. Overall, these developing technologies are expected to provide a broader insight into the mechanisms of toxicity and identify new markers of disease and toxicity.

 **1003** ANALYSIS OF MARKERS OF CANCER AND XENOBIOTIC EXPOSURE USING ANTIBODY MICROARRAYS.

R. C. Zangar<sup>1</sup>, S. M. Varnum<sup>1</sup>, D. S. Daly<sup>1</sup>, A. M. White<sup>1</sup>, C. Y. Covington<sup>2</sup>, S. Wiley<sup>1</sup>, B. D. Thrall<sup>1</sup> and R. D. Stenner<sup>1</sup>. <sup>1</sup>*Pacific Northwest National Laboratory, Richland, WA* and <sup>2</sup>*University of California School of Nursing, Los Angeles, CA.*

Proteomic and DNA microarray analyses are identifying large numbers of potential markers for toxicity and disease. Once this set of proteins is determined, additional studies are needed to define the utility of these biomarkers under various clinical or

experimental conditions. We have developed a sandwich enzyme-linked immunosorbent assay (ELISA) system in a high-density microarray format that can simultaneously assay 20 or more proteins. This system has sensitivities, dynamic ranges and quantitative characteristics comparable to commercial 96-well ELISAs, but the microarray system can perform these analyses using a few ul of sample. We are also developing software for the rapid evaluation of ELISA microarray data, including a variety of quality control measures. We have used this system to measure protein levels in nipple aspirate fluid, serum and cell-culture medium. These latter studies have provided insight into the molecular mechanisms that regulate the extracellular release of potential cancer biomarkers and have helped elucidate a mechanism of cell-signaling-pathway crosstalk involving regulated shedding of receptor ligands. Overall, the exceptional sensitivity, throughput and quantitative characteristics make the ELISA microarray system an attractive method for quantifying the levels of multiple proteins in large numbers of small samples.

 **1004** FINDING NEW SIGNAL TRANSDUCTION PARADIGMS USING PROTEIN-DOMAIN MICROARRAY.

M. T. Bedford, A. Espejo and J. Daniel. *MD Anderson Cancer Center, Bastrop, TX.* Sponsor: R. Zanger.

Protein domains mediate protein-protein interaction by binding to short peptide motifs in their corresponding ligands. These peptide recognition modules are critical for the assembly of multiprotein complexes. We have arrayed GST fusion proteins, with a focus on protein interaction domains, onto nitrocellulose coated glass slides to generate a protein-domain chip. Arrayed protein-interacting modules included WW, SH3, SH2, 14.3.3, FHA, PDZ, PH and FF domains - that focus on signal transduction pathways; and Chromo, Bromo, Tudor, SWIRM, CW and MBT domains - that are found in chromatin-accessioned proteins and will focus on "reading" the "histone code". Using peptides, we demonstrate that the arrayed domains retain their binding integrity. With this approach we recently identified tudor domains as a protein module that can recognize lysine methylate proteins. This protein-domain chip not only identifies potential binding partners for proteins, but also promises to recognize qualitative differences in protein ligands (caused by post-translational modification) from different sources. In addition, the effects of combinatorial posttranslational modifications on protein-protein interactions, at the level of transmembrane domain receptors, signalling molecules and histone tails can be investigated.

 **1005** PROTEOMIC ANALYSIS OF SERUM PROTEINS DURING ACUTE ACETAMINOPHEN TOXICITY IN RATS REVEALS ACUTE PHASE AND ANTIOXIDANT RESPONSE.

B. A. Merrick<sup>1</sup>, K. B. Tomer<sup>1</sup>, M. E. Bruno<sup>1</sup>, J. H. Madenspacher<sup>1</sup>, B. A. Wetmore<sup>1</sup>, R. Pieper<sup>2</sup>, C. L. Gatlin<sup>2</sup>, M. M. Andrew<sup>2</sup>, A. J. Makusky<sup>2</sup>, M. Zhao<sup>2</sup>, J. Zhou<sup>2</sup>, J. Taylor<sup>2</sup>, S. Steiner<sup>2</sup> and R. W. Tennant<sup>1</sup>. <sup>1</sup>*NCT, NIEHS, Research Triangle Park, NC* and <sup>2</sup>*Proteomics, LSBC, Germantown, MD.*

The serum proteome is an accessible biofluid that can be monitored for changes reflecting organ toxicity and host response. In this study, proteomic analysis of serum from acetaminophen (APAP) intoxicated rats was performed to identify altered serum proteins that might provide insights into acute liver toxicity. Fasted male, Fisher 344 rats, at five/group, were given an oral suspension of 0 (control), 150 and 1500 mg/kg of APAP. Sacrifice times of 6, 24 and 48 hr after APAP represented pre-toxic, toxic and recovery periods, respectively, for the high dose as verified by serum enzymes and histopathology. The control and low dose APAP groups showed few changes in liver pathology and serum proteins over the 48 hr period. Serum profiling was performed by two dimensional (2D) gel electrophoresis and mass spectrometry (MS). Prior to separation, serum was prepared by immunosubtraction of abundant proteins that were removed by affinity chromatography. Proteomic analysis showed the serum proteome was most greatly perturbed at the peak of toxicity. The numbers of significant serum protein changes different from controls were 1, 68 and 17 proteins at 6, 24 and 48 hr, respectively, after a toxic dose of 1500 mg/kg APAP. Increased or newly appearing serum proteins identified by MS at the 24 hr time after APAP included known structural, enzymatic and acute phase proteins, and some previously unidentified proteins including antioxidant enzymes. Followup studies at 24, 72 and 120 hr with 1500 mg/kg APAP showed maximal liver injury at 24 hr which had subsided by 72 hr and recovery by 120 hr. There was a correspondence found between the intensity of liver damage and serum cytokines and antioxidant enzyme activity. Results of proteomic analysis suggest an increase in serum antioxidant enzyme activity triggered by acute phase response to APAP toxicity may reflect a protective host response to acute liver injury.

## 1006 IDENTIFYING PROTEIN MODIFICATIONS RESULTING FROM OXIDATIVE STRESS USING LC/ESI/MS.

I. A. Blair, S. Lee and T. Oe. *Pharmacology, University of Pennsylvania, Philadelphia, PA.* Sponsor: R. Zanger.

Oxidative stress results in the formation of reactive oxygen species (ROS), which can damage cellular macromolecules such as DNA and proteins. DNA damage results directly from ROS, or from ROS-derived lipid-hydroperoxides that break down to the alpha, beta-unsaturated aldehyde genotoxins, 4-hydroperoxy-2-nonenal, 4-oxo-2-nonenal, 4-hydroxy-2-nonenal, and 4, 5-epoxy-2(E)-decenal. Lipid hydroperoxides are also formed enzymatically during oxidative stress from 5-lipoxygenase (5-LOX), 15-LOX, cyclooxygenase-1 (COX-1), and COX-2. There are numerous reports that 4-hydroxy-2-nonenal can covalently modify proteins. However, in many cases 4-oxo-2-nonenal shows increased reactivity when compared with 4-hydroxy-2-nonenal. Therefore, we have used LC/ESI/MS to systematically characterize the lesions that can occur in proteins. Functional studies have focused on histone proteins because of the possibility that lipid hydroperoxide-mediated epigenetic effects may be induced during oxidative stress. Using LC/MS/MS, 87 % amino acid coverage of the tryptic fragments derived from histone H4 was identified. Treatment of histone H4 with 4-oxo-2-nonenal resulted in decreased intensity of peptide D66-K77 by more than an order of magnitude (as determined by LC/ESI/MS) when compared with the unmodified protein. However, the Staph. Aureus V8 fragment N64-E74 was present in almost the same amount as in the unmodified H4. This indicated that modification had occurred on H(75)A(76)K(77). Using a combination of deuterium isotope labeling and LC/MS/MS, it was demonstrated that a cyclic peptide had been formed on the HAK motif. Current experiments are directed at demonstrating whether this modification can occur on histone proteins during oxidative stress *in vivo*. Modification of the HAK motif by lipid hydroperoxides is also being examined in other functionally important proteins. Supported by NIH RO-1 CA95586 and RO-1 CA91016.

## 1007 COMPARATIVE PROTEOMIC ANALYSIS OF CONTROL AND TUMOR-BEARING MOUSE PLASMA BY GEL-LC-MS/MS.

S. R. Tannenbaum, V. B. Bhat, M. Choi and J. S. Wishnok. *Biological Engineering Division, MIT, Cambridge, MA.*

In SJL mice, growth of RcsX lymphoma cells induces an inflammatory response by stimulating V $\beta$ 16+ T cells. During inflammation, given serum protein levels can increase (e.g. acute phase reactants) or decrease (e.g. albumin), and most of these altered proteins are thus potential biomarkers. Although blood plasma is a valuable sample for biomarker discovery for diseases or for novel drug targets, it is a highly complex proteome. We have focused on a comprehensive comparison of the plasma proteomes from control and RcsX tumor bearing SJL mice, and have developed a simple immunoaffinity spin filter method to remove albumin and IgG from 2  $\mu$ l of plasma. Depleted samples were resolved by 1D-SDS-PAGE, and the entire gel lane was cut into 30 slices and in-gel digested with trypsin. The extracted peptides were analyzed by using an Applied Biosystems nano-LC/MS/MS system, and the MS/MS spectra were analyzed on the Agilent's Spectrum Mill MS Proteomics Workbench. This analysis resulted in the identification of a total of 1113 non-redundant mouse plasma proteins; more than 498 in control and 816 in RcsX tumor bearing SJL mouse plasma. The molecular weights ranged from 2-876 kDa, covering the PI values between 4.22-12.09, and included proteins with predicted transmembrane domains. By comparing the plasma proteomic profile of control and RcsX-tumor-bearing SJL mice, we found significant changes in the levels of many proteins in RcsX-tumor-bearing mouse plasma. Most of the up-regulated proteins were identified as acute-phase reactants. Also, several unique proteins i.e., Proteasome subunits, L-selectin, Fetuin-B, 14-3-3 zeta, MAGE-B4 antigen, etc, were found only in RcsX tumor bearing SJL mouse plasma- either secreted, shed by membrane vesicles, or externalized due to cell death. These results affirm the effectiveness of this approach for protein identification from small samples, and for comparative proteomics in animal models of human disorders.

## 1008 UPDATE ON MECHANISMS FOR ENVIRONMENTAL TOBACCO SMOKE-INDUCED HEALTH EFFECTS.

C. A. Pritsos<sup>1</sup> and K. E. Pinkerton<sup>2</sup>. <sup>1</sup>*Nutrition, University of Nevada, Reno, NV* and <sup>2</sup>*Center for Health and the Environment, University of California, Davis, CA.*

Epidemiological evidence has demonstrated an association between exposure to environmental tobacco smoke (ETS) and disease. Diseases associated with ETS exposure include a variety of cancers, cardiovascular disease, COPD, asthma and a number of perinatal manifestations, to name a few. While many of these exposure/disease associations are strong, the mechanism(s) by which ETS exposure

influences the etiology of these diseases remains unclear. There are a great number of confounding factors which make ascribing any ETS-induced mechanism for disease difficult. Included amongst these factors is the immense complexity of the constituents which make up ETS. ETS is comprised of both a vapor phase and particulate phase with over 4000 chemicals identified to date. One must not only consider the effect of individual compounds but must also consider potential synergism between compounds. Another factor which needs to be considered is the fact that exposure to tobacco smoke compounds is substantially less than for smokers, due to dilution of the smoke. Chemical reactivity or "aging" of the ETS components can also modify their chemical nature. Also, an individual's susceptibility to the harmful effects of ETS exposure can be greatly influenced by their genetic makeup. While quite complex, certain mechanistic themes are beginning to emerge as characteristic of ETS's association with these diseases. The speakers will provide recent advances in our understanding of the mechanisms by which ETS can influence the etiology of these diseases and provide a linkage between the epidemiological and biochemical/pathophysiological bases of disease. The symposium will have two presentations each dealing with: ETS and cardiovascular disease, ETS and cancer and ETS and respiratory diseases.

## 1009 IMPACT OF WORKPLACE ETS EXPOSURE ON RISK FACTORS FOR CORONARY HEART DISEASE.

C. A. Pritsos<sup>1</sup>, G. R. Cutter<sup>2</sup>, S. St. Jeor<sup>3</sup>, J. A. Ashley<sup>1</sup>, S. Perumean-Chaney<sup>2</sup>, S. Clodfelter<sup>1</sup>, J. E. Woodrow<sup>1</sup>, A. C. Collier<sup>1</sup>, L. D. Bowen<sup>1</sup>, N. J. Martin<sup>1</sup> and K. L. Pritsos<sup>1</sup>. <sup>1</sup>*Nutrition, University of Nevada, Reno, NV*, <sup>2</sup>*Biostatistics, University of Alabama, Birmingham, Birmingham, AL* and <sup>3</sup>*Internal Medicine, University of Nevada, Reno, NV.*

Environmental Tobacco Smoke (ETS) remains an important source of workplace exposure to environmental contaminants in many bars, restaurants and casinos throughout the US. This study was designed to investigate the impact of workplace ETS exposure on risk factors associated with coronary heart disease and biomarkers of oxidative stress, and the potential moderation of these effects by antioxidant supplementation. Non-smoking bartenders, cocktail servers and casino workers in the Las Vegas and Reno, NV areas, exposed to ETS in the workplace but not in the home were recruited for the study. Following initial baseline analyses of risk factors for coronary heart disease and biomarkers of oxidative stress, subjects were randomized into one of three antioxidant supplement groups. Group 1 received a placebo. Group 2 received a low daily dose of an antioxidant cocktail approximating the recommended dietary allowances (RDA) (75 mg Vitamin C, 15 mg Vitamin E and 55 ug selenium). Group 3 received a higher daily dose approximating one-half the established upper limit for daily intake of these three antioxidants (1000 mg Vitamin C, 500 mg Vitamin E and 200 ug selenium). Subjects returned at 6 month intervals for up to two years to re-evaluate their risk factors and biomarkers. 8-hydroxy-2'-deoxyguanosine, homocysteine, C-reactive protein, total antioxidant capacity, oxidized LDL, cholesterol, LDL cholesterol, HDL cholesterol, superoxide dismutase, glutathione peroxidase and cotinine were determined in these subjects. Baseline values for this ETS exposed population were compared to national databases and each arm of the study was compared to assess the impact of the different levels of antioxidant supplementation. Preliminary results of this study suggest that antioxidant supplementation moderates some of the oxidative stress markers tested. This study was funded in part by NIEHS grant ESO9520.

## 1010 IMPACT OF PRENATAL CARDIOVASCULAR DISEASE RISK FACTOR EXPOSURE ON MITOCHONDRIAL DAMAGE AND ADULT HEART DISEASE DEVELOPMENT.

S. W. Ballinger<sup>1</sup>, Z. Yang<sup>1</sup> and A. Penn<sup>2</sup>. <sup>1</sup>*Pathology, University Alabama at Birmingham, Birmingham, AL* and <sup>2</sup>*Veterinary Medicine, Louisiana State University, Baton Rouge, LA.*

Although cardiovascular disease (CVD) has typically been considered an adult disease, it is a slow, complex inflammatory disease that can start in childhood and progress with age. Numerous factors can increase the risk of CVD development, and many have been shown to cause vascular mitochondrial damage and dysfunction; however, whether gestational and/or neonatal exposure to CVD risk factors influence the development of adult heart disease and mitochondrial dysfunction has not been fully investigated. Because the events that lead to atherosclerosis probably begin decades before the clinical manifestations of the disease become evident, the impact of prenatal exposure to environmental tobacco smoke (ETS) on adult CVD development was investigated in a mouse model of atherosclerosis to test the hypothesis that *in utero* ETS exposure promotes adult atherosclerotic lesion forma-

tion and mitochondrial damage. Atherosclerotic lesion formation, mitochondrial damage, antioxidant activity and oxidant load were determined in cardiovascular tissues from adult apoE  $-/-$  mice that were exposed to either filtered air or ETS *in utero*, and fed a standard chow diet from weaning until sacrifice. All measured parameters were significantly altered in male mice exposed to ETS *in utero*. These data support the hypothesis that prenatal ETS exposure is sufficient to promote adult cardiovascular disease development.

## 1011 IMMUNOLOGIC DETECTION OF CARCINOGEN-DNA AND PROTEIN ADDUCTS.

R. M. Santella, *Environmental Health Sciences, Columbia University, New York, NY*

Immunologic methods using polyclonal and monoclonal antibodies have been developed for measurement of carcinogens bound to DNA or protein. These antibodies can be used in competitive ELISA to measure adducts in DNA isolated from blood or tissue samples or for immunohistochemical detection of adducts in single cells or paraffin or frozen tissue sections. Protein adduct antibodies can be used for quantitation of albumin adducts in blood. These methods have been used to monitor human exposure to environmental carcinogens including those in cigarette smoke. Polycyclic aromatic hydrocarbon (PAH)-DNA adducts are elevated in mononuclear cells of women who smoke compared to nonsmokers but there was no significant effect of passive smoke exposure. Since PAH are ubiquitous environmental carcinogens, exposure from diet may limit ability to detect passive exposure. 4-Aminobiphenyl (4-ABP)-DNA adducts have been measured in paraffin sections of breast tumor and adjacent non tumor tissue of women with breast cancer. Exposure to 4-ABP is a less ubiquitous than to PAH. Adducts were significantly higher in non tumor tissue of women who smoke compared to those not exposed to active or passive cigarette smoke. While adducts were slightly higher in tissues of those with passive smoke exposure, these differences were not statistically significant. In some situations where it is not possible to get sufficient DNA for adduct analysis, protein adducts have been measured as a surrogate. Children of mothers who smoke had significantly higher levels of cotinine and PAH-albumin adducts than did children of nonsmoking mothers. These studies suggest that measurement of DNA or protein adducts using immunologic methods can provide useful information of individual exposure to environmental carcinogens. However, detection of DNA adducts in those with passive smoking exposure has not found significant increases compared to nonsmokers.

## 1012 ETS IMPACT ON ALLERGIC AIRWAYS RESPONSES TO ANTIGEN.

A. penn<sup>1</sup>, D. Paulsen<sup>2</sup> and D. Horovch<sup>3</sup>. <sup>1</sup>CBS, LSU Vet.Med., Baton Rouge, LA, <sup>2</sup>PBS, LSU Vet.Med., Baton Rouge, LA and <sup>3</sup>Vet. Sciences., University of KY, Lexington, KY.

Epidemiologic evidence supports a role for maternal smoking and for ETS exposure in subsequent development of allergic airway responses to antigens. We have been investigating ETS-antigen interactions in mice exposed to aerosolized, nose-only (N/O) ovalbumin (OVA) as young adults after being exposed *in utero* to ETS. We tested the hypothesis that *in utero* ETS exposure will subvert establishment of aerosol-induced tolerance to inhaled antigens, resulting in induction of adult-onset asthma. Pregnant mice were exposed to ETS or filtered air throughout pregnancy (10mg/m<sup>3</sup> TSP; 5hr/day). From 6-8 wks of age, offspring were exposed N/O to OVA or saline, as above. At 9 wks, ETS/ OVA-exposed mice exhibited small but significant increase in OVA-specific IgE compared to air/OVA-exposed mice. Subsequently, mice were injected i.p. with 100 $\mu$ g OVA in alum, followed by aerosol sensitization with 5% OVA (priming) and sacrifice at 16 wks. Air exposure *in utero* followed by inhaled OVA at 6 wks resulted in minimal levels of OVA-specific IgE after priming, consistent with establishment of aerosol tolerance. In contrast, ETS *in utero* followed by inhaled OVA at 6 wks produced elevated levels of OVA-specific IgE after priming, consistent with subversion of aerosol tolerance by ETS. Lungs of the ETS- and OVA-exposed (N/O; then primed) mice exhibited significantly increased inflammatory changes compared to lungs from air-exposed mice with the same OVA exposures. Again, this is consistent with subversion of aerosol tolerance by ETS. Plethysmograph measurements revealed expected Penh increases in air/saline/primed mice compared to air/OVA/primed mice. This is consistent with establishment of aerosol tolerance in OVA/primed mice. Surprisingly, ETS exposures resulted in sharply decreased Penh values in saline/primed mice. Their Penh profiles were not different from those of OVA/primed mice. These results are not consistent with ETS subverting aerosol tolerance. This apparent discrepancy between pulmonary function results and pathology/immunology results is being investigated.

## 1013 GESTATIONAL STAGE-SPECIFIC ETS-INDUCED OXIDATIVE DNA DAMAGE.

L. M. Anderson<sup>1</sup>, A. Maciag<sup>1</sup>, I. Espiritu<sup>2</sup>, A. Bialkowska<sup>1</sup>, K. Kasprzak<sup>1</sup> and H. Witschi<sup>2</sup>. <sup>1</sup>Lab. Comparative Carcinogenesis, National Cancer Inst., Frederick, MD and <sup>2</sup>Center for Health and the Environment, University of California, Davis, CA.

Sidestream tobacco smoke contains carcinogens and long-lived prooxidant radicals. Both humans and animals exposed to sidestream or environmental tobacco smoke (ETS) show cellular increases in 8-hydroxy-2'-deoxyguanosine (8-oxo-dG), a pro-mutagenic lesion. An important issue is whether transplacental exposure of fetuses to the carcinogens or oxidants received by mothers in ETS may result in DNA damage, with possible carcinogenic consequences. Tobacco smoking by fathers could in this way contribute to risk of childhood cancer. We investigated whether exposure of pregnant rats to ETS would result in an increase in 8-oxo-dG in the tissues of their fetuses. Timed pregnant SD rats were exposed to ETS from Kentucky 1R4F research cigarettes in inhalation chambers. Levels of 8-oxo-dG were analyzed by HPLC/EC. Tissues analyzed were liver, lung, kidney, heart, and brain. Increases in 8-oxo-dG occurred selectively in certain tissues. Changes were relatively small and somewhat variable, but were of statistical significance. Results varied with the stage of gestation. For the mothers, there were increases in 8-oxo-dG with ETS exposure for gestation days 4-16, in liver and kidney, but not in heart or brain. However, when exposure was continued until the end of gestation, days 4-21, no differences were seen in any tissue. For the fetuses, exposure for days 4-16 resulted in increased 8-oxo-dG in kidneys only. Fetal exposure for days 4-21 led to increased 8-oxo-dG in livers and in female brains, but not in other tissues. The effects in the livers measured on day 16 were significantly different compared with day 19, for both mothers and fetuses. These results imply that (1) ETS can indeed act transplacentally to cause potentially mutagenic changes in fetuses; (2) sensitivity is tissue-specific and varies during ontogeny, probably due in part to degree of differentiation and maturation of relevant enzymes; and (3) pregnant females may have special sensitivity to reactive oxygen damage from ETS.

## 1014 EFFECTS OF ENVIRONMENTAL TOBACCO SMOKE ON CYTOKINES AND NEUROTROPHINS IN THE NEONATAL LUNG.

K. E. Pinkerton, J. P. Joad and M. Yu. *Center for Health and the Environment, University of California, Davis, CA.*

Epidemiological studies have associated ETS with asthma in early childhood. The role of Th2 cytokines in allergic response has been well demonstrated. Recent work suggests that neurotrophins are critical mediators between allergic inflammation and airway hyperresponsiveness. To determine the alteration of cytokine response and neurotrophin profile in newborn rhesus monkeys caused by ETS during perinatal period, exposure was started at 50 days gestational age at a total suspended particulate concentration of 1 mg per cubic meter, 6 hours per day, 5 days per week, and continued to 2.5 months postnatal age. Bronchoalveolar lavage (BAL), measurement of protein levels of interleukin (IL)-2, interferon-gamma, IL-4, IL-5, BDNF, and nerve growth factor (NGF) were done one day after the exposure. Compared with control animals, significant increase was found in the differential percentage of monocytes, lymphocytes, and eosinophils in BAL recovered cells (287%, 347%, 478% of control, p<0.05, respectively), total protein level in the BAL fluid (228% of control, p<0.05), levels of IL-4 and BDNF in the cell culture supernatant of peripheral blood mononuclear cells (PBMCs) (170% and 440% of control, p<0.05, respectively), plasma level of BDNF (335% of control, p<0.01), or IL-5 level in the lung tissue extract (159% of control, p<0.05), respectively. Statistically decreased levels of IL-2 in PBMC culture supernatant (81% of control, p<0.05) and NGF in BAL fluid (24% of control, p<0.01) were also determined. According to the results obtained from newborn monkeys, we conclude that perinatal exposure to ETS causes chronic pulmonary inflammation and BDNF-associated Th2 weighted imbalance of cytokine profile.

## 1015 IN VITRO TOXICITY TESTING OF AIR POLLUTANTS: PROS AND CONS.

M. Gilmour<sup>1</sup> and J. Seagrave<sup>2</sup>. <sup>1</sup>NHEERL, USEPA, Research Triangle Park, NC and <sup>2</sup>LRRI, Albuquerque, NM.

The increasing evidence for adverse health effects resulting from acute and chronic exposure to air pollution has driven efforts to identify which components cause these effects and by what mechanisms. This, in turn, has created need for rapid, cost-effective methods for *in vitro* screening and mechanistic studies. The respiratory tract is the first target of aerosols, but *in vitro* studies of this system are complicated by species differences, varied regional anatomy and physiology, as well as the fact that aerosols interact at the gas/air inter-phase of the lung surface. In addition to containing over forty different cell types that may respond quite differently to a

given stimulus, host susceptibility factors that may be driven by genetics, and previous exposures may impact on observed effects. The purpose of this session is to review issues regarding the selection of models, exposure methods, doses, and endpoints and to determine how these systems may reflect inhalation exposures in the exposed population.

## 1016 CELL POPULATIONS WITHIN THE RESPIRATORY TRACT.

C. G. Plopper. *Anatomy, Physiology and Cell Biology, University of California, Davis, CA.*

The respiratory system serves as one of the principal interfaces between the organism and its environment. The nature of the effects induced by inhaled materials, such as particulates, reactive gases, and pathogenic microbes, on the respiratory system depends on the aerodynamic properties of the three-dimensional architecture of the conducting air passages and interactions occurring between inhaled toxicants, the airway surface lining and the epithelial lining cells. The respiratory system is highly complex architecturally and the cells organized to form the unique compartments resulting from this organization are very heterogeneous. Each set of cells organizes its own unique microenvironment. The epithelial cell populations change in phenotypic expression in different locations within the tract. Nasal cavity, larynx, trachea, bronchi, bronchioles and alveoli each have their own populations. Even where the populations are structurally similar, they often have different metabolic and functional potential. The extracellular matrix and the mesenchymal cells of the interstitium also vary greatly by position within the tract. Meaningful *in vitro* studies require well-defined cell populations.

## 1017 SYSTEMS FOR EXPOSING LUNG CELLS TO AEROSOLS.

J. Seagrave and J. D. McDonald. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

*In vitro* systems of cultured lung cells offer considerable advantages in assessing the mechanisms by which aerosol toxicants may affect an organism. However, there are significant challenges in assuring that the materials to which the cells are exposed accurately represent the appropriate physical/chemical form of these potential toxicants. In conventional culture, cells are cultured on plastic substrata and collected materials from the aerosol of interest are mixed with the culture medium. Although this method is relatively simple and the concentrations of the materials in the medium can be known, changes in the physical/chemical composition during the collection and resuspension of the aerosol components are unavoidable, and responses to gas-phase components cannot easily be measured. Recently, several methods have been developed to expose lung cells to aerosols in a more physiological manner. These methods include exposing cultured cells or precision-cut lung slices intermittently to aerosols in roller bottles or rockers. Alternatively, direct air-liquid interface exposure systems have been developed. In these systems, cells are grown on a semi-permeable membrane, with culture medium present below the membrane. The apical surfaces are then directly exposed to the atmosphere. Advantages include more physiological exposure and the ability to quantify both the exposure concentrations and in many cases, the actual doses received at the cell surface. Disadvantages include the limitations of only short-term exposures, and the difficulty of performing simultaneous parallel doses or atmospheres. Critical features for appropriate use of these models include adequate pH regulation and humidity, confirmation of uniformity of exposures both among wells and across the surface of individual wells, a means of assessing the dose to the cells, and appropriate controls for exposure to clean air. Careful attention should also be paid to the reproducibility of the exposures and the cellular responses. Supported by FreedomCAR and Vehicle Technology Program of the US Department of Energy, Office of Energy Efficiency and Renewable Energy.

## 1018 ANALYTICAL TOOLS FOR ASSESSING AIR POLLUTION TOXICITY USING DIFFERENT *IN VITRO* CELL CULTURE MODELS.

I. Jaspers. *CEMALB, University of North Carolina, Chapel Hill, NC.*

The primary targets for inhaled air pollutants are cells lining the respiratory tract and resident monocytes/macrophages. Several cell culture models are available to assess air pollution toxicity *in vitro*. These cell culture models are based on either immortalized cell lines, representing certain cell types of the respiratory tract, or primary cells obtained from either laboratory animals or humans. Immortalized cell lines and primary cells can be cultured either under submerged conditions or on membranous support at air-liquid interface (ALI) conditions. Furthermore, pri-

mary respiratory epithelial cells cultured under ALI conditions undergo mucociliary differentiation into a pseudotrified epithelium, which mimics many of the features seen *in vivo*, including large beds of beating cilia. These *in vitro* models of respiratory epithelial cells or macrophages are a valuable tool to determine cellular mechanisms of air pollution toxicity. For example, detailed analysis of signal transduction cascades induced upon exposure to air pollutants can be examined by applying commercially available pharmacological agents. In addition, manipulation of the expression of defined genes using techniques such as siRNA-mediated knock-down and plasmid-mediated overexpression are helpful in determining cellular mechanisms of air pollution toxicity. Furthermore, activities and interactions of signaling components can easily be examined using *in vitro* approaches. Some of these techniques can only be applied to a limited extent in primary cells or cells grown on membranous support. However, cell culture models using respiratory cells grown on membranous support can examine whether there is any polarity with regards to mediator release. In addition, these cell culture models facilitate co-culture with different cell types, which are useful to determine cell-cell interactions. In the context of emerging scientific questions regarding the mechanisms by which air pollutants exert their toxicity on the respiratory system, the advantages and disadvantages of using these various *in vitro* models will be discussed.

## 1019 *IN VITRO* CORRELATION WITH *IN VIVO* EXPOSURES.

R. Devlin and L. Dailey. *USEPA, Research Triangle Park, NC.*

In principle, *in vitro* toxicology studies offer several advantages over *in vivo* animal or human studies, for example by providing a way to rapidly screen toxicants in lieu of *in vivo* exposures, or by characterizing mechanisms in ways not possible with *in vivo* studies. However, to be of optimal use, there must be confidence that the information obtained from such studies can be applicable to *in vivo* exposure studies. This presentation will describe information obtained from exposure of human primary lung epithelial cells and alveolar macrophages to air pollutants. Studies will be presented which show that the response of cultured epithelial cells to different PM size fractions or components is comparable to lung inflammation observed in rats or humans exposed to the same particles. *In vitro* mechanistic studies will also be described which use cutting edge molecular biology approaches to better understand the pathophysiological effects observed following *in vivo* exposure of animals and humans to air pollutants. This abstract does not necessarily reflect EPA policy.

## 1020 TOXICOLOGY INFORMATION AND DATA UPDATE.

P. Wexler. *Toxicology and Environmental Health Information Program, National Library of Medicine, Bethesda, MD.*

As the Web and its online resources continue to expand and change rapidly, there is an increasing plethora of databases, documents, and other digital tools available to the toxicology community. Toxicologists with even formidable research skills are often knowledgeable about only a small fraction of what is available, and they are often not kept apprised of the newest developments. This symposium highlights major Web-based resources from all sectors - government, academia, industry, nonprofits - which can benefit toxicologists in their daily research and other work. This program takes a look at a few of these resources. The National Library of Medicine's Toxicology and Environmental Health Information Program is a major purveyor of toxicological information and data through its TOXNET system and other databases, geared to both the professional and the public. The Center for Research on Environmental and Occupational Toxicology (CROET) focuses on health and safety in the workforce and supports a number of information activities, including its Toxicology Information Center. The National Institute of Environmental Health Sciences (NIEHS) and the National Toxicology Program offer a number of unique online databases and make available online numerous test reports and the Report on Carcinogens. EPA has recently unveiled its Distributed Structure Searchable Toxicity (DSS-TOX) database, another powerful tool of potential interest.

## 1021 THE NATIONAL LIBRARY OF MEDICINE'S (NLM) WORLD LIBRARY OF TOXICOLOGY, CHEMICAL SAFETY AND ENVIRONMENTAL HEALTH.

P. Wexler. *Toxicology and Environmental Health Information Program, National Library of Medicine, Bethesda, MD.*

NLM's Toxicology and Environmental Health Information Program (TEHIP) provides an extensive suite of databases and other information resources for the toxicology community, ancillary professional groups, and the public. In addition to collaborative arrangements with other government agencies and non-profit organizations, NLM also offers links to other relevant sites. With increasing inter-

dependence among countries and the expansion of information and telecommunication technologies, it has become increasingly obvious that a coordinated global approach to toxicology information is a resource waiting to happen. NLM's World Library of Toxicology, Chemical Safety and Environmental Health is a Web-based tool that attempts to fill the void. With information supplied, maintained and updated by country national representatives, the World Library serves as a forum to stimulate collaborative projects between nations and to minimize duplication of effort, providing a special benefit to the developing world. Among the many information sources included are those provided by governmental organizations and non-government groups, and universities and other educational programs. Also presented is legislation, country gateway information, databases, TOXLINE references, news, publications and meeting announcements.

 **1022** WEB-BASED RESOURCES SPONSORED BY THE NATIONAL INSTITUTE OF ENVIRONMENTAL HEALTH SCIENCES (NIEHS) AND THE NATIONAL TOXICOLOGY PROGRAM (NTP).

L. L. Wright. *US Department of Health and Human Services, National Institute of Environmental Health Sciences, Research Triangle Park, NC.* Sponsor: P. Wexler.

The presentation begins with a brief overview of NIEHS and NTP web-based resources with information on major programs, research portfolios, announcements, extramural funding opportunities through grants, contracts as well as postings of in-house vacancies including pre-doctoral, post-doctoral, staff-fellow and full-staff employment opportunities. Thereafter discussions focus on the resources developed by the NTP: its mission, participating agencies, announcements (Federal Register, press releases, meetings and post-meeting updates), annual plans, official reports, toxicity testing programs and summaries in databases searchable by substance, organ site, lesion morphology, models and alternative models, historical controls and more. Database queries follow through to links providing full-text of technical reports and publications relevant to the search

 **1023** THE CENTER FOR RESEARCH ON OCCUPATIONAL AND ENVIRONMENTAL TOXICOLOGY (CROET).

F. Berman. *Oregon Health and Science University, Portland, OR.* Sponsor: P. Wexler.

The Center for Research on Occupational and Environmental Toxicology (CROET) Description: CROET comprises more than 100 scientists and research staff exploring a range of questions relating to the prevention of injury and disease - and the promotion of health - in the workforce of Oregon and beyond. In addition to the conduct of basic and applied research on a variety of occupational safety and health issues, CROET is charged with providing outreach and education to business, labor and professionals through conferences, direct consultation and, most importantly, via the web. CROET's website, [www.CROETweb.com](http://www.CROETweb.com), is an occupational safety and health resource directory that contains links to 1000+ occupational safety and health (and toxicology) resources that focus on day-to-day workplace issues. Links are hand selected and organized topically under a variety of headings, including Occupations and Industries, Chemical and Biological Hazards, Ergonomics Issues and other Workplace Safety Issues. The website also provides links to a variety of toxicology and other databases, including the full suite of National Library of Medicine databases. Link selection criteria and guidelines for the evaluation of health-based websites will be discussed. Center for Research in Occupational and Environmental Toxicology Oregon Health and Science University Portland, Oregon, USA

 **1024** DSSTOX STRUCTURE-SEARCHABLE PUBLIC TOXICITY DATABASE NETWORK: CURRENT PROGRESS AND NEW INITIATIVES TO IMPROVE CHEMO-BIOINFORMATICS CAPABILITIES.

A. M. Richard<sup>1</sup> and B. A. Rogers<sup>1</sup>. <sup>1</sup>USEPA, Research Triangle Park, NC and <sup>2</sup>NCCU Student COOP, USEPA, Research Triangle Park, NC. Sponsor: L. King.

The EPA DSSTox website (<http://www.epa.gov/nheerl/dssto>) publishes standardized, structure-annotated toxicity databases, covering a broad range of toxicity disciplines. Each DSSTox database features documentation written in collaboration with the source authors and toxicity experts, standardized chemical structure annotation, inclusion of data fields designed to enhance the utility of these files for structure-activity exploration and discovery, and full and open public access. In addition, the DSSTox website offers a range of information resources and tools to encourage public participation in the project and to facilitate use of these structure-searchable databases in relational database applications and structure-activity relationship (SAR) model development. Long-term goals of the DSSTox project are to:

expand database offerings into a wider range of toxicology study areas; coordinate development and adoption of standardized toxicity data fields that will expand structure-activity exploration capabilities across wide-ranging areas of toxicology; incorporate XML chemical structure (NIST-ICHI) identifiers; and encourage and facilitate expanded chemo-bioinformatics capabilities in toxicogenomics. In collaboration with the NIEHS/National Center for Toxicogenomics, and the Chemical Effects in Biological System Knowledge Base (CEBS), DSSTox standard chemical fields are being incorporated into the annotation of toxicogenomics datasets resulting from chemical exposure. This will create linkages from CEBS to DSSTox historical toxicity databases, and enable sophisticated searches across multiple domains of information (chemical structure analogs, toxicity endpoint, gene, pathway, etc.). Chemical structure, and the chemistry underlying toxicity in biological systems, provide a natural common metric for exploration across diverse types of biological data and will be an essential information component to the next generation of predictive toxicology and chemo-bioinformatics capabilities. This abstract does not represent EPA policy.

 **1025** CURRENT AND FUTURE SCIENCE-BASED APPROACHES TO DRUG SAFETY EVALUATION: AN ASSESSMENT OF POTENTIAL CANCER RISK.

M. Moore. *DGRT, NCTR, Jefferson, AR.*

Currently the preclinical safety evaluation of pharmaceuticals for potential cancer risk includes the application of genetic toxicology assays and the rodent cancer bioassay. While data from rodent carcinogenicity studies are generally available prior to marketing approval, data from short-term studies is used to assess cancer risk during the drug development phases. Although this has generally been a successful approach there is wide discussion as to the appropriate role of the genetic toxicology assays and the possibility that other assays such as the Syrian hamster embryo (SHE) test and the shorter term transgenic cancer bioassays (Trp53 and rasH2) might be useful. The emerging "omics" technologies provide for possible new and improved approaches to understanding whether new drugs might cause an increased cancer risk. In addition, both present and future technologies have the potential to be applied within the context of the clinical trials. This session will provide a forum to discuss these issues. The first speaker will provide an overview of the current approaches and issues relevant to preclinical drug safety assessment. Additional speakers will discuss the current thinking on the use of genetic toxicology assays, the SHE assay and the transgenic cancer bioassays. The last two speakers will consider both the present and potential future applications of "omic" technologies and our ability to utilize individuals in clinical trials to provide a better assessment of the potential human cancer risk from pharmaceutical drugs.

 **1026** OVERVIEW OF THE CANCER SAFETY ASSESSMENT IN CDER/FDA.

A. Jacobs. *USFDA, Rockville, MD.*

It is difficult to ascertain the carcinogenic potential of drugs from epidemiologic data. Thus, the Center for Drug Evaluation and Research (CDER) of the US Food and Drug Administration relies on short-term genetic toxicology studies to assess risk to patients involved in clinical trials and on rodent carcinogenicity studies to assess cancer risk for drug approval. Carcinogenicity studies are conducted according to ICH guidelines, generally for drugs for chronic conditions. Protocols for carcinogenicity studies are submitted by drug sponsors to the CDER executive carcinogenicity assessment committee (exec-CAC) for concurrence. The exec-CAC may suggest protocol revisions, such as elimination of unnecessary measurements and even lowering of the top dose. After the studies are completed, the exec-CAC also gives concurrence for what findings are considered to be drug related. The evaluation of cancer risk is the result of an integrated assessment of what is known about the drug, and risk is considered in the context of the clinical benefit

 **1027** THE ROLE OF GENETIC TOXICOLOGY ASSAYS IN A WEIGHT-OF-EVIDENCE CANCER ASSESSMENT FOR NEW PHARMACEUTICALS.

D. Jacobson-Kram<sup>1</sup>. <sup>1</sup>FDA, Rockville, MD and <sup>2</sup>Office of New Drugs, Center for Drug Evaluation and Research, USFDA, Rockville, MD.

The Center for Drug Evaluation and Research (CDER) relies on two-species rodent bioassays to determine potential carcinogenicity of new drugs. However, the results of these studies are typically not available until the time of drug approval. As a result, CDER relies on surrogate markers of carcinogenicity during the course of drug development. Clinical trials often involve exposure of healthy subjects and

large numbers of patients to pharmacologically active doses of the drug for protracted time periods. Typically, CDER review divisions rely on genetic toxicology studies to assess cancer hazard during this phase of drug development. Positive results in *in vivo* genetic toxicology studies are rare; however, positive *in vitro* chromosomal aberration assays and positive mouse lymphoma assays are not infrequent. Review divisions must decide if it is ethical for sponsors to proceed with a clinical trial, often in healthy subjects, in the face of positive genotoxicity findings. Some review divisions have requested that sponsors perform Syrian hamster cell transformation assays or p53 carcinogenicity studies before proceeding to repeated dose clinical trials. Current CDER policy gives sponsors a broader range of options in coping with positive genetic toxicology results. These include a weight-of-evidence assessment as to whether the results present a hazard to humans under the conditions of the clinical trial, use of mechanistic studies to understand and explain positive findings and the use of additional *in vitro* and *in vivo* studies to address the relevance of positive findings.

**1028** TRANSGENIC CANCER BIOASSAYS: A USEFUL ADDITION TO CANCER SAFETY ASSESSMENT OF NEW PHARMACEUTICALS?

R. D. Storer, *Safety Assessment, Merck Research Laboratories, West Point, PA.*

International guidelines allow for use of a short-term cancer bioassay (26 weeks) in transgenic mice as a substitute for one of the two required long-term rodent bioassays in the preclinical safety evaluation of pharmaceuticals. The substitution may be allowed, or encouraged, when preclinical safety and/or pharmacology data suggest that an alternative assay could provide additional information not likely to be obtained from a second long-term bioassay. Utilization of these models in preclinical safety evaluation can significantly reduce animal use, time and manpower. The two models which have gained general acceptance by both sponsors and regulators are the CB6F1-RasH2 mouse hemizygous for the human H-ras transgene and the B6.129N5-Trp53 mouse heterozygous for a p53 null allele. These models have shown potential to provide, in addition to a short-term tumorigenicity endpoint, insight into mechanisms involved in tumor induction. Utilization of the p53+/- model is of particular value for compounds with residual concern that genotoxic activity may contribute to tumorigenesis; the RasH2 model however may be accepted as an alternative without regard to evidence of genotoxic potential. In considering the utility of the p53 model, many genetic toxicologists view the ICH test battery and available adjunct assays as sufficient for evaluating the potential risk of genotoxic carcinogenesis and for making decisions with respect to initiation of clinical trials. However, results from a p53 assay can make an important contribution to the weight of evidence assessment of mode of action (genotoxic vs non-genotoxic) from any tumor findings in the long-term bioassay. In addition, since results from a short-term bioassay can be obtained relatively early in drug development, there is the potential for more timely assessment of cancer risk for individuals in clinical trials. For the RasH2 model, responses to non-genotoxic carcinogens and the rationale for use of this model will be discussed in the context of the debate as to which classes of compounds in this category are most important to detect.

**1029** INTEGRATION OF OMIC DATA INTO CANCER RISK ASSESSMENT.

Y. Dragan, *Hepatic Toxicology, NCTR, Jefferson, AR.*

In order to minimize the risk of cancer development, two year carcinogenicity studies are performed in rodents to determine dose and exposure conditions that may result in a carcinogenic risk to humans. Cancer risk assessment methods are dependent upon the extrapolation of the data obtained in rodent experiments performed at maximum tolerated dose to humans exposed at environmental or therapeutic levels. This requires two leaps of faith; one a belief that rodents are good models for understanding humans and two that high dose exposures predict risk at lower exposures. Appropriate interpretation of cancer bioassay data developed under this paradigm requires that the black box between rodent exposure and response data and human exposure conditions be illuminated. The detection of a carcinogenic potential in the rat provides a mechanism to predict mode of action. Rodent models provide the opportunity to examine the biomarkers and patterns of alteration that occur early in the cancer development process. In addition, rodent models of cancer development can be used to examine the pathways that contribute to cancer development under various conditions. The ability to examine gene and protein expression patterns in a parallel manner permits one to examine human cancer development in the tissue of interest through microarray and proteomic analysis. Alternatively, one can develop biomarkers of cancer in biofluids through metabolomic and proteomic approaches. The utility of OMIC approaches lies in clarification of the dose response and the ability to extrapolate across species.

**1030** CANCER BIOMARKERS: CAN THEIR APPLICATION IN CLINICAL TRIALS IMPROVE THE SAFETY ASSESSMENT OF NEW PHARMACEUTICALS?

R. J. Albertini, *Genetic Toxicology Lab., University of Vermont, Burlington, VT.*  
Sponsor: M. Moore.

Biomarkers for evaluating *in vivo* genotoxicity in humans are conventionally classified as indicators of exposure, effect or individual susceptibility. Their practical utility depends on their validation in terms of intended purpose, i.e. (exposure) sensitivity in reflecting internal doses, (effect) accurate reflection of mechanisms or, if used as a surrogate for clinical outcome, ability to predict disease and (susceptibility) heightened predisposition to deleterious outcomes. Validation requires rigorous field studies and is more highly developed for biomarkers of exposure than for those of effect or susceptibility. However, it is the latter that are most likely to be useful in clinical trials. Traditionally, chromosome aberrations and somatic mutations indicating irreversible changes in DNA are the prototypic effect biomarkers. These changes can be in reporter regions of the genome, being related to cancer by molecular analogy, or in regions directly associated with carcinogenesis. Cell, flow and molecular based assays are available, some with high throughput capabilities. DNA adducts are also potential biomarkers of effect; their utility in safety assessments being dependent on thresholds before irreversible DNA alterations occur. Methods for assessing cellular responses in terms of gene expression (genomics, proteomics) are also available. Susceptibility biomarkers include the genotypes for metabolic, repair or other functions. Validated biomarkers of effect and susceptibility, with the latter serving as modifiers of the former, will have the potential for improving the safety assessment of new pharmaceuticals in clinical trials, especially those biomarkers previously studied in animals in the context of cancer bioassays. Clinical trials can assign relative risks for biomarker responses in treated versus untreated subjects with cancer inferences being dependent on biomarker validation and confidence that the underlying biological changes truly reflect carcinogenic mechanisms.

**1031** MOLECULAR PATHWAYS TO TOXICANT-INDUCED OSTEOPOROSIS.

M. H. Bhattacharyya<sup>1</sup>, E. Puzas<sup>2</sup>, J. B. Lian<sup>3</sup>, D. J. Novack<sup>4</sup> and M. J. Ronis<sup>5</sup>.  
<sup>1</sup>*Biosciences Division, Argonne National Laboratory, Argonne, IL*, <sup>2</sup>*University of Rochester School of Medicine, Rochester, NY*, <sup>3</sup>*University of Massachusetts Medical School, Worcester, MA*, <sup>4</sup>*Washington University School of Medicine, St. Louis, MO* and <sup>5</sup>*University of Arkansas Medical Sciences, Little Rock, AR*.

Osteoporosis is a disease characterized by low bone mass and structural deterioration of bone tissue, leading to bone fragility and an increased susceptibility to fractures of the hip, spine, and wrist. This disease is responsible for more than 1.5 million fractures annually; 44 million Americans have low bone mass such that they either have osteoporosis or are at significant risk of developing the disease. Of the 10 million who actually have osteoporosis, 80 percent are women. Men suffer one-third of all hip fractures that occur, and approximately one-third of these men will not survive more than one year after the fracture. Our population is increasing in the fraction of elderly persons faster than at any other time in human history. Understanding ways in which toxicants contribute to the development of osteoporosis is an important undertaking. In this workshop, we will provide 1) basic information on pathways of bone formation and bone resorption and their role in the development of osteoporosis, 2) new insights into how the important metals, lead and cadmium, affect bone cell pathways and contribute to metabolic bone disease, 3) the role that alcohol consumption may play in the development of osteoporosis, and 4) discussion by workshop participants of the results presented with respect to their application and relevance to human health.

**1032** MOLECULAR PATHWAYS REGULATING OSTEOBLAST GROWTH AND DIFFERENTIATION.

J. B. Lian and G. S. Stein, *Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA.* Sponsor: M. Bhattacharyya.

Bone remodeling in the adult skeleton is essential to respond to physical stresses on bone and to support calcium homeostasis for regulating vital cellular functions. Bone remodeling requires a perfect balance between bone resorption and bone formation events in order to maintain skeletal mass in the adult. Much has been learned related to the multiple pathways that result in formation of the skeleton in the developing embryo and it is now clear that the morphogenetic, growth factor signaling and gene transcriptional controls essential for the induction of bone formation can be recapitulated for bone renewal in the adult skeleton. Runx2/Cbfa is a central regulator of bone formation and osteogenic differentiation. Ablation of Runx2 in the mouse results in complete absence of a mineralized skeleton. Numerous properties of Runx2 have now been characterized that further establish

this transcription factor as a master regulatory switch for bone formation. Runx2 functions as a platform protein to integrate the signals from developmental signal transduction cascades for positive and negative regulation of gene transcription required for progression of mesenchymal stem cells through the osteoblast lineage for formation of a mineralized bone extracellular matrix. A balance between positive and negative regulation of skeletal turnover in the adult can be achieved through the gene regulatory activities of Runx2. Runx interaction with numerous coregulatory proteins that mediate the responses to developmental signals including BMP, TGF $\beta$ , and c-Src, regulates osteoblast expressed genes that control both bone formation and bone resorption. An overview of the unique properties of Runx2 and the potential for the translation of these properties into therapeutic strategies for the treatment of osteoporosis will be discussed.

### **1033** MOLECULAR PATHWAYS REGULATING OSTEOCLAST DIFFERENTIATION AND FUNCTION.

D. Novack. *Medicine/Bone and Mineral, Washington University School of Medicine, St. Louis, MO.* Sponsor: M. Bhattacharyya.

Osteoclasts (OCs), the multinucleated, monocyte lineage cells responsible for normal and pathological bone resorption, differentiate under the influence of macrophage colony stimulating factor (M-CSF) and receptor activator of NF- $\kappa$ B (RANKL), expressed in membrane-bound and soluble forms by osteoblasts and their precursors. Other soluble cytokines, (eg, TNF, IL-1, and PTH) modulate osteoclastogenesis, particularly in pathologic states. RANKL is a TNF family cytokine that binds to the transmembrane receptor RANK, present on OCs. Ligation of RANK leads to recruitment of TRAFs and initiates signaling through NF- $\kappa$ B, all 3 major MAPKs (p38, ERK, and JNK), as well as PI3K/Akt and src-family kinases. Inhibitor and murine knockout experiments have demonstrated that all these events are required for optimal osteoclastogenesis. Activation of NF- $\kappa$ B occurs via the classical pathway involving degradation of I $\kappa$ B $\alpha$ , as well as through the alternative pathway downstream of NIK and IKK $\alpha$ . TNF $\alpha$  is osteoclastogenic, but only in the presence of RANKL. TNF $\alpha$  activates all of the same signaling pathways as RANKL with the exception of the alternative NF- $\kappa$ B pathway. RANKL is required at all stages of osteoclastogenesis, providing differentiation, resorptive and survival signals. M-CSF, also known as colony stimulating factor (CSF-1), binds to c-fms, a receptor tyrosine kinase related to the PDGF family receptors. Activation of c-fms also leads to signaling via PI3K/Akt and src-family kinases, as well as through MAPKs (particularly ERK). M-CSF is also required at all stages, stimulating proliferation of precursors, survival, and motility. In some circumstances related cytokines such as VEGF and HGF have similar roles, and can substitute for M-CSF. The activities of OCs are linked to those of osteoblasts (OBs), a process known as coupling. In normal bone turnover, OCs remove a portion of bone, and OBs are rapidly recruited to these sites to add new bone matrix. This coordination is often disrupted in disease states, leading to an imbalance in favor of either resorption or formation.

### **1034** LEAD-INDUCED OSTEOFOPOROSIS.

J. E. Puzas. *Department of Orthopaedics, University of Rochester School of Medicine, Rochester, NY.*

Greater than 90% of the body burden of lead resides in the skeleton. In bone, this toxic element has a half life that has been estimated to be over 20 years. Yet bone cells have been an unappreciated target for the effects of this agent. Our laboratory and others have shown that bone cells (i.e. osteoblasts and osteoclasts) exposed to low levels of lead are adversely affected in their function. Both cell types are blunted in their ability to carry out normal bone formation and resorption processes, respectively. However, it appears that the effects of lead are more pronounced on osteoblasts. At all concentrations of lead, *in vitro*, the effect on osteoblast function (such as collagen synthesis, osteocalcin production, alkaline phosphatase activity, etc) is greater than the effect on osteoclast activity (i.e. pit formation on cortical bone wafers). If these findings persist *in vivo*, they would contribute to an accelerated rate of bone loss later in life. In the historical medical literature, lead exposure has never been considered a risk factor for osteoporosis. This is because densitometric studies utilizing DEXA technology have shown no significant decreases in bone mineral density in patients with a large lead burden. However, and most importantly, our recent findings suggest that these historical studies may be in error. We have found that the early generation DEXA scanners overestimate bone mineral density when trace amounts of lead are present in the bone being measured. At the lead levels found in the general population (i.e. 10-100  $\mu$ g/g bone) the overestimates range from 4-11%. This effect is due to the presence of a heavy metal atom in the x-ray beam. The newer generation DEXA scanners do not appear to have this problem. Thus, lead induces two serious situations in the skeleton. It affects bone

cells in a way that would predispose an individual to more rapid bone loss and, in early studies, it masked the detection of low bone density. Given these considerations, our conclusion is that lead exposure is a new risk factor for osteoporosis.

### **1035** FROM ITAI-ITAI TO OSTEOCLASTS: PATHWAYS TO CADMIUM-INDUCED BONE LOSS.

M. H. Bhattacharyya, A. Regunathan and D. A. Glesne. *Biosciences Division, Argonne National Laboratory, Argonne, IL.*

To identify pathways to Cd-induced bone loss, a whole-mouse genome c-DNA microarray was used to analyze bone cell gene expression after a single Cd gavage to mice. Time points were 2h and 4h after gavage for a Cd dose that released calcium from bone starting at 8h. Three mouse strains were studied to identify a robust mechanism that applied across mouse strains. Results showed that ~18 genes increased significantly in mRNA levels. High to low in Cd responsiveness were: cysteine-rich protein 61 (Cyr61), metallothionein 2 (MT2), transferrin receptor, glutamine synthetase pseudogene 1, MT1, acidic chitinase, RIKEN cDNA 3930401B19, src-like adaptor protein, vacuolar proton pump ATPase, integrin alpha v, aquaporin 1, and p38 MAPK. No genes showed analogous decreases. Increases in expression were small but were validated by Northern analyses. Gene changes fit into the following hypothesis: Cd could, perhaps by estrogen receptor activation, increase expression of Cyr61 in osteoblasts (OBs). Cyr61, shown to be high in OBs, is a secreted extracellular matrix-associated protein that binds the integrin dimer, alpha-v beta-3. Cyr-61 secretion from OBs could attract osteoclasts (OCs) and bind to their surface integrin molecules, stimulating OC migration, adhesion and activation. Activation would stimulate expression of other OC genes, including integrin alpha-v (signaling molecule involved in activation), vacuolar proton pump ATPase (provides acid to dissolve bone calcium and activate acid proteases that degrade bone matrix), transferrin receptor (provides needed iron), acid chitinase (acidic polyglucosamine hydrolase, involved in bone matrix degradation?), and aquaporin 1 (water channel for osmotic regulation?). OC precursors contain high levels of p38 MAPK compared to other bone cells, and this kinase is required for OC formation. The latter pathways could explain existing evidence that Cd stimulates bone loss by increasing both OC formation and activation.

### **1036** MECHANISMS OF ETHANOL-INDUCED BONE LOSS DIFFER WITH PHYSIOLOGICAL STATE.

M. J. Ronis<sup>1,2</sup>, T. Badger<sup>1,2</sup>, C. Lumpkin<sup>1</sup>, J. Aronson<sup>1</sup>, M. Hidstrand<sup>1</sup>, K. Shankar<sup>1</sup> and R. Haley<sup>1,2, 3</sup>. <sup>1</sup>*University of Arkansas for Medical Sciences, Little Rock, AR* and <sup>2</sup>*Arkansas Children's Nutrition Center, Little Rock, AR.*

Epidemiological studies indicate that ethanol abuse is a risk factor for the development of osteoporosis. However, the molecular mechanisms underlying ethanol-induced bone loss remain the subject of dispute with some studies showing ethanol effects on osteoblastogenesis and others on bone resorption. In these series of investigations, we have demonstrated dose-dependent ethanol-induced bone loss in both pregnant and cycling female Sprague-Dawley rats. However, the severity of skeletal toxicity was substantially greater in cycling rats at an equitoxic urine ethanol concentration and the molecular mechanism of bone loss was shown to differ. Peripheral computerized tomography, histomorphometry and molecular markers of bone turnover demonstrated that in pregnant rats bone formation was inhibited with no effects on osteoclasts while in cycling females bone resorption was stimulated by ethanol accompanied by increased expression of osteoclast specific genes including tartarate resistant acid phosphatase (TRAP) and a 70 kD vacuolar ATPase. Estradiol treatment of cycling rats to produce plasma concentrations comparable to those found in pregnancy significantly protected against ethanol-induced bone loss. In addition, in physiological conditions where anabolic bone formation predominates such as in female rats following weaning and in rats undergoing distraction osteogenesis, ethanol was found to selectively block osteoblastogenesis. Ethanol-induced bone loss was accompanied by disrupted vitamin D homeostasis. In addition, effects on bone formation were blocked by inhibitors of TNF alpha. These studies illustrate that alternative pathways of ethanol-induced bone loss exist and that the effects of ethanol on the skeleton are multifactorial and dependent on physiological and endocrine status. (This work was supported by NIAAA AA12928 M.R. and AA012223 C.K.L.)

### **1037** TOXICITIES OF NANOMATERIALS.

C. Quan<sup>1</sup>, S. Wilson<sup>2</sup> and L. Chen<sup>1</sup>. <sup>1</sup>*School of Medicine, NYU, Tuxedo, NY* and <sup>2</sup>*New York University, New York, NY.*

Manufactured nanomaterials have fascinating properties and may have great impact to our society, but the environmental risks of the use of these materials are mostly unknown. Although toxic effects after instillation of carbon nanotubes in rats had

been reported, the mechanism of their toxicity is uncertain. In this study, we seek to understand the toxic mechanisms of nanoparticles using an *in vitro* model and relevant biological endpoints to provide a foundation to further investigate the toxicity of nanotubes *in vivo*. Representative fullerene and carbon nanoparticle samples were obtained and characterized, including impurity profiles. BEAS-2B cells were exposed to different doses of nanoparticles ranging from 0.1 $\mu$ g/ml to 1000 $\mu$ g/ml suspended in DMEM medium by sonication. Cell viability measurements using neutral red uptake and trypan blue exclusion, and nuclear factor kB (NF-kB) activation measurement by luminometer were conducted immediately after 24 hrs of exposure. The *in-vitro* study shows that the combustion fullerene soot (98% fullerene) produced greater NF-kB activation than Arc fullerene soot (7% fullerene), while both of these particles produced greater response than fine or ultrafine TiO<sub>2</sub>, and less than that produced by crystalline SiO<sub>2</sub>. Based on the dose-response obtained by *in-vitro* study, each kind of particles were intratracheally instilled to CAF1/J mice at 100 and 250 $\mu$ g/mice suspended in 50 $\mu$ l 1% DMSO in normal saline. Lung lavage parameters were measured 24 hrs post exposure. In both arc and combustion fullerene exposed mice at both doses, total cell counts and protein levels were elevated comparing to saline-exposed control mice, although no differences were observed between arc and combustion fullerene exposed mice for these parameters. These data suggest that exposure to fullerene soot may lead to pulmonary toxicity and that the response appeared to depend on the types of nano-material used and their impurities.

### 1038

#### EXPOSURE TO ULTRAFINE ELEMENTAL CARBON PARTICLES (UCP) SIGNIFICANTLY INCREASE THROMBOGENESIS.

V. M. Silva, N. Corson, A. Elder, R. Gelein and G. Oberdorster. *Environmental Medicine, University of Rochester, Rochester, NY.*

Recent studies indicate that exposure to ultrafine particles (UFP) can increase thrombogenesis. We have established a non-invasive model of *in vivo* thrombo-genesis in ear veins of rats. We have shown with this model that intravenous (IV) and intratracheal (IT) administration of ultrafine aminated-polystyrene particles significantly induced thrombus formation. The objective of this study was to determine if environmentally-relevant UFP such as ultrafine elemental carbon particles (UCP), affect coagulation when administered to rats through IV, IT and inhalation routes. For this purpose, UCP were generated as an aerosol with count median diameters (CMDs) of 25-35 nm (GSD=1.7) using electric spark discharge of ultra-pure graphite electrodes in argon. Particles were collected on filters, and then suspended in saline (250 $\mu$ l) at various concentrations (4, 20, 100 and 500 g/kg) for IV or IT administration into rats. In inhalation studies animals were exposed to UCP for 30 min to 3 hrs in whole-body inhalation chambers at concentrations of 200 and 70 $\mu$ g/m<sup>3</sup>. Our data show that IV doses as low as 4 $\mu$ g UCP/kg (-1g/rat) significantly shorten the time of thrombus formation in rat ear veins. Although the effect of the different IV doses is not significantly different from each other, there seems to be a trend indicating that the lower the dose of UFP in the system the better the response. Similar results were obtained when particles were IT instilled into rats. In this case, even a lower dose (0.8 $\mu$ g/kg or 0.2 $\mu$ g/rat) of UCP enhanced thrombus formation. Inhalation of 25-35nm carbon particles significantly induced coagulation regardless of the dose. Interestingly, this response did not change with time of exposure. These results are consistent with the hypothesis that UCP deposited in the lung translocate to the blood circulation and can activate platelets directly. Furthermore, these data demonstrate that the non-invasive ear vein model is useful to study UFP-induced thrombogenic effects after inhalation exposure.

#### NANOPARTICLE DEPOSITION EFFICIENCY IN HUMAN NASAL AIRWAY REPLICAS.

B. A. Wong<sup>1</sup>, J. T. Kelly<sup>2</sup>, J. S. Kimball<sup>1</sup> and B. Asgharian<sup>1</sup>. <sup>1</sup>*CIIT CHR, Research Triangle Park, NC* and <sup>2</sup>*University of California, Davis, CA.*

Particles in the nanometer size range (1-100 nm) may be released to the environment by various means, including escape during manufacturing processes, production during combustion processes, and formation by condensation from gaseous precursors. Toxicologists have long been concerned with, and have studied the respiratory toxicology of particles in the micrometer and submicrometer size range. However, less is known about potential toxicity associated with nanoparticles. The overall deposition efficiency of nanoparticles in the nasal airways provides information about the relative dose between the upper and lower respiratory tract. We studied nanometer particle deposition efficiency in plastic replicas of nasal airways and compared our results with other models. Two replicas were manufactured using stereolithography techniques with morphological data from an MRI scan of a human nose. Monodisperse particles of nanometer and ultrafine sizes from 5 to 150 nm were generated into a constant air flow of 10 and 20 L/min. Deposition efficiency was determined by measuring the particle concentration at the entrance and

outlet of the nasal replica. Deposition efficiency was less than 10% for particles > 30 nm and increased for particles < 30 nm. The increase was attributed to increased particle diffusivity. Our deposition measurements were comparable with deposition values reported for other models. These results suggest that differences in nasal airway morphometry do not significantly affect the overall deposition efficiency of nanometer-sized particles.

### 1040

#### ELECTRON MICROSCOPIC STUDY ON THE TRANSLOCATION OF ULTRAFINE CARBON BLACK PARTICLES AT THE AIRWAY-CAPILLARY BARRIER IN LUNG.

A. Shimada, N. Kawamura, T. Kaewamatawong, M. Okajima, M. Sawada and T. Morita. *Veterinary Pathology, Tottori University, Tottori-shi, Japan.*

Ultrafine particles (UFP) may induce adverse respiratory and cardiovascular effects. Inhaled UFP have been shown to translocate to systemic circulation. Precise mechanisms of the anatomical translocation (crossing the airway-capillary barrier) of inhaled UFP are not fully understood. We examined anatomical location of the intratracheally instilled UFP at light and electron microscopic levels. Ultrafine carbon black (UFCB) particles, printex 90 (Degussa, Frankfurt, Germany), 14nm in diameter, were instilled to the trachea of 10-week-old ICR female mouse at a concentration of 1mg/0.05ml/body. Lung, regional pulmonary lymph nodes, liver and spleen were removed at 0, 5, 10, 30 min, 1, 2, 6, 12 and 24 hrs after instillation (n = 3 at each time point). Paraffin sections cut at 2um were processed for Factor VIII-immunohistochemistry to define blood vessels. Formalin-fixed lung samples were processed for electron microscopy. Aggregates of UFCB were observed in the capillaries of the alveolar walls soon after instillation. UFCB particles, which confined to the cytoplasm of the mononuclear cells with morphological appearance of dendritic cells, appeared in the regional pulmonary lymph nodes at 24 hrs after instillation. No UFCB particles were observed in the liver and spleen. Electron microscopy demonstrated aggregates of UFCB between the edges (epithelial pores) of the elongated thin cytoplasm of type I alveolar epithelial cells. Endothelial cells of the alveolar capillaries appeared to be highly activated with extensive folding, a large number of pinocytic vesicles and ribosomes. The thickness of the basement membrane (BM) varied from point to point. Occasional UFCB were observed in the matrix of the BM, pinocytic vesicles and in the spaces between the folded cytoplasm (fenestration) of the endothelial cells. These results suggest that pro-inflammatory chemokines responsible for the morphological alterations observed may be involved in the passage of the instilled UFCB through the airway-capillary barrier.

#### PULMONARY TOXICITY OF CARBON NANOTUBES.

E. Kisin<sup>1</sup>, A. R. Murray<sup>3</sup>, V. Johnson<sup>2</sup>, O. Gorelik<sup>4,5</sup>, S. Arepalli<sup>4,5</sup>, V. Z. Gandelsman<sup>4,5</sup>, A. F. Hubbs<sup>1</sup>, R. R. Mercer<sup>1,3</sup>, P. Baron<sup>6</sup>, V. E. Kagan<sup>7</sup>, V. Castranova<sup>1,3,7</sup> and A. A. Shvedova<sup>1,3</sup>. <sup>1</sup>*PPRB, HEID/NIOSH, Morgantown, WV, 2*<sup>TMBB, HEID/NIOSH, Morgantown, WV, 3<sup>Physiology & Pharmacology, WVU, Morgantown, WV, 4<sup>Lockheed Martin Corporation, Engineering Directorate, Material & Processes Branch, NASA-JSC, Houston, TX, 5<sup>Nanotube Team, GBTech, Inc., NASA-JSC, Houston, TX, 6<sup>MRSA/DART, NIOSH, Cincinnati, OH and 7<sup>University of Pittsburgh, Pittsburgh, PA.</sup></sup></sup></sup></sup></sup>

Carbon nanotubes (CNT) are new members of carbon allotropes similar to fullerenes and graphite. Because of their unique electrical, mechanical and thermal properties, carbon nanotubes are being evaluated for novel applications in the electronics, aerospace and computer industries. Previously, we have observed that exposure of human bronchial epithelial cells to CNT induced iron-dependent oxidative stress, depletion of antioxidants, morphological changes, cytotoxicity, and apoptosis. In the current study, we investigated pulmonary toxicity of CNT in C57BL/6 mice after pharyngeal aspiration. End points were examined on days 1, 3, 7, 14, 28, and 60 post-exposure. We found that CNT caused dose-dependent formation of granulomatous bronchointerstitial pneumonia, fibrosis, and altered pulmonary function. Administration of CNT to C57BL/6 mice also resulted in a dose-dependent augmentation of inflammation biomarkers quantified by cell counts, total protein, lactate dehydrogenase (LDH) and  $\gamma$ -glutamyltranspeptidase (GGT) activities in bronchoalveolar lavage (BAL) fluid samples. Markers of pulmonary cytotoxicity were associated with the development of inflammation, collagen accumulation, and pulmonary fibrosis. TGF- $\beta$  was maximally increased in BAL fluid of mice 7 days after CNT exposure and correlated with morphometric evidence of collagen formation as well as pulmonary function changes. Mice exposed to an equal mass of ultrafine carbon black or fine crystalline silica exhibited less PMN recruitment and cytotoxicity than mice receiving CNT. Our data suggest that exposure to CNT leads to pulmonary toxicity involving inflammation and oxidative stress, which culminates in the development of multifocal granulomatous pneumonia and fibrosis.

## RESPONSES OF LUNG PARENCHYMA TO CARBON NANOTUBES.

R. R. Mercer<sup>1,2</sup>, J. Scabilloni<sup>1,2</sup>, K. Kisin<sup>1</sup>, O. Gorelik<sup>3,4</sup>, S. Arepalli<sup>3,4</sup>, A. R. Murray<sup>2</sup>, V. Castranova<sup>1,2</sup> and A. A. Shvedova<sup>1,2</sup>. <sup>1</sup>HELD, NIOSH, Morgantown, WV, <sup>2</sup>Physiology and Pharmacology, West Virginia University, Morgantown, WV, <sup>3</sup>Engineering Directorate, Materials and Processes, Lockheed Martin Corporation, Houston, TX and <sup>4</sup>Nanotube Team, GBTech, Inc. NASA-JSC, Houston, TX.

An increasing number of applications have been and are being developed for new carbon allotropes such as carbon nanotubes (CNT). Pharyngeal aspiration by C57BL/6 mice was used to determine the pulmonary toxicity of CNT. Morphometry of paraffin sections from fixed lung tissue was used to determine the size of deposited CNT and the size of granulomatous lesions produced in response to the aspiration. Measurement of the Sirius red staining in sections was used to assess the connective tissue response. Lung responses were studied at 1 day, 7 days, 1 month and 2 months after a single CNT exposure of 0, 10, 20 or 40 µg/mouse. Examination of lung sections 1 day after aspiration, demonstrated that deposition of the CNT mass was generally in the first or second alveolar ducts proximal to the terminal bronchiole with an average diameter of 15.2±0.6 µm (mean±SE, n=12). At 1 day, CNT deposits were infiltrated with alveolar macrophages. At 7 days significant connective tissue accumulation was apparent within the CNT deposits. At 1 and 2 months, the granulomatous masses were encased in cuboidal epithelial cells. At 2 months, the granulomatous lesions accounted for 0, 0.7±0.1, 2.4±0.2 and 4.6±0.6 % of the alveolar parenchyma at doses of 0, 10, 20 and 40 µg/mouse, respectively. In addition to the granulomatous lesions there were also changes in the alveolar walls. For instance, the average thickness of Sirius red stained connective tissue in alveolar regions, excluding the granulomatous areas, was 0.10±0.03, 0.20±0.09, 0.3±0.09 and 0.5±0.1 µm at doses of 0, 10, 20 and 40 µg/mouse, respectively. The results demonstrate that CNT produce a rapid response in the alveolar region with both focal granulomatous lesions and a more generalized fibrotic response that is dose dependent.

## PULMONARY TOXICITY SCREENING STUDIES WITH NANO VS. FINE-SIZED QUARTZ AND TIO2 PARTICLES IN RATS.

D. B. Warheit<sup>1</sup>, K. Reed<sup>1</sup>, T. Webb<sup>1</sup>, C. Sayes<sup>2</sup> and V. Colvin<sup>2</sup>. <sup>1</sup>DuPont Haskell Laboratory, Newark, DE and <sup>2</sup>Rice University, Houston, TX.

For most low solubility dusts such as titanium dioxide, the limited database suggests that fine-sized particles (e.g. pigment-grade) are less toxic than nano-sized particles of the same chemical composition. Fine-sized Min-U-Sil quartz particles are known to be extreme pulmonary toxicants and are classified as IARC Category 1 carcinogens, i.e., human carcinogens. Thus, is it the case that nanoquartz particles could be even more potent than fine-sized quartz particles? This study was designed as a preliminary screen to test 1) the nanoparticle vs. fine-size hypothesis of pulmonary toxicity. In this regard, we assessed whether the Min-U-Sil quartz particles, a known cytotoxic dust, impart significantly greater pulmonary toxicity in the lungs of rats when compared to nano-size quartz particles. In the first experiment with quartz, fine sized quartz (Min-U-Sil) (average diameter = 1.6 µm) particles or nanoscale quartz particles (mean particle size = 50 nm) were instilled into the lungs of rats at doses of 1 or 5 mg/kg. Postexposure evaluations of bronchoalveolar lavage fluids were conducted at 1 day, 1 week, 1 and 3 months postexposure. Exposures to the Min-U-Sil quartz particles produced a significantly greater pulmonary inflammatory response. However, in a second experiment, following exposures to 1 or 5 mg/kg of Min-U-Sil quartz, another nanoquartz sample (10 nm) or fine-sized, sub-micron quartz particles (400 nm), the results suggested that the order of inflammatory potency was nano-Min-U-Sil-fine-sized quartz particles. In a third pulmonary bioassay study, rats were exposed to fine-sized TiO<sub>2</sub> particles, TiO<sub>2</sub> nanorods, and TiO<sub>2</sub> nanodots at 1 or 5 mg/kg with postexposure evaluations at 1 day, 1 week, 1 and 3 months. No significant differences were measured in the inflammatory responses among any of the groups at any postexposure time periods. Our interim results suggest that the pulmonary toxicity of each fine-sized and nano-sized particle type needs to be evaluated on a case-by-case basis.

## DEVELOPMENT OF ANIMAL MODELS OF INHALATION FEVER USING FINE AND NANOPARTICLE ZINC OXIDE EXPOSURES.

K. Reed, T. Webb and D. Warheit. DuPont Haskell Laboratory, Newark, DE.

Occupational fume fever is characterized by a transient flu-like syndrome associated with the inhalation of freshly formed metal ultrafine particles (UFP), notably zinc oxide (ZnO). The aims of this study were to 1) develop an animal model of metal fume fever in rats using either fine-sized (i.e. > 100 nm) or nano (NP - < 100 nm) ZnO particles. These studies are designed to better define the conditions and properties of ZnO nanoparticles (NP) vs. fine-sized ZnO particles that may be associated

with lung injury and fume fever. Successful development of animal models could provide important scientific insights into fever development. Rats were exposed by inhalation for 1 or 3 hours to aerosols of fine-sized zinc oxide particles at 25, 35, or 50 mg/m<sup>3</sup>. Following recovery periods of 24 hrs, 72 hrs or 1 week, the lungs of ZnO and sham-exposed rats were lavaged and cells and BAL fluids were measured for cellular indicators (i.e., inflammatory cells) or noncellular mediators of inflammation and cell injury (e.g. BAL fluid levels of LDH, microprotein, or alkaline phosphatase). Our preliminary results with fine-sized ZnO demonstrated transient, pulmonary inflammatory effects. In this regard, animals exposed for 1 hr to ZnO at 25 or 35 mg/m<sup>3</sup> demonstrated no inflammatory and very mild inflammatory response, respectively. Rats exposed for 3 hours to ZnO particles at concentrations ranging from 25 to 50 mg/m<sup>3</sup> demonstrated transient pulmonary inflammatory responses which were evident after 24 and 72 hours but returned to control levels by 1 week postexposure. In subsequent experiments, groups of rats were exposed for 1 or 3 hrs to nano zinc oxide particles (mean particle size = 65 nm) at 25 mg/m<sup>3</sup> and evaluated at 24, 72 and 168 hrs postexposure. The transient inflammatory effects of nano ZnO particles were not significantly different from exposures to fine-sized ZnO particles. Studies are ongoing to conduct experiments in rats with nano ZnO particles for 1 and 3 hrs at 35 and 50 mg/m<sup>3</sup>. Thusfar, we have not observed differences between the pulmonary responses to nano or fine-sized ZnO particles.

## PULMONARY EXPOSURE TO CARBON NANOTUBES INDUCES VASCULAR TOXICITY.

Z. Li, R. Salmen, T. Huldermen, E. Kisin, A. Shvedova, M. I. Luster and P. P. Simeonova. HELD/TMBB, NIOSH, Morgantown, WV.

Cardiovascular diseases, which in majority of cases stem from atherosclerosis, continue to be the principal cause of death in the United States. In addition to personal factors like hyperlipidemia and obesity, some environmental factors including cigarette smoking and air pollution, have been associated with cardiovascular diseases. Engineered nanosized particles, such as carbon nanotubes (CNT), are new materials of emerging technological importance in different industries. The unique physical characteristics of these particles raise concerns that they may have not only pulmonary toxicity but also extra-pulmonary toxicity. In the present study, we hypothesized that CNT pulmonary exposure is associated with oxidative and inflammatory responses in the vascular system, which might be a prerequisite of atherosclerosis. C57BL/6 mice were exposed to CNT in doses (0.5; 1; 2 mg/kg) by single intra-pharyngeal installation and the mice were sacrificed at different time points (1; 7; 28; 60 days) after the exposure (the experimental settings have been related to pulmonary toxicity). By extra long quantitative PCR of mitochondrial (mt) DNA, we found that CNT exposure induced a dose-dependent aortic mtDNA damage, an oxidative stress dependable parameter, at day 7, 28 and 60 after exposure. Furthermore, by real-time PCR, we demonstrated that the CNT-induced oxidative changes are accompanied by altered expression of inflammatory genes, including MCP-1 and VCAM-1, in the heart. These effects might be a direct result from CNT which penetrate to the circulation or an indirect result of the lung inflammation. The direct effects of CNT were evaluated *in vitro* in human aortic endothelial cells (HAEC). After 2 hours exposure to CNT, we observed an increase of MCP-1, VCAM-1 and IL-8 mRNA levels in HAECs. CNT also dose-dependently induced low density lipoproteins (LDL) oxidation in the presence of HAECs. In conclusion, CNT induces direct or indirect toxic effects which might be predisposing factors for atherosclerosis.

## TOXICOGENETIC AND TOXICOGENOMIC ANALYSIS OF ALCOHOL-INDUCED LIVER INJURY.

I. Rusyn<sup>1</sup>, M. Lee<sup>2</sup>, W. Tak<sup>1</sup>, J. Milton<sup>3</sup>, B. Bradford<sup>1</sup>, A. Maki<sup>1</sup>, M. Wheeler<sup>3</sup>, D. Threadgill<sup>4</sup> and J. Marron<sup>2</sup>. <sup>1</sup>Environmental Sciences and Engineering, UNC-CH, Chapel Hill, NC, <sup>2</sup>Statistics and Operations Research, UNC-CH, Chapel Hill, NC, <sup>3</sup>Nutrition, UNC-CH, Chapel Hill, NC and <sup>4</sup>Genetics, UNC-CH, Chapel Hill, NC.

Severe steatohepatitis is a hallmark of continuous exposure to alcoholic beverages and a significant health concern due to the development of fibrosis, cirrhosis and hepatocellular carcinoma. The mode of action for alcohol-induced liver damage is thought to involve multiple cell types and mediators with reactive oxygen species and inflammatory cytokines playing the major role. Despite the measurable progress in alcohol research in liver, little is known about the genetic factors that may contribute to a large variability in susceptibility to liver disease in humans. The development of a mouse intragastric model of alcohol-induced liver injury, an excellent model for human disease, allowed a number of important discoveries with help from genetically engineered animals. Here, we tested the hypothesis that by combining a state-of-the-art *in vivo* model of liver toxicity, our prior knowledge of the mechanisms of alcohol-induced liver injury, novel genomic and toxicologic analyses with knowledge of the genetic diversity in mouse inbred strains, a liver toxicity susceptibility state may be defined. A panel of six mouse inbred strains (male

mice) was subjected to acute (5 g/kg, 6 hrs), or sub-chronic (17-24 g/kg/day, 28 days) exposure to alcohol. Liver tissue and serum were collected from naive and alcohol-treated mice. The analysis of our results produced mouse strain-specific baseline and alcohol-induced toxicological and gene expression matrices in liver. This unique dataset allowed us to develop and test novel computational strategies for integration of toxicity data with other multi-dimensional data types such as gene expression profiles. The phenotype-specific genotypic anchoring of alcohol-induced expression changes with liver injury provides invaluable insight into genetically-determined individual variability in response to liver toxicants. Supported by grants from NIH AA11605, ES11391, ES11660, and ES10126.

**EVIDENCE FOR OSTEOPONTIN INDUCTION *IN VIVO* AND *IN VITRO*: A POSSIBLE MECHANISM FOR HIGHER NEUTROPHIL TRANSMIGRATION AND HIGHER LIVER INJURY IN FEMALE ALCOHOLICS.**

**A. Banerjee, U. M. Apte and S. K. Ramaiah.** *Pathobiology, Texas A&M University, College Station, TX.*

Alcoholic liver disease (ALD) accounts for more than 450, 000 deaths and public health costs are more than \$184.6 billion per year in the US. In recent years, a three-fold increase in ALD has been observed in the US, and of them 13-33% are women. Although women are known to be more susceptible to ALD, the precise mechanism for increased susceptibility of females to ALD is not completely understood. The present study is based on the hypothesis that increased hepatic neutrophil infiltration and higher liver injury in females during alcoholic steatohepatitis (ASH) is due to enhanced hepatic OPN expression. ASH was induced in the male and female SD rats (weight matched) by feeding ethanol (EtOH) containing Lieber-DeCarli diet (36% calories by EtOH) for 6 weeks followed by a single injection of lipopolysaccharide (LPS, 10 mg/kg, ip). The control rats received an isocaloric diet with maltose-dextrin. Liver injury as measured by plasma transaminase elevations (ALT and AST), and confirmed by H&E stained liver sections, revealed a significantly higher liver injury (>20-fold) in the female ASH model compared to the males. Although steatosis, neutrophilic infiltration, and multifocal coagulative oncotic necrosis was evident both in the male and female rats, hepatic neutrophilic necrotic foci were noted much earlier and more frequently (-> 2-fold) in the females than in the male rats. Hepatic neutrophilic infiltration correlated with higher expression of cleaved OPN (cOPN) in the female EtOH-treated rats compared to their male counterparts. The *in vivo* rat OPN induction data was confirmed with HEPG2 cells exposed to different EtOH and a combination of EtOH+LPS concentrations. In conclusion, these data suggest that EtOH ingestion induces enhanced expression of cOPN *in vivo* in female rats and in HEPG2 cells. Furthermore, higher expression of OPN is likely playing a mechanistic role in the induction of ASH making females more susceptible to ALD (partially supported by NIEHS Grant# ES09106)

**ACETAMINOPHEN (APAP) USE IN ALCOHOLICS: HEPATIC FUNCTION DURING AND FOLLOWING THERAPEUTIC DOSING.**

**R. C. Dart<sup>1</sup>, J. L. Green<sup>1</sup>, E. K. Kuffner<sup>1</sup>, G. M. Bogdan<sup>1</sup>, P. Knox<sup>2</sup> and E. Casper<sup>1</sup>.** <sup>1</sup>*Denver Health/Rocky Mountain Poison & Drug Center, Denver, CO* and <sup>2</sup>*Recovery Centers of King County, Seattle, WA.*

**BACKGROUND:** Therapeutic dosing of APAP is considered safe. Retrospective reports suggest that therapeutic use of APAP in alcoholics may be associated with liver injury, but this phenomenon has not been investigated in prospective clinical trials. This study evaluated hepatic effects in alcoholics during and following 4 g/day APAP dosing for 2 and 3 days. **METHODS:** Two prospective, double-blind, randomized, placebo-controlled trials of alcoholics were conducted at 2 detoxification centers. Patients in the first trial were randomized 1:1 APAP (1g every 4-hrs for 4 doses) or placebo for 2 days. Randomization in the second trial was 2:1 (APAP:placebo) with study drug administered for 3 days. Serum ALT was measured at baseline, day 2 of study drug administration, and 36 h following last dose. Exclusion criteria included elevated baseline AST, ALT or INR. **RESULTS:** There were no differences in demographics, nutritional status or baseline laboratory measures between groups in 586 patients (364 APAP, 222 placebo). ALT means on day 2 of study drug administration were 40±29 IU/L for the APAP group and 42±31 IU/L for placebo group ( $p=0.419$ ). ALT levels 36 h after last study dose were 52±42 IU/L APAP group and 50±44 IU/L placebo ( $p=0.654$ ). 213 placebo group patients and 359 APAP group patients qualified for within group analysis. The ALT mean of the APAP group went from 44 IU/L at baseline to 40 IU/L on day 2 to 52 IU/L 36 h after last dose ( $p<0.001$ ). The ALT mean of the placebo group went from 42 IU/L at baseline and day 2 to 50 IU/L 36 h after last dose ( $p<0.001$ ). A total of 8 patients (5 APAP, 3 placebo;  $p=0.999$ ) developed an ALT ≥200 IU/L (range 203–

312 IU/L) 36 h after last study dose. **CONCLUSIONS:** No differences were found in ALT between the placebo and APAP treatment groups at baseline, day 2 or 36 h after last study dose. ALT fluctuations are common in alcoholics. APAP does not appear to affect hepatic function in alcoholics during and following 2 or 3 days of maximal therapeutic dosing.

**PHENOBARBITAL AND PHENYTOIN INDUCED ACETAMINOPHEN HEPATOTOXICITY DUE TO DIRECT INHIBITION OF UGT1A6 AND UGT1A9.**

**S. Kostrubsky<sup>1</sup>, S. C. Strom<sup>2</sup>, E. Urda<sup>1</sup>, S. Kulkarni<sup>1</sup>, J. F. Sinclair<sup>3,5</sup> and A. Mutlib<sup>4</sup>.** <sup>1</sup>*Safety Science, Pfizer, Ann Arbor, MI*, <sup>2</sup>*Pathology, Pittsburgh Medical School, Pittsburgh, PA*, <sup>3</sup>*Pharmacology/Toxicology, Dartmouth Medical School, Hanover, NH*, <sup>4</sup>*Pharmacokinetic, Dynamic and Metabolism, Pfizer, Ann Arbor, MI* and <sup>5</sup>*Veterans Administration Medical Center, White River Jct, VT.*

Here we present a preclinical model, using cultured human hepatocytes, to assess drug-drug interactions leading to toxicity. Treatment with the antiepileptics phenobarbital (PB) or phenytoin (PH) has been associated with increased incidence of acetaminophen (APAP) hepatotoxicity in patients. This was previously attributed to induction of CYPs. In human hepatocytes, we found that pretreatment with PB for 48 h prior to APAP treatment did not increase APAP toxicity. However, the toxicity of APAP was increased by simultaneous treatment with phenobarbital or phenytoin. Cells treated with APAP in combination with PB or PH experienced decreases in protein synthesis as early as 1 hr, ultrastructural damage to mitochondria by 24 h, and release of liver enzymes by 48 h. Toxicity developed with no induction of CYPs. Maximum toxicity occurred at 2 mM PB or 0.2 mM PH combined with 5 mM APAP and correlated with inhibition of APAP glucuronidation and increased accumulation of APAP-glutathione. Inhibition of APAP glucuronidation was not competitive since PB and PH were not glucuronidated. PB or PH inhibited APAP glucuronidation in rat and human liver microsomes. We analyzed the kinetics of PB and PH inhibition of APAP glucuronidation by expressed forms of human UGTs. The IC50 of inhibition of APAP glucuronidation by PB and PH were 1.7 mM and 0.28 mM for UGT1A6, and 3.7 mM and 0.145 mM for UGT1A9, respectively. As with intact hepatocytes, PB and PH were not glucuronidated, suggesting non-competitive inhibition. Our findings suggest that in multiple drug therapies, an inhibitory complex between UGT and one of the drugs can lead to decreased glucuronidation and increased toxicity of a co-administered drug. This human hepatocyte system provides an *in vitro* screen to detect such interactions.

**1050**

**GENDER DIFFERENCE OF ACETAMINOPHEN-INDUCED HEPATOTOXICITY IN MOUSE.**

**G. Dai, N. Chou, L. He, M. Gyamfi, A. J. Mendy and Y. Y. Wan.** *Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Although acetaminophen (APAP) hepatotoxicity has been extensively investigated, there is no report on gender difference of hepatotoxicity induced by overdose of APAP. In this study, both male and female mice were injected with a toxic dosage of APAP (i.p., 500 mg/kg). By examining serum alanine aminotransferase (ALT) and sorbitol dehydrogenase (SDH) activities and liver histology, our data showed that female mice were resistant to the hepatotoxic effects of APAP. To investigate the mechanism underlying the gender difference in APAP hepatotoxicity, the expression of genes involved in APAP detoxification, hepatic glutathione (GSH), and APAP metabolites were examined. Female mice showed higher basal Cyp2e1 mRNA levels than males. However, the levels of Cyp2e1 and Cyp3a11 mRNAs were significantly reduced in female mice, but not in male mice, after APAP treatment. Consistent with these findings, free APAP levels in the liver were higher in female than male mice one hour after APAP injection. Surprisingly, glutathione (GSH) levels were lower in female than male mice after starvation overnight and before APAP treatment. Female mice have significantly lower Gst pi mRNA levels compared with male mice. This finding concurred with a previous report which showed that Gst pi knockout mice were also protected from APAP-induced liver toxicity. However, unlike Gst pi knockout mice which have elevated mRNA levels of the antioxidant protein heme oxygenase-1 (HO-1), HO-1 mRNA expression was significantly lower in female than male mice. Among other phase II enzymes, liver Ugt1a1 mRNA levels were higher in females than males. There were no significant gender differences on the APAP-glucuronide and APAP-sulfate concentrations in bile, urine, and serum. Taken together, these data suggest that the conversion of APAP into N-acetyl-p-benzoquinone imine (NAPQI), the toxic metabolite of APAP, is slower in female than male mice, which might in part explain why females are protected from APAP-induced liver toxicity.

ALTERED HEPATOBILIARY DISPOSITION OF ACETAMINOPHEN GLUCURONIDE IN MRP3 KNOCKOUT MICE AND THEIR SUSCEPTIBILITY TO HEPATOTOXICITY.

J. E. Manautou<sup>1</sup>, R. de Waart<sup>2</sup>, N. Zelcer<sup>3</sup>, C. Kunne<sup>2</sup>, M. Goedken<sup>1</sup>, P. Borst<sup>3</sup> and R. Oude Elferink<sup>2</sup>. <sup>1</sup>Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT, <sup>2</sup>Liver Center, Academic Medical Center, Amsterdam, Netherlands and <sup>3</sup>The Netherlands Cancer Institute, Amsterdam, Netherlands.

Administration of the organic anion indocyanine green (ICG) to male mice reduces the biliary excretion of acetaminophen (APAP) conjugates, suggesting that these metabolites share hepatobiliary transport with ICG. Studies with transport-deficient (TR<sup>-</sup>) hyperbilirubinemic rats showed the involvement of the multidrug resistance protein 2 (Mrp2) in the biliary excretion of APAP conjugates. The urinary output of acetaminophen-glucuronide (APAP-GLUC) was significantly higher in TR<sup>-</sup> rats than in normal rats. This indicates that enhanced expression of the basolateral transporter Mrp3 in TR<sup>-</sup> rats results in greater hepatic excretion of APAP-GLUC into blood. To further investigate the role of Mrp3 in the hepatobiliary disposition of APAP and its metabolites, male Mrp3 knockout and wild-type mice were fasted overnight and the bile duct was cannulated. APAP (150 mg/kg) was administered and bile was collected at 20 min intervals for 120 min. Other groups of mice received 400 mg APAP/kg for assessment of hepatotoxicity at 24 hr. The results show that the biliary excretion of APAP and most conjugates was not altered in Mrp3 null mice. However, the cumulative amount of APAP-GLUC in bile increased from 0.5% in wild-types to 6% of the administered dose in null mice. Concomitantly, there was a dramatic accumulation of APAP-GLUC in the liver of null mice to approximately 20% of the dose in comparison to less than 1% in wild-types. Plasma content of APAP-GLUC in null mice was also consistent with the reduced basolateral excretion of this conjugate. In toxicity studies, Mrp3 knockouts had 70% lower plasma levels of liver transaminases ALT and AST than wild-types. This was confirmed by histopathology. These studies show that the basolateral excretion of APAP-GLUC is almost exclusively dependent on the presence of Mrp3 and that this altered disposition is associated with a lower risk for hepatotoxicity.

RAPID ACTIVATION OF WNT/β-CATENIN PATHWAY FOLLOWING ACETAMINOPHEN-INDUCED LIVER INJURY AND REGENERATION.

U. M. Apte, A. Micsenyi and S. Monga. Department of Pathology, University of Pittsburgh School of Medicine, Pittsburgh, PA.

Over dose of acetaminophen (APAP), the leading analgesic and antipyretic agent causes acute liver failure. Understanding the mechanism of surviving hepatocytes and comprehending its molecular basis would have strong clinical relevance. Previously we have demonstrated Wnt/β-catenin pathway activation in liver regeneration following partial hepatectomy. The current study was designed to investigate role of Wnt/β-catenin pathway in regeneration following APAP-induced liver injury. Male CD-1 mice were injected with a sublethal dose (500 mg/kg) of APAP and markers of liver injury (plasma ALT and histopathology) and liver regeneration (proliferation analysis by PCNA) were assessed over a time course of 0-48 hr. Liver injury increased within 6 hr, peaked at 12 hr, and decreased by 48 hr. Increase in hepatocyte proliferation was observed at 6 hr and continued till 24 hr after APAP treatment. Western blot analysis showed an increase in total and activated β-catenin protein within 1 hr after APAP treatment, which remained higher till 6 hr, returning to control levels by 12 hr. A concomitant increase in cyclin D1 was observed between 1-6 hr post-APAP treatments. There was no change in total glycogen synthase kinase 3-β (GSK-3β) protein, a negative regulator of β-catenin, however a significant increase was noted in its serine phosphorylation (inactivation) at 1 hr after APAP treatment. Thus, we demonstrate a rapid activation of Wnt/β-catenin pathway following APAP-induced liver injury and subsequent regeneration that appears to be mediated via GSK-3β inactivation. These data indicate that Wnt/β-catenin pathway might play a crucial role in initiation of liver regeneration following APAP-induced liver injury (supported by RSG-03-141-01-CNE and NIH -1R01DK62277 to SPSM).<sup>β</sup>

ROLE OF MITOCHONDRIAL BAX TRANSLOCATION IN ACETAMINOPHEN-INDUCED HEPATIC NECROSIS IN MICE.

M. Bajt<sup>1</sup>, J. J. Lemasters<sup>2</sup> and H. Jaeschke<sup>1</sup>. <sup>1</sup>Liver Research Institute, University of Arizona, Tucson, AZ and <sup>2</sup>Cell and Developmental Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Acetaminophen (AAP) overdose causes centrilobular necrosis in human and mouse livers. Mitochondria are the main source of oxidant stress and peroxynitrite formation after AAP (reviewed in Toxicology Lett 144:279, 2003) and the mitochondrial membrane permeability transition (MPT) pore opening is a critical event in AAP-

induced liver cell death (Hepatology, in press, 2004). Translocation of the pro-apoptotic Bcl-2 family member Bax to the mitochondria has been observed (Mol Pharmacol 60:907, 2001) but the pathophysiological significance of this event remained unclear. To address this issue, C57BL/6 wildtype and Bax-deficient mice (Bax<sup>-/-</sup>) were treated with 300 mg/kg AAP. In wildtype mice, Bax translocation to mitochondria was observed as early as 2 h after AAP and persisted up to 6 h. Bax translocation to the mitochondria correlated with the release of cytochrome c and Smad from the intermitochondrial membrane space. However, consistent with our previous observations, no activation of caspase-3 was detected. Nitrotyrosine staining as indicator of mitochondrial oxidant stress and peroxynitrite formation, DNA fragmentation and an increase in plasma ALT levels as indicator of cell injury were observed at the earliest at 3 h with a further increase of all parameters at 6 h after AAP overdose. In contrast, in Bax<sup>-/-</sup> mice the AAP-induced translocation of cytochrome c and Smad into the cytosol, nitrotyrosine staining, DNA fragmentation and the increase in plasma ALT activities were significantly attenuated but not completely eliminated. Conclusion: Our findings suggest that the early translocation of Bax to mitochondria precedes mitochondrial dysfunction and oxidant stress, DNA fragmentation and liver cell necrosis. The fact that these events were attenuated in Bax<sup>-/-</sup> mice suggests that Bax is involved in inducing mitochondrial dysfunction leading to cell necrosis after AAP overdose.

ACETAMINOPHEN-INDUCED UPREGULATION OF PI-3K AND NF-κB IN MOUSE LIVER: REGULATION BY TNFα AND CAVEOLIN-1.

C. Gardner<sup>1,3</sup>, H. Chiu<sup>1</sup>, J. D. Laskin<sup>2,3</sup> and D. L. Laskin<sup>1,3</sup>. <sup>1</sup>Rutgers University, Piscataway, NJ, <sup>2</sup>UMDNJ-RWJ Med. School, Piscataway, NJ and <sup>3</sup>EÖHSI, Piscataway, NJ.

Increasing evidence suggests that macrophages and inflammatory mediators contribute to acetaminophen (AA)-induced tissue injury. Of particular interest is TNFα which appears to play a dual role in the pathogenic process, initially promoting injury and subsequently inducing hepatocyte proliferation and tissue repair. The present studies analyzed mechanisms mediating the actions of TNFα in the liver. Treatment of wild type control mice with acetaminophen (300 mg/kg, i.p.) resulted in a time-dependent induction of centrilobular hepatic necrosis and increased serum transaminase levels, which reached a maximum after 18 hr. This was associated with a biphasic induction of TNFα at 3 hr and 18 hr post treatment, consistent with its role in injury and repair. TNFα signaling involves the phosphatidylinositol 3'-kinase/protein kinase B (PI3K/PKB) pathway, which is important in NF-κB activation and the generation of pro- and anti-inflammatory mediators, as well as anti-oxidants, growth factors and proteins regulating tissue repair. AA administration resulted in increased phospho-PI3-K expression (within 3 hr) followed by increased NF-κB binding activity (6-12 hr) in the liver. These responses were attenuated in TNFR1 (p55) knockout mice, which exhibit increased AA-induced tissue injury, reduced hepatocyte proliferation and delayed expression of matrix remodeling enzymes suggesting that TNFα signaling through p55 is involved in tissue repair. Caveolin-1 (Cav-1) is an integral membrane protein known to negatively regulate PI3-K and NF-κB activation. Western blot and immunohistochemical analysis revealed significant expression of Cav-1 in the livers of control animals. AA treatment of mice markedly down regulated Cav-1 expression within 3 hr. These data, together with our findings that TNFα suppresses Cav-1 expression in cultured macrophages, suggest that TNFα-induced signaling molecules activated when Cav-1 is down regulated play an important role in AA toxicity and tissue repair. (NIH GM34310, ES04738, and ES05022).

EXPOSURE TO METHYLMERCURY AND PCB153 DURING PREGNANCY AND LACTATION. EFFECTS ON BRAIN AND LYMPHOCYTE CHOLINERGIC MUSCARINIC RECEPTORS IN RAT DAMS AND PUPS.

T. Coccini<sup>1</sup>, A. F. Castoldi<sup>1</sup>, G. Randine<sup>1</sup>, P. Grandjean<sup>2</sup> and L. Manzo<sup>1,3</sup>.

<sup>1</sup>Toxicology Division, Maugeri Foundation, Pavia, Italy, <sup>2</sup>University of Odense, Odense, Denmark and <sup>3</sup>University of Pavia, Pavia, Italy.

The cholinergic muscarinic receptors (MRs) are a likely target for the food neurodevelopmental contaminants methylmercury (MeHg) and the ortho-substituted polychlorinated biphenyls (e.g., PCB153). The same receptors, expressed in the lymphocytes, are considered a potential peripheral marker of central nervous system function. The effects of the oral perinatal administration of MeHg (1 mg/kg/day, GD7-PND7) and/or PCB153 (20 mg/kg/day, GD10-GD16) were investigated on the density (Bmax) of cerebral and lymphocyte MRs in the rat offspring and dams on day 21 post-partum by saturation binding studies. Brain and blood Hg levels were also measured by cold-vapor atomic absorption. A common finding to the cerebral cortex of dams, male and female pups was the significant increase in MR density (27-60%) caused by MeHg and PCB153, either alone or combined (respective control Bmax: 583±13, 503±31, 545±10 fmol/mg protein).

In cerebellum, MeHg still augmented MRs in dams (87%; control Bmax: 83±17 fmol/mg prot) and pups (27%; control Bmax 119-127 fmol/mg protein) while PCB153 reduced it by ~30%. After the combined treatment, the MR changes were similar to those caused by PCB153 alone. Brain Hg levels (μg/g) were 7-9 in dams, 1.67±0.43 in males and 1.52±0.33 in females. In blood Hg values (μg/l) were 11330±2258 in dams, 1351±395 in males and 1313±397 in female pups. As observed in the brain, in the lymphocytes MeHg given alone always augmented the MR Bmax (control Bmax: 30-60 fmol/million cells). Similarly to the cerebellum, MeHg affected more markedly the adult (+139%) than the pup lymphocyte receptors (+45-85%) and PCB153 totally masked MeHg effect. MeHg enhanced cerebral and lymphocyte MRs more in dams than in pups in accordance with the higher Hg levels detected in the adult tissues. The trend of MR changes caused by MeHg and PCB153 in the lymphocytes partially mirrored that of the cerebellum (EU Grants: QLK4-CT-2001-00186; FOOD-CT-2003-506543).

## 1056 DEVELOPMENTAL NEUROPATHOLOGY OF METHYL MERCURY CHLORIDE.

D. M. de Groot<sup>1</sup>, B. Bisselink<sup>1</sup>, S. A. Hartgring<sup>1</sup>, L. van der Horst<sup>1</sup>, M. Pelgrim<sup>1</sup>, M. Waanders<sup>1</sup>, M. Kuijpers<sup>1</sup>, J. O'Callaghan<sup>2</sup>, W. Kaufmann<sup>3</sup>, J. Lammers<sup>4</sup>, B. Pakkenberg<sup>4</sup>, I. Waalkens<sup>1</sup> and H. Gundersen<sup>5</sup>. <sup>1</sup>TNO Nutrition and Food Research, Zeist, Netherlands, <sup>2</sup>NIOSH, Morgantown, VA, <sup>3</sup>BASF, Ludwigshafen, Germany, <sup>4</sup>Research Laboratory for Stereology and Neuroscience, Copenhagen, Denmark and <sup>5</sup>University of Aarhus, Aarhus, Denmark. Sponsor: V. Feron.

The susceptibility of the brain to chemicals and drugs appears to depend on its developmental stage at the time of exposure. Adverse effects on brain morphology (abnormal proliferation, differentiation and/or migration of cells) can arise, often resulting in quantitative changes, e.g. changes in neuron numbers at their final destination. Excessive neuron loss in the developing brain has negative consequences for the mental and physical abilities of the adult individual, becoming even more pronounced during senescence. However, such quantitative developmental morphological changes may go unrecognized by the morphological approach, proposed in current test guidelines for regulatory Neurotoxicity Testing, as demonstrated in the present study (American Chemistry Council, Ref.nr. 1847). A Developmental Neurotoxicity study was carried out in rats with methyl mercury chloride (MeHg) (5 dose levels). A tiered morphological approach (gross macroscopy, brain weight, slide reading, morphometry (brain layer width) was applied (EPA Guideline OPPTS 870.6300), and stereology (brain region volume, neuron number) as final step, in addition. A significant loss of cerebellar granular neurons and reduction of granular layer volume by MeHg was demonstrated using stereology. These effects, or any other effect on brain morphology, could not be depicted with previous steps in the tiered approach. The results indicate that powerful neuropathology endpoints are required to identify early effects of toxicants on developing brain morphology and suggest that stereology may provide a valuable, additional tool.

## 1057 PRENATAL EXPOSURE TO METHYL MERCURY OR METHYLAZOXY METHANOL: EFFECTS ON EARLY POSTNATAL MOTOR ACTIVITY.

D. M. de Groot<sup>1</sup>, M. Kuijpers<sup>1</sup>, J. O'Callaghan<sup>2</sup>, M. van Dael<sup>1</sup>, H. Gundersen<sup>3</sup>, S. Hartgring<sup>1</sup>, L. van der Horst<sup>1</sup>, W. Kaufmann<sup>4</sup>, M. Otto<sup>1</sup>, B. Pakkenberg<sup>5</sup>, M. Pelgrim<sup>1</sup>, I. Waalkens<sup>1</sup> and J. Lammers<sup>1</sup>. <sup>1</sup>TNO Nutrition and Food Research, Zeist, Netherlands, <sup>2</sup>NIOSH, Morgantown, VA, <sup>3</sup>University of Aarhus, Aarhus, Denmark, <sup>4</sup>BASF, Ludwigshafen, Germany and <sup>5</sup>Research Laboratory for Stereology and Neuroscience, Copenhagen, Denmark. Sponsor: V. Feron.

Developmental Neurotoxicity testing according to specific test guidelines is required for disclosure of the potential adverse effects of industrial chemicals and agricultural pesticides on the developing nervous system. Motor activity is included in these guidelines as an apical behavioural endpoint with the intent to evaluate a range of potential effects on the developing nervous system. It is known that different activity measures may be differently affected by chemicals and drugs, depending on the dose and type of agent. Also, other nervous system functions may be changed and may lead to changes in motor activity. In addition, motor activity may be indirectly affected as a result of systemic toxicity (e.g. adverse effects on body temperature or body weight). In research, supported by the American Chemistry Council (ACC Ref.nr. 1847), we studied motor activity in rats, prenatally exposed to methyl mercury chloride (MeHg) or methylazoxymethanol acetate (MAM) (5 dose levels each). MAM and MeHg were chosen as model neurotoxicants. They both affect brain morphology during development. MeHg, however, primarily causes systemic toxicity. Motor activity was tested on PN 13, 17, 21 and 60-62, as indicated in the EPA guideline OPPTS 870.6300 for Developmental Neurotoxicity testing. The results showed that prenatal exposure to MAM or MeHg affected early postnatal motor activity differently. The results will be shown and the relevance of the effects with regard to developmental neurotoxicity will be discussed in relation to the results obtained for other endpoints (maternal and developmental in-life data, and pathology).

## 1058 METHYLMERCURY (MEHG) ELICITS ACUTE AND LONG-TERM EFFECTS ON NEWBORN RAT HIPPOCAMPAL NEUROGENESIS THROUGH CELL CYCLE MACHINERY.

K. Burke<sup>1</sup>, Y. Cheng<sup>1</sup>, K. Reuhl<sup>2</sup>, A. Petrov<sup>1</sup> and E. DiCicco-Bloom<sup>1</sup>. <sup>1</sup>Neurosci & Cell Biol, Robert Wood Johnson Med. Sch, Piscataway, NJ and <sup>2</sup>Pharmacol & Toxicology, Rutgers University, Piscataway, NJ.

While high MeHg exposure causes gross brain defects, effects of lower levels on development are undefined. Acute changes in early neuron production, or neurogenesis, may influence later brain formation. Previous studies indicate injected factors stimulate or inhibit proliferation by regulating cell cycle progression (Cheng, 2002; Carey, 2002). To examine acute neurotoxicant effects on DNA synthesis, we injected P7 rats with MeHg and [3H]thymidine 6h later, measuring incorporation 2h later. At 8h DNA synthesis was reduced 16% at 0.1, 50% at 3, and 80% at 30μg/g in hippocampus, indicating effects on DNA synthesis. Two weeks later, rats injected with MeHg at P7 exhibited reduced hippocampal cell number, indicated by a 17% decrease in total DNA at 3μg/g. In contrast, MeHg did not affect DNA synthesis or cell number in cerebellum though blood flow and Hg content were similar in both regions, and DNA synthesis in cultured granule precursors was inhibited 25%. To examine cell cycle mechanisms, we defined effects on E14.5 cortical precursors: At 6h DNA synthesis was reduced 49% at 3 and 98% at 10μM MeHg, with no change in cell number, suggesting a G1/S block. MeHg elicited a 75% reduction in cyclin E, the stimulatory subunit of CDK2, whose levels were unchanged. Further, MeHg did not increase either p27 or p57, CDK inhibitors commonly stimulated by endogenous anti-mitogens, such as PACAP (Carey, 2002). These studies identify the cell cycle machinery as new MeHg targets, specifically cyclin E. The decreases in DNA synthesis at 6h in hippocampus *in vivo* and cortical precursor cultures suggest MeHg inhibits neurogenesis by interfering with cell cycle progression. Furthermore, the studies indicate that MeHg rapidly and directly alters brain development through modulating regional neurogenesis. NIEHS 11256, USEPA R82939101

## 1059 MEHG DIFFERENTIALLY AFFECTS KINETICS OF sIPSCS OF RAT CEREBELLAR PURKINJE AND GRANULE CELLS.

Y. Yuan and W. D. Atchison. Pharmacology/Toxicology, Michigan State University, East Lansing, MI.

We previously showed that the GABAergic spontaneous inhibitory postsynaptic currents (sIPSCs) in Purkinje and granule cells in cerebellar slices exhibited differential sensitivity to methylmercury (MeHg). Because of the differential expression of α1 and α6 subunits of GABA<sub>A</sub> receptor in Purkinje and granule cells, and different kinetics between α1- and α6-containing GABA<sub>A</sub> receptors, we hypothesized that MeHg affects kinetics of sIPSCs in Purkinje and granule cells differently. To test this, effects of MeHg on kinetics of sIPSCs in Purkinje and granule cells in cerebellar slices were examined using whole cell recording techniques. In the control, the mean 10-90% rise time of sIPSCs in Purkinje cells was 0.84 ± 0.03 ms. For currents fitted with two exponentials, the mean fast and slow decay time constants were 9.8 ± 0.6 and 83.9 ± 46.6 ms, respectively. The fraction of the slow component to the peak current of sIPSCs in Purkinje cells was small. After MeHg exposure (10-100 μM), the mean 10-90% rise time of sIPSCs in Purkinje cells did not change significantly. Similarly, neither the mean for the fast nor the slow decay time constant was affected by MeHg. The mean fraction of the slow component to the peak current was virtually unchanged. Thus, MeHg did not appear to affect kinetics of sIPSCs in Purkinje cells. In granule cells, MeHg first transiently shortened and then prolonged the 10-90% rise time of sIPSCs. Effects of MeHg on sIPSC decay phase in granule cells were inconsistent. In most granule cells, MeHg slowed slightly sIPSC decay phase and prolonged the slow decay time constant. However in some granule cells, MeHg actually hastened the decay phase. The inconsistency in responses to MeHg may be due to different composition of GABA<sub>A</sub> receptor subunits in individual granule cells tested. In addition, the mean fraction of slow component to the peak current was decreased by MeHg. Thus, these data suggest that MeHg also differentially affects kinetics of GABAergic sIPSCs of cerebellar Purkinje and granule cells. Supported by NIH grants R01ES033299 and R01ES11662.

## 1060 GESTATIONAL LEAD EXPOSURE PRODUCES ROD-MEDIATED ELECTRORETINOGRAPHIC (ERG) SUPERNORMALITY AND DECREASES IN RETINAL DOPAMINE METABOLISM OF ADULT RATS.

D. A. Fox<sup>1</sup> and S. Kala<sup>2</sup>. <sup>1</sup>University of Houston, Houston, TX and <sup>2</sup>Baylor College of Medicine, Houston, TX.

Children with blood lead concentrations ([BPb]) at or below 10 μg/dL have persistent impairments in retinal, auditory, cognitive and visual-motor function. Our recent study of 7-10 year old children with gestational and continuous postnatal

lead exposure revealed that they have SUPERNORMAL rod-mediated (scotopic) ERGs (Rothenberg et al., IOVS 2002). These unique ERGs are characterized by increased a-wave and b-wave amplitude and sensitivity. Only maternal [BPb] during the first trimester, from 4 to 14  $\mu$ g/dL, had a dose-response relation with these ERGs. Similar persistent supernormal ERGs occur in monkeys with high lifetime lead exposure. Our goal was to determine if similar dose-response scotopic ERG changes occurred in 90 day old (PN90) Long-Evans hooded rats following low-level lead exposure from conception through PN10 (equivalent human gestation period). Retinal histology and dopamine (DA) metabolism also were examined at PN90: the latter to examine one mechanism underlying supernormal ERGs. At PN10, [BPb] in controls and two lead groups were 0.5-1, 10-15 and 20-25  $\mu$ g/dL, respectively. At PN90, [BPb] were similar in all three groups. Retinal histology appeared similar in all three groups, which was interesting since lead exposure during lactation (PN0-21) at similar [BPb] produced rod selective apoptosis and subnormal ERGs. In contrast, our gestationally lead-exposed PN90 rats had significant dose-response scotopic a-wave and b-wave ERG supernormality, and significant decreases in retinal DA metabolism. Thus, the lead-induced supernormal scotopic ERGs occurred in the absence of elevated [BPb] and histological abnormalities. These results suggest that the decreases in DA activity, via a loss of DA amacrine cells and/or an effect on DA metabolism, may underlie the ERG supernormality. These findings further reveal that the early developing retina is a sensitive target site of low-level lead exposure and suggest that long-term retinal alterations may occur in lead-exposed children. Supported by NIH Grant ES012482.

**GESTATIONAL LEAD EXPOSURE PRODUCES A SELECTIVE DECREASE IN MOUSE RETINAL DOPAMINERGIC AMACRINE CELL DENSITY AND DISTRIBUTION.**

J. E. Johnson, A. Giddabasappa, Q. Chen and D. A. Fox. *University of Houston, Houston, TX.*

Gestational lead exposure produces supernormal rod-mediated electroretinograms (ERGs) in children, monkeys and rats. The latter two also have decreased retinal tyrosine hydroxylase (TH) immunofluorescence (Kohler et al., *Neurotoxicology* 1997) or decreased dopamine (DA) metabolism (Fox and Kala, SOT 2005). Our goal was to develop a clinically relevant model of gestational lead exposure in C57BL/6 mice. Mice were exposed to low levels of lead from conception through postnatal day 10 (PN10): equivalent human gestation period. Retinal histology and immunocytochemical studies with light and confocal microscopy were conducted using PN60 mice. At PN10, the blood lead concentrations [BPb] in controls and two different lead groups were 0.5-1, 10-15 and 20-25  $\mu$ g/dL, respectively. At PN60, the [BPb] were similar in all three groups. In PN60 controls, vertical cryostat sections and whole mounts showed that the density of TH positive DA amacrine cells was low (20-25 cells/sq. mm) and uniform across the retina with dendrites ramifying in sublamina 1 of the innerplexiform layer. At PN60, retinal histology in lead-exposed mice appeared similar to controls. In contrast, in the lead-exposed mice the overall density of DA amacrine cells was decreased. This selective decrease in DA amacrine cells was not uniform across the retina, suggesting quadrant specific effects reminiscent of the rod photoreceptor loss during postnatal only lead exposure (He et al., PNAS 2003). The number and intensity of TH positive dendrites were decreased in regions where DA cell density was lowest. These results are consistent with similarly lead-exposed rats that have persistent scotopic ERG supernormality and decreased retinal DA metabolism. Together, these results suggest that the DA amacrine cells of the early developing mammalian retina are especially vulnerable to low-level lead exposure. These persistent changes in DA cells may underlie the novel scotopic ERG supernormality observed in prenatally lead-exposed children and animals. Supported by NIH Grants ES012482, EY007551 and EY007024.

**1062**

**DEVELOPMENTAL EXPOSURE TO LEAD ELEVATES APP AND  $\beta$ LEVELS IN THE AGING BRAIN BUT DOES NOT ALTER THE PROTEOLYTIC PROCESSING OF APP.**

M. Basha, M. Murali, W. Wei, H. K. Siddiqi and N. H. Zawia. *Biomedicai and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.*

Alzheimer's disease (AD) is characterized by excessive deposits of aggregated beta-amyloid peptides ( $\beta$ ), which are snippets of the amyloid precursor protein (APP). The predominately sporadic nature of AD suggests that the environment must play a role in neurodegeneration, however, few environmental risks for AD have been identified.  $\beta$  is a 39-42 residue peptide which is produced following the proteolytic processing of APP at various sites within the molecule by  $\alpha$ -secretase,  $\beta$ -secretase, and  $\gamma$ -secretase. Cleavage of APP by  $\beta$ - and  $\gamma$ -secretases releases the 39-42 amino acid A which aggregates into long filaments outside the cell, and along with fragments of dead and dying neurons, microglia, and astrocytes forms the plaques that are characteristic of AD brains. We found that the developmental exposure

(postnatal day 1-20) to lead (Pb) results in a latent over-expression of APP mRNA and an elevation in APP and A levels in aged animals; however animals exposed to Pb during old age were unresponsive. We also monitored the levels of the activity of enzymes involved in the proteolytic cleavage of APP and found that the activity levels of these enzymes were not altered by Pb-exposure. These results suggest that the increase in A in developmentally Pb-exposed animals is due to de novo synthesis of APP. Therefore we conclude that developmental exposure to Pb causes alterations in the regulation of the APP gene and does not interfere in the enzymatic processing of APP.

**1063**

**DEVELOPMENTAL EXPOSURE TO LEAD MODULATES THE OCT-2 TRANSCRIPTION FACTOR AND ITS TARGET GENES IN THE RAT HIPPOCAMPUS.**

S. A. Bakheet and N. H. Zawia. *Biomedicai and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.*

Lead exposure is highly neurotoxic particularly to the developing central nervous system. A possible mechanism through which lead may cause neuronal damage is by perturbations of brain gene expression through alterations in numerous transcription factors and signal transduction intermediates involved in development and differentiation. We conducted *in vivo* macroarray analysis in an attempt to identify unknown transcription factors that may be involved in the response to lead-exposure during growth and development. We observed that many transcription factors exhibited distinctive temporal patterns of expression. The most prominent changes were exhibited by the Sp and Oct families. These two transcription families appear to play a critical role in mediating lead-induced disturbances in developmental gene expression. While the involvement of the Sp1 zinc finger protein transcription factor in the response to lead exposure has been previously shown, the changes in Oct-2 expression identify the POU domain as a novel target for lead-induced neurotoxicity. To examine whether lead exposure alters the functionality of Oct-2, we performed DNA-binding assays using the electrophoretic mobility shift assay (EMSA). We found that the DNA-binding of Oct-2 was modulated as well as the developmental expression of its target genes: tyrosine hydroxylase, nitric oxide synthase and synapsin. Thus lead exposure may interfere with brain development via alterations in the expression of Oct-2 target genes important for neurotransmission

**1064**

**MODULATION OF BRAIN CYTOKINE GENE EXPRESSION BY LEAD.**

J. Kasten-Jolly, N. Pabello and D. A. Lawrence. *Wadsworth Center, Albany, NY.*

Lead (Pb) can perturb the central nervous system (CNS) in a number of ways. While its effect on neural transmission has been well documented, its effect on CNS cytokine expression has only begun to be considered. To examine Pb effects on CNS cytokine expression BALB/c mouse litters were exposed to 0.5 mM lead acetate through mothers milk from 0-21 days of age. On day 21 the pups were sacrificed and total RNA was isolated from the brain and spleen by the TRIzol method, followed by further purification using a Qiagen column. The study included 4 litters each, composed of Pb- and non-Pb-exposed mouse pups. Individual cytokine RNAs were quantified by means of real-time RT-PCR using kits developed by Search-LC. Gene expression was measured using a Roche Light-Cycler for cytokines IL-4, IL-5, IL-10, IL-15, IL-16, IL-18, IFN $\gamma$ , and LT $\beta$ . Interestingly, the most highly constitutively expressed cytokines in the CNS of control day 21 pups are IL-18>IL-16>IL-15>IL-5>LT $\beta$ >IFN $\gamma$ >IL-10>IL-1=IL-6>TNF $\alpha$ . IL-4 expression in the brain is negligible. Results indicated that male and female mouse pups had different cytokine gene expression profiles characteristic to their gender. It was noted that Pb had the greatest effect on CNS cytokine expression of females; Pb significantly increased the expression of IL-10, IL-15, and IL-18 ( $p<0.05$ ) and significantly decreased the expression of IL-16 ( $p<0.05$ ). Increased, but not significant, expression was also observed for IL-5, IFN $\gamma$ , and LT $\beta$  in females. Pb had very little effect on the cytokine expression profile of male brains, with the exception of LT $\beta$  where a small decrease in expression was observed. Differential cytokine expression between males and females was also observed in the spleen, but Pb had no significant effect on cytokine gene expression in this organ with respect to the males or females. The results suggest that the primary effect of Pb on cytokine expression occurs in the CNS and that females are more vulnerable to these effects than males. Supported by NIH grant ES11135.

**1065**

**NMDAR SUBUNITS WERE AGGRESSIVELY REDUCED BY PB-EXPOSURE IN THE EARLY DEVELOPMENT OF RAT BRAIN.**

S. xu and B. Rajanna. *Alcorn State University, Alcorn state, MS.*

Chronic Pb exposure has been recognized to induce children memory dysfunction and learning retardation. Our previous studies showed that Pb dose-dependently reduced N-methyl-D-aspartate receptor (NMDAR)-NR1, NR2A and NR2B expression at mRNA and protein levels in primary cultured neuronal cells. The present study was purposed to evaluate effect of Pb exposure on NMDAR subunits in

brain stem (BS), cerebellum (CB), hippocampus (HC) and frontal cortex (FC) in the developing rat brain. Sprague-Dawley (SD) pregnant rats were allowed to drink 0.1% Pb acetate dissolved in distilled deionized water (DDW) from gestation day 6 through 21s postnatal day (PND). Control rats were allowed to drink DDW. Pups were sacrificed on PND 3, 5, 7 and 15. The brain was immediately excised and separated into BS, CB, HC and FC. NMDAR-NR1, NR2A and NR2B on the membrane from brain tissue were examined. Antigens were first enriched with protein A agarose by immunoprecipitation, and later detected by western blotting with specific antibodies. Protein concentration was determined by Lowry's method. Meanwhile, total RNA was extracted from tissue with Trizol. RT-PCR was employed to detect mRNA expressions of NMDAR- NR1, NR2A and NR2B with specific primers. Each experiment was triplicated (n=3). Emerged results indicated that the above NMDAR subunits' protein levels in Pb-treated samples were reduced on FC at PND3. Their mRNA levels were greatly reduced in HC and FC. Furthermore, Pb aggressively reduced both protein and mRNA levels of these subunits on PND5, 7 and 15 in HC and FC, but had a little reduction in BS and CB. Among three examined NMDAR subunits, the reduction of NR1 appeared significant. Starting on PND3, the protein levels of these subunits were gradually decreased from PND 5 and 7 to 15 in BS and CB regions as much as in HC and FC. Our study suggests that Pb aggressively reduces NMDAR-NR1, NR2A and 2B on HC and FC in the early development of rat brain.

## 1066

### PRENATAL EXPOSURE TO INHALED MANGANESE ALTERS DOPAMINERGIC SUSCEPTIBILITY TO POSTNATAL METHAMPHETAMINE NEUROTOXICITY.

A. rinderknecht<sup>1</sup> and M. T. Kleinman<sup>2</sup>. <sup>1</sup>*Environmental Health Science and Policy, University of California, Irvine, Irvine, CA* and <sup>2</sup>*Community and Environmental Medicine, University of California, Irvine, Irvine, CA*.

Manganese (Mn) is an essential element but neurotoxic when in excess. Unlike ingested Mn, inhaled Mn bypasses all known homeostatic mechanisms. Intake of Mn through nasal passages and lung accumulates within selective brain regions. Therefore, industrial, agricultural and automobile Mn-based emissions place many populations at risk for over-exposure to Mn. Since Mn is necessary for proper brain development, we hypothesize that maternal exposure to low-level inhaled Mn disrupts fetal neurodevelopment that may augment neuro-response to pharmaceuticals and drugs of abuse affecting similar brain regions. Pregnant rats were exposed nose-only to a primary MMT-gasoline combustion by-product manganese sulfate aerosol over a two-day period for 90 minutes per day at a concentration of  $0.70 \pm 0.04 \text{ mg Mn/m}^3$  (MMAD=0.55  $\mu\text{m}$ ,  $\sigma_{\text{g}}=1.5$ ). Modeled with 0.14 total pulmonary deposition fraction and 100% absorption for particles  $< 1 \mu\text{m}$ , the total absorbed dose was  $2.4 \mu\text{g Mn}$ . At one month of age, progeny were administered methamphetamine (Meth). This popular drug of abuse, like Mn, affects dopaminergic transmission. Brain tissues were evaluated for histological augmentation and dopamine concentration. Prenatal Mn exposure greatly reduced Meth-induced swelling of axonal projections through the caudate-putamen. Gestational Mn exposure substantially depleted Meth-induced dopamine levels and altered dopaminergic metabolism when compared to control groups and animals exposed only to Mn or Meth. These results provide evidence that prenatal exposure to aerosolized Mn: 1) alters neurodevelopment of axonal projections into the caudate-putamen and 2) interacts with Meth to enhance dopaminergic toxicity. This Mn-Meth neuronal interaction suggests a drug-environment and gene-environment interference that affect fetal and adolescent neurodevelopment and have incredible potential to impact large populations at high risk for susceptibility to drug addiction and/or neurodegenerative diseases.

### EFFECTS OF PRENATAL EXPOSURE OF MICE TO CHROMIUM PICOLINATE, CHROMIUM CHLORIDE, OR PICOLINIC ACID.

M. M. Bailey<sup>1</sup>, R. D. Hood<sup>2,1</sup>, J. F. Rasco<sup>1</sup>, J. G. Boohaker<sup>1</sup>, V. Stegall<sup>1</sup>, J. J. Jernigan<sup>3</sup> and J. B. Vincent<sup>4</sup>. <sup>1</sup>*Department of Biological Sciences, The University of Alabama, Tuscaloosa, AL*, <sup>2</sup>*Ronald D. Hood & Associates, Toxicology Consultants, Tuscaloosa, AL*, <sup>3</sup>*Department of Biology, Stillman College, Tuscaloosa, AL* and <sup>4</sup>*Department of Chemistry, The University of Alabama, Tuscaloosa, AL*.

Chromium (III) Picolinate [Cr(Pic)<sub>3</sub>] is a widely marketed dietary supplement. However, Cr(Pic)<sub>3</sub> has recently been associated with oxidative damage to DNA in rats and mutation and DNA fragmentation in cell cultures. In isolated case reports, Cr(Pic)<sub>3</sub> supplementation has been associated with adverse effects, such as anemia, renal failure, liver dysfunction, and neuronal impairment. Studies have shown that not all forms of Cr(III) produce toxic effects or inhibit the rate of development. In *Drosophila*, chromium picolinate, but not chromium chloride, is associated with a dose-related decrease in viability and an increased incidence of developmental delays. In the present study, pregnant mice were fed Cr(Pic)<sub>3</sub>, CrCl<sub>3</sub>, or picolinic acid to determine if either picolinic acid or Cr(Pic)<sub>3</sub> is a developmental toxicant. On gestation days (GD) 6-17, groups of pregnant CD-1 mice were fed a diet containing 200 mg/kg CrCl<sub>3</sub>, 200 mg/kg Cr(Pic)<sub>3</sub>, 174 mg/kg picolinic acid, or the diet

only. The dams were killed on GD 17, and their litters were examined for teratogenic effects. Additional diet-only and Cr(Pic)<sub>3</sub> treated dams were allowed to litter, and their pups were tested for effects on sensory-motor development. A significant increase in bifurcated cervical arches was observed in fetuses from the Cr(Pic)<sub>3</sub> group in comparison with all other groups. Similarly, significant delays in righting reflex and hind limb grasp and deficiencies in motor skills were observed in the offspring of Cr(Pic)<sub>3</sub> fed dams. These results suggest that high maternal exposures to chromium picolinate can cause morphological and neurobehavioral defects in developing offspring. ### DEXAMETHASONE ALTERS NEURONAL DEVELOPMENT: CELL ACQUISITION AND DIFFERENTIATION IN PC12 CELLS.

R. R. Jameson, F. J. Seidler and T. A. Slotkin. *Pharmacol/Cancer Biol, Duke U Med. Ctr, Durham, NC*.

Dexamethasone (DEX) is used to prevent respiratory distress in preterm infants, but may increase the chance of subsequent cognitive problems. To determine whether this reflects direct effects on neuronal cell replication and differentiation, we exposed undifferentiated and differentiating PC12 cells to DEX (10 nM to 10  $\mu\text{M}$ ) for brief or extended times (24 h to 168 h). DEX progressively reduced cell number (DNA content) in a dose-dependent fashion, reaching deficits >50% by 168 h. DEX had no effect on cell viability (trypan blue exclusion), suggesting that it decreased cell numbers by impairing mitotic activity. This conclusion was supported by the observation that DEX enhanced the rate of neuronal differentiation: DEX augmented cell growth (total protein/DNA) by 25-50% and accelerated appearance of the cholinergic phenotype, as evidenced by a rise in choline acetyltransferase activity per cell (ChAT/DNA). At low concentrations (10 nM), DEX enhanced membrane expansion associated with neurite formation (membrane/total protein) but high concentrations impaired this index. Our results thus suggested that DEX terminates cell replication in favor of differentiation. To test that hypothesis, we assessed the effects of nerve growth factor (NGF), which also initiates differentiation, on the response to DEX. In the presence of NGF, low concentrations of DEX no longer promoted differentiation but concentrations at or above 100 nM still impaired neurite formation and reduced cell numbers. With NGF cotreatment, DEX decreased ChAT instead of increasing it, indicating impairment of the cholinergic phenotype. Our results suggest that low concentrations of DEX promote differentiation at the expense of replication, while high concentrations, in the range of those associated with the therapeutic use of glucocorticoids in preterm delivery, inhibit differentiation and expression of the cholinergic phenotype. Since learning and memory are dependent on cholinergic function, our findings suggest a mechanistic connection between antenatal steroid administration and cognitive dysfunction. ### PRENATAL OR NEONATAL GLUCOCORTICOID TREATMENT, AT DOSES COMMENSURATE WITH PHARMACOTHERAPY IN PRETERM INFANTS, DISRUPTS BRAIN DEVELOPMENT AND EVOKE LASTING BEHAVIORAL ABNORMALITIES.

M. L. Kreider, E. D. Levin, F. J. Seidler and T. A. Slotkin. *Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC*.

Glucocorticoid administration is the current consensus treatment for the prevention of respiratory distress syndrome in preterm infants. However, recent evidence indicates that long-term impairments in learning and memory may emerge as a result of this treatment. The purpose of this work is to determine the mechanisms by which glucocorticoid exposure during development results in neurobehavioral abnormalities. We administered dexamethasone in doses ranging from well below clinical usage up to the therapeutic level (0.05, 0.2, or 0.8 mg/kg/day) to pregnant and neonatal rats during three different periods, gestational day (GD) 17-19, or postnatal days 1-3 or 7-9. We then evaluated biomarkers of cholinergic synaptic function and neuronal cell development in forebrain regions both 24 hours after the last injection and in adulthood (PN75). In each case, dexamethasone caused immediate and persistent deficits in neural cell numbers (DNA content) as well as in cholinergic synaptic activity, as indicated by reductions of hemicholinium-3 binding to the choline transporter (a marker for impulse activity) as compared to choline acetyltransferase activity (a constitutive marker for cholinergic nerve terminals). We then assessed the effect of 0.2 mg/kg dexamethasone administered to pregnant rats on GD17-19, on later performance of the offspring in the figure-8 maze, when they were adolescents and reward-based learning in the 8-arm radial maze when they were adults. In the figure-8 maze, dexamethasone exposure reduced initial locomotor activity and impaired habituation in females. In the radial-arm maze, dexamethasone delayed learning. These results indicate that, even at doses at or below those used in preterm delivery, dexamethasone perturbs neuronal development and cholinergic function and impairs learning and memory later in life. ## PERSISTING BEHAVIORAL CONSEQUENCES OF PRENATAL DOMOIC ACID EXPOSURE IN RATS.

E. D. Levin<sup>1</sup>, K. Pizarro<sup>1</sup>, J. Harrison<sup>1</sup>, W. Pang<sup>1</sup> and J. S. Ramsdell<sup>2</sup>.

<sup>1</sup>Department of Psychiatry and Behavioral Sciences, Duke University Med. Ctr, Durham, NC and <sup>2</sup>Marine Biotoxins Program, NOAA-National Ocean Service, Charleston, SC.

Domoic acid is a neurotoxin produced by Pseudo-nitzschia phytoplankton. Domoic acid is concentrated in fish and shellfish species, which are in turn consumed by humans. Neurotoxic effects of high doses of domoic acid have been demonstrated in adult humans. A hallmark of the neurobehavioral toxicity of domoic acid in adults is cognitive impairment. However, little is known about the possible neurotoxic risks of domoic acid exposure in developing organisms. To investigate the persisting behavioral effects of prenatal exposure to domoic acid, pregnant female Sprague-Dawley rats were injected (sc) with 0, 0.3, 0.6, or 1.2 mg/kg of domoic acid on gestational day 13. No overt clinical signs of toxicity were seen with these doses. The offspring were then run through behavioral testing to determine the developmental effects of the domoic acid on locomotor activity, spontaneous alternation in a T-maze, and working memory function in a radial-arm maze. No significant differences on test performance were found in the T-maze spontaneous alternation. Locomotor activity measured in the Figure-8 maze detected a persisting effect of the 1.2 mg/kg domoic acid dose, which significantly ( $p < 0.05$ ) increased the rate of habituation over the hour-long activity test session. This was characterized by higher initial activity followed by greater decline in activity. In the radial-arm maze the control vehicle treated rats showed the normal sex-related difference in spatial learning and memory with males outperforming females. Developmental domoic acid exposure decreased this effect such that the normal sex difference in spatial memory was not seen with the 1.2 mg/kg domoic acid dose. This study demonstrates persisting neurobehavioral effects of acute prenatal exposure to domoic acid at doses that do not cause overt clinical signs of toxicity.

## PERINATAL PERCHLORATE EXPOSURE IN THE RAT: DOES THYROID STATUS AFFECT BRAIN MORPHOMETRY?

S. Schettler<sup>1</sup>, M. R. Seeley<sup>1</sup>, T. A. Lewandowski<sup>2</sup> and B. D. Beck<sup>1</sup>. <sup>1</sup>Gradient Corporation, Cambridge, MA and <sup>2</sup>Gradient Corporation, Seattle, WA.

Perchlorate inhibits iodide uptake by the thyroid and excessive perchlorate exposure can reduce thyroid hormone (TH) levels. In rats, severe reductions in maternal TH levels during development have been linked to adverse neurological outcomes, such as reduced myelination and small brain size. To assess some of the evidence for such effects from perinatal perchlorate exposures, we analyzed methods and findings from a recent study in rats exposed to perchlorate *in utero* and via lactation (York 2001). We focused on changes in brain morphometry, specifically size of the posterior corpus callosum (CC) and striatum. York observed an inverted U-shaped dose-response curve for the CC, with an increase in size of about 20% at the middle dose level of perchlorate, and an increase of about 12% at both the highest and lowest dose levels. For the striatum, York also observed size increases of 4% to 9% but with no evidence of dose-response for perchlorate exposure. However, these CC and striatum size increases are inconsistent with a reduction in TH levels, which are generally associated with reduced, not increased, brain size. This may be due to the use of coronal rather than sagittal cross-sections for reviewing brain morphometry. Moreover, there were no accompanying histopathological alterations in the brain (*e.g.* no increase in cell size or cell number), as might be expected if the brain morphometry effects were related to perchlorate. Lastly, there was no apparent dose-response for the changes in brain morphometry and thyroxine ( $T_4$ ) levels in the dams or pups, as would be expected if the observed changes were due to perchlorate-induced TH changes. Thus, given the paradoxical increase in size of the CC and striatum, the absence of accompanying histopathological changes, and the lack of association between changes in  $T_4$  and alterations in brain morphometry, we conclude that it is unlikely that the observed changes are related to perchlorate exposure. Rather, we suggest that the observed changes may be due to issues related to sample analysis.

## BEHAVIORAL EFFECTS ASSOCIATED WITH CHRONIC DEVELOPMENTAL EXPOSURE TO KETAMINE OR REMACEMIDE IN RATS.

L. K. Wright<sup>2,1</sup>, C. M. Fogle<sup>1</sup>, E. Pearson<sup>3</sup>, T. Hammond<sup>3</sup> and M. G. Paule<sup>1,2</sup>.

<sup>1</sup>Division of Neurotoxicology, NCTR, Jefferson, AR, <sup>2</sup>Department of Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR and <sup>3</sup>AstraZeneca Safety Assessment, Leics, United Kingdom.

The effects of chronic exposure to ketamine or remacemide on the acquisition and performance of complex, food-reinforced behaviors were assessed in developing female Sprague-Dawley rats. Ketamine is an N-methyl-D-aspartate (NMDA) receptor antagonist, whereas remacemide has both NMDA receptor antagonist and sodium channel blocking properties. Learning (LRN), audio/visual discrimination (AVD) and motivation were modeled using incremental repeated acquisition, conditioned position responding and progressive ratio tasks, respectively. Ketamine (10 or 100 mg/kg/day), remacemide (100 or 150 mg/kg/day) or water alone was administered daily (7 days/week) via orogastric gavage beginning on postnatal day (PND) 23 and Monday through Friday behavioral assessments began on PND 27. Chronic treatment with either dose of ketamine or remacemide significantly decreased response rates in all tasks, suggesting decreased motivation and/or motoric capabilities. Chronic treatment with the high dose of either ketamine or remacemide significantly decreased accuracy of AVD task performance. However, neither ketamine nor remacemide had an effect on accuracy of LRN task performance at any dose tested. These findings for remacemide are in marked contrast with those in young monkeys where chronic remacemide had profound disruptive effects on the acquisition of LRN task performance and suggest important species differences. In addition, these findings for ketamine were quite different from those of MK-801 (the prototypic NMDA receptor antagonist) in a previous rat study in which MK-801 severely disrupted the acquisition of both AVD and LRN task performance. These observations suggest important differences in the mechanism of action between ketamine and MK-801.

During the brain growth spurt (BGS) the brain grows and develops at an accelerated rate. In mice and rats this period spans the first 3–4 weeks of life whereas in human it begins in the third trimester of pregnancy and continues throughout the first 2 years of life. Apoptosis or physiological programmed cell death is the natural process by which biologically redundant or unsuccessful neurones are deleted from the developing central nervous system. Anaesthetic agents appear to enhance the apoptosis during the BGS, which may result in deficits in brain development. The aim of this study was to examine the influence on apoptosis of the anaesthetic agent ketamine at different days during the BGS. Rate of neurodegeneration in different brain regions corresponding to the day of exposure and finally, consequences on spontaneous motor activity and learning in adulthood. Neonatal mice aged 3, 10 or 19 days were administered ketamine 25 mg/kg b.wt. or vehicle (0.9% NaCl) by subcutaneous injection. Neurodegeneration was examined 24 hours after treatment using the Fluoro-Jade staining technique and by measuring the expression of brain-derived neurotrophic factor (BDNF). BDNF is an important regulator of naturally occurring cell death. Behavioural tests were initiated at PND (postnatal day) 55 and consisted of spontaneous motor activity and radial arm maze. Ketamine significantly triggered apoptotic neurodegeneration in hippocampus and striatum in mice exposed on PND 3 and PND 10. These two groups also showed hypoactivity, lack of habituation and less learning ability during the behavioural tests. The effects were most pronounced in mice exposed on PND 10. BDNF levels were significantly decreased in frontal cortex and hippocampus in the ketamine group exposed PND 10 compared to vehicle group exposed the same day. The results show that the time of exposure during the brain development is critical for the amounts of neurodegeneration and behavioural deficits produced.

## DEVELOPMENTAL TOXICOLOGY IN THE NEONATAL MOUSE: THE USE OF RANDOMLY SELECTED INDIVIDUALS AS STATISTICAL UNIT COMPARED TO THE LITTER IN MICE NEONATALLY EXPOSED TO PBDE 99.

P. Eriksson<sup>1</sup>, D. von Rosen<sup>2</sup>, H. Viberg<sup>1</sup> and A. Fredriksson<sup>1</sup>. <sup>1</sup>Department of Environmental Toxicology, Uppsala University, Uppsala, Sweden and <sup>2</sup>Department of Biometry and Engineering, Swedish University of Agricultural Sciences, Uppsala, Sweden.

In traditional behavioural teratology and/or developmental toxicology the chemical to be tested is given to the mother. The exposure period can include both the gestational and lactation period. In such a case the litter generally should be considered the statistical unit. In several reports we have shown that low-dose exposure of environmental toxic agents such as PCB, DDT, brominated flame-retardants, pyrethroids, organophosphates, and nicotine, can cause persistent developmental neurotoxic effects when administered directly to pups during a defined critical period of neonatal brain development in the mouse. In the present study the use of the litter or randomly selected individuals as a statistical unit in developmental toxicology in the neonate is evaluated. In this investigation 18 different litters were

used. Pregnant NMRI mice were randomly selected and purchased from a commercial breeder. Male pups at the age of 10 days were given either one single oral dose of the brominated flame-retardant, 2, 2', 4, 4', 5-pentabromo diphenyl ether (PBDE 99) 1.4  $\mu$ mol/kg bw, or a vehicle (20% fat emulsion). Spontaneous motor behaviour was studied in 2-month-old-mice. Statistical evaluation was made by both using the litter (n=9) as a statistical unit and randomly selected individuals (n=9, 3 mice randomly selected from 3 different litters). Both statistical evaluations, using ANOVA, showed a significant deranged behaviour in the PBDE 99 exposed mice compared to controls, defects that we earlier have reported on. This study shows that there is no difference whether the litter or the randomly selected individuals are used as the statistical unit. This study also shows that randomly selected animals from different litters (at least 3) have the same statistical effect and power compared to the use of litter based studies to evaluate developmental neurotoxicity in neonatal mice.

## 1075

### POSTNATAL DEVELOPMENTAL NEUROTOXICITY (DNT): EVALUATION OF P-MENTHANE 3, 8, DIOL BY DERMAL ADMINISTRATION IN NEONATAL RATS.

J. F. Barnett<sup>1</sup>, D. B. Learn<sup>1</sup>, A. M. Hoberman<sup>1</sup>, U. Vedula<sup>2</sup> and T. G. Osimitz<sup>3</sup>. <sup>1</sup>Center for Photobiology, Charles River Discovery and Development Services, Argus Division, Horsham, PA, <sup>2</sup>S.C. Johnson & Sons, Inc., Racine, WI and <sup>3</sup>Science Strategies, LLC, Charlottesville, VA.

The potential neurotoxicity of p-menthane 3, 8 diol, an EPA registered component of dermally applied insect repellants, was evaluated in neonatal rats using occluded dermal application. Three hundred and twenty rat pups/sex were assigned to four dose groups (80 pups/sex/group) at doses of 0, 400, 800 and 1000 mg/kg/day. P-menthane 3, 8 diol or water (0) was applied to the backs of the pups on postnatal day (PND) 10 through 21. Doses were adjusted daily for body weight changes and administered at approximately the same time each day. The skin application site was occluded for the 6 hour exposure period to prevent oral ingestion and minimize the loss of the test substance formulation. Pups were separated from the dams for the 6 hour exposure period. One male pup and one female pup from each litter were evaluated as follows: PND 22 brain weights and neurohistology; watermaze and passive avoidance; motor activity and acoustic startle habituation; and adult brain weights and neuropathology examinations. Small but statistically significant reductions in body weight gain occurred at various points early in the study in rat pups of either sex in the 800 and 1000 mg/kg/day dosage groups. However, p-menthane 3, 8 diol did not cause any specific effects (developmental neurotoxicity) as measured by these neurobehavioral evaluations. Additionally, the study design is appropriate for investigating the potential effects of test article or test substance exposure to neonatal rat pups as early as PND 10.

## 1076

### WATER DISINFECTANT BYPRODUCTS (DBP) AND ADVERSE PREGNANCY OUTCOMES (APO): CHLOROACETONITRILE (CAN) INDUCES GROWTH RESTRICTION AND ALTERS GENE EXPRESSION IN FETAL BRAIN.

S. Jacob<sup>1</sup>, T. Wood<sup>2</sup>, H. Fouad<sup>1</sup> and A. E. Ahmed<sup>1</sup>. <sup>1</sup>Pathology, University of TX Medical Brach, Galveston, TX and <sup>2</sup>Molecular Genomics, University of TX Medical Brach, Galveston, TX.

Disruption of developmental processes; cell proliferation, differentiation and apoptosis result in reduced proliferation leading to growth restrictions and APO. There is an association between DBP and susceptibility to APO such as skeletal defects, growth retardation and CNS anomalies. Correlation between spontaneous abortion and consumption of chlorinated tap water was also demonstrated. Our objective is to examine the mechanism of DBP-induced APO, using brain development as a predisposing factor. Pregnant mice at gestation day 6 (GD6) were treated with the DBP; CAN (25 mg/kg/day, p.o.) until GD18. Animals were then anesthetized and fetuses were collected and weighed. Fetal brains were extracted, weighed and RNA was isolated. cDNA synthesis was performed and biotin labeled target cRNA was prepared. Target cRNA was hybridized on a mouse genome chip and biotin-cRNA was quantitated using Gene Array Scanner and Affymetrix software. Genes with two-fold change in hybridized target intensity were identified. The results indicated that CAN treatment caused a significant decrease in fetal weight (78% of control) and in fetal brain weight (80% of control). Concordance analysis identified 39 genes with unidirectional change (increase/decrease). Five genes demonstrated an increased RNA expression and 34 genes showed decreased level of expression as compared to control. Thirteen of the down-regulated genes belonged to the crystalline family. Four-fold decrease was indicated in parathyroid hormone related peptide (PTHrP) and cartilage matrix protein genes. RT-PCR analysis indicated that mRNA levels of PTHrP were significantly lower in treated mouse brain. In

conclusion, as PTHrP regulates fetal development, down regulation of PTHrP and matrilin genes may be a factor in the observed decrease in fetal weight. The current study provides a general outlook on the mechanism of the fetal changes that occurred following CAN treatment. Future studies will explore the molecular cascades of DBP-induced APO.

## 1077

### METHAMPHETAMINE-INITIATED NEURODEVELOPMENTAL DEFICITS ARE ENHANCED IN COCKAYNE SYNDROME B (CSB) KNOCKOUT MICE.

A. W. Wong<sup>1</sup>, W. Jeng<sup>1</sup> and P. G. Wells<sup>1,2</sup>. <sup>1</sup>Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada and <sup>2</sup>Department of Pharmacology, University of Toronto, Toronto, ON, Canada.

Reactive oxygen species (ROS) increase 8-oxoguanine (8-oxoG), a form of oxidative DNA damage that causes mutations and transcription blockage. 8-OxoG is repaired on the nontranscribed strand of DNA by oxoguanine glycosylase (Ogg1), and on the transcribed strand via the transcription-coupled repair (TCR) pathway, catalyzed by the Cockayne Syndrome group B (CSB) protein. CSB may also regulate Ogg1. We have shown that treatment of pregnant *ogg1* knockout mice with the ROS-initiating neurotoxin methamphetamine (METH) causes enhanced 8-oxoG levels in fetal brain [Toxicologist 72(S-1): 342 (No. 1663), 2003] and postnatal neurodevelopmental deficits [Toxicologist 78(S-1):379 (No. 1843), 2004]. Similarly, the fetal brains of METH-exposed CSB knockout mice exhibited enhanced 8-oxoG levels [Toxicologist 78(S-1):380 (No. 1844), 2004]. Here we investigated the developmental role of CSB in protecting the fetus from postnatal functional deficits following *in utero* METH exposure. METH (40 mg/kg ip) or its saline vehicle was administered on gestational day 17 to pregnant heterozygous (+/-) CSB females (mated to CSB +/- males). Beginning at 6 weeks after birth, the offspring were tested for motor coordination using the rotarod apparatus. Female CSB +/- offspring exposed *in utero* to METH had enhanced coordination deficits compared to +/+ littermates at 8 and 12 weeks (p=0.01 and p=0.02, respectively), and compared to +/- littermates at 8, 10 and 12 weeks (p=0.002, p= 0.004 and p=0.002, respectively). *In utero* exposure of male +/- offspring to METH also resulted in enhanced coordination deficits compared to +/+ and +/- littermates at 10 weeks (p<0.05). This is the first evidence of enhanced neurodevelopmental deficits in CSB-deficient offspring exposed *in utero* to ROS-initiating toxins, and suggests that fetal CSB, in addition to Ogg1, protects against METH-initiated developmental neurotoxicity. (Support: Canadian Institutes of Health Research; SOT Covance Fellowship [WJ])

## 1078

### PERINATAL DIMETHYLTIN EXPOSURE ALTERS SPATIAL LEARNING ABILITY IN ADULT RATS.

K. D. Ehman<sup>1</sup>, K. L. McDaniel<sup>2</sup>, P. M. Phillips<sup>2</sup> and V. C. Moser<sup>2</sup>. <sup>1</sup>Curriculum in Toxicology, UNC, Chapel Hill, NC and <sup>2</sup>NTD/NHEERL, USEPA, Research Triangle Park, NC.

Dimethyltin (DMT) is widely used as a heat and light stabilizer in PVC and CPVC piping, and has been detected in domestic water supplies. Due to the lack of developmental neurotoxicity data on DMT, we initiated studies to evaluate long-term neurobehavioral changes in offspring following perinatal exposure. In the first study, female Sprague-Dawley rats were exposed via drinking water to DMT (0, 3, 15, 74 ppm) before mating and throughout gestation and lactation. As adults, male offspring were tested for spatial learning and retention in the Morris water maze. Acquisition of the platform location occurred over 9 days (2 trials/day), and on the 10th day, the platform was removed to assess retention in a probe trial. The middle dose group (15 ppm) took significantly longer to find the platform during Week 1; however, by Week 2, the 15 ppm males reached asymptotic performance though they continued to spend less time in the middle zone (near the platform), and more time searching in the outer zone. In a second study, DMT exposure, at the same doses, occurred from gestational day 7 to weaning. Learning deficits in the 15 ppm dose group were confirmed in both the male and female offspring tested as adults. The 15 ppm dose group displayed increased latencies throughout the entire acquisition period, and both sexes spent less time in the middle zone and more time in the outer zone. Neither study revealed retention deficits among the 15 ppm group; however, in the second study, they continued to display the same search strategy (i.e. more time in the outer zone). The results of both studies demonstrate a reproducible effect of 15 ppm perinatal DMT exposure on spatial learning. Additionally, in both studies, 74 ppm DMT caused decreased dam and litter weights, but no changes in water maze performance. Compensatory mechanisms might be activated as a result of exposure to the high dose, partially explaining learning deficits at 15 ppm but not at 74 ppm. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

PERTURBATION OF NEURAL CELL DAMAGE  
RESPONSE SENSITIZES NRF2 KO MICE, INCREASING  
THE DURATION AND SEVERITY OF KAINEATE-  
INDUCED SEIZURES.

A. D. Kraft<sup>1</sup>, J. Lee<sup>2</sup> and J. A. Johnson<sup>1,3,4</sup>. <sup>1</sup>Pharmacy, University of Wisconsin, Madison, WI, <sup>2</sup>Mass General Hospital, Boston, MA, <sup>3</sup>Waisman Center, University of Wisconsin, Madison, WI and <sup>4</sup>Toxicology, University of Wisconsin, Madison, WI.

Systemic administration of kainate is known to cause a selective loss of hippocampal neurons, increased GFAP immunoreactivity, and a seizure phenotype reminiscent of human temporal lobe epilepsy. In response to various stressors of the cellular environment, the transcription factor Nrf2 facilitates the induction of a battery of detoxification genes via the antioxidant response element (ARE) promoter. Interestingly, ARE-driven genes such as NQO1 and HO-1 are known to be increased subsequent to toxins such as kainate and MPTP, and are more highly expressed in diseases of neurodegeneration. These Nrf2-mediated genetic changes to the cellular reducing potential may reflect an intrinsic damage response of neurons or glia in the brain to harmful toxicants. To test this hypothesis, mice containing an hPAP reporter construct expressed in concert with activation of the ARE (ARE-hPAP mice), Nrf2 knockout (KO) mice, or wild type (WT) mice were exposed to varying doses of kainate via intraperitoneal injection. This led to a robust increase in ARE-mediated hPAP reporter activation in the cerebellum, as well as a specific increase in the CA3 subfield of kainate-injected mice. Additionally, Nrf2 KO mice were more sensitive to kainate toxicity as exhibited by increased seizure scores, prolonged seizure duration, and altered GFAP levels. Further, analysis of the hippocampus and cerebellum revealed a region-specific decrease in HO-1 and NQO1 mRNA in the KO mice compared to WT animals, both basally and after kainate injection. Two-by-two microarray analyses of six-month KO vs WT mice revealed not only the expected changes to detoxification and metabolism-related genes, but also changes associated with ion sensitivity and myelination. These results suggest a pivotal role for Nrf2 in the neural cell defense response of the adult brain against toxins that alter synaptic function and conductivity. (Support: ES08089 ES10042-NIEHS)

EFFECTS OF PERINATAL EXPOSURE TO PCB 153 ON  
THE TURNOVER OF BRAIN NEUROTRANSMITTERS  
OF OFFSPRING RATS.

T. Honma, M. Miyagawa, R. Wang, M. Suda and K. Kobayashi. Department of Research Planning, National Institute of Industrial Health, Kawasaki, Japan.  
Sponsor: M. Chiba.

Previous reports have suggested that exposure to PCB mixtures at perinatal period may affect the development of the central nervous system both in humans and animals, however, developmental neurotoxicity of each congener remains still unclarified. To investigate the effects of *in utero* exposure to PCB 153 (2, 2', 4, 4', 5, 5'-hexachlorobiphenyl), a representative non-planer PCB congener, on hormonal and neurobehavioral development in the offspring of rats, pregnant CD (SD) IGS rats were given PCB 153 (0, 16, 64 mg/kg/day) orally on Gestation Day 10 (GD 10) to Day 16 (GD 16). Offspring rats were examined at different weeks of age regarding the effects of PCB 153 on (1) endocrine system (thyroid and testis), (2) brain neuroactive substances, and (3) cognitive functions (learning and memory). PCB exposure did not produce any significant effects on the body weights of dams during gestation and lactation. There were no dose-dependent changes in body weight, body length, tail length, liver weight, and kidneys weight in offspring of all ages and both sexes. Anogenital distance (AGD) or AGD indices were increased in females in the PCB 153-exposed groups. Plasma concentrations of thyroxine (T4) and tri-iodothyronine (T3) were decreased in the 64 mg/kg group of both sexes. At 36-week, the blood testosterone concentration was significantly lower in the high PCB dose group, and in comparison, the LH in this group was at high level. In this paper, we described the effects of PCB 153 on the turnover of the brain neuroactive monoamines of the offspring. On the post natal day (PND) 7, the ratio of 5-hydroxyindoleacetic acid (5HIAA, serotonin metabolite) content to serotonin (5HT) content of the brain of male rats increased in a dose-dependent manner. These results suggest that 5HT turnover was accelerated in male offspring following perinatal exposure to PCB 153. The exposure to relatively high-dose of PCB 153 at the early stage of life may induce neurochemical changes in the brain of offspring rats.

## 1081

CHANGES IN GENE EXPRESSION PROFILE IN THE  
CEREBELLUM AND THE HIPPOCAMPUS FOLLOWING  
DEVELOPMENTAL EXPOSURE TO A  
NEUROTOXICANT.

P. R. Kodavanti, T. R. Ward and J. E. Royland. Neurotoxicology Division, USEPA, Research Triangle Park, NC.

The vast literature on the group of chemicals known as polychlorinated biphenyls (PCBs) makes it a unique model to understand major issues related to environmental mixtures of persistent chemicals. At background levels of exposure, PCBs have

been shown to affect human health including learning and memory dysfunction. Although the cellular and molecular basis for PCB-induced developmental neurotoxicity is still unclear, a series of *in vitro* and *in vivo* studies have revealed that the disruption of Ca<sup>2+</sup> homeostasis and Ca<sup>2+</sup> mediated signal transduction play a significant role. The culminating event in a variety of signal transduction pathways is the regulation of gene expression, which ultimately has an effect on the growth and function of the nervous system. Therefore, we examined the gene expression profile in cerebellum and hippocampus coupled with toxicity pathways following PCB developmental exposure. Pregnant rats (Long Evans) were dosed perinatally with 0 or 6 mg/kg/day of Aroclor 1254 (AccuStandard Inc., Lot # 124-191) from gestation day 6 through postnatal day (PND) 21. For the present study, only the cerebellum and the hippocampus from PNDs 7 and 14 animals were analyzed. RNA was extracted for analysis on Affymetrix mouse genome 430 2.0 chips. Preliminary analysis of the data indicated that expression levels of ~1600 genes in the cerebellum and ~1200 genes in the hippocampus were changed by >1.5 fold from PND7 to 14. Of those genes, 370 were common in these two brain regions. Following exposure to Aroclor 1254, the number of genes affected > 1.5 fold were greater at PND 7 (~150 genes) compared to PND 14 (~ 100 genes) in hippocampus and cerebellum. The greatest proportions of genes altered were related to signal transduction, cell communication, and transcription factors. These results suggest that changes in intracellular signaling and related gene expression may be involved in mediating PCB-induced neurotoxic effects. (The abstract does not necessarily reflect USEPA policy).

## 1082

EFFECTS OF PCB 84 ATROPISOMERS ON [<sup>3</sup>H]  
PHORBOL ESTER BINDING IN RAT CEREBELLAR  
GRANULE CELLS AND <sup>45</sup>Ca<sup>2+</sup>-UPTAKE IN RAT  
CEREBELLUM.

<sup>1</sup>Occupational and Environmental Health, University of Iowa, Iowa City, IA,  
<sup>2</sup>National Exposure Research Laboratory, Ecosystems Research Division, USEPA,  
Athens, GA and <sup>3</sup>Neurotoxicology Division, Cellular and Molecular Toxicology  
Branch, USEPA, Research Triangle Park, NC.

There is evidence that Polychlorinated biphenyl (PCB) congeners with ortho substituents have the potential to cause neurotoxicity. Many PCB congeners implicated in these neurotoxic effects are chiral. It is currently unknown if the enantiomers of a chiral PCB congeners have different neurotoxic effects. We herein report the effect of racemic 2, 2', 3, 3', 6-pentachlorobiphenyl (PCB 84) and its enantiomers on two neurochemical measures, PKC translocation as determined by [<sup>3</sup>H]phorbol ester binding in cerebellar granule cells and Ca<sup>2+</sup> sequestration as determined by <sup>45</sup>Ca<sup>2+</sup> uptake by microsomes isolated from adult rat cerebellum. Milligram quantities of the PCB 84 enantiomers were separated using HPLC. The (+)- and (-)-PCB samples were enantiomerically pure as determined by chiral gas chromatography. Both (+)- and (-)-PCB 84 increased [<sup>3</sup>H]phorbol ester binding in a concentration-dependent manner with (-)-PCB 84 being slightly more potent. Racemic PCB 84 was significantly more potent compared to the pure enantiomers alone. This suggests a synergistic increase of [<sup>3</sup>H]phorbol ester binding by the PCB 84 enantiomers. (-)- and (+)-PCB 84 both inhibited microsomal <sup>45</sup>Ca<sup>2+</sup> uptake to a similar extent, whereas racemic PCB 84 was more potent at inhibiting <sup>45</sup>Ca<sup>2+</sup> uptake compared to either enantiomer. In microsomes both PCB 84 enantiomers apparently cause a synergistic inhibition of <sup>45</sup>Ca<sup>2+</sup> uptake. These results indicate that PCB 84 enantiomers alone have similar potencies in both assays whereas a synergistic effect can be observed for the racemic mixture. These findings may have important implications for understanding the mechanism of neurotoxicity of chiral PCB congeners (Supported by ES 012475 and ES 07380 from NIH; this abstract does not necessarily reflect USEPA policy).

## 1083

PCBs REDUCE THE NUMBER OF DOPAMINE  
NEURONS AND INDUCE NEURONAL CELL DEATH IN  
ORGANOTYPIC CO-CULTURES OF DEVELOPING RAT  
STRIATUM AND SUBSTANTIA NIGRA.

G. D. Lyng<sup>2</sup>, A. Snyder-Keller<sup>1,2</sup> and R. F. Seeger<sup>1,2</sup>. <sup>1</sup>NYS Department of Health,  
Wadsworth Center, Albany, NY and <sup>2</sup>Biomedical Sciences, School of Public Health,  
University at Albany, Albany, NY.

We used an organotypic co-culture system of embryonic rat striatum (E21) and substantia nigra (SN) (E14) to examine the effects of developmental exposure to polychlorinated biphenyls (PCBs), an environmental neurotoxicant, on dopamine (DA) function and cell death. Co-cultures were maintained for 3 days prior to the addition of either 2 or 8 μM PCBs. Co-cultures were then maintained for an additional 7 days, with PCB-supplemented media changed 3 times per week. After exposure, cultures were either examined immunohistochemically or the striatum and

SN were separated and DA concentrations were determined using HPLC with electrochemical detection. Immunohistochemical results indicate a significant reduction (45%) in tyrosine hydroxylase positive (TH+) neuronal cell bodies (DA neurons) in the SN exposed to 8 $\mu$ M PCBs, compared to vehicle-exposed tissue. Additionally, Fluoro Jade B (FJB), a fluorescent marker of neuronal cell death, indicated significant increases in fluorescent intensity in both the striatum and SN of 8 $\mu$ M exposures and in the striatum of 2 $\mu$ M exposure, compared to control tissue. Significant reductions in striatal DA concentrations were seen after PCB exposure, with a 45% reduction at 2 $\mu$ M and a 55% reduction at the 8 $\mu$ M exposure level, while no significant changes were seen in the SN. These results demonstrate that PCBs: (1) reduce the number of DA neurons in the SN; (2) increase neuronal cell death; and (3) reduce striatal tissue DA concentrations at concentrations as low as 2 $\mu$ M. These findings are similar to those seen in continuous cell lines and adult animals exposed to PCBs and validate this *in vitro* model of nigrostriatal development as a means of examining toxicant effects on neuronal development. Supported in part by NIH grant 1P01ES11263-01 and EPA grant R-82939001.

**1084** ALTERED COGNITIVE FUNCTION AND DENDRITIC GROWTH IN WEANLING RATS EXPOSED DEVELOPMENTALLY TO AROCLOR 1254.

D. Yang and P. Lein. *CROET, Oregon Health & Science University, Portland, OR*.

Polychlorinated biphenyls (PCBs) are persistent environmental contaminants. Epidemiological evidence suggests an association between perinatal exposure to low levels of PCBs and non-persistent cognitive deficits in children. These observations have not been tested in juvenile animal models. Risk assessments are further complicated by a paucity of information regarding specific neurodevelopmental events targeted by PCBs. To address these issues, we tested: 1) the feasibility of using weanling rats to assess the impact of developmental PCB exposures on spatial learning and memory using the Morris water maze; and 2) the hypothesis that developmental PCB exposure alters dendritic growth and maturation as measured by quantitative RT-PCR analysis of dendrite-specific proteins and morphometric analysis of layer widths in the brain. Gestational and lactational exposure to Aroclor 1254 at 1mg/kg, but not 6mg/kg, in the maternal diet causes subtle but significant deficits in spatial learning and memory in weanling rats (postnatal day 24, PN24). These effects were not gender specific, and did not persist into adulthood. Aroclor 1254 significantly increased expression of RC3/Neurogranin and spinophilin mRNA in the cerebellum and cortex, but not hippocampus, of PN4 rats. This effect was greatest in the 1 mg/kg treatment group. Aroclor 1254 significantly decreased the width of molecular layers in the cerebellum, but not the hippocampus and cortex, of PN31 rats. Again, 1 mg/kg caused a greater effect than did 6 mg/kg. These results suggest the validity of using this model to evaluate PCB effects on cognitive development, and implicate PCB-induced alterations in dendritogenesis as an underlying cause of cognitive deficits.

**1085** DEVELOPMENTAL EXPOSURE TO PCBs CAUSES AUDITORY IMPAIRMENTS IN RATS.

B. E. Powers<sup>1</sup>, J. J. Widholm<sup>2</sup>, D. M. Gooler<sup>1</sup>, R. E. Lasky<sup>3</sup> and S. L. Schantz<sup>1</sup>.  
<sup>1</sup>*Neuroscience, University of Illinois, Urbana, IL*, <sup>2</sup>*Psychology, College of Charleston, Charleston, SC* and <sup>3</sup>*Health Science Center, University of Texas, Houston, TX*.

It has been reported that developmental exposure to PCBs can result in hearing impairments. A cochlear site of action is supported by recent research from our laboratory, showing compromises in the mechanical integrity of the cochlea of PCB-exposed rats through the measurement of distortion product otoacoustic emissions (DPOAEs). In the current study, we utilized a unique PCB mixture, which was formulated to model the congener profile of PCBs found in fish consumed by a human cohort we are studying in northeastern Wisconsin. The goal is to determine whether developmental exposure to PCBs through maternal consumption of contaminated fish can induce auditory impairments. Female Long-Evans rats were dosed orally with PCBs beginning 28 days prior to breeding and continuing until pups were weaned. Dams were fed one-half of a cookie onto which was pipetted 0, 1, 3, or 6 mg/kg of the PCB mixture dissolved in corn oil vehicle. On PND 21 pups were weaned and one male and one female from each litter were randomly selected for auditory assessment. DPOAE testing was conducted under sedation at approximately 100 days of age. The DPOAEs were generated by simultaneously presenting two sinusoids differing in frequency (the lower frequency labeled f1 and the higher frequency f2) into the sealed ear canal. Seven stimulus pairs were used for DPOAE testing which included f2 = 1, 2, 3, 4, 6, 8, and 12 kHz (f2/f1 = 1.2). The amplitude of the 2f1-f2 distortion product was measured by recording the pressure in the sealed ear canal, and DPOAE thresholds were determined by reducing the f1 and f2 primaries in 5 dB steps. PCB-exposure caused a dose-dependent reduction in DPOAE amplitude as well as an increase in DPOAE threshold across the entire range of frequencies tested. The results are indicative of damage to the outer hair cells of the cochlea. Our future studies will use similar methodologies to assess auditory function in newborn infants born to women consuming contaminated fish.

**1086** PCB INDUCED HYPOTHYROIDISM ALTERS OLIGODENDROCYTE NUMBERS IN TWO WHITE MATTER TRACTS OF THE DEVELOPING RAT BRAIN.

D. Sharlin, R. Bansal and R. Zoeller. *Biology Department, University of Massachusetts, Amherst, MA*.

Developmental polychlorinated biphenyl (PCB) exposure is associated with a number of neurological deficits that overlap with deficits associated with maternal and fetal thyroid dysfunction. These similarities have prompted a number of investigators to propose that the adverse effects of PCBs may be attributed, in part, to their ability to interfere with thyroid hormone (TH) action during development. One target of TH during development is the timing of generation and maturation of oligodendrocytes. There are *in vitro* and *in vivo* data supporting the hypothesis that TH plays a role in controlling the number of oligodendrocytes that ultimately populate white matter tracts. To test the hypothesis that developmental exposure PCBs alters oligodendrocyte generation, pregnant rats were fed either PCBs (Aroclor1254; 5mg/kg/day), methimazole and perchlorate (MMI/Per) *ad libitum* in drinking water to induce hypothyroidism, or a combination of PCB and MMI/Per, starting at gestational day-6 (G6) until sacrifice at postnatal day-15 (P15). Using *in situ* hybridization directed against the oligodendrocyte marker, myelin associated glycoprotein (MAG), the number of MAG-positive cells and the cellular level of MAG mRNA levels were determined in the anterior commissure (AC) and corpus callosum (CC) of experimental animals. The results presented here show that perinatal PCB exposure and MMI/Per treatment cause a significant reduction in circulating thyroxine (T4) levels and a reduction in the number of MAG-positive cells that populate the AC/CC. Cellular levels of MAG mRNA were not affected by PCB exposure but were significantly reduced in animals that received MMI/Per. These studies suggest that PCBs have an effect similar to MMI/Per on serum T4 levels, on the total number of cells that populate the AC/CC, and on the generation of oligodendrocytes. However, cellular levels of MAG mRNA indicate that the effects of PCBs on thyroid hormone mediated oligodendrocyte maturation may not be due to lower serum T4.

**1087** VITAMIN A HOMEOSTASIS IS DISRUPTED IN OFFSPRING OF RAT DAMS EXPOSED TO PBDES DURING GESTATION AND LACTATION.

R. Ellis-Hutchings, G. N. Cherr and C. L. Keen. *Nutrition, University of California-Davis, Davis, CA*.

Vitamin A and thyroid hormones are critical mediators of nervous system development. Polybrominated diphenyl ether (PBDE) exposure can disrupt nervous system function and alter adult and neonatal thyroid hormone concentrations. PBDE exposure can also decrease adult hepatic vitamin A levels. We tested the hypothesis that vitamin A homeostasis and thyroid hormones are more severely disrupted in DE-71 (a commercial PBDE mixture) exposed dams and offspring under conditions of suboptimal vitamin A nutriture. Female Sprague-Dawley rats (controls) were fed a vitamin A sufficient (VAS) diet throughout the study. To induce a marginal vitamin A status rats were fed a vitamin A deficient diet for 5 weeks prior to mating and through gestation day (GD) 5, and then fed a vitamin A marginal diet (VAM) from GD 6 through the remainder of the study. Within each diet group, subsets of rats were administered daily intragastric corn oil (vehicle) or 18 mg/kg DE-71, from GD 6 through lactation day (LD) 18. Plasma and tissues were collected from dams on LD 19 and pups on postnatal day (PND) 3, 12, 18 and 30. DE-71 exposure significantly decreased liver retinol in both diet groups but only reduced maternal and pup plasma retinol and retinol binding protein (RBP) levels under VAM conditions. Plasma thyroxine (T4) was decreased in both diet groups dosed with DE-71, while thyroid-stimulating hormone was elevated only in the VAM group dosed with DE-71. There was no difference in transthyretin (TTR) levels between the groups. A reduction in T4 binding to plasma TTR from only the animals dosed with DE-71 suggests an interaction between PBDEs and the TTR-RBP complex. Ongoing studies are investigating PBDE-induced alterations in embryonic vitamin A signalling and nervous system development. These data support the concept that women with marginal vitamin A status are at an increased risk of adverse pregnancy outcomes upon exposure to PBDEs. **1088** TCDD MODULATES GENE EXPRESSION ASSOCIATED WITH CEREBELLAR GRANULE NEURON MIGRATION AND DIFFERENTIATION.

M. Williamson and L. Opanashuk. *Department Environmental Medicine, University of Rochester, Rochester, NY*.

2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) is a ubiquitous and persistent environmental contaminant known to exert developmental toxicity in many species by binding to the aryl hydrocarbon receptor (AhR), a transcription factor that regu-

lates the expression of drug metabolizing enzymes, inflammatory mediators, and genes that participate in cell cycle regulation. Epidemiological and neurobehavioral studies have suggested that the cerebellum is a target for TCDD induced developmental neurotoxicity. We have previously determined that AhR is expressed and transcriptionally active in cerebellar granule neurons during critical developmental periods. These observations led us to hypothesize that TCDD exposure interferes with granule neuron developmental programs by disrupting normal gene expression patterns. In this study, gene profiling experiments indicated that oral exposure to 1 $\mu$ g/kg TCDD increased the expression of several differentiation and migration markers in mouse granule neuroblasts 8 hours after exposure on postnatal day 5 (P5). Immunohistochemical staining demonstrated enhanced expression of the early onset differentiation marker TAG-1 and aberrant cerebellar granule neuron migration patterns on P6 and P10 following TCDD exposure on P3 and P6, respectively. In granule neuroblast cultures, 10nM TCDD accelerated neurite outgrowth and fasciculation, as evidenced by altered TuJ1 expression patterns. Additionally, TCDD produced a concentration dependent increase in the number of PSA-NCAM positive neurons 72 hours after treatment. Taken together these findings suggest that TCDD disrupts cerebellar granule neuron maturation by precociously activating the spatiotemporal gene expression program that regulates differentiation. Therefore, TCDD might exert neurotoxicity by hijacking AhR from its intrinsic roles, thus interfering with genetic programs that potentially control cell cycle regulation, differentiation, and migration during granule neuron development. Supported by NIH ES00375, ES07026, and ES01247.

## 1089

### DEVELOPMENT OF A QUANTITATIVE ASSAY FOR DETERMINATION OF TCDD TOXIC EQUIVALENTS IN F1 GENERATION CNS TISSUES.

L. Brown<sup>1</sup>, E. Harris<sup>2</sup>, A. Smith<sup>3</sup>, J. Wu<sup>1</sup>, S. Johnson<sup>1</sup> and D. B. Hood<sup>1</sup>.

<sup>1</sup>Department of Pharmacology & Center in Molecular and Behavioral Neuroscience, Meharry Medical College, Nashville, TN, <sup>2</sup>Department of Biology, Xavier University of Louisiana, New Orleans, LA and <sup>3</sup>Department of Biology, Alabama A & M University, Huntsville, AL.

There is a critical need for the development of assays that quantify 2, 3, 7, 8, -tetrachlorodibenzo-p-dioxin (TCDD) toxic equivalents (TEQ) in central nervous system tissues as an alternative to the very expensive mass spectrophotometric methods. TCDD is a prototypical halogenated aromatic hydrocarbon environmental contaminant that is structurally distinguishable from the class of chemicals known as polychlorinated biphenyls (PCBs). TCDD is of particular relevance to human health because of its body burden and its potential to produce a wide range of toxicological responses. Here we describe the development of a quantitative *in vitro* assay that will be used to determine the residual levels of TCDD in F1 fetal brain after exposure on gestational day 15. The overall objective of developing this *in vitro* assay is to quantify the perinatal dose-dependent disposition of TCDD to critical central nervous system structures. HEPA-1c1 cells were grown to confluence and dosed to final TCDD concentrations of 1, 10, 100 fMol; 1, 10, 100pMol; 1, 10 and 100nMol; and finally 1 $\mu$ Mol from a stock solution in DMSO. HEPA cells were incubated in TCDD for 24 hours then total RNA was isolated, and semi-quantitative PCR was performed where the levels of CYP1A1mRNA/18s RNA were quantified. The results from this HEPA cell assay revealed a concentration-dependent increase in CYP1A1 mRNA as a result of TCDD exposure. TCDD TEQ values from F1 generation CNS tissue were calculated by comparing the up-regulated CYP1A1 mRNA induced by F1 generation CNS tissue against the dose-response curve generated in HEPA cells. From a cumulative risk-assessment perspective, development of this assay will allow for the quantitation of perinatal levels of TCDD TEQ that give rise to brain burdens that can be correlated with plasticity/behavioral learning and memory deficits in adult animals.

## 1090

### THE RETURN OF THE "DARK" NEURON. A HISTOLOGICAL ARTIFACT COMPLICATING NEUROTOXICOLOGIC INTERPRETATION.

B. S. Jortner. *Laboratory for Neurotoxicity Studies, Virginia Tech, Blacksburg, VA.*

It has been known for years that the "dark" neuron is a histological artifact due to post-mortem trauma of unfixed or poorly fixed brain or spinal cord (Cammermayer J- in Structure and Function of Nervous Tissue 6:131-251, 1972, Bourne GH, ed). When studied histologically using the routine hematoxylin and eosin (H&E) staining, these cells are shrunken, hyperchromatic and basophilic, and often seen among populations of histologically normal neurons. Although the artifactual nature of these "dark" cells is clear, a spate of recent papers interpret such cells as representing dying/degenerating neurons (see J. Toxicol. Environment Health. 67:163 and 67:331, 2004 and Exper. Neurol. 172:153, 2001 for examples). This change was thought to be related to neurotoxic effects of agents such as pyridostigmine bromide, D $\delta$ ET, permethrin and malathion, alone or in combination. To help assess the validity of this interpretation, brain tissue was obtained

from young adult control male Sprague-Dawley rats (n=4) following CO<sub>2</sub> euthanasia and gentle blunt dissection to obtain samples for regional neurochemistry (for another study). The residual brain tissue was immersion-fixed in formalin, embedded in paraffin, sectioned and stained with H&E. Light microscopy revealed many "dark" neurons in multiple brain regions, similar to those illustrated in the above indicated papers. The generation of such cells by gentle post-mortem trauma in brains of normal rats raises questions as to the validity of the neuropathologic findings in cited (and similar) works. It is recommended that toxicologists, journal editors, risk assessors and regulatory agency officials acquaint themselves with this common artifact when making scientific judgments.

## 1091

### TEN-DAY EXPOSURE TO CARBONYL SULFIDE PRODUCE BRAINSTEM LESIONS AND CHANGES IN BRAINSTEM AUDITORY EVOKED RESPONSES IN FISCHER 344N RATS.

D. W. Herr<sup>1</sup>, J. E. Graff<sup>1</sup>, P. B. Little<sup>2</sup>, V. C. Moser<sup>1</sup>, P. M. Phillips<sup>1</sup>, K. M. Crofton<sup>1</sup>, D. L. Morgan<sup>3</sup> and R. C. Sills<sup>3</sup>. <sup>1</sup>NTD, USEPA, Research Triangle Park, NC, <sup>2</sup>PAL, Research Triangle Park, NC and <sup>3</sup>NIEHS, Research Triangle Park, NC.

Carbonyl sulfide (COS) is an intermediate in the production of pesticides and herbicides, a metabolite of carbon disulfide, a byproduct of combustion of organic material, and occurs naturally. COS was included in a Toxic Substances Control Act data request, and was listed as a Clean Air Act hazardous air pollutant. We have reported that 12-week exposure to 400 ppm COS produces brainstem lesions and altered brainstem auditory evoked responses (BAERs). To determine if shorter duration exposures produce similar effects, and to examine additional behavioral endpoints, male Fischer 344N rats were exposed by inhalation to 0, 300, or 400 ppm COS for 6 h/day, 5 days/week, for 2 weeks. Animals were tested 5-11 days after the last exposure using a functional observational battery and white noise prepulse inhibition (PPI) of the startle response. About 19 days after COS exposure, subjects were implanted with electrodes over the cerebellum and visual cortex and were allowed to recover for 1 week. Animals were presented with auditory stimuli consisting of rarefaction clicks (50, 65, 80 dB SPL), tone pips (4 and 16 kHz at 80 dB SPL), and flash stimuli (15 and 146 lux-s). Rats exposed to 400 ppm COS had lower motor activity and grip strengths, a slightly altered gait, and a few animals lacked the forelimb proprioceptive placing response. No changes were observed in sensory responses. White noise PPI of the startle response was not altered in COS-treated animals. Exposure to COS decreased BAER amplitudes (peak P<sub>4</sub> region). Histopathology confirmed brainstem lesions in the anterior olfactory complex and posterior colliculus. Flash evoked responses were not altered by COS exposure. We have shown that short-term exposure to COS produces mild motor deficits, brainstem lesions, and alters BAERs (without changes in PPI of the startle response), with no change in visual evoked responses. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

## 1092

### SELECTIVE NEURONAL DEGENERATION IN THE CENTRAL NERVOUS SYSTEM OF RATS EXPOSED TO 3, 3'-IMINODIPROPIONITRILE (IDPN), ALLYLNITRILE (AN), CIS-CROTONONITRILE (CIS-CN), TRANS-CROTONONITRILE (TRANS-CN) AND 2, 4-HEXADIENENITRILE (HDN).

J. Llorens and P. Boadas-Vaello. *D. Ciències Fisiològiques II, Universitat de Barcelona, Hôpital de Llobregat, Catalunya, Spain.* Sponsor: K. Crofton.

IDPN, AN and *cis*-CN damage the vestibular, auditory, visual and olfactory systems of the rat. IDPN also causes a proximal neurofilamentous axonopathy in both central and peripheral axons. However, the possibility that neuronal degeneration in the central nervous system contributes to the behavioral effects of IDPN and AN remains a controversial issue. In addition, recent data indicate that the *trans* isomer of CN spares the sensory systems but induces selective central neurodegeneration. Adult male Long-Evans rats (250-350 g) received saline (control, n=2), IDPN (400 mg/kg/day, n=2), AN (60 mg/kg/day, n=3), *cis*-CN (110 mg/kg/day, n=3), *trans*-CN (250 mg/kg/day, n=2) or HDN (300 mg/kg/day, n=3) administered i.p. for 3 consecutive days. Tissues were examined at 7 days post-dosing. Fixed whole brain and representative segments of the spinal cord were sectioned at 50  $\mu$ m, and every third section was processed for Fluoro-Jade B staining, which selectively stains degenerating neurons. In rats exposed to IDPN or *cis*-CN no Fluoro-Jade B labeling was apparent other than that of nerve terminals in the glomeruli of the olfactory bulbs, indicating degeneration of the olfactory mucosa. AN rats showed a similar olfactory staining. Rats exposed to *trans*-CN and HDN showed a common pattern of selective neurotoxicity; major targets were the inferior olive and the piriform cortex. In three other areas (entorhinal, frontal cingulated, and motor frontal cortex) the effect of HDN was more pronounced than that of *trans*-crotononitrile. In conclusion, the nitriles that are toxic to sensory systems (IDPN, *cis*-CN and AN) cause

no selective neuronal degeneration in the central nervous system. In contrast, a distinct pattern of selective neuronal degeneration is induced by *trans*-CN and HDN, which spare the sensory systems and cause different behavioral effects. Supported by MCyT, Spain (BFI 2003-016060).

**1093**

**NORMAL VISUAL CONTRAST SENSITIVITY (VCS) AND COLOR VISION OF ADULTS AND SCHOOL-AGE CHILDREN FOUR TO FIVE YEARS AFTER EXPOSURE TO PERCHLOROETHYLENE (PERC).**

K. A. Mazor<sup>1</sup>, R. L. Shultz<sup>2</sup>, M. Meldrum<sup>1</sup>, E. Lewis-Michl<sup>1</sup>, L. Gensburg<sup>1</sup> and J. E. Storm<sup>1</sup>. <sup>1</sup>*Department of Health, New York State, Troy, NY* and <sup>2</sup>*Cornea Consultants of Albany, Slingerlands, NY.*

In 1998 NYS DOH found levels of 1, 800-2, 400 ug/m<sup>3</sup> perc in a daycare center located adjacent to a dry cleaner. Seven weeks after perc levels were reduced to < 50 ug/m<sup>3</sup>, 9 employees at the daycare center had significantly decreased VCS compared to 9 unexposed adults although VCS of both groups was within the normal range; color vision was decreased, but not significantly. Children attending the daycare center were not given vision tests because they were too young in 1998 to perform them reliably. Follow-up evaluations of this population were conducted in 2001-2002 to assess if: 1) VCS among employees was still decreased; 2) a color vision deficit had developed among employees; and, 3) VCS or color vision deficits were evident among the children. Participants were identified from among daycare center employees and attendees enrolled in the NYS Volatile Organic Compounds Exposure Registry. Participants completed FACT VCS and Farnsworth D15 and Lanthony's Desaturated 15 Hue color vision tests, as well as a thorough ophthalmologic exam. Five employees participated in the follow-up evaluation; none had deficits in VCS or color vision that can be attributed solely to perc exposure. Seventeen children who attended the daycare center prior to 1998 participated and 13 of them were age- and gender-matched to 13 children with no documented exposure to perc. Wilcoxon matched-pairs signed-rank tests indicated no difference between matched groups of children in VCS scores or color confusion indices. McNemar's Exact Test for Correlated Proportions indicated no differences in numbers of pairs of children with discordant clinical judgements (one abnormal, one normal color vision) or with discordant numbers of major errors (one with no errors, one with at least one error) on color vision tests. This investigation did not detect any long term effect on vision among adults or children previously exposed to perc. Funded through USEPA STAR Grant R827446010.

**NEW ASSESSMENT OF NEUROBEHAVIORAL CHANGES USING FUNCTIONAL OBSERVATIONAL BATTERY (FOB) IN MONKEYS.**

T. yoshikawa, Y. Deguchi, R. Anraku, K. Fukuzaki, G. Kito and R. Nagata. *shin Nippon Biomedical Laboratories, Ltd., (SNBL), Yoshida, Kagoshima, Japan.*

[Background and Purpose] The FOB is now widely used to identify potential neurotoxicity of new and existing chemicals in rats, but not in primates. The purpose of this study was to develop the assessment of behavioral and neurologic functions in cynomolgus monkeys, and to investigate differences between monkeys and rats in neurobehavioral evaluation. [Methods] Six male cynomolgus monkeys and Crj:CD(SD)IGS rats were used. The FOB using monkeys consisted of home-cage observations and manipulative measurements of spontaneous activity/excitability, sensorimotor, neuromuscular and autonomic nervous functions. The FOB test was conducted after the administration of chlorpromazine, haloperidol, diazepam and caffeine. [Results] In the FOB test in monkeys, chlorpromazine and haloperidol produced dose-related changes in parameters of behavioral and neurologic functions. The effective dosage that induced neurobehavioral toxicity on the central nervous system (CNS), such as catalepsy, was lower in monkeys than in rats. Diazepam appeared to have an antianxiety effect, including sociability and taming, at a low dosage in monkeys, which did not induce excessive sedation. However, diazepam induced only sedation in rats. Caffeine induced hypoactivity (low-dosage) and hyperactivity (high-dosage) in rats, but only hyperactivity in monkeys. The symptoms observed in monkeys resembled known clinical effects of these drugs. [Conclusion] These findings suggest that neurobehavioral evaluation in primates can be useful in preclinical studies in predicting the clinical effects of new CNS active compounds.

**NEUROBEHAVIORAL ASSESSMENT OF SIX NEUROTOXICANTS IN MALE SPRAGUE-DAWLEY RATS.**

K. Steinmerz, L. Rausch, A. Robb, G. Ganem, D. Lau, D. Middaugh and J. Mirsalis. *SRI Int, Menlo Park, CA.*

Sprague-Dawley (SD) rats are widely used for safety assessments, however there are few reports on Functional Observational Battery (FOB) and Motor Activity (MA) assays using SD rats. The goal of this study was to establish baseline data in male

SD rats after treatment with six model neurotoxicants: imidodipropionitrile (IDPN; 3 x 300 mg/kg, 10d prior to FOB), amphetamine (AMP 3-6 mg/kg), chlorpromazine (CPZ 3, 6 mg/kg), carbaryl (CRB 50-100 mg/kg), ethanol (ETH 1500 mg/kg), and 5-methoxy-N-N-dimethyltryptamine (MDMT 10 mg/kg). Rats were administered a single oral dose of each compound, and FOB and MA were performed 15-60 min after treatment (except as described for IDPN). All compounds induced behavioral changes consistent with previous reports. IDPN induced changes consistent with brain damage including head weaving, altered gait, and poor righting reflex. AMP induced changes consistent with CNS stimulants including increased reactivity to the observer, darting, increased rearing, repetitive head and jaw movements and exophthalmia. CPZ induced locomotor debilitation including markedly abnormal gait, little interest in surroundings, and reduced response to external stimuli. CRB induced behaviors consistent with acetylcholinesterase inhibition including salivation, twitches, flattened body posture, repetitive jaw movements (chewing), and whole body tremors. ETH induced intoxication evidenced by altered balance and gait as well as slow reaction time. MDMT induced changes for serotonergic agonists including hind-limb abduction, forepaw treading (slithering), and altered reflexes. AMP induced dramatic increases in all MA parameters: ambulation (14-fold), rearing (11-fold), and fine motor movement (5-fold). None of the other test articles yielded significant MA changes relative to controls. This study demonstrates that these compounds induced behavioral changes in male SD rats similar to changes reported in other rat strains, such as the Hooded Long-Evans rat, which have been reported in the literature more frequently for neurobehavioral studies. **ASSESSMENT OF NEUROTOXICITY USING ZEBRAFISH AS A MODEL ORGANISM.**

N. Roy, C. Ton, Y. Lin and C. Parng. *Phylonix Pharmaceuticals, Inc., Cambridge, MA.* Sponsor: D. Monteith.

Neurotoxicity occurs when exposure to toxicants alters the normal activities of the nervous system, including neural transmission, connection and survival. Neurotoxicity can result from exposure to substances used in chemotherapy, radiation treatment, drug therapy, and organ transplant as well as food additives and environmental toxicants. Numerous approved drugs have incomplete neurotoxicity profiles and cause neurotoxic side effects in patients. Moreover, there is no effective cure for many neuropathies. To establish an effective screening platform to understand potential neuropathy after drug treatment, we used zebrafish as a model organism. The transparency of zebrafish is a unique attribute for assessing drug effects directly on the nervous system using whole mount antibody staining and histochemistry. To assess pharmacological effects of drugs on the nerve systems, motor neurons, dopaminergic neurons, and optic nerves were visualized and assessed in zebrafish using whole mount immunostaining. Additionally, *in vivo* dye staining, histochemistry and *in situ* hybridization were used to assess neuronal apoptosis, proliferation, myelin structure and gene expression. Here we showed that compounds inducing neurotoxicity in human also caused similar neurotoxicity in zebrafish including: dopaminergic neuron injury caused by 6-hydroxydopamine, MPTP, and reserpine; optic nerve loss caused by alcohol; demyelination caused by acrylamide and L-2-hydroxyglutaric acid; oxidative apoptosis caused by Angel's salt; peripheral axonal loss caused by anticancer drugs. These results show comparable pharmacologic effects in zebrafish and humans and support the use of zebrafish in assessing neurotoxicity. Conventional neurotoxicity assessment using histological, neurophysiologic and behavior studies are laborious and time consuming. Zebrafish can be used to screen potential neurotoxicity of compounds during drug development. This simple, rapid, whole animal zebrafish assay format will bridge the gap between cell-based and mammalian testing, streamlining the pre-clinical drug development process.

**SENSITIVE DETECTION OF BEHAVIORAL IMPAIRMENTS IN MODERATELY LESIONED MPTP MICE BY AUTOMATED GAIT ANALYSIS.**

T. Guillot<sup>1</sup>, J. R. Richardson<sup>1,2</sup> and G. W. Miller<sup>1,2</sup>. <sup>1</sup>*Center for Neurodegenerative Disease, Atlanta, GA* and <sup>2</sup>*Environmental and Occupational Health, Rollins School of Public Health, Atlanta, GA.*

Overt behavioral symptoms of Parkinson's disease (PD) are typically not observed until there is over 80% loss of striatal dopamine. Similarly, behavioral manifestations in the 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP) mouse model of PD require large doses of MPTP and are often transient. Previously, using novel behavioral tests, we identified alterations in stride length and gait parameters in mice administered low doses of MPTP. These behaviors were highly correlated with decreases of striatal dopamine and undetected by standard locomotor and rotarod tests. To provide more detailed measures of MPTP-induced deficits in stride length and gait, we have utilized a sophisticated gait-analysis system from Mouse Specifics, Inc. In this system, a mouse walks on a transparent conveyor belt and the

paw placement is captured digitally from below with a video camera which allows for sensitive analysis of gait dynamics. Eight week old C57 BL/6j mice were administered a moderate dose MPTP (2x10 mg/kg s.c.). Seven days after MPTP treatment, patterns of gait dynamics for each limb were analyzed for stride length and time, stance time, braking time, and propulsion were analyzed using Cleversys software. MPTP treatment decreased striatal dopamine levels by 45-50% and dopamine transporter and tyrosine hydroxylase levels by 75%. Gait analysis revealed significant decreases in forepaw (10%) and hindpaw (11%) stride length and hindpaw stance (8%) and stride time (9%). The most robust effects were observed with forepaw and hindpaw brake time which were increased and decreased by 20%, respectively. These data suggest that automated gait analysis is a sensitive and detailed method for detecting behavioral deficits in mice with moderate dopaminergic lesions and may aid in testing of therapeutics for PD. (Supported by DAMD 00267036, NIH U54ES012068, F32ES013457, and EPA STAR Fellowship #91643701-0).

### ALTERATIONS OF GENE EXPRESSION IN MICE INDUCED BY MPTP ADMINISTRATION: APPLICATION OF MICROARRAY ANALYSIS.

Z. A. Xu<sup>1</sup>, D. R. Cawthon<sup>1</sup>, T. Han<sup>2</sup>, T. A. Patterson<sup>1</sup>, L. Shi<sup>2</sup>, H. Fang<sup>3</sup>, S. Ali<sup>1</sup> and W. Slikker<sup>1</sup>. <sup>1</sup>Neurotoxicology, NCTR, Jefferson, AR, <sup>2</sup>System Toxicology, NCTR, Jefferson, AR and <sup>3</sup>Division of Bioinformatics, Z-Tech Corporation, NCTR, Jefferson, AR.

1-methyl-4-phenyl-1, 2, 4, 6, -tetrahydropyridine (MPTP) is a selective neurotoxin which produces dopamine depletion and causes parkinsonism like symptoms in humans and is used to generate animal models for Parkinson's disease (PD). In this study, C57BL/6N mice were dosed daily with 10 mg/kg (i.p.) MPTP for 5 consecutive days. Mice were sacrificed 72 hours after the last dose, and the brain tissue was collected. Agilent mouse oligo 22K microarrays were used to examine alterations of gene expression in substantia nigra. Bioinformatics tools were used for data analysis and data mining. A list of over 400 genes were determined to be expressed differentially (down- or up-regulated) using a 1.5-fold cut-off and false discovery rate at 0.05. GOFFA found that most of the genes are involved in molecular functions, biological-process and cellular-component. Pathway finding tools indicated that multiple biological pathways are involved in the mechanism of MPTP-induced neurotoxicity in mice. These include, but not limited to, the MAPK pathways, neuroactive ligand-receptor reactions, ubiquitin mediated proteolysis, Wnt signaling pathways, apoptosis, and cytokine-cytokine interactions. A group of genes that are related to dopaminergic pathways were also identified in the gene list that were altered with MPTP treatment. These include tyrosine hydroxylase (TH), dopa decarboxylase (AAAD), dopamine transporter (DAT) and vesicular monoamine transporter 2 (VMAT2), indicating the disorder of dopaminergic systems. However, dopamine metabolic enzymes (MAOa, MAOb, COMT) were not found, suggesting these genes are not affected by MPTP. These results were consistent with our previous findings with acute MPTP treatment using real-time PCR. Further analyses on the pathways detected in this study are needed to elucidate the mechanism of MPTP-induced neurotoxicity.

## 1099

### MICROARRAY ANALYSIS DETECTED GENE EXPRESSION CHANGES IN PC12 CELLS AFTER EXPOSURE TO THE NEUROTOXIN MPP<sup>+</sup>

S. F. Ali<sup>1</sup>, Z. A. Xu<sup>1</sup>, T. Han<sup>2</sup>, T. A. Patterson<sup>1</sup>, L. Shi<sup>2</sup>, H. Fang<sup>3</sup>, D. R. Cawthon<sup>1</sup> and W. Slikker<sup>1</sup>. <sup>1</sup>Neurotoxicology, NCTR, Jefferson, AR, <sup>2</sup>Systems Toxicology, NCTR, Jefferson, AR and <sup>3</sup>Division of Bioinformatics, Z-Tech Corporation, NCTR, Jefferson, AR.

MPP<sup>+</sup> is the active metabolite of the neurotoxin 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP) and it has been shown to deplete dopamine and elicit cell death in PC12 neuronal cell cultures. However, the mechanism of MPP<sup>+</sup>-induced neurotoxicity has not been adequately elucidated. Agilent rat oligo 22K microarrays were used to examine alterations in gene expression of PC12 cells after 500  $\mu$ M MPP<sup>+</sup> exposure. Bioinformatics tools were used to analyze gene expression of control and treated cells. High correlation ( $R^2 = 0.98$ ) between the two dye channels (Cy3:Cy5) using self-self hybridization analysis (technical replicates) indicated a good quality microarray experiment. Raw data from each microarray slide scan were input into the ArrayTrack database, and data quality for each microarray slide was monitored using the ArrayTrack quality control tool. The raw data was then normalized using a Lowess normalization method to eliminate the dye factor before further statistical analysis. ArrayTrack visualization tools, Spotfire and JMP statistical software were used for further data quality control. The relative expression values of each gene are the average of the Cy3 and Cy5 log intensity from the dye-flipped slides. SAM (Significance Analysis of Microarray Data) was used to pick the genes with 2-fold changes and statistical significance (False discovery rate<0.05). After analysis, above 200 genes showed highly differential expression (up- or down- regulation) with MPP<sup>+</sup> treatment. Biological significance of these genes was analyzed using the ArraytrackTM linked libraries, including Kegg, Pathart pathway library and GOFFA library.

### COMPARISON OF MEMBRANE POTENTIAL-SENSITIVE FLUORESCENT DYES FOR MEASUREMENT OF TOXIN-INDUCED DEPOLARIZATION IN MURINE NEOCORTICAL NEURONS: CHARACTERIZATION OF BREVETOXIN-AND KCL-INDUCED DEPOLARIZATION.

J. H. Peterson and T. F. Murray. *Physiology and Pharmacology, University of Georgia, Athens, GA.*

Brevetoxins (PbTx1-10) represent a series of structurally related polyether, lipophilic neurotoxins that are produced by the dinoflagellate *Karenia brevis* and have been implicated in numerous epizootics off the coasts of Florida, Texas, and North Carolina. Brevetoxins also pose a threat to humans as those who consume shellfish contaminated with the toxin can develop Neurotoxic Shellfish Poisoning, a syndrome involving gastroenteritis along with a range of neurological sequelae. Brevetoxin exerts its effects by binding to voltage-gated sodium channels in the brain and maintaining them in an open state, thereby propagating continuous action potentials and causing subsequent excitotoxicity in postsynaptic neurons. Due to brevetoxin's ability to depolarize neurons, this depolarization may be measured using membrane potential-sensitive fluorescent dyes. We have accordingly optimized assay conditions for two such dyes using murine neocortical cells in primary culture. We compared the two dyes, DiBAC and the Membrane Potential Assay Kit (Molecular Devices Inc., blue dye) in an effort to optimize these types of assays for intact neurons. We found with DiBAC, a dye concentration of 2.5  $\mu$ M provided the optimum signal, whereas the blue dye gave the greatest signal at one-half the manufacturer suggested concentration. Using these techniques, we further developed standard conditions that allowed us to quantify the magnitude of PbTx-2-induced depolarization through a comparison to that produced by KCl in neocortical cells. The use of concentrations of brevetoxin and KCl that produce equivalent levels of depolarization will further permit mechanistic studies exploring brevetoxin's influence on neuronal signaling.

## 1101

### BREVENOL, A NATURAL BREVETOXIN ANTAGONIST: COMPETITIVE ANTAGONIST OR ALLOSTERIC MODULATOR?

E. P. Gold<sup>1,2</sup>, H. Jacocks<sup>2</sup>, A. J. Bourdelais<sup>2</sup> and D. G. Baden<sup>2,1</sup>. <sup>1</sup>Biological Sciences, UNCW, Wilmington, NC and <sup>2</sup>Center for Marine Science, UNCW, Wilmington, NC.

Polyether brevetoxins (PbTx<sub>s</sub>) and analogs are bioactive compounds produced by the dinoflagellate *Karenia brevis*, which bind to site 5 of mammalian voltage-gated sodium channels and cause membrane depolarization. Prior studies have also shown that site 5 is allosterically-linked to other receptor sites located on voltage-gated sodium channels. PbTx<sub>s</sub> themselves have been used as tools in neurotoxicology to understand the molecular structure and conformational changes of sodium channels. Brevenal, a natural antagonist of PbTx with a 6-7-6-7-7 ring motif, has been shown to compete for tritiated brevetoxin (<sup>3</sup>H-PbTx-3) binding sites in rat brain synaptosomes (Bourdelais et al., 2004). In this present study, the nature of specific brevenal binding is characterized. Tritium labeled brevenal is produced using tritiated NaBH<sub>4</sub> in the presence of cerium chloride (CeCl<sub>3</sub>) in order to provide a radiolabeled probe for specific receptor binding studies. Brevenal (reduced brevenal), radioactive and unlabeled, were purified using HPLC and the identity of brevenol was confirmed using NMR. Displacement receptor binding studies showed <sup>3</sup>H-brevenol is displaced by brevenal or its analogs. The calculated dissociation constant ( $K_d$ ) for <sup>3</sup>H-brevenol is 4.8nM which correlates favorably with the calculated PbTx  $K_d$  of 1.8nM. Conversely, PbTx-3 was unable to displace <sup>3</sup>H-brevenol from rat brain synaptosomes. Since it has been shown that brevenal exhibits a dose-dependent displacement of <sup>3</sup>H-PbTx-3, we postulate that brevenal may bind to an allosterically-linked receptor site on sodium channels peripheral to site 5. Future research will further characterize the brevenal binding site, a potential new pharmacophore located on voltage-gated sodium channels. Reference: Bourdelais, AJ; Campbell, S; Jacocks, H; Naar, J; Wright, JLC; Carsi, J and DG Baden. Brevenal is a natural inhibitor of brevetoxin action in sodium channel receptor binding assays. *Cell. Mol. Neurobiol.* 2004. 24(4): 553-563.

## 1102

### FEASIBILITY OF CONTINUOUS INTRACEREBRO-VENTRICULAR (ICV) INFUSION IN THE RAT FOR 28 DAYS

K. Tenneson and C. Copeman. *Toxicology, CTBR, Senneville, QC, Canada.* Sponsor: M. Vezina.

This study was performed to determine the feasibility of drug administration by continuous intracerebro-ventricular (ICV) infusion to the Sprague-Dawley rat for 28 consecutive days. Five males and 4 females were cannulated into the lateral ventricle and assigned to the study. Following arrival, CTBR's standard infusion jacket was placed on each animal and an Infusdisk<sup>TM</sup> infusion pump attached to the

jacket using a Velcro® patch. The catheters were filled with 0.9% Sodium Chloride, U.S.P., connected and tucked under the jacket to prevent damage. The infusion rate of 0.03 mL/h was selected based on the available rate of the pump and the rate of CSF production/flow. During the study, the reservoir was changed every 7 days to maximize use of each pump and pre and post weights of the infusate were performed for dose accountability purposes. Clinical signs (daily) and body weights (weekly) were monitored following receipt. Verification of the catheter placement and integrity of the catheter were performed at necropsy. Infusion was considered overall well-tolerated. Infusion-related clinical signs included swelling of the cranium in 2/9 animals, noted between Days 2 and 24, and single occurrences of convulsions when handled (sustained or non-sustained on Days 2 or 13) in 2/9 animals, which were short in duration. While body weights were lower when compared to expected ranges for non-catheterized and catheterized rats of a similar age, percent gain was higher than expected ranges in both sexes. At necropsy, the catheter tip was found in the left ventricle of the brain in 9/9 animals, and the integrity was confirmed in 8/9 animals. Macroscopic changes that could have been related to the experimental procedure (catheterization) were observed subcutaneously along the catheter in the dorsal cervical region and/or dorsal aspect of the head and described as thickening (8/9), swelling (1/9) and/or mass (1/9). In conclusion, continuous intracerebro-ventricular (ICV) infusion in the rat for 28 days was considered to be a feasible design for safety toxicity or efficacy assessments.

**1103** TEMPORAL ANALYSIS OF OPIATE-INDUCED INTRATHECAL GRANULOMATOUS MASSES PROGRESSION AND REGRESSION USING MRI.

J. W. Allen<sup>1</sup>, K. Horais<sup>1</sup>, N. Tozier<sup>1</sup>, J. Corbeil<sup>2</sup>, R. F. Mattrey<sup>2</sup> and T. L. Yaksh<sup>1</sup>. <sup>1</sup>*Anesthesiology, University CA-San Diego, La Jolla, CA* and <sup>2</sup>*Radiology, University CA-San Diego, La Jolla, CA*.

Continuous intrathecal (IT) delivery of morphine sulfate (MS) for 28 days can produce aseptic subdural inflammatory masses (granulomas) localized at the catheter tip. The rate at which these IT masses develop, and if they regress after MS infusions are terminated are unknown. To assess this, we performed serial MRI scans with gadolinium (Gd) enhancement in dogs. Beagle dogs were implanted with chronic IT lumbar catheters and were infused at 0.96 ml/day for 28 days. Dogs received a 100% granuloma inducing concentration of MS (12.5 mg/ml) or the maximum tolerable concentration of fentanyl HCl (2 mg/ml). *Ex vivo* studies with dog dura suggest that MS, but not fentanyl, produce activation of duram mast cell. Before MS infusions, MRI scans were obtained with a Siemens Symphony 1.5 Tesla system while dogs were anesthetized with propofol. Dogs had repeated MRI scans at intervals ranging from 3 to 14 days, for up to 45 days, with IV Gd (Optimark, 0.2 mmol/kg). One group of dogs had saline substituted for MS at the first appearance of a mass by MRI. A second group of dogs continued to receive MS for 28-days, when saline was substituted for MS. On the day of the final scan, 1 ml of Gd (Magnevist) 1:400 in saline was injected IT. With MRI, masses in some MS dogs were apparent as early as 3 days and in all by 14 days. Termination of MS resulted in a rapid regression of the masses. This was greater in dogs receiving MS for 14 days vs. 28 days. Fentanyl did not produce IT granulomas. Repeat MRI scans with propofol anesthesia and IV Gd were well tolerated in dogs with no lasting negative effects noted. Morphine-induced IT masses form and regress quickly. Histology of the masses correlated well with MRI images. Mass size and behavioral were not well correlated but faster growing masses produced greater behavioral signs. IT fentanyl as predicted by lack of dural mast cell activation, did not produce IT masses and may be a therapeutic alternative to MS. Supported in part by DA-15353.

**1104** A COMPARATIVE EVALUATION OF ANIMAL CHARACTERISTICS AND DEVELOPMENT OF CHOROIDAL NEOVASCULARIZATION (CNV) IN A LASER-INDUCED NON-HUMAN PRIMATE MODEL OF MACULAR DEGENERATION.

M. Wills. *Development and Discovery Services, Charles River Laboratories, Sparks, NV*. This study evaluated the relationship of animal characteristics (age, sex, study history, origin and weight) and location of laser lesion to development of CNV. 34 cynomolgus monkeys were evaluated. Laser lesions were placed in the perimacular region. Lesions that developed a clear luminescent circle on fluorescein angiograms were counted as CNV. Animals were divided into age groups (2-5 years and over 5 years) and weight groups (2-3.5 kg and 3.5-5.2 kg). Incidence was compared for males vs. females, naive vs. non-naive and Chinese vs. Indonesian origin. 25/27 animals aged 2-5 years developed CNV. 10/10 animals aged 2-3.5 developed CNV in at least one eye; 15/17 animals aged 3.6-5 years developed CNV in at least one eye. 6/7 animals over the age of 5 developed CNV in at least one eye. 26/29 males developed CNV in at least one eye, 5/5 females develop CNV in at least one eye. 1/19 non-naive animals did not develop CNV in either eye. 2/15 naive animals did not develop CNV at least one eye. 26/28 Chinese animals developed CNV; 5/6

Indonesian animals developed CNV. 18/19 animals weighing 2-3.5 kg developed CNV in at least one eye. 13/15 animals weighing 3.6 to 5.2 developed CNV. There was no clear evidence of age- or weight-related differences in the propensity to develop CNV. An insufficient number of females were available to conclusively determine a sex-related difference, although this has been noted in rodent species. Non-naive animals developed CNV at a similar rate as naive animals, indicating that reuse of animals that have not been on previous ocular studies is acceptable. Laser lesions placed adjacent to or directly above the macula and in lesions placed nasal and superio-nasal to the macula appear to be most likely to develop CNV.

**1105** ALZHEIMER'S DISEASE: THE CYNOMOLGUS MONKEY AS A MODEL IN TOXICOLOGICAL RESEARCH?

E. Buse, G. Habermann, S. Friderichs-Gromoll, J. Kaspareit and P. Nowak. *Covance Laboratories GmbH, 48163 Muenster, Germany*. Sponsor: G. Weinbauer.

Alzheimer's disease describes a human degenerative brain disorder with an age-related increasing incidence. The present work was undertaken to evaluate whether aged cynomolgus monkeys (*Macaca fascicularis*) exhibit alterations indicative of Alzheimer's disease. Twenty animals, aged between 2 and > 20 years, were examined. Specifically, the beta amyloid proteins 1-40 (Ab40) and 1-42 (Ab42) as well as the hyperphosphorylated Tau protein were studied. Examinations were conducted in both cerebrospinal fluid and formalin-fixed and frozen brain tissue. Evaluations considered the 1. similarity of parameters between the cynomolgus monkey and humans, 2. age as a factor relative to the degree of parameter expression and 3. suitability of parameters in toxicological research. With advancing age, progression of Ab42 content and change of the Ab42/Ab40 ratio in cerebrospinal fluid were observed in primates older than 15 years. These proteins were also detected in the brain and were found to be comparable to a great degree with those of ageing human beings. In the respective primate brain tissue, development of plaque burden and Tau pathology were detected using immunocytochemical methods as well as silver and standard staining procedures. Hyperphosphorylated Tau (paired helical filaments) was present in both nerve cells and oligodendrocytes. Furthermore, vascular amyloidosis could also be diagnosed. In conclusion, a close principal relationship of Alzheimer's disease parameters between cynomolgus monkeys and humans was found. The in-life access to humoral parameters via sampling of cerebrospinal fluid during an extended period of the individual primate development, the similarity of primate and human brain pathology, as well as the possibility to histologically confirm the diagnosis post mortem in the primate brain tissue suggest that the cynomolgus monkey can serve as a potential relevant model for development of drugs against Alzheimer's disease.

**1106** EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS (EAE) IN THE FEMALE LEWIS RAT.

S. Rowton and S. Grainger. *Covance Laboratories Ltd., Harrogate, United Kingdom*. Sponsor: D. Everett.

EAE is an established and well-documented animal model used for investigating autoimmune disease of the central nervous system (CNS). In this model, clinical signs exhibited by the animals, histopathology of the CNS and the progression of the disease, are comparable in many ways to multiple sclerosis in humans. EAE can be induced by a number of agents and in several different species and strains of animal. We have validated this model in the female Lewis rat, using whole guinea pig spinal cord and carbonyl iron as the encephalitogenic agent. On Day 1, each rat received a 1mL intraperitoneal injection of guinea-pig CNS material:carbonyl iron (1:1 ratio). On Day 1 to Day 15, rats were dosed intraperitoneally once daily with vehicle, prazosin (4 mg/kg) or cyclosporin (4 mg/kg) in 20% Dalivit (a multivitamin). In addition, a fourth group of rats received 1mL (300mg) of whole guinea pig spinal cord intraperitoneally on Day 3 and 4. Administration of large doses of CNS material was expected to act upon the T cells, suppressing the EAE response by causing the T cells to self-destruct. Animals were observed daily from Day 1 to Day 26 for signs of EAE. All vehicle-treated rats successfully developed EAE (66% exhibited a minimum of a completely limp tail (a score of 23)), followed by spontaneous recovery. EAE signs in this group were first apparent on Day 8, peaked on Day 11 and by Day 17 had completely disappeared. Cyclosporin in Dalivit prevented EAE development in 58% of rats, minimal signs were seen in the remaining animals, with only one animal displaying a completely limp tail (a score of 3). Rats treated with CNS material prevented EAE in 25% of rats, with 50% scoring at least 3. All prazosin-treated rats developed EAE, with 83% scoring 3 or more. Subsequent studies, which examined EAE histopathologically, have shown a close correlation between the degree of perivascular cuffing, leukocyte infiltration and EAE severity in the female Lewis rat. In conclusion, EAE in the Lewis rat provides a useful model to investigate the potential immunosuppressant properties of a compound.

ANALYSIS OF MYELIN LOSS USING SCANNING ELECTRON MICROSCOPY (SEM) UNDER FULLY HYDRATED CONDITIONS: VALIDATION IN A MOUSE MODEL OF EXPERIMENTAL AUTOIMMUNE ENCEPHALITIS.

V. Behar<sup>3</sup>, E. Blaugrund<sup>3</sup>, A. Mayk<sup>3</sup>, E. Raymond<sup>3</sup>, N. Russek<sup>2</sup>, M. Horowitz<sup>2</sup> and A. Nyska<sup>1</sup>. <sup>1</sup>Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC, <sup>2</sup>QuantomiX, Ltd., Ness Ziona, Israel and <sup>3</sup>Research & Development, Teva Pharmaceuticals Ltd., Sapir Industrial Zone, Israel.

Experimental allergic encephalomyelitis (EAE), induced in the Biozzi AB/H (anti-body high) mouse by sensitization with spinal cord homogenate (SCH) in adjuvant, is a model for the human disease of multiple sclerosis (MS). Histopathologically, the disease is characterized by inflammation and axonal degeneration. We investigated the utility of a newly developed technology of scanning electron microscopy (SEM) designed for analysis of fully wet tissue specimens. We used 21, 7-9-wk-old Biozzi female mice; 5 were untreated, and in the other 16, relapsing remitting (RR) EAE was induced. Animals were sacrificed 60 days after disease induction. The clinical signs were scored, and following deep anesthesia and perfusion, spinal cord tissues were dissected out and processed either for conventional histopathology or analysis by wet SEM. Histologic evaluation was performed on H&E-stained sections cut adjacent to those analyzed by wet SEM. Four anatomical sides (dorsal, lateral right, lateral left, ventral) of the spinal cord (SC) white-matter were viewed at X400, and in each side, two fixed areas of interest, each one of 90, 000 micron<sup>2</sup> were selected at random and photographed. The relative number of axons having rings with irregular thickness and fragmentation or loss of myelin sheath was scored. Our investigation indicated that the wet SEM methodology rendered myelin sheaths, axons, and inflammatory cells simple to differentiate. The identity of normal and pathological components was confirmed and correlated by light microscopy. We conclude that the wet SEM technology provides a quick, accurate, and detailed structural evaluation of the SC and can be applied as a routine test for potential new MS therapies.

NEONATAL/PREPUBERTAL EXPOSURE TO BUTYL BENZYL PHTHALATE, BUT NOT BISPHENOL A, CAUSES SUBTLE ALTERATIONS TO THE RAT FEMALE REPRODUCTIVE TRACT.

C. A. Lamartiniere and E. Abdalla. *Pharmacology and Toxicology, University Alabama at Birmingham, Birmingham, AL.*

Exposure to environmental chemicals during critical periods of early development may play an important role in cancer susceptibility later in life. We hypothesized that exposure to estrogenically-active chemicals alone, and in combination, during early critical periods of development will alter predisposition for breast cancer. We exposed rats to bisphenol A (BPA) or butyl benzyl phthalate (BBP) during the neonatal/prepubertal periods only. Lactating dams were gavaged with 250 ug BPA/kg body weight (BW) or 500 mg BBP/kg BW or an equivalent volume of the vehicle (sesame oil) on days 1-21 (Mondays-Fridays only). On day 21, offspring were weaned and the treatments were discontinued. Mammary tissue was collected for genomic, proteomic, gland differentiation and cell proliferation analysis. Here, we report on morphometric determinations. Neonatal/prepubertal exposure to BBP, but not to BPA, resulted in precocious vaginal opening compared to controls. Also, neonatal/prepubertal exposure to BBP resulted in 3/14 female rats as compared to 1/14 in control or PBA exposed rats to have irregular estrous cycles (diestrus phase). Neonatal/prepubertal exposure to BPA and BBP did not significantly alter BWs or uterine wet weights at 21, 35, 50 or 100 days from controls. However, when the data was expressed as uterine to BW ratio BBP-, but not BPA-, exposed females had significantly increased ratio at day 21 only. These results demonstrate that neonatal/prepubertal exposure to BBP, but not to the selected dose of BPA, resulted in subtle alterations to the developing female offspring. It will be interesting to see how these treatments will affect genomics, proteomics, gland morphology and cell proliferation in the mammary gland of the developing offspring, and susceptibility for mammary cancer.

THE ARYL HYDROCARBON RECEPTOR (AHR) IS REQUIRED FOR NORMAL OVULATION IN THE MOUSE.

D. Tomic, C. Greenfeld, J. K. Babus and J. A. Flaws. *Epidemiology, University of Maryland School of Medicine, Baltimore, MD.*

The AhR is ligand-activated transcription factor that mediates the toxicity of a variety of environmental chemicals. Although little is known about the physiological role of the AhR, studies suggest that it might play an important role in female reproduction. Female AhR deficient (AhRKO) mice have impaired folliculogenesis and reduced fertility compared to wild-type (WT) mice. Because alterations in folliculogenesis can affect the ability to ovulate, the objective of this study was to test

the hypothesis that AhR deficiency interferes with the ability of follicles to grow to the ovulatory stage and to ovulate in response to gonadotropin treatment. To test this hypothesis, WT and AhRKO mice were dosed with the pregnant mare serum gonadotropin (PMSG; 5 IU) to induce follicular growth and after 72 hours, ovaries were collected and processed for histological evaluation of the number of corpora lutea (an indicator of ovulations). In addition, WT and AhRKO mice were dosed with PMSG (5 IU) to induce follicular growth and after 48 hours, the mice were dosed with either 2.5 or 5 IU of human chorionic gonadotropin (hCG) to induce the ovulation. After 24 hours, oocytes were collected from the oviducts and counted. The data indicate that AhRKO ovaries contain fewer corpora lutea compared to WT ovaries after PMSG treatment (WT=6.5±0.4, AhRKO=3.2±0.8, n=5, p≤0.02), suggesting that AhRKO ovaries have a reduced capacity to ovulate compared to WT ovaries in response to PMSG. The data also indicate that both WT and AhRKO mice ovulate similar numbers of eggs in response to 5 IU hCG, but that AhRKO mice ovulate fewer eggs than WT mice in response to 2.5 IU hCG (WT=25.8±2.0, AhRKO=18.2±1.2, n=5, p≤0.02), suggesting that AhRKO ovaries are less sensitive to gonadotropins than WT ovaries. Collectively, these data indicate that AhRKO follicles have a reduced capacity to ovulate compared to WT follicles. Thus, in addition to mediating toxicity of environmental chemicals, the AhR is required for normal ovulation. (Supported by NIH HD38955 and T32HD07170)

EFFECTS OF ESTROGEN RECEPTOR MODULATORS ON UTERINE PATHOLOGY AND GENE EXPRESSION.

D. T. Gray<sup>1</sup>, J. A. Styles<sup>1</sup>, P. Greaves<sup>2</sup> and I. N. White<sup>1</sup>. <sup>1</sup>Cancer Studies and Molecular Medicine, MRC Molecular Endocrinology Group, Leicester, United Kingdom and <sup>2</sup>MRC Toxicology Unit, University of Leicester, Leicester, United Kingdom. Sponsor: A. Smith.

Tamoxifen, a selective estrogen receptor modulator (SERM), is an effective treatment for breast cancers. In the CD-1 mouse model, neonatal oral dosing with tamoxifen leads to the development of adenomyosis. Subcutaneous dosing with tamoxifen or 4-hydroxyestradiol leads to adenocarcinomas after 12 to 18 months. Both 4-hydroxyestradiol and tamoxifen can form DNA-reactive metabolites and may be involved in carcinogenesis of the uterus. We compared the uterotrophic response of these compounds and their effects on uterine pathology and gene expression. 14-day-old CD-1 female mice were orally dosed daily for 3 days with estradiol benzoate (1-100µg/kg), tamoxifen (250-5000µg/kg), or 4-hydroxyestradiol (76.3-1920µg/kg). After 4 days uterine weights were recorded, then sections processed for PCNA staining. Maximal uterotrophic doses for weight increase over controls (fold change ± s.d.) were: estradiol (100µg/kg) 2.6 ± 0.003, 4-hydroxyestradiol (385µg/kg) 6.7 ± 0.03 and tamoxifen (250µg/kg) 2.6 ± 0.005. PCNA staining showed maximal cell proliferative effects at this time were not related to uterine weight increases. Estradiol inhibited the development of glandular epithelium, whereas tamoxifen was able significantly to increase the number of glands. Maximal uterotrophic dose of estradiol (100µg/kg) was given orally to newborn CD1 mice on days 2 to 5 after birth and gene and pathological changes examined in the uterus at 3 months after dosing. No adenomyosis was seen. Gene expression changes showed up-regulation of typical estrogenic response genes including *actb*, *sp1* while other genes such as *ngfa* and *spp1* were down-regulated. This study shows that neonatal estradiol treatment brings about long-term changes in gene expression in the absence of apparent pathological changes.

THE ARYL HYDROCARBON RECEPTOR (AHR) REDUCES EXPRESSION OF ENZYMES IN THE ESTROGEN BIOSYNTHESIS PATHWAY.

C. B. Mainor<sup>1</sup>, K. Barnett<sup>2</sup>, D. Tomic<sup>2</sup> and J. Flaws<sup>2</sup>. <sup>1</sup>University of Maryland Baltimore County, Baltimore, MD and <sup>2</sup>University of Maryland School of Medicine, Baltimore, MD.

The AhR is a ligand-activated transcription factor that mediates the toxic effects of environmental contaminants. Previous studies have shown that AhR deficient (AhRKO) mice have reduced fertility compared to wild-type (WT) mice. The reduced fertility in AhRKO mice is due, in part, to a reduced number of ovarian antral follicles and reduced levels of estradiol (E2). The reasons that AhRKO mice have decreased levels of E2 are unknown, however, it is possible that they stem from defects in estrogen biosynthesis. During estrogen biosynthesis, cholesterol is taken across the mitochondrial membrane by the steroidogenic acute regulatory protein (StAR). Cholesterol is then converted into androgens and finally into E2 by a series of enzymes including cytochrome P450 side chain cleavage (CYP 450ccc), CYP17α (CYP 17), aromatase, 17-beta hydroxysteroid dehydrogenase (17β-HSD), and 3-beta hydroxysteroid dehydrogenase (3β-HSD). To determine whether levels of these enzymes are altered in AhRKO ovaries compared to WT ovaries, ovaries were collected from WT and AhRKO mice on postnatal day (PD) 90. Total RNA was extracted, reverse transcribed to cDNA, and subjected to both semi-quantitative and real time polymerase chain reaction (PCR). The results show that

the levels of P450scc, 3 $\beta$ -HSD, and 17 $\beta$ -HSD were similar in WT and AhRKO ovaries (n=3). In contrast, real-time PCR analysis shows that the levels of CYP17 in AhRKO ovaries were lower than those of WT ovaries (WT=1.23 $\pm$ 0.02, AhRKO=0.05 $\pm$ 0.0005 genomic units, n=3, p<0.0001). Further, the levels of StAR were lower in AhRKO ovaries compared to WT ovaries (WT=0.7 $\pm$ 0.09, AhRKO=0.38 $\pm$ 0.06 genomic units, n=5, p<0.02). Collectively, these data suggest that AhR deficiency reduces the levels of key steroidogenic enzymes in the mouse ovary. Support provided by the Howard Hughes Medical Institute Undergraduate Scholars Program at UMBC, HHMI Foundation, and NIH grants GM072195-01 and NIH HD38955.

## 1112 THE ARYL HYDROCARBON RECEPTOR (AHR) REGULATES OVARIAN FOLLICLE GROWTH *IN VITRO*.

K. Barnett, D. Tomic and J. Flaws. *University of Maryland School of Medicine, Baltimore, MD.*

The AhR plays an important role in mediating the toxicity of various environmental toxicants that cause adverse effects on the development and function of the female reproductive tract. Studies using AhR-deficient (AhRKO) mice have shown that the AhR has an important physiological role in the mouse ovary. Previous studies in our lab have demonstrated that AhRKO ovaries have a decreased number of antral follicles compared to wild-type (WT) ovaries. Since our previous studies also indicate that AhR deficiency does not affect atresia (follicle death via apoptosis) of antral follicles, the purpose of these studies was to determine whether AhR deficiency reduces follicle numbers by slowing follicular growth. Further, since antral follicles produce estradiol (E2) and E2 is required for normal follicular growth, these studies also tested whether AhR deficiency results in decreased synthesis of E2 by antral follicles. To test these hypotheses, antral follicles were isolated from AhRKO and WT ovaries and cultured for 168 hours. During culture, follicle growth was assessed by daily measurements of follicular diameter. After culture, media was collected and E2 levels were measured using an enzyme-linked immunoassay (ELISA). AhRKO and WT ovaries were also subjected to measurements of proliferation using immunohistochemistry (IHC) for proliferating cell nuclear antigen (PCNA) antibody. Our results show that WT follicles grew significantly larger than AhRKO follicles by 168 hours of culture (WT: 615.5 $\pm$ 17.15 mm; AhRKO: 489 $\pm$ 17.03 mm; p<0.001; n=3 mice per genotype, 10 follicles per mouse). The results also show that WT follicles produced significantly more E2 compared to AhRKO follicles (WT: 2463 $\pm$ 508 pg/ml, n=15 follicles; AhRKO: 971 $\pm$ 316 pg/ml, n=9 follicles; p=0.007). Further results from IHC show that AhRKO follicles had less PCNA staining in granulosa cells compared to WT follicles. These data suggest that in addition to mediating toxicity of environmental chemicals, the AhR is an important regulator of ovarian follicle growth and E2 production. Supported by NIH grants GM072195-01, HD38955, and R25-GM55036.

## 1113 ACTIVATION OF TH1 PRO-INFLAMMATORY CYTOKINE EXPRESSION BY ARYL HYDROCARBON RECEPTOR (AHR) LIGANDS IN HUMAN UTERINE ENDOMETRIAL CELLS.

K. Shiverick<sup>1</sup>, T. Medrano<sup>1</sup>, N. Chegini<sup>2</sup> and M. James<sup>3</sup>. <sup>1</sup>*Department of Pharmacology & Therapeutics, University of Florida, Gainesville, FL*, <sup>2</sup>*Department of Obstetrics & Gynecology, University of Florida, Gainesville, FL* and <sup>3</sup>*Department of Medicinal Chemistry, University of Florida, Gainesville, FL*.

The environmental contaminants polychlorinated biphenyls and dioxins are known to modulate immune function and have been linked to infertility, uterine disease and low birth weight in animal and human studies. This study used the human uterine endometrial adenocarcinoma RL95-2 cell line as a model for investigation of the effects of prototype environmental organochlorines on pro-inflammatory Th1 cytokine expression. Cells were cultured in the presence of three coplanar ligands for the aryl hydrocarbon receptor (AhR), 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), poly-chlorobiphenyl CB-77 (3, 3■, 4, 4■) and CB-126 (3, 3■, 4, 4■, 5), respectively, as well as the AhR non-ligand CB-153 (2, 2■, 4, 4■, 5, 5■). Analysis of mRNA levels by quantitative real-time PCR showed that TCDD, CB-77 and CB-126 significantly increased expression of IL-1 $\alpha$ , IL-1B, and IL-8. The AhR antagonist alpha-naphthoflavone (aNF) partially or completely blocked the PCB-126 mediated-induction of IL-1 $\alpha$ , IL-1B and IL-8. In this regard, the chemokine IL-8 is known to be a key attractant for cells during inflammatory immune responses. An ELISA assay for IL-8 showed that the three AhR ligands significantly increased IL-8 secreted protein levels, which was found to be suppressed by aNF, the AhR antagonist. In addition, a correlation was observed between CYP1A1 protein levels and IL-8 secretion for TCDD and 9 PCB congeners, including several hydroxy-metabolites. In summary, the AhR appears to mediate coordinate changes in the expression of multiple pro-inflammatory cytokines in the RL95-2 uterine endometrial cell line. A shift to enhanced expression of pro-inflammatory Th1 cytokine pathways by AhR ligands may be a fundamental mechanism for adverse reproductive effects associated with infertility and uterine disease. (Supported by NIH ES07375)

## 1114 STIMULATORY AND INHIBITORY EFFECTS OF GENISTEIN ON UTERINE LEIOMYOMA CELL GROWTH *IN VITRO* IS DETERMINED BY DOSE.

L. Castro, A. Moore, L. Yu, C. Bortner, M. Sifre, R. Newbold and D. Dixon. *NIEHS, Research Triangle Park, NC.*

Genistein, a phytoestrogen, is largely found in soy products commonly consumed by women in the USA. Due to dietary exposure of women to genistein and the estrogen responsiveness of a common gynecologic tumor of women, uterine leiomyoma (UtLM) "fibroid", we were interested in determining the response of cultured UtLM cells to genistein. We evaluated the effects of genistein (0, 0.001, 0.01, 0.1, 1, 10, 50 and 100  $\mu$ g/ml) on the growth, morphology and cell cycle progression of UtLM cells compared to normal uterine smooth muscle cells (UtSMC) following 24h and/or 7 days of treatment. Also, analysis of DNA content by flow cytometry was done to determine whether UtLM cell growth was altered due to apoptosis. We found that overall low doses of genistein (0.001, 0.1, and 1  $\mu$ g/ml) had a significant (p<0.01) stimulatory effect on the growth of UtLM cells, but not UtSMC; whereas, 10, 50, and 100  $\mu$ g/ml genistein significantly (p<0.01) inhibited UtSMC and UtLM cell growth. Morphologically, all cells given higher concentrations of genistein were fewer in number and had decreased cytoplasm and small nuclei. At lower concentrations cells maintained their normal elongated appearance. Cell cycle analysis of UtLM cells treated with 1  $\mu$ g/ml genistein for 24h showed an increase in the percentage of cells in the S phase compared to controls; however, at 50  $\mu$ g/ml genistein, there was a higher percentage of cells in the G2/M phase with decreased number of cells in the G1 phase compared to low dose and control groups. These effects were not seen with UtSMC. There was a 2.4-fold increase in the percentage of apoptotic cells detected in UtLM cells exposed to 50  $\mu$ g/ml genistein for 24h compared to controls. In summary, low doses of genistein stimulate UtLM tumor cell growth, but have no effect on normal UtSMC. At high doses, genistein has an inhibitory effect on both cell types. The inhibition observed with high doses of genistein in the UtLM cells may be due, in part, to altered progression of cells through the cell cycle and increased apoptosis.

## 1115 SUPEROXIDE ANION, HYDROGEN PEROXIDE, AND HYDROXYL RADICALS IN CIGARETTE SMOKE INHIBIT HAMSTER OOCYTE CUMULUS COMPLEX PICKUP.

C. Gieseke, R. Pederson and P. Talbot. *Cell Biology and Neuroscience, University of California, Riverside, Riverside, CA.* Sponsor: B. Krieger.

The hamster oviduct and oocyte cumulus complex (OCC) are targets of cigarette smoke. Pickup of the OCC by the ciliated oviduct is inhibited in hamsters during acute *in vitro* exposures of oviducts or OCCs to mainstream and sidestream smoke solutions. Smoke solutions inhibit OCC pickup by increasing adhesion between the OCC and oviduct. Cigarette smoke generates many reactive oxygen species including superoxide anion, hydrogen peroxide, and the hydroxyl radical. Our initial studies showed that superoxide anion and hydrogen peroxide are at least partially responsible for inhibiting OCC pickup. The antioxidants, superoxide dismutase and/or catalase, protected the hamster oviduct and oocyte cumulus complex from the inhibitory effects of cigarette smoke on OCC pickup rate and adhesion. When oviducts or OCCs were exposed to mainstream or sidestream whole, gas, or particulate smoke solution plus either superoxide dismutase or catalase, most adverse effects on OCC pickup rate and adhesion were eliminated. Mannitol, a hydroxyl radical scavenger, was used to determine if inhibition of OCC pickup was due to the direct action of superoxide anion or hydrogen peroxide or was due to their role in the formation of hydroxyl radicals. When oviducts were exposed to mainstream particulate, sidestream particulate or sidestream whole smoke solutions plus mannitol, the adverse effects on both OCC pickup rate and adhesion were eliminated. Mannitol also eliminated the adverse effect of mainstream whole on adhesion, but not OCC pickup rate. When OCCs were exposed to smoke solutions plus mannitol, the adverse effects of mainstream whole, mainstream particulate, sidestream whole, and sidestream gas on OCC pickup rate and adhesion were eliminated. Mannitol also eliminated the adverse effect of mainstream gas on adhesion, but not OCC pickup rate. These results clearly show that the hydroxyl radical is a major contributor to the adverse effect that cigarette smoke has on OCC pickup.

## 1116 CHARACTERIZING THE OVOTOXICITY OF CYCLOPHOSPHAMIDE METABOLITES ON CULTURED MOUSE OVARIES *IN VITRO*.

P. J. Devine. *Institut Armand-Frappier, Institut national de la recherche scientifique, Pointe Claire, QC, Canada.*

Toxic metabolites of cyclophosphamide (CP), a chemotherapeutic agent, are reported to target dormant primordial ovarian follicles in rodents and humans. Such damage is permanent, because this oocyte population cannot be replenished. CP is

activated by the liver to 4-hydroxy-CP, which spontaneously forms acrolein (ACR) and the ovotoxicant, phosphoramide mustard (PM). In order to investigate the specificity of PM-induced follicle loss, the sensitivity of ovaries in an *in vitro* system was characterized. Multiple products of CP were added to *in vitro* tissue cultures of intact postnatal-day-4 mouse ovaries on d0 of culture. Chemicals were removed on d2, cultures were continued until d8, then histology and follicle counts were done on each ovary. Whereas small numbers of follicles were continuously activated to grow and develop up to the secondary follicle stage in these ovaries, approximately 70% of all follicles remained dormant throughout the culture period. Exposures to either 4-hydroperoxy-CP (an activated form of 4-hydroxy-CP) or PM specifically depleted primordial and smallest primary follicles in a concentration-dependent manner ( $\geq 3\mu\text{M}$ ,  $p < 0.05$  for both), but did not alter populations of larger primary or secondary follicles ( $p > 0.05$ ). Follicle loss also occurred in unexposed ovaries cultured next to those exposed to 10 $\mu\text{M}$  PM, implicating a volatile breakdown product. PM-induced follicle loss became significant ( $p < 0.05$ ) by d2 or d6 following exposures to 10 $\mu\text{M}$  or 3 $\mu\text{M}$  PM, respectively. In contrast to PM, toxicity of ACR (1-100 $\mu\text{M}$ ) did not specifically deplete ovarian follicles, even when exposures were continued throughout the 8d culture. Thus, results suggest that 1) brief exposures to 4-hydroperoxy-CP or PM are sufficient to induce permanent follicle loss in ovaries, 2) that PM and/or a volatile breakdown product are likely the ultimate ovotoxicant, and 3) this *in vitro* system mimics effects reported *in vivo*. Further, the equal sensitivity of ovaries to 4-hydroperoxy-CP and PM suggests little detoxification of 4-hydroperoxy-CP occurred in ovarian cultures.

## 1117

### EFFECTS OF BUTHIONINE SULFOXIMINE TREATMENT ON THE EXPRESSION OF GLUTAMATE CYSTEINE LIGASE SUBUNITS IN THE RAT OVARY.

Y. D. Hoang<sup>1</sup>, A. P. Avakian<sup>2</sup> and U. Luderer<sup>2,1,3</sup>. <sup>1</sup>Community and Environmental Medicine, University of California Irvine, Irvine, CA, <sup>2</sup>Medicine, University of California Irvine, Irvine, CA and <sup>3</sup>Developmental and Cell Biology, University of California Irvine, Irvine, CA.

Glutathione (GSH), an antioxidant tripeptide, is found in moderately high levels in the ovary. GSH is important for detoxifying reactive oxygen species and exogenous chemicals. Its synthesis occurs in two steps, the first of which is controlled by the rate-limiting enzyme, glutamate cysteine ligase (GCL). GCL is a heterodimer consisting of a catalytic (GCLc) and modulatory (GCLm) subunit. Buthionine sulfoximine (BSO) depletes GSH by blocking the active site on GCL, inhibiting GSH synthesis. BSO treatment up-regulates GCL subunit expression in several cell culture models. We therefore hypothesized that BSO treatment would increase ovarian mRNA and protein levels of the GCL subunits *in vivo*. Adult female cycling Sprague-Dawley rats were given either BSO (5 mmol/kg) in saline vehicle or saline alone intraperitoneally on proestrous morning, and ovaries were harvested 8, 12, or 24 hours following a single injection or 12 h after two injections administered 12 h apart. Ovarian GSH concentrations were depleted by about 50% at 8h after a single dose of BSO and increased gradually at subsequent time points. Northern analysis showed that GCLc and GCLm mRNA levels were slightly increased at 8h after BSO ( $p < 0.05$ ), but there was no significant effect of BSO at the other time points. Western analysis showed no significant increases in GCLc or GCLm protein at 8, 12, or 24 h after a single injection of BSO. However, there was a modest, statistically significant increase in GCLc protein 12h after a second BSO injection. GCL enzymatic activity was not significantly increased at 24h after a single BSO injection compared to controls. These data indicate that the ovary is minimally able to up-regulate GSH synthesis in response to GSH depletion by BSO. This work was supported by NIH K08 ES10963.

## 1118

### CUMULATIVE EFFECTS OF THIRAM AND AMITRAZ ON PREGNANCY MAINTENANCE AND DEVELOPMENT IN THE RAT.

D. S. Best, M. G. Narotsky and R. L. Cooper. Reproductive Toxicology Division, USEPA, ORD, NHEERL, Research Triangle Park, NC. Sponsor: T. Stoker.

Amitraz and thiram are pesticides that have been shown to disrupt luteinizing hormone (LH) secretion in rats, albeit by different mechanisms. Amitraz acts via  $\alpha$ -noradrenergic antagonism; whereas thiram inhibits norepinephrine synthesis. Here, we sought to evaluate the cumulative effects of amitraz and thiram on pregnancy maintenance when administered during the LH-dependent period of pregnancy (days 7-10). To assess dose additivity, in Experiment 1, F344 rats were administered amitraz at 40 mg/kg (A40), thiram at 25 mg/kg (T25), or the two combined (AT-high) at 20 and 12.5 mg/kg, respectively, by gavage on gestation days (GD) 6-10. Controls received vehicle (1% methylcellulose). In Experiment 2, all doses were halved to yield treatments of A20, T12.5, and AT-low (A10 + T6.25). Tail-blood samples were taken from selected dams for assay of serum LH. Litters were examined on postnatal days (PD) 1 and 6. Full-litter resorption (FLR) was observed in 23 (79%), 8 (33%), and 18 (64%) of the dams in the A40, T25, and AT-high

groups, respectively, and in 7 (41%), 3 (25%), and 1 (7%) of the dams in the A20, T12.5, and AT-low groups, respectively. One (5%) control dam had full-litter loss, but, unlike the other cases, the loss appeared to occur near term. Reduced serum LH levels were observed on GD 10 in A40, T25, and AT-high dams with FLR, and in A40 dams with live litters. For dams with surviving litters, delayed parturition was noted in the A40, T25, and AT-high groups. Surviving A40 litters had increased resorption rates and increased incidences of eye defects (microphthalmia, anophthalmia). Pup weights were reduced on PD 1 at A40 and T25. Thus, both chemicals, alone and in combination at the high doses, caused FLR and delayed parturition; these findings are consistent with dose additivity. Whereas the low doses of each chemical alone also caused FLR, dose additivity was not clearly demonstrated by the AT-low combination. [This abstract does not necessarily reflect EPA policy.]

## 1119

### DIBROMOACETIC ACID ATTENUATES A DITHIOCARBAMATE-INDUCED SUPPRESSION OF THE LH SURGE IN THE RAT.

J. M. Goldman, A. S. Murr, A. R. Buckelew, W. McElroy and J. M. Ferrell. *Endocrinol. Br., RTD, NHEERL, ORD, USEPA, Res. Triangle Pk., NC.* Sponsor: A. Cummings.

Elevated concentrations of the haloacetic acid, dibromoacetic acid (DBA) can act as a reproductive toxicant in male and female rats. One effect in females is an increase in serum estradiol (E2) that may be due to a suppression in hepatic catabolism. In the rat, the normal rise in E2 beginning on diestrus up-regulates the brain mechanisms involved in triggering the proestrous luteinizing hormone surge (LH-S) that stimulates the process of ovulation. The present study investigated whether DBA is able to augment the LH-S and affect the established ability of the neurotoxicant sodium dimethylthiocarbamate (DMDC) to block the surge in ovariectomized (ovx), steroid-primed rats. Two experiments were performed: (1) to establish a dose-related DMDC suppression in the surge under exposure to a single concentration of DBA (60 mg/kg) & (2) to determine a dose-related effect of DBA combined with a single dose of DMDC. Young-adult S-D rats were gavaged daily for 2 wks with DBA. They were ovx on d11 and implanted with an estradiol benzoate capsule to generate daily LH-Ss. DMDC was injected i.p. on d14 (1300h) & blood sampled at 1400, 1600, 1800 & 2000h. DMDC (range 0-0.2 mM) caused a dose-related suppression in the surge. As a result, 0.1 mM DMDC was employed in Exp. 2, using DBA doses of 0, 37.5, 75 or 150 mg/kg. Since the areas under the LH curve (AUC) over the sampling times for the two lower doses (0 & 37.5 mg/kg) were almost identical, as were the AUC for the 2 higher doses (75 & 150 mg/kg), they were combined, forming high & low DBA groups that were significantly different from one another. Also, the number of rats showing a detectable LH-S was increased at 150 mg/kg. At 150 DBA/0.1 DMDC, the timing of an identifiable LH peak was comparable to non-DMDC females, unlike the 37.5 DBA/0.1 DMDC group. The results indicate that DBA can cause an attenuation in a dithiocarbamate blockade of the LH-S via a likely augmentation in the E2-associated up-regulation in the brain mechanisms stimulating the surge. (This abstract does not reflect USEPA policy)

## 1120

### A SINGLE DOSE OF 8-METHOXYPSORALEN REDUCES LUTEINIZING HORMONE LEVELS IN FEMALE RATS.

M. M. Diawara<sup>1</sup> and P. B. Hoyer<sup>2</sup>. <sup>1</sup>Biology, Colorado State University-Pueblo, Pueblo, CO and <sup>2</sup>Physiology, University of Arizona, Tucson, AZ.

Although mammalian females are endowed with a large supply of primordial follicles at birth, only a limited number of these follicles reach the antral stage for ovulation. Several environmental chemicals, including the psoralsen, have been shown to further deplete this pool of follicles that reach ovulation. The psoralsen occur naturally in plants. Further, synthetic forms of 8-methoxysoralen (8-MOP or methoxsalen) are used in combination with UVA irradiation to treat the skin condition psoriasis in the medical procedure referred to as PUVA. This drug has been implicated in a number of adverse reproductive effects in the female Wistar rat including decrease in ovulations, number of corpora lutea, levels of circulating 17 $\beta$ estradiol, granulosa cell population in antral follicles, and decrease in weights of the pituitary, ovaries, and full as well as empty uteri. This study was initiated to test the hypothesis that 8-MOP compromises reproduction in adult female rats by affecting the hypothalamic-pituitary axis. Thus, the effects of 8-MOP on circulating levels of gonadotropins were monitored during the post-dosing period. Adult female Wistar rats were given 200 mg/kg of 8-MOP (i.p.) or DMSO vehicle during diestrus and monitored at 6-hour intervals for up to 30 hours (6, 12, 18, 24, and 30 hrs). At those time points, rats were euthanized if they were in proestrus. Serum was collected to quantify levels of luteinizing hormone (LH) and follicle stimulating hormone (FSH). Exposure to 8-MOP significantly reduced LH production by female rats at 6 hours after dosing (18.65 ng/mL, 8-MOP, n = 10; 31.75 vehicle control, n = 6;  $p < 0.05$ ) and 12 hours after dosing (15.78 ng/mL, 8-MOP, n = 5; 21.95, control vehicle, n = 4;  $p < 0.05$ ). Dosing did not significantly affect FSH levels at these time points. The reduction in LH production is consistent with our previous

reports suggesting that 8-MOP induces an effect on the pituitary with a subsequent disruption of the pituitary-hypothalamic-ovarian axis. (Supported by NIH grant # 2S06 GM008197-20 MPRC-B to MMD)

## 1121 EFFECTS OF FEED RESTRICTION ON FERTILITY AND EARLY EMBRYONIC DEVELOPMENT IN FEMALE RATS.

M. S. Gilman, T. L. Fleeman, R. E. Chapin, M. E. Hurtt and K. K. Terry.  
*Pfizer Global Research & Development, Pfizer Inc., Groton, CT.*

Pharmaceuticals intended to reduce appetite and promote weight loss will generate safety data that will be challenging to interpret. To aid with this, the effects of feed restriction on rat fertility and early embryonic development were investigated. Purina Certified Rodent Diet 5002 was provided to female Sprague-Dawley rats (~60 days old and weighing ~200 g, n=20) ad libitum (control), 20, 15, 10, or 7.5 g/day (g/d). This feeding paradigm was administered 14 d prior to mating, during mating, and ended on gestation day (GD) 7 (plug/sperm positive=GD 0). From GD 8-14, ad libitum diet was provided to animals in all groups. On GD 14, uterine contents were evaluated. Vaginal cytology was analyzed daily up to GD 0 to monitor estrous cycle progression. For the 14 d of premating, control rats consumed ~21 g/d. On d 7, mean body weights in the 20, 15, 10, and 7.5 g/d groups were reduced by 5%, 12%, 18%, and 21% compared to control, respectively. On d 14, mean body weights were reduced by 5%, 16%, 27%, and 33% compared to control in those same respective groups. During the premating period, estrous cycle length was unchanged in groups receiving  $\geq 15$  g/d. In the 10 and 7.5 g/d groups, persistent diestrus reduced the number of occurrences of estrus by 16% and 45%, respectively. By d 14, all animals receiving 7.5 g/day were moribund and were euthanized. Mean time to mate, copulation and pregnancy rates were unaffected in the 20 and 15 g/d groups. At 10 g/d, mean time to mate was 3.6 times longer than control, and copulation and pregnancy rates decreased by ~40%. Control rats consumed ~28 g/d from GD 0-7. Compared to the control, mean body weight gain from GD 0-7 was reduced by 76% in the 20 g/d group, and body weight loss occurred in groups receiving 15 and 10 g/d. These data indicate an adverse effect on female rat fertility when food consumption was  $\leq 50\%$  of ad libitum values. When consumption remained  $> 50\%$  compared to ad libitum, maternal body weight gain was negatively impacted although fertility was unaffected.

## 1122 LATE GESTATIONAL ATRAZINE EXPOSURE ALTERS MATERNAL NURSING BEHAVIOR IN RATS.

J. L. Rayner<sup>1</sup> and S. E. Fenton<sup>2</sup>. <sup>1</sup>DESE, UNC-Chapel Hill, Chapel Hill, NC and <sup>2</sup>RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.

Atrazine, ATR, is a widely used herbicide shown to delay early mammary development and reduce body weight in female offspring of exposed Long Evans (LE) rat dams. To determine if ATR affects maternal behavior, dams were gestationally dosed and evaluated following parturition. Timed-pregnant LE rats were gavaged gestational days (GD) 17-19, 15-19, or 13-19 with 100 mg ATR/kg body weight (BW), an environmentally based mixture (EBM) of ATR and its metabolites (8.7 mg/kg total, 25% ATR) GD13-19, or vehicle (controls, C) GD13-19 (these treatments shown to have no effect on fetal weight). Pup BW was recorded on postnatal days (PND) 4 and 11 (analyzed by litter). By PND 4, female pup BW in ATR GD17-19 and 13-19 groups were decreased from control ( $p < 0.001$ ), and male pup BW in EBM, and ATR GD17-19 and 13-19 groups were decreased from control ( $p < 0.02$ ), leading us to believe there may be an effect of ATR on lactation. To assess maternal nursing behavior on PND 11, dams were removed from their litters for 3 hours to allow for milk accumulation. Pups were weighed immediately before dams were placed back with their litters. Pups in all groups were allowed to suckle for 30 consecutive minutes and then removed from their dam for weighing. Dams were sacrificed immediately. Maternal behavior was defined as crouching on litters for nursing, in an arched-back position. There was a significant effect of treatment on this maternal behavior, ( $p < 0.001$ ). Dams exposed to 100 mg/kg ATR GD17-19 and 15-19 took more than 2- and 3-fold longer to nest upon their litters, respectively, than control dams ( $p < 0.005$ ). Female pup BW in the ATR GD13-19 group was still decreased from control ( $p < 0.001$  pre-suckling,  $p < 0.02$  post-suckling). These results show that brief gestational exposures to ATR can alter maternal behavior specifically related to nursing. (This abstract is of a proposed presentation and does not reflect EPA policy; Supported by NHEERL-DESE, USEPA CT826513.)

## 1123 PERIPHERAL BENZODIAZEPINE RECEPTOR LIGAND PK11195 AFFECTS FEMALE FERTILITY AS DEMONSTRATED IN AN IN-VITRO MOUSE FOLLICLE BIOASSAY.

E. Gobbers<sup>1</sup>, K. Van Wemmel<sup>1</sup>, J. Smits<sup>2</sup> and R. Cortvriendt<sup>1,2</sup>. <sup>1</sup>EggCentris NV, Zellik, Belgium and <sup>2</sup>Follicle Biology Laboratory, Vrije Universiteit Brussel, Brussels, Belgium. Sponsor: R. De Coster.

The isoquinoline carboxamide PK11195 is a high affinity ligand of the peripheral benzodiazepine receptor (PBR) with potential anti-inflammatory properties. PBR are expressed in the somatic compartment of the ovary and play a role in the regu-

lation of steroidogenesis. To investigate possible effects of PK11195 on female fertility the multiparametric in-vitro mouse follicle bioassay was used, allowing the simultaneous multiparametric evaluation of the ovarian function and oocyte quality. Early preantral mouse ovarian follicles were cultured individually under physiological conditions during 12 days up to the pre-ovulatory stage. *In vitro* ovulation was triggered with hCG. Follicles were continuously exposed to a PK11195 dose range (1, 2.5, 5, 10, 15  $\mu$ g/mL). Results are reported from 460 follicles in 3 independent repeat experiments. The effect of PK11195 was determined on folliculogenesis, oogenesis and steroidogenesis. No effect was observed on follicle survival at any treatment dose, however the highest dose lowered the follicle differentiation capacity (antrum formation rate) to  $72 \pm 21\%$  versus  $98 \pm 4\%$  in the controls. PK11195 significantly decreased the oocyte nuclear maturation rate at doses of 5, 10 and 15  $\mu$ g/mL ( $P \leq 0.05$ ). Respectively  $65 \pm 10\%$ ,  $61 \pm 23\%$ ,  $38 \pm 18\%$  of the long-term exposed oocytes were able to extrude the first polar body versus  $95 \pm 6\%$  in the controls. PK11195 exposure did not affect testosterone and estradiol secretion patterns, but did elevate the progesterone output at the end of the follicular phase in a dose dependent way, while the hCG-induced progesterone remained unaltered in all treatment groups compared to controls. The multiparametric follicle bioassay demonstrated that long-term exposure to PK 11195 affects clearly oocyte quality in a dose dependent way, while folliculogenesis and steroidogenesis were only weakly affected. These data suggest that PK11195 can disrupt female fertility through the PBR pathway.

## 1124 THE CHEMICAL FORM OF ALUMINUM AFFECTS ITS PARACELLULAR FLUX ACROSS AND UPTAKE INTO CACO-2 CELLS.

Y. Zhou<sup>1</sup> and R. A. Yokel<sup>2,1</sup>. <sup>1</sup>Graduate Center for Toxicology, University of Kentucky, Lexington, KY and <sup>2</sup>College of Pharmacy, University of Kentucky, Lexington, KY.

Aluminum (Al) has been suggested to contribute to dialysis encephalopathy, a low-turnover osteomalacia and Alzheimer's disease. This study investigated the influence of the chemical form (species) of Al on its flux across and uptake into Caco-2 cells, to further understand the mechanisms of Al absorption from the gastrointestinal tract. Al, as the ion, fluoride, citrate, maltolate and hydroxide, was used. For the flux study, Caco-2 cell monolayers grown on porous membranes were mounted in vertical diffusion chambers. The 5 Al species were added to the medium on the apical side of the cells and the Al concentration determined on the basolateral side. Permeability of Lucifer yellow, a marker of paracellular flux, was concurrently measured. To study Al uptake, Caco-2 cells grown in 35 mm dishes were incubated with the 5 Al species for up to 240 min at 37 deg C or at various temperatures to create an Arrhenius plot. Lumogallion staining imaged by confocal laser microscope was used to localize Al in the Caco-2 cells. The apparent permeability (Papp) of Al ion, fluoride, citrate and maltolate correlated highly with Lucifer yellow Papp, whereas Al hydroxide, which has the lowest Papp, did not. The uptake kinetics of each of the 5 Al species was different from the others. The uptake rate of Al fluoride was  $>$  Al ion  $>$  Al maltolate  $>$  Al citrate  $>$  Al hydroxide. The activation energy of the Al ion, fluoride, and citrate, calculated from the Arrhenius plot, was 13-22 KJ/mol. The confocal images showed similar intracellular Al distribution after exposure to Al ion, fluoride, and citrate. The cell nuclei showed a high Al concentration. The results suggest soluble Al species diffuse through the paracellular pathway. Caco-2 cell uptake of Al is a diffusion process. The ligand may influence the rate of cellular Al uptake. Intracellular Al localization was heterogeneous. Funded by EPA STAR Grant 829783.

## 1125 ORAL ALUMINUM (AL) BIOAVAILABILITY FROM A FOOD CONTAINING AN AL FOOD ADDITIVE: RELEVANCE TO THE MAJOR SOURCES OF AL EXPOSURE FOR HUMANS.

R. A. Yokel<sup>1,2</sup> and R. L. Florence<sup>1</sup>. <sup>1</sup>College of Pharmacy, University of Kentucky Medical Center, Lexington, KY and <sup>2</sup>Graduate Center for Toxicology, University of Kentucky Medical Center, Lexington, KY.

Aluminum, a neurotoxicant, has been controversially implicated in the etiology of Alzheimer's disease. Food provides ~ 95% and drinking water 1 to 2% of typical daily Al intake. The primary food source of Al is approved food additives. The objective was to prepare a representative food containing the approved food additive, acidic sodium aluminum phosphate (SAIP), a leavening agent, and determine oral Al bioavailability from the food. To study Al absorption following consumption of an amount that models food consumption, 26Al was incorporated into the food. Extremely low levels of 26Al can be quantified by accelerator mass spectrometry. We prepared 26Al-containing Al(OH)<sub>3</sub> and incorporated it into the synthesis of 26Al-containing acidic SAIP (McDonald, US Patent #2550490, 1951). The 26Al-containing Al(OH)<sub>3</sub> and acidic SAIP were characterized by near infrared spectroscopy and x-ray powder diffraction. The 26Al-containing SAIP, also character-

ized by elemental analysis of Na, Al and P and thermogravimetric analysis, was incorporated into a biscuit, as 1 and 2% SALP (~ 1 nCi [50 ng] 26Al/gm biscuit). To determine oral Al bioavailability from this food, Fisher rats, acclimated to dietary conditions that resulted in no food in the stomach at the time of biscuit presentation and consumption of biscuit when presented, were given 1 gm of 26Al-containing biscuit. Concurrently studied rats received 26Al in water, replicating a previous study, or no treatment, to determine cross-contamination with 26Al. The bioavailability of Al from this representative food compared to water, in light of the daily intake of Al from food and water, suggests the major source of Al that reaches systemic circulation, thereby creating the greater potential for Al toxicity in the human. Supported by NIH Grant R01 ES11305.

## 1126

### DOES ALUMINUM WELDING FUME CAUSE CLINICALLY SIGNIFICANT PNEUMOCONIOSIS AND LUNG CANCER? - AN ANALYSIS OF SPECIFIC CAUSATION.

N. Zheng and B. Thomas. *Risk Assessment and Management Group, Inc., Houston, TX*. Sponsor: A. Jabbour.

We were asked to evaluate whether there was merit in a tort claim that a man's 22-year work history as an aluminum welder caused "aluminum pneumoconiosis" and ultimately caused or contributed to lung cancer from which he died. To assess "specific causation", we reviewed the available medical records, published scientific literature, and other information, then ask five questions: 1) evidence of exposure?; 2) known toxicology?; 3) onset of claimed symptoms consistent with known toxicology?; 4) resolution of claimed symptoms consistent with known toxicology?; and 5) relevance of alternative causes? Microscopic and chemical analysis of lung tissue confirmed extremely high levels of welding fume particles. Opposing experts argued that these particles caused pulmonary fibrosis that severely restricted the full expansion of the man's lung (i.e., a restrictive lung disease) and lung cancer, citing published data of lung fibrosis in aluminum flake workers (which they referred to generically as "aluminum pneumoconiosis") and lung cancer in aluminum smelter workers. After reviewing the medical records and published literature, it was demonstrated 1) that the exposure characteristics of aluminum welders are substantially different from those of aluminum flake workers and aluminum smelter workers; 2) that the Plaintiff's pulmonary problems were primarily obstructive lung disease and bronchogenic carcinoma most likely due to his long history of heavy cigarette smoking; and 3) that the Plaintiff's development of a "barrel chest" (hyper-expansion of the lungs secondary to his emphysema) confirms that aluminum welding fume (like iron welding fume) does not cause pulmonary fibrosis formation to an extent that results in a clinically significant pneumoconiosis that restricts lung expansion.

### PHYSICAL AND CHEMICAL CHARACTERIZATION OF BERYLLIUM PARTICLES FROM SEVERAL WORKPLACES IN QUEBEC - PART A: DETERMINING METHODS FOR THE ANALYSIS OF LOW LEVELS OF BERYLLIUM.

J. Zayed<sup>1</sup>, M. Rouleau<sup>1</sup>, C. Dion<sup>2</sup>, P. Plamondon<sup>3</sup>, G. Kennedy<sup>4</sup> and G. L'Esperance<sup>3</sup>. <sup>1</sup>*Environmental and occupational Health, University of Montreal, Montreal, QC, Canada*, <sup>2</sup>*Institut de recherche Robert-Sauve en sante et en securite du travail, Montreal, QC, Canada*, <sup>3</sup>*Centre for Characterization and Microscopy of Materials, Polytechnique School, Montreal, QC, Canada* and <sup>4</sup>*Physic Engineer, Polytechnique School, Montreal, QC, Canada*.

Chemical and physical characterizations of beryllium particles found in dust samples from four industries based in Quebec were attempted using a variety of analytical methods. These analyses were deemed important based on the hypotheses that: different chemical forms of Be do not present the same risks; different morphologies lead to different risks; the 2 ug/m3 standard value does not adequately protect workers from all chemical forms and furthermore the 2 ug/m3 standard value does not adequately protect the workers from all PM sizes and forms. Standards were used to prove the adequacy of the chosen methods prior to the analyses of industrial samples. However, low concentrations of beryllium in samples were a limiting factor for most methods: few detected Be in industrial samples. Only time-of-flight secondary ion mass spectrometry (TOF-SIMS) was able to detect Be in industrial samples as well as inductively coupled plasma-mass spectroscopy and flame atomic absorption spectrophotometry. Quantification of Be and characterization of Be particles determined that particle numbers are very high, even for concentrations below 100 ppm. Furthermore, Be seems to be present as fine particles of Be metal, possibly mechanically aggregated to larger particles or compounds such as cryolite. Other major elements present in the samples are limited to Na, Al, Ca, and F. We conclude that particle number represents an important exposure metric and that TOF-SIMS is a new valid method for characterization studies of Be. Funding for this research was provided by the Institut de recherche Robert-Sauve en sante et en securite du travail (IRSST).

## 1128

### PHYSICAL AND CHEMICAL CHARACTERIZATION OF BERYLLIUM PARTICLES FROM SEVERAL WORKPLACES IN QUEBEC, CANADA. PART B: TIME-OF-FLIGHT SECONDARY ION MASS SPECTROSCOPY.

J. Zayed<sup>1</sup>, M. Rouleau<sup>1</sup>, C. Dion<sup>2</sup>, P. Plamondon<sup>3</sup> and G. L'Esperance<sup>3</sup>. <sup>1</sup>*Environmental and occupational Health, University of Montreal, Montreal, QC, Canada*, <sup>2</sup>*Institut de recherche Robert-Sauve en sante et en securite du travail, Montreal, QC, Canada* and <sup>3</sup>*Centre for Characterization and Microscopy of Materials, Polytechnique School, Montreal, QC, Canada*.

The problematic of detecting and characterizing beryllium particles in industrial samples from Quebec (Canada) was already addressed by our research group. The present study is a continuation of the work aimed at redefining the current occupational exposure level for beryllium. The goals are to determine the principal chemical forms and the principal physical characteristics of Be particles sampled in four Quebec industries, using time-of-flight secondary ion mass spectroscopy (TOF-SIMS). Most of the samples gave similar results. For dust samples with concentrations of Be varying from 60 to 140 ug/g, the physical characteristics are convergent: numerous fine beryllium particles or aggregates evenly dispersed throughout the samples. Beryllium particles or aggregates are spread out homogeneously. Beryllium does not appear to be concentrated in large particles, but evenly distributed in numerous fine particles. However we were not able to confirm if these fine particles are combined to specific compounds, chemically or physically, or independent Be particles. Most of the particles containing Be are fine, with diameters less than 10 um, which is important from an occupational health and safety standpoint. TOF-SIMS is an appropriate technique for qualitative characterization of Be particles, a complement to the recognized quantitative methods ICP-MS and SAAF. Funding for this research was provided by the Institut de recherche Robert-Sauve en sante et en securite du travail.

### HUMAN SUSCEPTIBILITY GENE CONFFERS BERYLLIUM HYPERSENSITIVITY ON FVB MICE.

L. M. Tarantino<sup>1</sup>, C. Sorrentino<sup>1</sup>, Y. Zhu<sup>2</sup>, E. M. Rubin<sup>2</sup>, S. S. Tinkle<sup>3</sup> and T. Gordon<sup>1</sup>. <sup>1</sup>*Department of Environmental Medicine, NYU School of Medicine, Tuxedo, NY*, <sup>2</sup>*Department of Genome Sciences, Lawrence Berkeley National Laboratory, Berkeley, CA* and <sup>3</sup>*NIEHS, Research Triangle Park, NC*.

Beryllium (Be) is an indispensable metal for many national defense programs in aerospace, electronics, and weaponry due to its unique physico-chemical properties. Exposure to beryllium is an occupational hazard that can cause Chronic Beryllium Disease (CBD), an irreversible, debilitating granulomatous lung disease, in as many as 3-5% of exposed workers. CBD begins as an MHC Class II-restricted, Th1 hypersensitivity, and the Human Leukocyte Antigen, *HLA-DPB1 E<sup>69</sup>*, is associated with risk of developing CBD. Because inbred strains of mice are unable to contract CBD, we developed *HLA-DPB1 E<sup>69</sup>* transgenic mice. Each transgenic contains a single haplotype of *HLA-DPB1* that confers a different magnitude of risk for CBD: *HLA-DPB1\*0401* (OR = 0.2), *HLA-DPB1\*0201* (OR = 15), and *HLA-DPB1\*1701* (OR = 240). We employed the mouse ear swelling test to determine if these genes would support a hypersensitivity response to beryllium. The wild type FVB inbred strain provided the control. In three separate experiments, mice were placed into one of three groups: control/control (skin sensitized with vehicle and challenged with vehicle), control/Be (skin sensitized with vehicle and challenged with beryllium sulfate), and Be/Be (skin sensitized with beryllium sulfate and challenged with beryllium sulfate). In the *HLA-DPB1\*1701* mice, the strain with the highest risk transgene, the Be/Be group displayed increased ear thickness 24h post-challenge, an average of 12.3% over the baseline measurement within group and compared to 2.8 and 2.4% in the control/control and control/beryllium groups, respectively. No significant changes were observed in the other strains for any treatment condition. These results suggest that the *HLA-DPB1\*1701* transgene product is responsible for inducing a beryllium-sensitive phenotype and that this model will be a useful tool for investigating beryllium sensitization.

## 1130

### THE ROLE OF HYPOXIA INDUCIBLE FACTOR 1 $\alpha$ IN COBALT CHLORIDE INDUCED CELL DEATH IN MOUSE EMBRYONIC FIBROBLASTS.

A. Vengellur<sup>2,1</sup> and J. LaPres<sup>1,3,4</sup>. <sup>1</sup>*Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI*, <sup>2</sup>*Graduate Program in Genetics, Michigan State University, East Lansing, MI*, <sup>3</sup>*National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI* and <sup>4</sup>*Center for Integrative Toxicology, Michigan State University, East Lansing, MI*.

Cobalt has been widely used in the production of alloys, paints and batteries and in the treatment of anemia and as a hypoxia mimic in cell culture. It is known to activate hypoxic signaling by stabilizing the hypoxia inducible transcription factor 1 $\alpha$  (HIF1 $\alpha$ ) and cobalt exposure can lead to tissue and cellular toxicity. The present

study was conducted to determine the role of HIF1 $\alpha$  in mediating cobalt-induced toxicity. HIF1 $\alpha$  null mouse embryonic fibroblasts (MEFs) were used to show that HIF1 $\alpha$  protein can influence cobalt-induced cytotoxicity. In addition, the BH3 domain containing cell death gene, BNip3, is upregulated by cobalt chloride treatment in a HIF1 $\alpha$ -dependent manner. The cobalt-induced upregulation of BNip3 expression is time and dose dependent and directly correlated with an increase in BNIP3 protein levels. The time and dose dependent increase in BNIP3 levels also correlates with the presence of chromatin condensation, one marker for apoptosis. Interestingly, this increased chromosomal condensation was not coupled to caspase-3 activation as usually seen in a typical apoptotic response. Modulation of BNip3 expression levels correlated with toxicity upon cobalt chloride exposure. These results show that HIF1 $\alpha$  is playing a major role in mediating cobalt-induced toxicity in mouse embryonic fibroblasts and may offer a possible mechanism for the underlying pathology of injuries seen in workers exposed to environmental contaminants such as cobalt.

### 1131 STUDIES OF MECHANISMS OF POTASSIUM DICHROMATE-INDUCED NEPHROTOXICITY IN ISOLATED RAT RENAL CORTICAL SLICES.

J. chen and S. K. Chakrabarti. *Department of Environmental and Occupational Health, Faculty of Medicine, Universite de Montreal, Montreal, QC, Canada.*

The kidney is considered to be one of the target organs for Cr(VI) toxicity. The information regarding the mechanisms of Cr(VI)-induced nephrotoxicity is at present very limited. The present study was carried out to investigate the mechanisms of Cr6+(using potassium dichromate)-induced toxicity in isolated rat renal cortical slices. The dichromate (Cr6+) showed both concentration (0-4 mM) and time (0-3 hr) dependent toxicity, as measured by the MTT assay. The dichromate (1 mM) produced both time-dependent significant depletion of nonprotein sulfhydryl contents and significant increase in lipid peroxidation (LPO), which appeared much later than the former. Pretreatment of cortical slices with either mannitol or dimethylthiourea failed to reduce Cr6+-induced toxicity but reduced LPO. Similarly, pretreatment with either catalase or superoxide dismutase failed to reduce such toxicity. However, treatment with either excess glutathione (GSH) or pretreatment with excess ascorbic acid (Vit.C) reduced both the toxicity and LPO. Although Cr6+ induced mitochondrial permeability transition (MPT), cyclosporin A, or carnitine, or trifluoperazine (inhibitors of MPT) failed to prevent such toxicity, suggesting a non-significant role of MPT in such toxicity. Cotreatment with some modulators of intracellular calcium fluxes failed to prevent such toxicity indicating a nonsignificant role of calcium homeostasis. Pretreatment with carmustine failed to prevent Cr6+-induced toxicity suggesting a nonsignificant role of glutathione reductase activity in such toxicity. The results suggest that depletion of GSH might be a determinant step in the oxidative stress and subsequent nephrotoxicity and that Vit.C is a powerful antioxidant to prevent such toxicity.

### 1132 PROTECTIVE EFFECT OF ALPHA-TOCOPHEROL ON RENAL INJURY CAUSED BY CHROMATE EXPOSURE.

L. Arreola-Mendoza<sup>1</sup>, J. L. Reyes<sup>2</sup>, M. C. Namorado<sup>2</sup>, D. Martin<sup>2</sup> and L. M. Del Razo<sup>1</sup>. <sup>1</sup>*Toxicology, Cinvesta-IPN, Mexico D.F. Mexico and* <sup>2</sup>*Physiol. Biophys. & Neurosci, Cinvesta-IPN, Mexico D.F. Mexico.*

Chromate Cr(VI) is a common industrial waste product and environmental pollutant. It is also a recognized human carcinogen. Some toxic effects of Cr(VI) exposure have been related with its oxidative capacity. In the kidney, exposure to Cr(VI) has been associated with proximal tubular necrosis, although its mechanism remains unclear. Our aim was to examine acute renal damage caused by the exposure of Cr(VI), to disclose the degree of lipid peroxidation (LPO) caused by this metal and the functional consequences on different nephron segments (glomeruli, proximal and distal tubules). We also assessed the segmental selectivity of the protective effect of  $\alpha$ -tocopherol on these alterations. Wistar female rats (200 g bw) received potassium dichromate (15 mg/kg, sc, single dose). LPO and renal function were monitored on days 0, 1, 2, 3, 7, 10 y 14 after Cr(VI) administration. A second group received  $\alpha$ -tocopherol (125 mg/kg/day, gavage), 5 days before and 7 days after Cr(VI), and were monitored on 0, 2 and 7 days of Cr(VI) exposure. LPO was quantified in renal tissue; creatinine clearance, glucose and sodium fractional excretions, free-water and osmolal clearances were also measured. Results showed oxidative damage 48 h after exposure to Cr(VI) with spontaneous recovery after day 7. Renal function was maximally altered on day 3 and thereafter recovery ensued. Glomerular filtration decreased, glucose and sodium fractional excretions increased and free water and osmolal were affected. These changes showed a similar time-course to that of the oxidative damage.  $\alpha$ -tocopherol-treated group showed less oxidative damage and preservation of proximal tubule function. In contrast, glomerular and distal function did not show difference with the group that received Cr(VI) alone. These results suggest that Cr(VI) causes alterations along different segments

of the nephron and the antioxidant treatment had protective effect only on the injury caused by Cr(VI) on the proximal tubular function. (Funded in part by G34511 Conacyt).

### 1133 CHROMIUM(VI) ACTIVATES STAT3 IN BRONCHIAL EPITHELIAL CELLS.

K. A. O'Hara, R. J. Vaghjiani, L. R. Klei and A. Barchowsky. *Environmental and Occupational Health, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA.*

Inhaled hexavalent chromium (Cr(VI)) promotes pulmonary diseases through poorly defined mechanisms, and modification of signaling proteins may play a significant role in this etiology. Although several transcription factors have been demonstrated to respond to Cr(VI) exposures, most studies have focused solely on acute changes in NF- $\kappa$ B or NF- $\kappa$ B in combination with activator protein-1 (AP-1). Thus, we hypothesized that non-cytotoxic levels of Cr(VI) may promote pulmonary disease by increasing Stat activity in bronchial epithelial cells (BEAS-2B). A 24 h Cr(VI) (5  $\mu$ M) exposure caused an 8.5-fold increase in nuclear protein binding to the Stat5 *cis*-response element. To validate this finding, BEAS-2B cells were exposed to Cr(VI) for 1, 4 and 24 h. Cr(VI) caused a transient activation of Stat1 at 1 h that was diminished by 4 h. Stat3 remained phosphorylated after 4 h while Stat5 was not activated at any of the time-points. Sub-chronic investigations were initiated to mimic realistic exposure times. After 24, 48, and 72 h, Cr(VI) increased nuclear levels of phosphorylated Stat3, minimally activated Stat1, and had no effect on Stat5. Immunofluorescence microscopy confirmed that Cr(VI) increased nuclear levels of phosphorylated Stat3. Inhibition of Lck, a Src family kinase, with specific siRNA sequences caused a 2-fold reduction in Cr(VI)-induced Stat3 phosphorylation. These data suggest that Cr(VI) activates tyrosine kinases to effect long-term shifts in transcription factor signaling and gene expression, which may underlie disease prone phenotypes in lung epithelium. Supported by NIEHS grant ES10638.

### 1134 CARCINOGENIC LEAD CHROMATE INDUCES DNA DOUBLE-STRAND BREAKS AND ACTIVATES ATM KINASE IN HUMAN LUNG CELLS.

H. Xie<sup>1,2</sup>, S. S. Wise<sup>1,2</sup>, A. L. Holmes<sup>1,2</sup> and J. P. Wise<sup>1,2</sup>. <sup>1</sup>*Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME and* <sup>2</sup>*Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME.*

Hexavalent chromium (Cr(VI)) is a widespread environmental contaminant and a known human carcinogen, generally causing bronchial cancer. Studies have shown that it is the particulate forms of Cr(VI) that are the potent carcinogens. Particulate Cr(VI) is known to induce a spectrum of DNA damage such as DNA single strand breaks, Cr-DNA adducts, DNA-protein crosslinks and chromosomal aberrations. However, particulate Cr(VI)-induced DNA double strand breaks (DSBs) have not been reported. Thus the aim of this study is to determine if particulate Cr(VI)-induces DSB in human lung cells. Using the single cell gel electrophoresis assay (comet assay), we found that lead chromate (LC) induced concentration dependent increases in DSBs with 0.1, 0.5, 1, 5 and 10  $\mu$ g/cm<sup>2</sup> lead chromate inducing a 0.21, 0.50, 0.62, 1.10 and 1.68-fold relative increase in tail integrated intensity ratio, respectively. To begin to understand the mechanisms in the repair of these lesions, we detected H2AX foci formation in cells treated with LC. H2AX becomes rapidly phosphorylated (r-H2AX) on residue serine 139 and forms foci surrounding damaged DNA in response to DSBs. r-H2AX foci formation is believed to be a sensitive signal for the existence of DSBs. By using immunofluorescence, we found that lead chromate induced concentration-dependent increases in r-H2AX foci formation with 0.1, 0.5, 1, 5 and 10  $\mu$ g/cm<sup>2</sup> LC inducing a 1.4, 1.5, 2.1, 2.2, 2.4 fold increase relative to control, respectively. The ataxia telangiectasia mutated (ATM) protein plays a central role in early stages of DSBs detection and controls cellular responses to this damage. We also found that LC activates ATM at concentrations that are both genotoxic and cytotoxic. Future experiments will focus on elucidating the role of ATM and related genes in the mechanism of DSBs repair. This work was supported by NIEHS grant ES10838 (J.P.W.).

### 1135 REPAIR OF CHROMATE-INDUCED CHROMOSOME DAMAGE IS MEDIATED BY XRCC1.

E. G. Duzevik<sup>1,2</sup>, S. S. Wise<sup>1,2</sup>, R. C. Munroe<sup>1,2</sup> and J. P. Wise<sup>1,2</sup>. <sup>1</sup>*Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME and* <sup>2</sup>*Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME.*

Chromium (VI) compounds are established human carcinogens that induce chromosomal aberrations and DNA damage. The mechanisms by which this damage is repaired is unknown. DNA repair mechanisms include several proteins necessary

for the successful repair of DNA damage. XRCC1 is a protein involved in the repair of DNA single strand breaks (SSB). In this study we examined the role of XRCC1 in cell survival and repair of chromosomal aberrations induced by particulate and soluble chromium compounds in Chinese hamster ovary (CHO) cells. Three different cell lines were used: AA8 (parental), EM9 (XRCC1 mutant) and H9T3 (EM9 complemented with human XRCC1 gene). Results show a concentration-dependant decrease in relative survival in all cell lines. Relative survival in AA8 cells treated with 0.1, 0.5, 1.0, 5.0  $\mu\text{g}/\text{cm}^2$  lead chromate (LC) was 103, 98, 98 and 83%, and was 89, 82, 69 and 37% in XRCC1 deficient (EM9) cells, respectively. However, relative survival was not different in EM9 compared to AA8 and H9T3 cells treated with 1.0, 2.5, 5.0 and 10.0  $\mu\text{M}$  sodium chromate (SC). LC was clastogenic inducing 0.25, 0.78 and 0.52 aberrations/cell at 0.1, 0.5 and 1  $\mu\text{g}/\text{cm}^2$  respectively in AA8 cells. In EM9 cells, 0.1, 0.5 and 1  $\mu\text{g}/\text{cm}^2$  LC caused 0.61, 0.85 and 0.96 aberrations/cell respectively. Recovery experiments show that repair was efficient in the parental cell line and the number of chromosomal aberrations was not increased, while in EM9 cells total damage was dramatically increased, especially at higher concentrations. Results for the H9T3 cells were similar to those for parental cell line. These data indicate that XRCC1 is important for cell survival of particulate chromate treated cells, but not in sodium chromate treated cells. XRCC1 is required for repair of particulate and soluble chromate induced chromosomal aberrations. Future studies will be directed towards further examining the functional role of XRCC1 in repair of chromium(VI)-induced DNA SSB. This work was supported by NIEHS grant ES10838(JPW).

#### IMPAIRMENT OF CHROMIUM-DNA ADDUCT FORMATION BY HYPOXIA.

T. J. O'Brien<sup>1,2</sup>, H. G. Mandel<sup>1,2</sup>, K. D. Sugden<sup>4</sup>, A. Komarov<sup>3</sup> and S. R. Patierno<sup>1,2,7</sup>. *Pharmacology and Physiology, The George Washington University Med. Ctr., Washington, DC, <sup>2</sup>The GW Cancer Institute, The George Washington University Med. Ctr., Washington, DC, <sup>3</sup>Biochemistry and Molecular Biology, The George Washington University Med. Ctr., Washington, DC and <sup>4</sup>Chemistry, University of Montana, Missoula, MT.*

The reduction of hexavalent chromium [Cr(VI)] generates several genetic lesions. While mechanisms include both direct metal-DNA interactions and the generation of radical intermediates, the precise role of oxygen in this process is unclear. We studied the formation of Cr-induced lesions in DNA *in vitro* reacted with either Cr(VI) and ascorbic acid (Asc), or Cr(III), under both ambient and hypoxic conditions. Hypoxia had no effect on the kinetics of Cr(VI) reduction by Asc, but decreased, by ~50%, the levels of Cr(VI)/Asc-induced Cr-DNA adducts and DNA polymerase-arresting lesions (PALs) following a 2 hour treatment. In addition, hypoxia impaired the formation of Cr-induced DNA interstrand crosslinks by ~2-fold in plasmid DNA treated with Cr(VI)/Asc. Although the effects of oxygen deprivation were pronounced after 2 hours; following a 20 hour incubation of DNA with Cr(VI)/Asc, Cr-DNA adduct levels were again similar under both ambient and hypoxic conditions indicating that hypoxia reduced the rate at which Cr interacted with DNA, but not the ultimate steady state level of Cr-DNA binding. The inhibitory effect of hypoxia on Cr(VI)/Asc genotoxicity could not be explained by alterations in the reactivity of intermediate Cr species [i.e. Cr(V)] because Cr(III)-induced DNA damage (adducts, PALs, ICLs) was also impaired by hypoxia. Moreover, the production of Cr(V), as detected by electron spin resonance (ESR), was similar in ambient and hypoxic reactions. These effects were specific for Cr(III) because hypoxia did not affect the generation of ICLs by cisplatin, another inorganic DNA crosslinking agent. Taken together, the results from this study reveal a novel oxygen-dependent step in Cr genotoxicity wherein molecular oxygen facilitates the formation of coordinate Cr(III)-DNA complexes.

### 1137

#### ACUTE INHALATION TOXICITY OF TRIMETHYL GALLIUM IN RATS.

G. R. Kiplinger<sup>1</sup>, G. P. Rosini<sup>2</sup>, S. V. Kala<sup>3</sup>, E. C. Bisinger, Jr.<sup>4</sup> and J. L. Orr<sup>4</sup>. *<sup>1</sup>WIL Research Laboratories, Inc., Ashland, OH, <sup>2</sup>Akzo Nobel Polymer Chemicals LLC, Chicago, IL, <sup>3</sup>Baylor School of Medicine, Houston, TX and <sup>4</sup>Akzo Nobel Chemicals Inc., Chicago, IL.*

Trimethyl gallium (TMG) is a pyrophoric liquid used in the semiconductor industry. TMG produces a flame or visible aerosol (smoke) when exposed to air, but can produce an invisible aerosol containing TMG degradation products at lower concentrations. There are no inhalation data available on TMG and therefore a screening inhalation study was performed using groups of 10 Crl:CD(SD)IGS BR rats (5/sex/group). Rats were exposed once for 30 minutes in a nose-only exposure system to either TMG (highest non-smoking concentration in air) or air only on Day 0. Gallium (Ga) levels were measured in blood and urine samples collected on Days 1 and 14 and in lung and kidney specimens collected at necropsy on Day 14. Ga was analyzed using Inductive Coupled Plasma Mass Spectrometry. There were no significant clinical observations, body weight effects or gross necropsy findings in

either the control or the exposed groups. On Day 1, exposed group blood and urine Ga levels ( $21 \pm 2$  and  $45 \pm 5 \mu\text{g}/\text{L}$ ) were significantly higher ( $p < 0.05$ ) than those of the control group ( $2 \pm 0.1$  and  $1 \pm 0.3 \mu\text{g}/\text{L}$ ). On Day 14, exposed group blood and urine Ga levels ( $3 \pm 0.2$  and  $8 \pm 1 \mu\text{g}/\text{L}$ ) were still significantly higher ( $p < 0.05$ ) than those of the control group ( $2 \pm 0.1$  and  $0.5 \pm 0.0 \mu\text{g}/\text{L}$ ), however, between day 1 and day 14, blood and urine Ga levels in the exposed group had decreased by approximately 80%. Exposed group lung and kidney samples contained  $66 \pm 12$  and  $47 \pm 11 \text{ ng/g}$  of Ga, respectively. Ga was not detected in control animal lung and kidney samples. The results of this screening study showed that acute inhalation exposure to TMG did not induce observable signs of toxicity. Measurable amounts of Ga in kidney indicated systemic uptake of Ga from the lung, however, this study suggests that the urine is an important excretion route for clearance of inhaled Ga from the body.

### 1138

#### OAT1 TRANSPORTS N-ACETYL CYSTEINE (NAC)-S CONJUGATES OF BOTH METHYLMERCURY AND INORGANIC MERCURY IN MDCK CELLS.

S. Ahmad and R. K. Zalups. *Basic Sciences, School of Medicine, Mercer University, Macon, GA.*

The renal proximal tubule has been shown to be one of the primary targets where inorganic and organic forms of mercury ( $\text{Hg}^{2+}$ ) accumulate and induce pathologic effects *in vivo*. We recently demonstrated that type II Madin-Darby Canine Kidney (MDCK) cells stably transfected with human organic anion transporter 1 (hOAT1) gain the ability to transport certain thiol-conjugates of  $\text{Hg}^{2+}$ . Based on these findings, the present study was designed to investigate role of OAT1 and amino acid transporters in the basolateral uptake of the potentially relevant NAC conjugate of  $\text{Hg}^{2+}$  (NAC-Hg-NAC) and  $\text{CH}_3\text{Hg}^+$  ( $\text{CH}_3\text{Hg-NAC}$ ). Uptake of both NAC-Hg-NAC and  $\text{CH}_3\text{Hg-NAC}$  was significantly greater in the hOAT1-transfected cells than the control MDCK cells. The  $K_m$  values for transport of NAC-Hg-NAC and  $\text{CH}_3\text{Hg-NAC}$  in hOAT1-transfected cells were  $144 \pm 29 \mu\text{M}$  and  $35.8 \pm 2.77 \mu\text{M}$ , respectively. Transport of both conjugates was also time-dependent and temperature-sensitive. In the presence of well-established inhibitors of OAT1, the uptake of NAC-Hg-NAC and  $\text{CH}_3\text{Hg-NAC}$  were significantly inhibited only in the hOAT1-transfected cells. Significant amount of uptake of  $\text{CH}_3\text{Hg-NAC}$  (but not NAC-Hg-NAC) was also noted in control MDCK cells. In the presence of L-type amino acids (such as leucine, isoleucine, cysteine, phenylalanine, histidine and tyrosine), the uptake of  $\text{CH}_3\text{Hg-NAC}$  was significantly inhibited in both control MDCK and hOAT1-transfected cells. The uptake of  $\text{CH}_3\text{Hg-NAC}$  was further decreased (in an additive manner) only in hOAT1-transfected cells in the presence of leucine & glutarate or leucine & adipate as compare to that in corresponding cells exposed to leucine, glutarate or adipate alone. Overall these findings indicate that the activity of OAT1 is likely responsible for basolateral uptake of both NAC-Hg-NAC and  $\text{CH}_3\text{Hg-NAC}$ . Our data also indicate that amino acid transporters are also involved in uptake of  $\text{CH}_3\text{Hg-NAC}$ .

### 1139

#### MERCURIC CHLORIDE ALTERS BAX-BCL2 RATIO IN LEYDIG CELLS TOWARD APOPTOTIC PATHWAY.

M. Mansour, J. Persaud, R. Ricks, K. Ali, H. El-kholi and A. Atkinson. *College of Veterinary Medicine, Nursing & Allied Health, Tuskegee University, Tuskegee, AL.* Sponsor: R. Dalvi.

Bax (Bcl2-associated X protein) and Bcl2 (B-cell CLL/lymphoma 2) are well known countermolecules, which regulate apoptosis with Bax acting as a promoter of apoptosis and Bcl2 as anti-apoptosis. Also, Bax has been shown to form heterodimers with Bcl2. The ratio of Bax to Bcl2 determines death or survival of cells following apoptotic stimuli such as exposure to toxic chemicals. In this study, Leydig cells were exposed *in vitro* to mercuric chloride ( $\text{HgCl}_2$ ) at a dose of 27  $\mu\text{m}/\text{ml}$  for 0, 1, 3, 12, and 24 hours. The ratio of Bax to Bcl2 was then determined by RT-PCR. The results showed that  $\text{HgCl}_2$  significantly up-regulated Bax in a time-dependent manner when compared to the control. In contrast, Bcl2 showed no dose response when compared to the control. The data suggest that  $\text{HgCl}_2$  may induce apoptosis in Leydig cells through the mitochondrial pathway. Furthermore, death of Leydig cells by apoptosis may consequently reduce the amount of testosterone secreted by these cells. Hence, reduced fertility *in vivo* could result from decreased testosterone production due to environmental exposure to mercury. Supported by DHHS/NIH/NCRR/RCMI grant (G12RR03059-17).

### 1140

#### EFFECTS OF SUBCHRONIC EXPOSURE TO MERCURIC CHLORIDE ON RAT FERTILITY AND REPRODUCTIVE PERFORMANCE: A CROSSOVER MATING TRIAL STUDY.

K. A. Ali, A. Atkinson, H. El-Kholi, M. Mansour, C. Harris, D. Chaney and M. Campbell. *College of Veterinary Medicine, Nursing & Allied Health, Tuskegee University, Tuskegee, AL.* Sponsor: R. Dalvi.

Our previous multigenerational reproductive and fertility study indicated that exposure of male and female rats to mercuric chloride (MC) resulted in significant differences in fertility indices. The objectives of this study were 1) To determine

which sex, male, female or both, contributed most to the reproductive and fertility effects and 2) To evaluate semen quality by computer-assisted sperm motion analysis (CASA). Three combinations of breeding pairs were used in a crossover mating trial study. The treatment groups were control males (0.0 mg Hg/kg/day) x control females (0.0 mg Hg/kg/day), control males (0.0 mg Hg/kg/day) x high dose females (2.5 mg Hg/kg/day) and control females (0.0 mg Hg/kg/day) x high dose males (2.0 mg Hg/kg/day). The results showed that the fertility and 4-day survival indices were reduced in the combination of treated female x control male to 57% and 88%, respectively. In contrast, the fertility in treated male x control female was only reduced to 75%. The male body weights in the treated group were significantly decreased during the entire treatment period (91 days) when compared to the control. There were no statistical difference between the body weights of exposed and control females except in week two. Testicular, epididymal and prostate weights were significantly decreased when compared with the control. Conversely, uterine and ovarian weights were not different from the control. Motile sperm and progressive motility percentage were significantly decreased when compared with the control. Parameters indicative of sperm motion showed no dose response. The experimental results presented in this study would suggest that subchronic MC exposure in rats affects the reproductive and fertility performance of both male and female rats but the reduction of fertility indices was more severe in the treated female x control male pair. Supported by DHHS/NIH/NCRR/RCMI grant (G12RR03059-17).

**1141 MN INDUCED PULMONARY VEGF-EXPRESSION IN VIVO: A POTENTIAL MECHANISM OF PULMONARY TOXICITY.**

K. K. Divine, M. M. Falgout, T. H. March and S. Bredow. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Toxic effects of pulmonary Manganese (Mn) exposure have largely escaped notice given the invariable overlap with more dominant neurological symptoms. We hypothesize that chronic Mn exposure affects pulmonary Vascular Endothelial Growth Factor (VEGF), whose altered expression over time changes lung vasculature, potentially enhancing pulmonary disease susceptibility. In normal lung, the role of VEGF in vascular function remains to be clarified. VEGF is a potent positive regulator of angiogenesis, the sprouting and growth of new blood vessels from existing vasculature. Its expression is tightly controlled; expression levels are usually low, elevated levels reflect excessive angiogenesis, which is linked to many diseases. In murine lung 3 major VEGF isoforms have been identified. VEGF<sub>120</sub> and VEGF<sub>164</sub> normally have low expression levels. VEGF<sub>188</sub>, the physiologically important isoform, increases during development and remains elevated in adulthood. Here we demonstrate increased pulmonary VEGF<sub>188</sub> and VEGF<sub>164</sub> mRNA levels from exposure to an environmentally relevant Mn concentration. Female FVB/N mice (11-12 weeks) were exposed to MnCl<sub>2</sub> (concentration: 2 ± 0.36 mg/m<sup>3</sup>; particle size: 1.98 ± 0.12 µm) via nose-only inhalation for 6 hours/day. A 5-day exposure produced 2.5 and 2-fold increases in VEGF<sub>188</sub> and VEGF<sub>164</sub> mRNA levels (determined by RT-PCR) respectively. This increase was still detectable 2 and 7 days after exposure cessation. No histological evidence of inflammation was observed in exposed mouse lungs. Mn-induced changes in vasculature seem likely: Endoglin, an endothelial cell surface marker whose expression in the vasculature under normal physiological conditions is low, was also upregulated 2.5-fold. The vasculature in diseased tissues displays multiple abnormalities, which are potentially reversible by therapeutic intervention. Elucidating vascular alterations in response to metals such as Mn may provide insight into the pathophysiology of environmentally relevant pulmonary diseases such as asthma and other chronic airway inflammation diseases.

**1142 A POTENTIAL MECHANISM FOR PULMONARY MANGANESE-TOXICITY: MANGANESE INDUCES PULMONARY VEGF EXPRESSION IN VITRO.**

S. Bredow, M. M. Falgout and K. K. Divine. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

The respiratory tract constitutes a major route of entry and absorption for airborne Manganese (Mn) dust and fume particles. Although chronic Mn-exposure causes toxic responses in lung, little is known about the underlying mechanisms that mediate these effects. In non-pulmonary cell lines Mn induces cellular expression of Vascular Endothelial Growth Factor (VEGF) *in vitro*. VEGF is perhaps the most important positive regulator of angiogenesis, the sprouting and growth of new blood vessels from the existing vasculature. Angiogenic activity, which is usually low under normal physiological conditions, contributes to the pathogenesis of many diseases, and elevated VEGF levels frequently correlate with poor prognosis and disease outcome. Here we demonstrate that Mn increases VEGF expression *in vitro* in several human pulmonary epithelial cell lines (A549, Calu-3, NCI-H292). Cells were transiently transfected with a reporter plasmid containing the gene for firefly luciferase under the control of the VEGF wild type-promoter. Twenty-eight hours later, MnCl<sub>2</sub> was directly added to the medium in concentrations ranging from 50

to 1000 µM. The cells were incubated for another 20 hours and then lysed. Analysis of the cell lysates for firefly activity revealed cell- and dose-dependent increases in promoter activity between 1.5 and 3.5-fold. Interestingly in comparison to non-treated controls, exposure to 0.25 mM MnCl<sub>2</sub> for 20 hours increases promoter activity 2-fold for up to 24 hours after Mn is removed. Further, growing the cells in the presence of 0.25 mM MnCl<sub>2</sub> for 2 weeks did not affect their viability. These data suggest that Mn might promote changes in pulmonary angiogenic growth factor expression, which, over time, could affect lung vasculature morphology, leading to enhanced susceptibility to disease. Further studies may provide an insight into the pathogenesis of, and therapeutic targets for, lung diseases such as asthma and other chronic inflammatory airway diseases.

**1143 THE DISTURBANCE OF CELLULAR IRON REGULATION BY SOLUBLE NICKEL EXPOSURE AND ITS POSSIBLE MECHANISMS.**

H. Chen, T. Davidson and M. Costa. *Environmental Medicine, New York University, Tuxedo, NY.*

Proper cellular iron level is maintained by coordinated actions of different iron metabolic proteins, most of which are post-transcriptionally regulated by iron regulatory protein 1 (IRP-1). IRP-1 gains its binding activity under iron-deplete condition or some stimuli, such as H2O2, nitric oxide or activated protein kinase C. When iron is replete, IRP-1 loses its RNA binding activity and is converted to cytosolic aconitase. Here, we found that nickel exposure decreases cellular aconitase activity and increases IRP-1 binding activity. The increased activity of IRP-1 after nickel exposure resulted in the increase of transferrin receptor mRNA and antagonized the induction of ferritin light chain protein by iron. Direct incubation of cellular extract with nickel does not cause a decrease in aconitase activity, suggesting nickel needs some mediators for its effect. Although nickel is able to induce hypoxia inducible factor 1 alpha and activate protein kinase C, these factors were not found to be responsible for the effects of nickel on aconitase and IRP-1. It was found that nickel exposure decreased total cellular iron in a dose- and time- dependent manner, which likely caused the observed decrease in aconitase activity and the increase of IRP-1 activity. Cotreatment with iron reverted the effect of nickel on cytosolic aconitase and iron regulatory protein 1. Since iron plays important roles in cell growth and energy metabolism, it is expected that the disturbance of cellular iron homeostasis by nickel may have a great impact on the ability of the cell to function properly.

**1144 SOLUBLE NICKEL ALTERS IRON HOMEOSTASIS.**

T. L. Davidson<sup>1</sup>, H. Chen<sup>1</sup>, M. D. Garrick<sup>2</sup>, S. Singleton<sup>2</sup> and M. Costa<sup>1</sup>.

<sup>1</sup>*Department of Env. Med., New York University, Tuxedo, NY* and <sup>2</sup>*Department of Biochemistry, SUNY Buffalo, Buffalo, NY.*

Nickel compounds have been identified as human carcinogens/cocarcinogens in both *in vivo* studies and epidemiological evaluations. Exposure of cells to soluble nickel turns on the hypoxic response pathway, which may be involved in carcinogenesis, by stabilizing hypoxia inducible factor-1a (HIF-1α). The stability of the HIF-1α protein is directly controlled by a family of prolyl hydroxylases, whose activity is dependent on iron, ascorbic acid, and 2-oxoglutarate. Here, we study the ability of nickel to affect iron homeostasis by competing with iron for entry into the cell and inhibiting the activity of iron dependent enzymes. Using a human cell line (HEK293) with a tetracycline inducible vector expressing divalent metal ion transporter-1 (DMT1), we show that nickel is transported into the cell via DMT1. In addition, we demonstrate that soluble nickel can compete with iron for DMT1-dependent entry into the cell. Levels of total iron in A549 cells, a human lung cancer line, were then analyzed using graphite furnace atomic absorption after exposure to soluble nickel. Exposure to soluble nickel decreased total iron levels in a dose and time dependent manner. Since total iron levels were lower, we expected that the activity of iron dependent enzymes would also be affected. The enzyme activity of aconitase, catalase and prolyl hydroxylase were all decreased by exposure to soluble nickel. Interference with iron dependent processes may be involved in nickel-induced carcinogenesis. Our data may give new insight into the mechanisms of nickel-induced carcinogenesis, as well as, contribute important information for the treatment and prevention of occupational diseases.

**1145 CHRONIC EXPOSURE TO LEAD IONS FROM LEAD CHROMATE INTERFERES WITH NORMAL MITOTIC PROGRESSION.**

A. L. Holmes<sup>1,2</sup>, S. J. Sandwick<sup>1,2</sup>, S. S. Wise<sup>1,2</sup>, N. Gordon<sup>3,2</sup> and J. P. Wise<sup>1</sup>.

<sup>2</sup><sup>1</sup>*Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME*, <sup>2</sup>*Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME* and <sup>3</sup>*Department of Chemistry, University of Southern Maine, Portland, ME.*

Hexavalent chromium (Cr(VI)) compounds are established human lung carcinogens. Solubility plays a key role in the carcinogenicity of Cr(VI), with the most potent carcinogens being the particulate Cr(VI) compounds, however, it remains un-

known why. Lead chromate(LC) and sodium chromate(SC) were used as model particulate and soluble Cr(VI) compounds, respectively. We tested the hypothesis that the Pb cation may disrupt normal mitotic progression after chronic exposures to LC, by determining the presence of c-anaphase cells after exposure to LC, SC and lead glutamate (LG). LC induced concentration and time-dependent increases in intracellular Cr ions, but only concentration-dependent increases in intracellular Pb ions. LC induced concentration-dependent increases in chromosome damage after a 24 h exposure, but only a small increase in c-anaphase cells. However, more chronic exposures to LC induced a greater increase in c-anaphase cells. Specifically, after exposure to 0.5  $\mu\text{g}/\text{cm}^2$  LC for 24, 48 and 72 h, c-anaphase cells increased from 1 to 6 to 16%, respectively, with none in the control. Concentrations of 0.5, 1 and 2.5  $\mu\text{M}$  SC, which have similar intracellular Cr levels as the LC treatments, did not induce c-anaphase cells indicating that the Cr ions are not causing this effect. We next selected soluble Pb ion treatments (50 and 100  $\mu\text{M}$  LG), that mimicked the amount of Pb ions inside the cell after LC exposure and found that Pb ions did induce an increase in c-anaphase cells. Specifically, 50 and 100  $\mu\text{M}$  LG induced a 3.5 and 6.5% increase in c-anaphase cells, respectively. These data indicate that chronic exposure to Pb ions from LC disrupts normal mitotic progression in human lung cells and may be exerting an epigenetic effect as part of the overall carcinogenic mechanism of lead chromate. This work was supported by NIEHS grant ES10838 (J.P.W.).

## 1146

### MICRONUCLEUS FREQUENCY IN BLOOD LYMPHOCYTES FROM CHILDREN ENVIRONMENTALLY EXPOSED TO LEAD.

M. Moreno<sup>1,2</sup>, F. Rios<sup>1</sup>, M. Sordo<sup>3</sup>, E. Vera<sup>2</sup>, L. C. Acosta-Saavedra<sup>2</sup>, M. E. Cebrian<sup>2</sup>, E. S. Calderon-Aranda<sup>2</sup> and P. Ostrosky<sup>3</sup>. <sup>1</sup>Facultad de Ciencias Químico Biológicas, UAG, Chilpancingo, Gro., Mexico, <sup>2</sup>Toxicología, Cinvestav, Mexico, DF, Mexico and <sup>3</sup>Instituto de Investigaciones Biomedicas, UNAM, Mexico, DF, Mexico.

Lead has been classified as a possible human carcinogen by the EPA since results from animal models had shown genotoxic effects. However, in adult humans results are controversial and studies to determine genotoxic effects in children environmentally exposed are not available. Thus, we evaluated micronucleus (MN) frequencies in peripheral blood lymphocytes of 47 children from a rural area in a mining zone in Mexico. We used a cross-sectional study design in boys and girls aged 6 to 10 years environmentally exposed to different levels of Pb. Information on socio-demographic status and factors affecting exposure were obtained by parent interviews. Blood lead concentration (PbB) was evaluated using a Zeeman graphite furnace atomic absorption spectrophotometer. Total arsenic (tAs) was determined in urine by hydride generation atomic absorption spectrophotometry as a possible confounding factor. MN were determined in binuclear cultured lymphocytes. Children had PbB values ranging from 2.8 to 20.4  $\mu\text{g}/\text{dl}$  (mean of 9.7  $\mu\text{g}/\text{dl} \pm 3.8$ ). The average tAs concentration was 15.6  $\mu\text{g}/\text{L}$  (ranging from 4.2 to 64.2  $\mu\text{g}/\text{L}$ ). Four percent of the population had urinary tAs levels above 50  $\mu\text{g}/\text{L}$ . MN found in studied children ranged from 0 to 7 MN, within the range of values found in non-exposed children. Preliminary statistical analysis showed no significant correlations between MN frequencies and lead or arsenic levels. This work was partially supported by FOMIX GUE-2002-C01-5456.

## 1147

### SPERM NUCLEUS UPTAKES LEAD FROM TESTIS AND EPIDIDYMIS, ALTERING SPERM CHROMATIN CONDENSATION.

I. Hernandez-Ochoa<sup>1</sup>, M. Solis-Heredia<sup>1</sup>, V. Rosales-Garcia<sup>2</sup> and B. Quintanilla-Vega<sup>1</sup>. <sup>1</sup>Toxicology Section, CINVESTAV-IPN, Mexico City, D.F., Mexico and <sup>2</sup>Central Laboratory, CINVESTAV-IPN, Mexico City, D.F., Mexico.

Sperm chromatin is reorganized during late stages of spermatogenesis when protamines, basic proteins rich in cysteine residues, replace histones to bind DNA. During epididymal transport, thiol groups of sperm protamines become oxidized into disulfide bonds condensing the DNA into a compact structure. Lead (Pb) has been associated with detrimental effects on sperm chromatin condensation, but this is still under investigation. The aim of this study was to evaluate sperm Pb uptake during testicular development and epididymal maturation and the effects on sperm chromatin. After a chronic exposure (0.075% PbCl<sub>2</sub>/16 weeks, drinking water), adult male mice (NMRI, n=8) were sacrificed and sperm from caput epididymis (CE) and cauda epididymis-vas deferens (E-VD) were obtained. Chromatin condensation in sperm from E-VD was measured by the SCSA parameter: High DNA Stainability (HDS). Lead in sperm, in reproductive tissues and in blood (PbB) was measured by AAS. Lead levels in sperm from E-VD were significantly higher (28%) than those in sperm from CE, showing that sperm uptakes Pb from testis, but also during the passage through the epididymis, where disulfide cross-links occur to condense sperm chromatin. A significant decrease (43%) in HDS was showed in E-CD sperm from the Pb-exposed group, indicating an increase in chromatin con-

densation, maybe by Pb binding to protamine-thiol groups. EDTA-treatment of Pb-exposed sperm decreased the chromatin condensation, indicating that the sperm nucleus accumulates Pb. Lead distribution in the reproductive tissues was: coagulating glands>prostate>seminal vesicles>testes, suggesting that sexual glands may be additional sources of Pb during ejaculation. Finally, PbB levels in Pb-exposed mice were 75.62  $\mu\text{g}/\text{dL}$ , and no alterations in sperm quality were observed. This study shows that epididymis is an additional Pb source to sperm nucleus altering sperm chromatin, probably by the interaction with thiol groups, since Pb binding to sulphydryl groups explains many of its toxic effects.

## 1148

### ASSOCIATIONS AMONG URIC ACID, LEAD BIOMARKERS, RENAL FUNCTION AND GENETIC POLYMORPHISMS IN KOREAN LEAD WORKERS.

V. M. Weaver<sup>1</sup>, B. S. Schwartz<sup>1</sup>, B. G. Jaar<sup>1</sup>, A. C. Todd<sup>2</sup>, K. Ahn<sup>3</sup>, K. T. Kelsey<sup>4</sup>, E. K. Silbergeld<sup>1</sup>, J. Wen<sup>1</sup> and B. Lee<sup>3</sup>. <sup>1</sup>Johns Hopkins University BSPH, Baltimore, MD, <sup>2</sup>Mount Sinai School of Medicine, New York, NY, <sup>3</sup>SoonChunHyang University, Asan, South Korea and <sup>4</sup>Harvard School of Public Health, Boston, MA.

Increasing evidence suggests that both lead and uric acid (UA) may be nephrotoxic at lower levels than previously recognized. Lead is also associated with increased UA; therefore UA may be involved in lead-related nephrotoxicity. UA, blood urea nitrogen, serum creatinine, measured and calculated creatinine clearances, urinary N-acetyl- $\beta$ -D-glucosaminidase (NAG) and retinol-binding protein and lead biomarkers were measured in 803 lead workers. Genetic polymorphisms included  $\delta$ -aminolevulinic acid dehydratase (ALAD), endothelial nitric oxide synthase and the vitamin D receptor. Mean (SD) tibia and blood lead were 37.2 (40.4)  $\mu\text{g}/\text{g}$  bone mineral and 32.0 (15.0)  $\mu\text{g}/\text{dl}$ , respectively. After adjustment, none of the lead biomarkers was associated with UA. However, when effect modification by age on these relations was examined, blood lead was a significant predictor of UA among workers in the oldest age tertile (age > 46.0 years;  $\beta = 0.0111$ ;  $p < 0.01$ ). Effect modification by ALAD genotype on associations between lead dose and UA was also observed in older workers (age > median). Next, the six renal function measures were modeled as outcomes; UA was significantly ( $p < 0.05$ ) associated with all except NAG. Finally, previously published analyses in this population showed tibia and blood lead to be predictors of worse renal function, primarily among workers in the oldest age tertile. In models restricted to the oldest tertile of workers, fewer associations between the lead biomarkers and the clinical renal outcomes were significant ( $p \leq 0.05$ ) following adjustment for UA. These data suggest that older workers comprise a susceptible population for increased UA due to lead; ALAD genotype could be a factor as well. UA may be one, but not the only, mechanism for lead-related nephrotoxicity.

## 1149

### PBPK MODELING OF THE EFFECT OF MICROGRAVITY ON THE RELEASE OF LEAD FROM BONE INTO BLOOD.

H. D. Garcia<sup>1</sup> and S. Hays<sup>2</sup>. <sup>1</sup>Life Sciences Systems and Services, Wyle Laboratories, Houston, TX and <sup>2</sup>Intertox, Lyons, CO. Sponsor: C. Lam.

Although ~95% of the body burden of lead (Pb) is stored in the bones and ~1% is in the blood, the adverse cognitive and other systemic effects of Pb exposure correlate with the levels of Pb in blood (PbB). If the release of stored Pb from bone due to microgravity-induced accelerated osteoporosis were to significantly increase astronauts' PbB, it could be a health issue for astronauts. Crewmembers on the International Space Station (ISS) lose an average of ~1% of bone mass/month and may stay on orbit 6 months or more. Measured PbDW levels on ISS normally range from <1 to <10  $\mu\text{g Pb/L}$ , while water from drinking fountains at NASA's Johnson Space Center contains 2 - 7  $\mu\text{g Pb/L}$ . The lead PBPK model developed by Ellen O'Flaherty (Environment Health Persp. 1998, 106: 1495-1503) was modified to calculate PbB resulting from various rates of osteoporosis while exposed to various levels of Pb in drinking water (PbDW). O'Flaherty's default input parameters were modified to reduce the calculated current PbB levels to equal the measured PbB values reported by the National Health And Nutrition Evaluation Survey III (NHANES III) (EPA OSWER #9258.7-52, 2002). NHANES reported an average PbB for the 36 - 45 year-old US population of about 2  $\mu\text{g}/\text{dL}$ . Using the modified PBPK model, estimated astronaut PbB levels were calculated for 1000 days of microgravity and exposure to drinking water containing 0, 1, 5, 10, 15, 25, 50, and 100  $\mu\text{g Pb/L}$ . Predicted astronaut PbB levels increased rapidly when exposed to high levels of PbDW but rapidly decrease again when PbDW levels are reduced. However, the predicted PbB levels for astronauts in microgravity decreased below pre-launch levels when the drinking water contained 0 or 1  $\mu\text{g Pb/L}$ , but the decline was less than it would have been for a person at full gravity exposed to the same PbDW. For US astronauts, the predicted increase of PbB due to microgravity-induced acceleration of osteoporosis does not reach harmful levels and can be completely cancelled by minor reductions in PbDW levels.

1150

PHARMACOKINETICS OF LEAD (PB) IN SALIVA OF RATS FOLLOWING AN ACUTE ORAL EXPOSURE.

K. K. Weitz, D. A. Moore, R. A. Gies, H. Wu and C. Timchalk. *Pacific Northwest National Laboratory, Richland, WA*.

Biological monitoring for Pb is based upon a determination of blood concentration; however, efforts are underway to use saliva as a non-invasive biomatrix for assessing exposure. The pharmacokinetics of Pb were evaluated in whole blood (WB), red blood cells (RBC), plasma, parotid gland, and saliva following a single exposure to Pb-acetate in rats. Saliva volume, pH, total saliva protein and amylase activity were also determined to evaluate salivary gland function. Five male Sprague-Dawley rats per time-point (0, 0.5, 1, 5, 12 and 24 hr post-dosing) were gavaged with 100 mg Pb-acetate/kg and the animals were anesthetized (ip; ketamine/xylazine) and administered pilocarpine (ip; 1 mg/kg) to induce salivation. Saliva was collected, the animals were humanely sacrificed and samples of blood, parotid gland and saliva were collected, weighed, and processed for Pb analysis by ICP-MS. Saliva protein and amylase were determined spectrophotometrically. Pb was detectable in all samples by 30 min post-dosing. In blood components the average peak Pb concentrations were 8.8 and 6.7  $\mu\text{g}/\text{ml}$  at 1 hr post-dosing for WB and RBC, respectively, and 0.2  $\mu\text{g}/\text{ml}$  at 5 hr post-dosing in plasma. Peak saliva Pb concentration (~0.2  $\mu\text{g}/\text{ml}$ ; 5 hr post-dosing) was comparable to plasma. Overall, the relative concentration of Pb followed the order: WB>RBC>>plasma=saliva. The average amount of Pb in the parotid gland was ~0.04  $\mu\text{g}$  at 30 min and increased to 0.12  $\mu\text{g}$  by 24 hr post-dosing. The average saliva pH decrease to a minimum (8.12) at 12 hr, but returned to control levels (8.45) by 24 hr post-dosing. Average saliva amylase activity likewise decreased from 18 U/ml (control) to 10 U/ml by 24 hr post-dosing; whereas, total saliva protein did not appreciably change over time. These results demonstrate a feasibility to rapidly detect Pb in saliva, and suggest that a high dose of Pb may impact salivary gland function. Future studies will evaluate a prolonged Pb exposure on Pb clearance and salivary gland function. (Supported by NIH/NIESH grant 1 R01 ES010976-01A2)

LEAD DISTRIBUTION FOLLOWING RESPIRATORY EXPOSURE TO LEAD-CONTAINING MATERIALS IN SPRAGUE-DAWLEY RATS.

G. M. Fent<sup>1</sup>, T. J. Evans<sup>1</sup>, D. Bannon<sup>2</sup>, M. Dunsmore<sup>1</sup> and S. W. Castle<sup>1</sup>.

<sup>1</sup>*Veterinary Pathobiology, University of Missouri, Columbia, MO* and <sup>2</sup>*US Army center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD*.

Lead (Pb) is a ubiquitous environmental contaminant that especially threatens the health of pre-school age children in the US. Although the major route of Pb exposure is ingestion, inhalation of air-borne Pb also occurs and little is known about the toxicokinetics of Pb following this type of exposure. Two preliminary experiments were conducted with objectives of determining the disposition of Pb in tissues following tracheal instillation (TI) of a Pb-containing soil or lead acetate (PbAc) and comparing the distribution of Pb between TI and oral gavage (GI) routes of exposure. In the first experiment, 54 anesthetized male rats underwent TI of double distilled water (dd water) or 225  $\mu\text{g}$  of Pb/kg of body weight (BW) as either Pb-containing soil or PbAc, and were sacrificed at 0, 3, 6, 12, 24, 48, 72, or 96 hours post-TI. Based on the results of the first experiment, another 50 rats were exposed to dd water, Pb-containing soil (100 or 200  $\mu\text{g}/\text{kg}$  BW), or PbAc (112.5 or 225  $\mu\text{g}/\text{kg}$  BW), either by TI or GI, and were sacrificed at 96-hours post exposure. In each of these experiments, blood, lung, liver, kidney, and bone were collected and analyzed for Pb using atomic absorption spectrophotometry, at a detection limit (dl) of 10 ppb in blood and tissues and .5 ppm in bone. In the first experiment all tissues had measurable Pb concentrations at 96 hours post-exposure and the kidney cortex had the highest Pb concentration of the tissues collected. In the second experiment, all lung Pb concentrations were below the dl and all other tissue Pb concentrations were higher in the TI versus GI groups, with the kidney cortex Pb concentration being approximately 20-fold higher in the TI groups. These preliminary results indicate that respiratory exposure to Pb, even at low doses, will result in elevated tissue and blood Pb concentrations and the kidney is the site of lead accumulation following respiratory tract exposure.

1152

ROLE OF PLASMA GLUTATHIONE IN HEPATIC TOXICITY CAUSED BY VANADIUM COMPOUNDS IN MICE.

T. Hasegawa<sup>1</sup>, M. Satoh<sup>2</sup> and Y. Seko<sup>1</sup>. <sup>1</sup>*Environmental Biochemistry, Yamanashi Institute of Environmental Sciences, Fujiyoshida, Yamanashi, Japan* and <sup>2</sup>*Department of Hygienics, Gifu Pharmaceutical University, Gifu, Japan*.

Ammonium metavanadate (V[5]; pentavalent vanadium compound) is more toxic than vanadyl sulfate (V[4]; tetravalent vanadium compound). It is known that the pentavalent vanadium is reduced to the tetravalent vanadium form by antioxidants. Therefore, the reduction process is regarded as a mechanism for the detoxifi-

cation of vanadium. The present work was undertaken to elucidate the role of plasma reduce glutathione (GSH) in hepatic toxicity caused by vanadium compounds in animals. Male ICR mice were injected with V[5] (0.1-0.3 mmol/kg, s.c.) or V[4] (0.1-0.9 mmol/kg, s.c.) and sacrificed 6 h after the injection. Activities of AST and ALT were increased dose-dependently with both compounds. The hepatic toxicity caused by V[5] was higher than the toxicity by V[4]. The role of GSH in the prevention of toxicity caused by the vanadium compounds, was explored in mice treated with BSO, a specific inhibitor of GSH synthesis. The depression of both intracellular and extracellular (plasma) GSH levels in mice pretreated with BSO, markedly enhanced the hepatic toxicity by V[5] and hepatic vanadium content. In animals treated with V[4], the toxicity and vanadium content was not affected by BSO pretreatment. To gain some insight into the mechanism of enhancement of vanadium toxicity, we examined the effect of GSH administration on the BSO-enhanced hepatic toxicity of V[5]. Contents of GSH in tissues of mice 1 h after administration of V[5] were measured. Levels of GSH in plasma and liver were decreased by the administration of V[5] or BSO. Pretreatment by GSH protected against the decrease of GSH level in plasma by the administrations, but not affected hepatic GSH level. Furthermore the pre-administration of GSH to BSO-treated mice protected against hepatic toxicity of V[5], and decreased the height vanadium accumulation in the liver. These data suggest that plasma GSH plays a protective role by reducing V[5] to V[4], resulting in the decreased hepatic vanadium uptake and toxicity.

Avila-Casado<sup>1</sup>, V. Delgado<sup>1</sup>, F. Pasos<sup>1</sup>, B. Chavez<sup>1</sup> and M. AVILA-COSTA<sup>2</sup>. <sup>1</sup>*Biología Celular Y Tisular, Facultad de Medicina, UNAM, Mexico* and <sup>2</sup>*Neuromorfología, Fes Iztacala, UNAM, Mexico, Mexico*.

A previous report from our group informed the presence of thrombocytosis as a consequence of Vanadium inhalation. This time, we decided to evaluate the effects of this element on the mice spleen, to identify the morphological modifications in this hematopoietic organ. CD-1 mice inhaled V2O5 0.02M one hour, twice a week during 12 weeks. Spleens were extracted, weighed, and processed by the usual histological technique. The main changes observed were: an increase in the white pulp and in the amount of megakaryocytes in those mice exposed to V (Figs. 1, 2). These findings explain in part, the thrombocytosis reported previously, and the question about platelets function remains to be elucidated. DGAPA IN\_204304 P.O.S. Institute

1154

ROLE OF OXIDATIVE STRESS IN THE MODULATION OF AHR-REGULATED GENE EXPRESSION BY HEAVY METALS.

R. H. Elbekai and A. O. El-Kadi. *University of Alberta, Edmonton, AB, Canada*.

Since heavy metals, mainly arsenite ( $\text{As}^{3+}$ ), cadmium ( $\text{Cd}^{2+}$ ) and chromium ( $\text{Cr}^{6+}$ ), have been shown to exert their toxicity, at least partly, by the generation of reactive oxygen species (ROS), we evaluated the role of metal-induced ROS on the expression of AHR-regulated genes: Cyp1a1, NAD(P)H:quinone oxidoreductase (QOR), and glutathione S-transferase Ya (GST Ya). For this purpose, Hepa 1c1c7 cells were treated with 5  $\mu\text{M}$  of  $\text{As}^{3+}$ ,  $\text{Cd}^{2+}$  or  $\text{Cr}^{6+}$  in the presence or absence of TCDD (1 nM), an AHR ligand. All three metals caused perturbations in cellular glutathione redox status, but only  $\text{Cd}^{2+}$  and  $\text{Cr}^{6+}$  increased the production of ROS. Although all three metals potentiated the induction of Cyp1a1 mRNA by TCDD, they decreased the stability of the induced protein and inhibited the induction of its activity. Pre-treatment with the thiol antioxidant N-acetylcysteine (NAC) did not alter Cyp1a1 mRNA levels but completely abrogated the inhibition of Cyp1a1 activity induction by all three metals. In parallel, Cyp1a1 mRNA expression was further potentiated whereas Cyp1a1 activity was further inhibited when cells were pretreated with the glutathione synthase inhibitor, L-buthionine-[S, R]-sulfoximine (BSO). Furthermore, all three metals induced the expression of heme oxygenase-1 (HO-1) which was further potentiated with BSO but inhibited with NAC pretreatments. Additionally, metals alone induced Cyp1a1 mRNA expression, which was superinduced in the presence of the protein synthesis inhibitor, cycloheximide. All three metals, alone or in the presence of TCDD, enhanced QOR and GST Ya activities and mRNA levels, an effect that was completely abrogated with NAC pre-treatment and markedly potentiated with BSO. Pre-treatment with the DNA transcription suppressor, actinomycin-D, abolished the induction of QOR and GST Ya mRNA levels by the three metals. Our data clearly show that  $\text{As}^{3+}$ ,  $\text{Cd}^{2+}$ , and  $\text{Cr}^{6+}$

induced ROS production modulates Cyp1a1 activity by decreasing Cyp1a1 protein stability and inducing HO-1, but induces QOR and GST Ya activities at the transcriptional level, likely regulated by the antioxidant response element.

INTEGRATIVE ANALYSIS OF GENOME-WIDE GENE EXPRESSION AND PATHWAY MAPPING IN MOUSE EMBRYONIC FIBROBLAST (MEF) EXPOSED TO CADMIUM, ARSENIC AND METHYLMERCURY: INDUCTION OF OXIDATIVE STRESS, DISRUPTION OF UBIQUITIN-PROTEASOME SYSTEM AND CELL CYCLE REGULATION.

X. Yu, J. S. Sidhu, J. F. Robinson, S. Hong and E. M. Faustman. *Environmental Health, IRARC, UW, Seattle, WA.*

Environmental and occupational exposures to heavy metals including Methylmercury (MeHg), arsenic (As) and cadmium (Cd) pose significant health risks to humans. Although many toxicological impacts have been associated with these metals exposure, the underlying mechanisms of toxicity have not been clearly defined. We conducted gene expression array analysis by using the CodeLink Mouse UniSet 10K oligonucleotide-based platform to explore the gene alterations caused by metals. We treated mouse embryonic fibroblast cells (MEF) with environmentally relevant doses of MeHg (2.5 $\mu$ M), Cd (5.0 $\mu$ M) and As (5.0  $\mu$ M) for 24 h. A classical proteasome inhibitor, MG132 (0.5  $\mu$ M), was included to compare its pattern of gene expression with metals to determine if disruption of ubiquitin-proteasome system (UPS) is a critical mechanism of metal-induced toxicity. The doses selected were consistent with our previous studies where minimal impacts were observed on stress signaling and apoptotic pathways. Following normalization of the array data, we have employed multi-level analysis tools to explore the data, including group comparisons, cluster analysis and gene annotations analysis using MAPPFinder. Furthermore we applied knowledge-based pathway mapping of our gene expression data by using GenMAPP. Using these integrated approaches, we identified significant alterations in UPS, antioxidant and phase II enzymes, DNA repair and damage pathway and cell cycle regulation pathways across the three metals. The results suggest the critical roles of above pathways in metal-induced toxicity. Furthermore, this study demonstrated that the integration of toxicogenomic and knowledge-based pathway mapping is a powerful approach to elucidate molecular mechanism of toxicity. 1156

EFFECT OF COMBINED LEAD, CADMIUM AND ARSENIC EXPOSURE ON THE EXPRESSION OF CELLULAR PROTECTIVE FACTORS IN RAT KIDNEYS AT LOEL DOSE LEVELS.

G. Wang, X. Chen, M. M. Lipsky, M. H. Whittaker and B. A. Fowler. *Toxicology Program, University of Maryland, Baltimore, MD.*

Lead (Pb), Cadmium (Cd) and Arsenic (As) are ubiquitous toxic metals/metalloids in the environment. We have previously demonstrated the oxidative DNA adduct, 8-hydroxy-2-deoxyguanosine (8-OHdG), and induction of heme oxygenase-1 (HO-1), a sensitive indicator of oxidative stress, in rat kidneys in the Cd x As and Pb x Cd x As 180-day treatment group, respectively. We also found that rats displayed compensatory responses when exposed to these elements for 90 days, as compared to 30- and 180- day exposure. The present studies were undertaken to further investigate cellular and molecular mechanisms contributing to these phenomena focusing on the mRNA expression of metallothionein (MT), heat shock proteins (HSPs) and anti-oxidant enzymes. Male Sprague-Dawley rats (15/group) were exposed to deionized drinking water containing Pb (25ppm), Cd (10 ppm), As (5 ppm), or PbxCd, PbxAx, CdxAx or PbxCdAx mixtures for 30, 90, or 180-days. At each time point kidneys were collected and subjected to real-time polymerase chain reactions (RT-PCR) for MT1 and MT2, HSP 32 and HSP60, glutathione peroxidase (GPx) and superoxide dismutase (SOD). At 30 days MT1 and MT2 mRNA expression were down-regulated in the PbxAx group; HSP60 mRNA was up-regulated in the PbxAx group, but down-regulated in the Cd xAs group; GPx mRNA expression was up-regulated in the As, Cd xAs and Pb x Cd xAs groups. At 90 days GPx mRNA expression was up-regulated in the PbxAx, Cd xAs and Pb x Cd xAs groups and SOD mRNA expression was down-regulated in all treatment groups; Further, HSP60 expression was decreased in the Pb and Pb x Cd groups, and MT2 expression was decreased in Cd and As groups. By 180 days SOD was up-regulated in the Cd, Cd xAs and Pb x Cd xAs groups and GPx was up-regulated in the PbxAx group and HSP60 was decreased in the Pb treatment group. These results indicate that single and combined exposure to Pb, Cd and As alters the expression patterns of protective enzymes/proteins in the rat kidneys. 1157

COMPARISON OF METALS IN CYTOTOXICITY, FREE RADICAL GENERATION, AND HEAT SHOCK PROTEIN EXPRESSION IN A HUMAN BRONCHIAL EPITHELIAL CELL LINE, BEAS-2B.

S. Han<sup>1,2</sup> and V. Vallathan<sup>1</sup>. <sup>1</sup>*Pathology and Physiology Research Branch, National Institute for Occupational Safety and Health, Morgantown, WV* and <sup>2</sup>*Genetics and Developmental Biology, West Virginia University, Morgantown, WV.*

A number of toxic heavy metals such as arsenic (As), chromium (Cr), cadmium (Cd), mercury (Hg), nickel (Ni), vanadium (V), and manganese (Mn) are widely used in occupational settings, and exposure to these metals is associated with the development of pulmonary disease. Cytotoxicity, apoptosis, and reactive oxygen species (ROS) generation were tested to compare the biological reactivity of these heavy metals using a human bronchial epithelial cell line, BEAS-2B. Also, heat shock protein 70 (Hsp70) expression was observed as an early and sensitive biomarker of cellular stress. Exposure to metals (50 microM) for 24 hr caused significant cytotoxicity for all the metals tested. Among the metals tested, As (20%), Cr (10%), Cd (30%), and Mn (44%) showed less than 50% survival rate compared to control cells. Apoptosis was significantly increased in the cells exposed to 50 microM of As (2.2-fold), Cr (4.5-fold), and Cd (2.5-fold). Intracellular ROS generation has the capacity to induce DNA damage, alter signal transduction, and cause lipid peroxidation leading to either apoptosis or carcinogenesis. Electron spin resonance (ESR) was used to detect short-lived free radical intermediates generated in the reaction of metal with cells. Hydroxyl radical generation was greater in the presence of As, Cr, Cd, and Hg compared to the other metals. As, Cd, and Hg showed a high expression of Hsp70 protein in Western blotting and ELISA while Cr, Ni, V, and Mn did not show any significant increase of Hsp70 protein. These results suggest that both cytotoxicity and apoptosis were significant with all metals tested; however As, Cd, Cr, and Hg were relatively most toxic metals tested. Generation of ROS may be involved in metal induced lung cell damage. Metal-induced Hsp70 expression could be a sensitive indicator of lung cell injury by As, Cd, and Hg.

1158

METAL-INDUCED OXIDATION OF THIOREDOXIN-1 AND THIOREDOXIN-2.

J. M. Hansen and D. P. Jones. *Medicine, Emory University, Atlanta, GA.*

Exposure to metals can elicit numerous deleterious effects leading to apoptosis, carcinogenesis and a variety of other diseases. Some metals have been described as being reactive and binding to free sulfhydryls en route to toxicity. While much data has been collected regarding the effects of metals on glutathione, the primary intracellular antioxidant, very little is known about the effects of metals on another important intracellular antioxidant system, the thioredoxin system. Here, we evaluate the effects of arsenic, cadmium, cesium, copper, iron, mercury, nickel and zinc on cytoplasmic/nuclear thioredoxin-1 (Trx1) and mitochondrial thioredoxin-2 (Trx2) redox states. HeLa cells were grown to 80% confluence and then treated with either 10 or 100  $\mu$ M of each metal listed above for 4 h. Cells were collected and derivatized with iodoacetic acid for Trx1 and 4-acetamido-4'-maleimidylstilbene-2, 2'-disulfonic acid (AMS) for Trx2 and analyzed following separation of the reduced and oxidized forms via redox Western techniques. Trx1 was significantly oxidized up to +30 mV from control (-278 mV) with arsenic, cadmium and mercury. The other metals tested showed no Trx1 effects. Similarly, arsenic, cadmium and mercury significantly oxidized Trx2 (-352 mV in controls) but significant oxidation was also noted with cesium as well. Copper, iron, nickel and zinc showed no Trx2 effects. Mitochondria are believed to be protected by metallothionein during the toxic, oxidative effects of some metals, including cadmium and mercury. Our findings show that metal exposure can cause both cytoplasmic/nuclear and mitochondrial oxidation as principal effects of metal toxicity.

1159

INDUCTION OF OXIDATIVE STRESS IN RESPONSE TO INGESTION OF LEAD, CADMIUM AND ARSENIC MIXTURES.

M. H. Whittaker, B. A. Fowler, G. Wang, C. Xue-Qing and M. Lipsky. *Toxicology Program, The University of Maryland, Baltimore, Baltimore, MD.*

Human populations are commonly exposed to mixtures of chemicals. To date, relatively few studies have examined potential interactive effects using a statistical factorial design. Multiple drinking water studies were performed to test the hypothesis that exposure to arsenic, lead, or cadmium (or their combinations) for 30, 90, or 180 days at lowest-observed-effect levels (LOELs) results in increased levels of oxidative stress in the kidney, which is a target organ for trace element-induced toxicity. Male Sprague-Dawley rats were exposed to lead, cadmium, arsenic, or mixtures of these three trace elements for 30, 90, or 180 days via drinking water. Oxidative stress levels (as measured by increases in kidney carbonyls) were generally increased at 30 days and decreased at 90 and 180 days. At 30 and 180 days, cadmium appeared to attenuate carbonyl increases among mixture groups. Among all treatment

groups, increases in kidney carbonyls were lowest among the PbxCdxAs group at all three timepoints. Cellular adaptation to trace element-induced oxidative stress is suggested by the attenuation of increases in kidney carbonyls at the 90 and 180 day timepoints. Statistically significant increases in kidney glutathione levels (measured as nonprotein thiols) were measured after 30 and 180 days of exposure among most treatment groups, with some of the greatest increases measured among the four combination groups at the 30 day timepoint (96%-145% increase) and the 180 day timepoint (20%-70% increase). In contrast, kidney non-protein thiols were statistically significantly decreased in 4 of 7 treatment groups after 90 days of exposure (28%-33% decrease). These data demonstrate that low-level exposure to trace elements or their mixtures results in measurable increases in oxidative stress and up-regulation of cellular defensive mechanisms [Supported by USEPA Star Grant R827161-01-0].

### CHANGING METAL ACCUMULATION IN NEW ORLEANS: DIFFERENCES BETWEEN SURVEY I (1992) AND SURVEY II (2000).

H. W. Mielke<sup>1</sup>, E. Powell<sup>1</sup>, C. Gonzales<sup>1</sup> and P. Mielke (Emeritus)<sup>2</sup>. <sup>1</sup>*College of Pharmacy, Xavier University, New Orleans, LA* and <sup>2</sup>*Statistics, Colorado State University, Fort Collins, CO*.

New Orleans soils have been surveyed and mapped twice. Survey I was completed in 1992 and Survey II was completed in 2000. This study evaluates the possibility for change between the two surveys. All samples were collected in residential neighborhoods at least one block from a busy street. The Survey I collection had 4, 026 samples stratified by 283 census tracts and Survey II had 4, 389 samples stratified by 286 census tracts. The extraction methods used the same protocol for pH (1 M Nitric acid), room temperature and 2 hour shaker time. They differed in amount of sample extracted, 4.0 g (Survey I) compared with 0.4 g (Survey II). ICP-AES techniques were used to measure 8 metals. The analytical results of the extraction methods were evaluated with homogenized soil samples from the Wageningen Evaluating Programs for Analytical Laboratories, International Soil-analytical Exchange (WEPAI; ISE). All correlation results were linear and the Survey I results were converted to make them equivalent with the Survey II results. Geographic Information Science (GIS) evaluation was done by assigning a median soil metal result to the centroid of each census tract; Kriging interpolation of the above data with Surfer; Importing ASCII grids into ArcView GIS using the grid machine extension; Forming a new grid by Survey II divided by Survey I grid cells. Changes in metals were observed. Most prominent were increases in the inner city Pb, Zn, Cu. Amounts of Cr, Cd and Mn appear to be about the same, and V, and Ni decreased. Reasons for increases of Pb and Zn include: Power sanding of New Orleans old wood homes with Pb-based paint; Zn is a constituent of tires and paints. The suburb lacks similar metal sources and new soils are commonly added for landscaping purposes. Overall, residential soil metals appear to undergo a relatively high rate of change. Pb, Zn and Cu appear to continue accumulating in the inner-city.

## 1161

### TOXICOGENOMICAL STUDY ON HUMAN BLADDER EPITHELIUM EXPOSED TO ARSENIC.

X. Zheng<sup>1</sup>, T. G. Bredfeldt<sup>1</sup>, G. S. Watts<sup>2</sup> and A. Gandolfo<sup>1</sup>.

<sup>1</sup>*Pharmacology/Toxicology, College of Pharmacy, University of Arizona, Tucson, AZ* and <sup>2</sup>*Arizona Cancer Center, University of Arizona, Tucson, AZ*.

In this study, human urothelium (UROtsa) cells were exposed to arsenite [As(III)-30  $\mu$ M], monomethylarsenous acid [MMA(III) 1-5  $\mu$ M], or buthionine sulfoximine [BSO-25  $\mu$ M] followed by [As(III)-1  $\mu$ M] for up to 18 hr and the changes in gene expression determined by using a human oligonucleotide chip (18, 861 genes). The hybridizations were performed at least three times using independent total RNA preparations to ensure reproducibility. Differentially expressed genes were identified based on 2-fold cut off and gene significantly different from the control cells (t-test analysis,  $p<0.05$ ). Only up-regulated genes have been assessed. Both As(III) and MMA(III) treatments produce an oxidative stress response. Interestingly, MMA(III) exposure for 6 hr did not induce any metallothionein genes but induced numerous unique genes [such as dual specificity phosphatase (DUSP1, DUSP2); CDC like kinase (CLK1); DNA damage inducible transcript (DDIT3)] and even caused greater increases in stress genes [e.g. heat shock protein (HSP46, HSPA1A); DnaJ(HSP40)]. Reduction in cellular GSH content via BSO treatment followed by As(III) exposure for 6 hr exacerbate the gene expression-modifying effects of arsenite on UROtsa cells. The induction of heat shock protein (HSP1A1, HSPA6); metallothionein (MT1G); and solute carrier family (SLC30A) genes revealed synergistic effects of cytotoxicity for both As(III) and BSO. These results indicate that oxidative stress must be a common pathway in cellular response to exposure to different arsenicals. Furthermore, As(III) and MMA(III) induce genes involved in similar but different pathways. The absence of metallothionein gene induction by MMA (III) exposure may demonstrate different mechanism of recognition by the UROtsa cells or mechanism of toxicity (NIEHS 04940, SWEHSC 06694 and NCI 023074).

## 1162

### DIFFERENTIAL EFFECTS OF CHRONIC LOW LEVEL ARSENIC EXPOSURES ON TRANSCRIPTION FACTOR BINDING IN CARDIOVASCULAR TISSUES.

L. R. Klei<sup>1,2</sup>, M. A. Ihnat<sup>3</sup>, N. V. Soucy<sup>2</sup>, A. A. Nemeć<sup>1</sup> and A. Barchowsky<sup>1,2</sup>.

<sup>1</sup>*Environmental and Occupational Health, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA*, <sup>2</sup>*Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH* and <sup>3</sup>*Cell Biology, University of Oklahoma Health Sciences Center, Oklahoma City, OK*.

Chronic exposure to low levels of trivalent arsenic in drinking water promotes differential induction of cardiovascular genes, vascular remodeling, and vascular disease. To resolve the signaling pathways involved in arsenic-induced phenotypic change, proteomic analysis of transcription factor DNA binding arrays in nuclear extracts from mouse hearts or cultured porcine vascular smooth muscle cells were examined. *In vivo*, mice fed 10-50 ppb of sodium arsenite (AsIII) in their drinking water for 5 weeks had increases in nuclear proteins binding to AP-1, Ets, FKHR, GATA, HIF and Stat consensus DNA cis elements. Nuclear extracts from smooth muscle cells had similar, but more limited increases in the binding of these transcription factors. In contrast to previous reports for higher levels of exposure, there were no significant increases in stress response factors, NF- $\kappa$ B, or p53 DNA binding in either model with these AsIII exposures. AsIII exposures also decreased nuclear levels of a significant number of transcription factors. Gel mobility shift assays and western analysis of proteins from multiple animals and cell cultures were used to confirm increases seen in the array analyses. Genes induced by these AsIII exposures include vascular endothelial cell growth factor, plasminogen activator inhibitor-1, endothelin-1. These data demonstrate that chronic, low dose AsIII exposures activate multiple interacting signaling cascades to transcriptionally promote cardiovascular vascular remodeling and response genes. Supported by NIEHS SBRP grant ES07373

## 1163

### EUKARYOTIC TRANSLATION INITIATION FACTOR 4E IS A CELLULAR TARGET FOR ARSENIC BUT NOT CHROMIUM TOXICITY.

P. Joseph and S. Othumpangat. *NIOSH, Morgantown, WV*.

The mRNA cap binding translation factor, eukaryotic translation initiation factor 4E (eIF4E), was studied as a potential cellular target for the toxicity and cell death induced by arsenic and chromium. Human cell lines HCT15, PLC/PR/5, HeLa and Chang, were treated with sodium arsenite (As) and potassium dichromate (Cr). Exposure to both As and Cr resulted in significant cytotoxicity and cell death in all four cell lines. In all the cell lines treated with As and Cr, the transcript for eIF4E did not exhibit any change compared with the corresponding control cells. However, in the cells treated with As alone, the cellular expression level of eIF4E protein was significantly lower compared to the corresponding control cells. Further studies revealed that exposure of cells to As, but not to Cr, resulted in significant induction of ubiquitination of eIF4E protein. Results of the experiments involving inhibitors for the cellular proteasome pathway confirmed that the exposure of As but not Cr activated the proteolysis of eIF4E mediated through the ubiquitin/proteasome pathway. Whether the As-induced cytotoxicity and cell death were due to the inhibition of eIF4E was studied by specifically silencing the expression of eIF4E gene using a small interfering RNA (SiRNA) targeting eIF4E gene expression. The SiRNA-mediated silencing of eIF4E gene resulted in cytotoxicity and cell death suggesting that eIF4E is a potential cellular target for cytotoxicity and cell death due to exposure to As.

## 1164

### EFFECT OF ARSENITE ON PU.1, C/EBPS, AND NFKB ACTIVATION IN U937 PROMONOCYTIC LEUKEMIA CELLS.

M. Yamamoto<sup>1</sup>, S. Hirano<sup>1</sup>, C. R. Jefcoate<sup>2</sup> and F. Matsumura<sup>3</sup>. <sup>1</sup>*Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Ibaraki, Japan*, <sup>2</sup>*Pharmacology, University of Wisconsin-Madison, Madison, WI* and <sup>3</sup>*Environmental Toxicology, University of California-Davis, Davis, CA*.

Arsenite has been reported to exert dose-dependent dual effect; triggering apoptosis at relatively high concentration, whereas it induces partial differentiation at low concentration in leukemia cells. However its bilateral character regarding the molecular mechanisms remains to be clearly defined. We examined the effect of arsenite on key transcription factors for macrophage differentiation such as PU.1 and C/EBPs to find out how arsenite interacts with the signaling pathways for differentiation in U937 promonocytic leukemia cells. Electrophoretic mobility shift assays were used to analyze the interaction between arsenite induced signaling and these transcription factors. In addition the phorbol ester TPA which activates PKCs was compared with arsenite as a second type of differentiation inducer for leukemia cells. The PU.1 activation was not changed in the presence of 1  $\mu$ M or 10  $\mu$ M arsenite for 3, 6, or 24-hrs exposure. On the other hand, activation pattern of PU.1

was drastically changed in the presence of 10 nM TPA after 24-hrs exposure. Among C/EBPs, C/EBP $\alpha$  and C/EBP $\epsilon$  were slightly affected by arsenite, but their activation were suppressed by TPA after 24-hrs exposure. NF- $\kappa$ B was constitutively activated by serum free conditions in U937 cells and this activation was suppressed by arsenite. These results indicate that arsenite and TPA interact with key regulators by different pathway in monocytic differentiation of U937 cells.

## 1165 IDENTIFICATION OF MOUSE SLC39A8 AS THE TRANSPORTER RESPONSIBLE FOR CADMIUM-INDUCED TOXICITY IN THE TESTIS.

L. He<sup>1</sup>, T. P. Dalton<sup>1</sup>, B. Wang<sup>1</sup>, M. L. Miller<sup>1</sup>, L. Jin<sup>1</sup>, K. F. Stringer<sup>2</sup>, X. Chang<sup>1</sup>, C. S. Baxter<sup>1</sup> and D. W. Nebert<sup>1</sup>. <sup>1</sup>*Department of Environmental Health, and the Center for Environmental Genetics (CEG), University of Cincinnati, Cincinnati, OH* and <sup>2</sup>*Department of Pathology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*.

Testicular necrosis is a sensitive endpoint for cadmium (Cd++, Cd) toxicity across all species tested. Resistance to Cd-induced testicular damage is a recessive trait assigned to the Cdm locus on mouse chromosome 3. We first narrowed the Cdm gene-containing region to 880 kb. SNP analysis of this region from two sensitive and two resistant inbred strains demonstrated a 400-kb haplotype block consistent with the Cd-induced toxicity phenotype; in this region is the Slc39a8 gene encoding a member of the solute-carrier superfamily. Slc39a8 encodes SLC39A8(ZIP8), whose homologs in plant and yeast are putative zinc transporters. We show here that ZIP8 expression in cultured mouse fetal fibroblasts leads to a >10-fold increase in the rate of intracellular Cd influx and accumulation and a 30-fold increase in sensitivity to Cd-induced cell death. The complete ZIP8 mRNA and intron-exon splice junctions have no nucleotide differences between two sensitive and two resistant strains of mice; using *in situ* hybridization we found that ZIP8 mRNA is prominent in the vascular endothelial cells of the testis of the sensitive strains of mice, but absent in these cells of resistant strains. Slc39a8 is therefore the Cdm gene, defining sensitivity to Cd toxicity specifically in vascular endothelial cells of the testis.

## 1166 ROLE OF EUKARYOTIC TRANSLATION INITIATION FACTOR 4E (eIF4E) IN CADMIUM-INDUCED CYTOTOXICITY AND CELL DEATH.

S. Othumpangat and P. Joseph. *Toxicology and Molecular Biology Branch, NIOSH, Morgantown, WV*.

The role of eukaryotic translation initiation factor 4E (eIF4E), in cadmium-induced cytotoxicity and cell death was investigated. Exposure of human cell lines HCT15, PLC/PR/5, HeLa and Chang, to cadmium chloride (Cd) resulted in a dose-dependent toxicity and death. Western blot analysis of the cells demonstrated a significant inhibition of eIF4E gene (protein) in response to Cd exposure. Whether the inhibition of eIF4E was responsible for the observed toxicity and death was studied by silencing the cellular expression of eIF4E gene by employing a small interfering RNA (SiRNA) specifically targeting the eIF4E gene. The SiRNA-mediated silencing of eIF4E gene expression resulted in significant cytotoxicity and cell death suggesting that the cytotoxicity and cell death noticed among the Cd-treated cells were probably due to the chemical-induced inhibition of eIF4E gene expression. Transgenic Chinese hamster ovary cell lines overexpressing eIF4E were resistant to Cd-induced cytotoxicity and cell death. Results of Western blot analysis and immunoprecipitation experiments demonstrated a significant induction of ubiquitination of eIF4E in the Cd treated cells. Pre-exposure of cells to proteasome inhibitors blocked the Cd-induced inhibition of eIF4E gene expression as well as the resulting cytotoxicity and cell death. Furthermore, exposure of cells to Cd resulted in a significant inhibition of expression of the cell cycle and growth regulating gene, cyclin D1. Transfection of cells with SiRNA specifically targeting eIF4E gene expression also resulted in a significant inhibition of cyclin D1 gene expression suggesting that the observed inhibition of cyclin D1 gene in the Cd-treated cells is most likely mediated through inhibition of eIF4E gene. Taken together, our results demonstrate that the exposure of cells to cadmium chloride resulted in cytotoxicity and cell death due to the enhanced ubiquitination and proteolysis and the consequent inhibition of eIF4E gene expression leading to diminished cellular level of critical genes such as cyclin D1.

## 1167 MECHANISMS OF ARSENITE-STIMULATED HEMOXYGENASE-1 UPREGULATION IN HUMAN KERATINOCYTES.

K. L. Cooper and L. G. Hudson. *College of Pharmacy, University of NM, Albuquerque, NM*.

Hemeoxygenase-1 (HO-1) is the rate-limiting enzyme involved in heme catabolism. It is an oxidative stress responsive gene upregulated by various physiological and exogenous stimuli including heme, ultraviolet irradiation, heat shock, inflam-

matory cytokines, heavy metals and arsenite. HO-1 has many stress-activated recognition sites in the promoter region of its gene. These include NF- $\kappa$ B, heme response elements, antioxidant response elements and activator protein 1 (AP-1). Arsenic is a known dermatotoxin and chronic exposure has been associated with increased incidence of keratinocytic tumors. The mechanism of arsenic-mediated skin carcinogenesis is not well-understood, but activation of mitogen-activated protein kinases (MAPKs) and generation of reactive oxygen species (ROS) may contribute to tumor promotion and progression. We have reported that arsenite (AsIII)-dependent activation of ERK, but not p38, is dependent upon EGF receptor activity. In this study we investigated the potential contributions of ROS generation and AP-1 activation to AsIII-dependent regulation of HO-1 in HaCat cells, a spontaneously immortalized human keratinocyte cell line. Both EGF and AsIII induced ROS as observed via dihydroethidium (DHE) staining and fluorescence microscopy. Western blotting showed arsenite-induced sustained upregulation of HO-1 in a time-dependent (0-72h) and concentration-dependent (3-30 $\mu$ M) manner. Inhibition of EGF receptor, MEK I/II, and p38 activation moderately reduced HO-1 expression, but none completely abrogated the arsenite-induced response suggesting that the signaling proteins (EGF receptor, ERK and p38) were necessary but not sufficient for AsIII-induced HO-1 upregulation. Inhibition of Src-family kinases also slightly reduced HO-1 induction indicating a small contribution to the observed induction. The superoxide scavenger MnTTPyP also partially decreased the arsenite-induced expression of HO-1. These results suggest that both the stress-activated and EGF receptor pathway are involved in regulation of HO-1 expression in response to arsenite in keratinocytes.

## 1168 MERCURY, CADMIUM, ZINC, AND ARSENITE INHIBIT PAX3 DNA BINDING VIA THE PAIRED DOMAIN.

F. A. Leal<sup>1</sup>, A. F. Machado<sup>2</sup>, M. D. Collins<sup>1</sup> and J. M. Fukuto<sup>1</sup>. <sup>1</sup>*Molecular Toxicology IDP, University of California, Los Angeles, CA* and <sup>2</sup>*Department of Environmental and Occupational Health, California State University, Northridge, CA*. Sponsor: O. Hankinson.

Mercury, cadmium, zinc, and arsenite are common metallic environmental contaminants that have high affinities for endogenous thiols, such as glutathione and protein thiols. Pax3 is a murine transcription factor that is involved in a number of developmental processes, including neural tube closure. Using the Splotch mouse model, it has been shown that Pax3 haploinsufficiency confers added sensitivity to neural tube defects (NTDs) induced by arsenite. Previous studies have also shown that cysteine residues in the Pax3 paired domain (PD) are required for binding to PD-specific DNA target sites and that such binding is reduced or blocked entirely by pro-oxidants. The current study was undertaken to test whether the presence of an environmentally relevant metal is capable of abrogating Pax3 binding to a PD-specific DNA target, the e5 segment from the *Drosophila* even-skipped gene. Electrophoretic mobility shift assays (EMSA) were performed with 32P labelled e5 in the presence of 2mM glutathione, a cellularly relevant concentration. Mercuric chloride, cadmium chloride, zinc sulfate, and sodium arsenite were each able to dose-dependently inhibit Pax3 DNA binding with EC50s of 10, 50, 60, and 450  $\mu$ M, respectively. Thus far, this work demonstrates that, like the sensitivity to pro-oxidants, Pax3 binding to DNA targets via the PD is sensitive to the presence of thiophilic metals. Experiments are underway to examine the effect of the one-electron redox cycling metals, copper and iron, in the presence and absence of the one-electron reductant, ascorbate, to determine to what extent redox chemistry plays a role in mediating Pax3 DNA-binding inhibition. We are also examining the effect of GSH:GSSG ratios in the presence and absence of thiophilic or redox cycling metals to determine the role of redox environment in the inhibition of Pax3 DNA binding via the PD.

## 1169 NF $\kappa$ B MEDIATES ZINC-INDUCED COX-2 EXPRESSION IN HUMAN BRONCHIAL EPITHELIAL CELLS.

W. Wu<sup>1</sup>, <sup>1</sup>*Center for Environmental Medicine, University of North Carolina, Chapel Hill, NC* and <sup>2</sup>*Human Studies Division, USEPA, Research Triangle Park, NC*. Sponsor: M. Madden.

Upregulation of COX-2 expression is a pivotal event in inflammatory reactions induced by a variety of stimuli. Divalent zinc (Zn<sup>2+</sup>) component has recently been implicated as a causative agent in airway inflammation induced by exposure to ambient particulate matter. Our recent studies have shown that Zn<sup>2+</sup> exposure increases COX-2 expression through both transcriptional and posttranscriptional mechanisms in human bronchial epithelial cells. This study aims to determine whether the transcription factor nuclear factor  $\kappa$ B (NF $\kappa$ B) mediates Zn<sup>2+</sup>-induced COX-2 mRNA expression in these cells. Exposure to Zn<sup>2+</sup> had a minimal effect on I $\kappa$ B $\alpha$  breakdown and nuclear translocation of NF $\kappa$ B. However, Zn<sup>2+</sup> exposure caused a time-dependent phosphorylation of NF $\kappa$ B (p65), a component of the NF $\kappa$ B transcription factor, suggesting a transactivation mechanism activated by Zn<sup>2+</sup> exposure. Consistent with this, exposure of cells to Zn<sup>2+</sup> resulted in a time-dependent increase in NF $\kappa$ B reporter activity. Inclusion of human specific NF $\kappa$ B

p65 siRNA by means of transfection reagents selectively inhibited NF $\kappa$ B p65 expression as well as Zn<sup>2+</sup>-induced COX-2 mRNA expression with minimal effect on p42 MAPK expression. These findings suggest that exposure to Zn<sup>2+</sup> triggers NF $\kappa$ B transactivation through phosphorylation of p65, which is required for subsequent upregulation of COX-2 gene transcription in human bronchial epithelial cells.

**1170** COMPARISON OF BCNU AND SARCNU TOXICITY IN LONG-TERM CULTURES OF PRECISION-CUT LUNG SLICES.

C. A. Tyson, K. Amin, C. Ip and H. P. Behrsing, *Toxicology Laboratory, SRI International, Menlo Park, CA*.

Interstitial pneumonitis is a common histopathological manifestation of anticancer drug-induced injury to the lung and a precursor to dose-limiting pulmonary fibrosis in the clinic. *In vitro* systems from human lung tissue that model these responses would allow detailed mechanistic studies to help develop safer drugs and assays to select the most promising and effective clinical candidates. Since only primary multicellular systems comprising appropriate lung cell types and numbers in their native orientation and configuration would seem to have the best prospects for meeting this need, our laboratory has been reexamining precision-cut slices as a potentially useful model for this application. In this work, precision-cut slices were prepared from male F-344 rat lungs using a Krumdieck slicer and incubated in M-199 media under air/5% CO<sub>2</sub> in a roller organ culture system for up to 28 days. ED-1 immunochemical staining was used to document BCNU (carmustine)-induced changes in the number of activated macrophages (AM) in the slices and the results were compared with AM induced by SarCNU [(2-chloroethyl)3-sarcosinamide-1-nitrosourea], a less potent analogue. ED-1 counts in the slices were increased in a concentration-dependent manner following exposure to 1-100  $\mu$ M BCNU. There was an increase in collagen deposition with BCNU at 100  $\mu$ M that was evident only after 28 days of exposure whereas increased numbers of AM were seen as early as 7 days. In addition, there was an associated reduction in slice ALP and LDH. SarCNU in the same concentration range as BCNU was less potent as it exhibited relatively fewer AM, less change in slice ALP and LDH content, and no collagen deposition. These results confirm that long-term cultures of precision-cut lung slices are feasible and encouraging as a model system for ranking the relative potency of lung toxicants for these effects and for mechanistic studies. Supported by NIH grant CA097438.

**1171** A HIGH-THROUGHPUT *IN VITRO* MODEL OF HUMAN TRACHEAL/BRONCHIAL EPITHELIUM (EPIAIRWAY) FOR PRECLINICAL SAFETY AND EFFICACY TESTING OF PHARMACEUTICALS.

P. J. Hayden, G. R. Jackson, J. Kobilus, J. E. Sheasgreen and M. Klausner, *MatTek Corp., Ashland, MA*.

A growing need exists for high throughput *in vitro* models which can provide rapid, reliable safety and efficacy screening in preclinical drug development applications. The current poster describes development of an *in vitro* model of human tracheal/bronchial epithelium (TBE) in a 96-well high-throughput screening (HTS) format compatible with robotic manipulation. The HTS model is derived from normal human cells cultured at the air/liquid interface in 96-well microporous membrane plates to produce three-dimensional organotypic cultures. Histology of the culture model was evaluated by H&E staining of formalin fixed paraffin sections. The 96-well TBE culture is pseudostratified, and displays a differentiated mucociliary phenotype with barrier properties similar to native tracheal/bronchial or nasal epithelium, including development of transepithelial electrical resistance (TEER), conferred by functional tight junctions. Over the course of several consecutive culture lots, the intraplate and interlot barrier function reproducibility of the 96-HTS TBE cultures was determined by measurement of TEER. In initial studies to date, the average baseline TEER readings of all wells in a given 96-well plate (intraplate average) ranged from 388.6 to 445.0  $\Omega\text{-cm}^2$ . The average coefficient of variation between wells on the same plate (i.e. intraplate variability) was 19.5 %, while the variability between plates (i.e. interlot variability) was 6.8 %. The utility of the HTS TBE model was demonstrated by evaluation of the effects of various cytokine treatments on 15-lipoxygenase gene expression and TARC secretion. PCR analysis of total RNA isolated from the cultures showed that TNF- $\alpha$  plus IL-4 induced 15-lipoxygenase-2 expression. ELISA experiments revealed the same treatments also induced TARC secretion. The HTS airway model should find utility for *in vitro* irritation/toxicity screening, high content cell and molecular biology assays, as well as drug permeation studies. This work was supported by NIEHS grant #5R44 ES010237-03.

**1172** VASCULAR PERMEABILITY IN THE RAT.

S. Rowton and P. Robinson, *Covance Laboratories Ltd, Harrogate, United Kingdom*. Sponsor: D. Everett.

The ability of a compound to induce, or prevent an acute inflammatory response can be assessed in a number of ways. For screening purposes one of the simplest *in vivo* models for such investigation is the vascular permeability model in the rat. Intradermal administration of a phlogistic agent such as the mast cell degranulator compound 48/80 induces a localised inflammatory response with the release of histamine, prostaglandins and leukotrienes. These mediators cause dilation of arterioles and venules and an increase in vascular permeability. The increase in permeability allows for the passage of larger molecules such as plasma proteins to leak out of the vessels resulting in oedema. In this model, Evan's Blue given intravenously prior to the phlogistic agent, enables visualisation of permeability. As permeability increases the dye is able to seep out of the vessels in the vicinity of the intradermal injection sites. The degree of bluing is proportionate to permeability and hence the inflammatory response. When assessing the inflammatory potential of a test article, it is the test article that is administered intradermally. For anti-inflammatory assessment, the test article is administered by the intended clinical route of administration, at an appropriate time prior to intradermal injection of a known phlogistic agent. For validation purposes, the inflammatory effects of known phlogistic agents (histamine and compound 48/80) were examined. When compared to control injection sites, histamine and compound 48/80 produced a statistically significant increase in permeability as anticipated. Validation of the anti-inflammatory effect of test articles using this model employed the H1 anti-histamine, promethazine. Pretreatment of animals with promethazine (50, 150 or 300 mg/kg po) produced a statistically significant inhibition of compound 48/80-induced inflammation. In conclusion, the vascular permeability model in the rat provides a reliable and useful screening model for investigating the potential inflammatory or anti-inflammatory properties of novel test articles.

**1173** REDUCED STRESS IN GROUP HOUSED NON-HUMAN PRIMATES.

S. Grainger<sup>1</sup>, J. Hedley<sup>1</sup> and M. Niehof<sup>2</sup>, <sup>1</sup>*Covance Laboratories Ltd, Harrogate, United Kingdom* and <sup>2</sup>*Covance Laboratories GmbH, Munster, Germany*. Sponsor: D. Everett.

Group/pair housing of non-human primates undergoing toxicity studies is clearly of benefit to the animals, allowing the expression of a greater variety of natural behaviours. This type of housing is also claimed to have benefits to the 'science' of such studies in that the animals are exhibiting a more normal state with regard to behavioural and physiological parameters as a result of lower stress levels. However, little hard evidence of such reduction in stress levels has been satisfactorily demonstrated due to difficulties in measuring meaningful stress markers when animals are physically restrained for sampling, which in itself results in stress. Also there has been little data presented to substantiate claims that beneficial changes in physiological parameters are achieved by pair/group housing. By using a reliable method of determining faecal cortisol levels we have been able to confirm a significant reduction in the levels of cortisol present in group housed animals when compared with individually housed animals. These data suggest that group housed animals are subject to less stress than their individually housed counterparts. This reduces the potential for stress-exacerbated clinical signs and interactions with test materials which may manifest themselves during toxicity studies. Also, using radio telemetry to measure key physiological functions in fully conscious animals we have been able to demonstrate significant beneficial differences in values for pair housed cynomolgus macaques over those recorded for singly housed animals. Again, this reduces the potential for housing based influences to exacerbate or modify clinical reactions to test materials.

**1174** PREDICTING ANTI-EPILEPTIC DRUG TOXICITY USING HEPATIC PROTEIN COVALENT BINDING AND GENE EXPRESSION POTENTIAL.

A. M. Leone<sup>1</sup>, L. M. Kao<sup>1</sup>, M. McMillian<sup>1</sup>, A. Y. Nie<sup>1</sup>, J. B. Parker<sup>1</sup>, M. E. Kelley<sup>1</sup>, M. D. Johnson<sup>1</sup>, E. Usuki<sup>2</sup>, A. Parkinson<sup>2</sup> and P. Lord<sup>1</sup>, <sup>1</sup>*Mechanistic Toxicology, Johnson & Johnson Pharmaceutical Research & Development, L.L.C., Raritan, NJ* and <sup>2</sup>*XenoTech LLC, Lenexa, KS*.

The formation of one or more reactive metabolites is common to many anti-epileptic drugs associated with idiosyncratic drug reactions (IDR). The reactive metabolites may be detoxified or may cause deleterious effects through protein covalent binding or oxidative stress. To evaluate the IDR potential, six anti-epileptic drugs (AED), felbamate, carbamazepine, gabapentin, phenobarbital, phenytoin and valproic acid, were tested for hepatic protein covalent binding and hepatic gene expression changes. The covalent binding potential of AED was tested by incubation radiolabeled AED with rat liver and human microsomes and hepatocytes, and by *in*

*in vivo* treatment of radiolabeled AED to rats. cDNA microarrays were also used to characterize hepatic gene expression changes induced by the treatment of AED. Carbamazepine exhibited the strongest covalent binding potential *in vitro*, while valproic acid *in vivo*. The gene expression data showed both compound and dose related effects, but was generally consistent with a previously established oxidative stress / reactive metabolite profile. These results demonstrated that neither protein covalent binding nor changes in gene expression alone were sufficient to detect anti-epileptic drugs with known idiosyncratic potential. However, by combining the two techniques, the risk assessment was improved. Therefore, measurement of protein covalent binding and biomarkers of oxidative stress appear to be helpful supplemental tests that could be used early in drug development as part of the selection process for candidate anti-epileptic drugs.

**IN VIVO AND IN VITRO NON-CLINICAL DRUG SAFETY ASSESSMENT: A KEY PARTNER FOR ANTICANCER DRUG DEVELOPMENT.**

N. Lhote<sup>1</sup>, Y. Sibirl<sup>3</sup>, D. Bazot<sup>1</sup>, A. Beamonte<sup>1</sup>, J. Delongeas<sup>1</sup>, D. Parent-Massin<sup>3</sup> and N. Claude<sup>2</sup>. <sup>1</sup>*Servier Group, Gidy, France*, <sup>2</sup>*Servier Group, Courbevoie, France* and <sup>3</sup>*LTA EA3880, UBO Brest, France*.

Hematopoietic progenitor clonogenic assays are interesting tools for assessing the potential for bone marrow anticancer drugs toxicity. We evaluated the hematotoxic potential of a new cytotoxic antitumor compound, acting as an alkylating agent, both *in vivo* in mice, rats and dogs and *in vitro* on mice granulocyte-macrophage (CFU-GM) progenitors and human CFU-GM and megakaryocyte progenitors (CFU-MK). The maximal tolerated dose following single intravenous dose was 12, 4.5 and 6 mg/m<sup>2</sup> for mice, rats and dogs, respectively, and exclusively related to hematotoxicity. Total leucocyte count was reduced by about 50% on Days 4 or 7 after dosing at 3 mg/m<sup>2</sup> in rats and from 1.5 mg/m<sup>2</sup> in dogs. Corresponding maximal plasma exposure to the test item were 4.86 and 3.13 10-7 M for rats and dogs, respectively. Platelet count was reduced by 40% on Day 14 at 3 mg/m<sup>2</sup> in dogs, with corresponding maximal plasma exposure of 6.02 10-7 M. These changes correlated with concomitant bone marrow hypoplasia, thymic lymphoid atrophy and few active follicles in lymph nodes and tonsils. None of them were noted on Day 32, suggesting their full recovery. An inhibition of mice bone marrow cloning efficiency CFU-GM progenitors was observed *in vitro*, with an IC 90 equal to 3.44 10-7 M, which is well correlated with the *in vivo* toxicokinetic data. To assess the potential risk to human, we performed *in vitro* clonogenic assays on granulocyte-macrophage (CFU-GM) and megakaryocyte (CFU-MK) human progenitors. An inhibition of human megakaryocyte progenitors cloning efficiency was observed with an IC 90 equal to 6.43 10-8 M. Inhibitory effects on human CFU-GM were similar to those observed in mice, with an IC 90 equal to 1.38 10-7 M. These *in vitro* results were associated with *in vivo* data to anticipate hematotoxicity and the possible maximal tolerated dose in man, as previously accurately demonstrated for some other anticancer therapeutics.

**1176**

**PHARMACOKINETICS AND ENHANCED ORAL BIOAVAILABILITY OF NANOSTRUCTURED DRUG CRYSTALS: COMPARISON OF PARTICLE ENGINEERING TECHNOLOGIES FOR DANAZOL, KETOCONAZOLE AND NAPROXEN IN BEAGLE DOGS.**

G. G. Kupperblatt<sup>2</sup>, S. A. Saghir<sup>1</sup>, D. A. Markham<sup>1</sup>, T. L. Rogers<sup>2</sup>, C. J. Tucker<sup>3</sup>, J. E. Hitt<sup>2</sup> and E. J. Elder<sup>2</sup>. <sup>1</sup>*Toxicology & Environmental Research & Consulting, The Dow Chemical Company, Midland, MI*, <sup>2</sup>*Dowpharma, The Dow Chemical Company, Midland, MI* and <sup>3</sup>*Corporate R&D, The Dow Chemical Company, Midland, MI*.

Reports quote anywhere from 30-60% of drug candidates exhibit poor water solubility in physicochemical testing and poor absorption from the GI tract. Poor oral absorption limits the usefulness of a drug. In order to overcome this limitation, an emerging approach is to increase the surface area-to-volume ratio of drug crystals by applying particle engineering technologies and add excipients to prevent reaggregation. The Dow Chemical Company has developed a number of particle engineering technologies to produce novel nanostructured drug particles that enhance oral bioavailability of poorly water soluble drugs. Early determination of ways to enhance oral bioavailability of a drug candidate is important in order to generate accurate kinetic and toxicological data. Poorly absorbed drugs (danazol, ketoconazole and naproxen) were processed by various technologies, stabilized with various pharmaceutically acceptable excipients, and evaluated in beagle dogs. Different doses of the drugs were orally administered to dogs in capsule or tablet form and blood collected at various time-points post-dosing. Concentrations of parent drugs were determined in plasma by LC/MS/MS. WinNonlin was used for kinetic analysis. The technologies evaluated showed significantly higher oral bioavailability than the micronized drug as received or commercial products. The oral bioavailability of nanostructured naproxen, ketoconazole and danazol was 1.3, 3 and up to 64 fold

higher than the drug as received, respectively. Increase in oral bioavailability of nanostructured naproxen was 17-29% and of ketoconazole ~300% compared to the commercial products. Particle engineering did not cause much change in the  $T_{max}$  or plasma  $t^{1/2}$ . However, the  $C_{max}$  of the nanostructured drugs was several fold higher than the commercial or micronized drug as received.

**1177**

**REDUCTION AND REFINEMENT IN RADIOLABELLED PRIMATE METABOLISM STUDIES.**

J. Kelly, J. Hedley and R. Allen. *Covance Laboratories Ltd., Harrogate, United Kingdom*. Sponsor: D. Everett.

Traditionally, primate metabolism studies are conducted by performing each phase separately. In a typical intravenous/oral crossover study, animals are dosed up to four times - twice for the pharmacokinetic (PK) phase and twice for the mass balance phase. To minimise stress to the animals undergoing metabolism studies, the PK phase is often conducted in tandem with the excretion balance phase. The main draw back to this is that the monkeys have to be removed from their metabolism cages for sampling. This could be up to 12 occasions in the first 24 hours. The potential therefore exists for excreta losses, even though steps are taken to minimise them. In addition to the potential impact on the data generated from studies where animals are frequently removed from their home cages to undergo procedures, the welfare of the animals is not maximised. Development of a new style of caging was undertaken through consultation between experienced animal technicians and scientists. This new cage design allows the animals to be dosed and bled *in situ* without the risk of sample loss. This arrangement allows the different phases of the study to be run concurrently. Handling is therefore minimised thus reducing stress to the animals whilst on study. Consideration was also given to the macro-environment in which the animals were housed and steps taken to provide enrichment strategies designed to help reduce the stress created by the necessary isolation during the study period. The new cage design confers both improved welfare and an improved environment on the animals whilst at the same time allowing good scientific data to be generated from a study.

**1178**

**ADJUVANT ARTHRITIS IN THE MALE LEWIS RAT.**

S. Rowton and P. Robinson. *Covance Laboratories Ltd., Harrogate, United Kingdom*. Sponsor: D. Everett.

Adjuvant arthritis in the rat has many similarities to rheumatoid arthritis in humans and as such, is a frequently used *in vivo* model for the screening of compounds intended to alleviate arthritis. Administration of an adjuvant initially induces inflammation of the injected paw, this is known as the primary lesion. Some days after this response, secondary lesions appear, which are identified as inflammation of untreated areas, such as paws ears, nose and tail. Validation of this study employed both prophylactic or therapeutic study designs, using male Lewis rats. For the prophylactic study, on Day 1 each rat received 0.1mL of adjuvant (*Mycobacterium butyricum*) subcutaneously into the plantar surface of a designated hind paw. Paw oedema of both hind paws was measured using a plethysmometer prior to administration of the adjuvant and at various time-points up to Day 5 post-adjuvant. Animals were dosed orally once daily with vehicle, indomethacin (25mg/kg/day) or cyclosporin (3mg/kg/day) from Day 1 to Day 15. Animals were observed and scored for lesions from Day 5 to Day 22. For the therapeutic study, on Day 1 each animal received 0.1mL of adjuvant as described above. On Day 20, animals were allocated to treatments groups. Only those animals exhibiting lesions were used. Animals were dosed orally once daily with vehicle, indomethacin (25mg/kg/day) or cyclosporin (3mg/kg/day) from Day 20 to Day 34. Animals were observed and scored for lesions from Day 20 to Day 35. Primary and secondary lesions were exhibited by 100% of rats in both study designs. Lesion development in control animals had peaked by Day 20 and diminished thereafter. Cyclosporin and indomethacin, in the prophylactic study design, suppressed lesion development. Whereas in the therapeutic study, alleviation of established arthritic lesions was achieved following cyclosporin treatment, with indomethacin having little or no effect. In conclusion, adjuvant-induced arthritis in the rat provides a reliable and useful model for investigating the potential therapeutic and prophylactic effect of anti-arthritic compounds.

**1179**

**EVALUATION OF GENOTOXICITY AND SENSITIZATION POTENTIAL OF PEPTIDE COUPLING REAGENTS.**

D. A. Seid<sup>1</sup>, S. S. Kim<sup>2</sup> and S. Kim<sup>1</sup>. <sup>1</sup>*Applied Biosystems, Foster City, CA* and <sup>2</sup>*University of California, Berkeley, CA*.

Advances in biotechnology over the past decade have encouraged increased efforts toward the chemical synthesis of complex peptides. Success in the chemical synthesis of peptides, performed either in solution or via solid-phase techniques, relies

heavily upon efficient peptide coupling reagents. These agents enhance coupling yields, reduce racemization, and allow reduced cycle times during peptide synthesis. Peptide coupling reagents are reactive molecules and are capable of functioning as alkylating agents. In fact, some coupling agents have been reported to be potentially genotoxic and/or sensitizing. The potential for exposure to peptide coupling reagents exists during their use in the synthesis of polypeptides in the chemical and pharmaceutical industries, as well as during protein synthesis in the recombinant DNA industry. Considering the chemical reactivity of peptide coupling agents, it is important to determine the genotoxicity and sensitizing potential of selected peptide coupling agents. This presentation describes the results of short-term mutagenicity and dermal sensitization assays for several peptide coupling reagents and/or their derivatives.

### COMPARISON OF PHOTOTOXICITY TESTING METHODS USED TO SCREEN LEAD COMPOUNDS L. LEE, G. STEVENS, AND B. JESSEN, PFIZER GLOBAL R&D.

L. Lee, *Pfizer Global R&D, San Diego, CA*. Sponsor: G. Stevens.

New chemical entities that absorb light within the visible range have the potential to form reactive intermediates. Photoactivation of small molecules can lead to photo-irritation or UV-associated carcinogenesis after topical or systemic administration. Current ICH guidelines recommended assessment for phototoxicity if the molar extinction/absorption coefficient is greater than 10 liter x mol<sup>-1</sup> x cm<sup>-1</sup>. The initial phototoxicity assay recommended by ICH is an *in vitro* viability assessment using murine 3T3 fibroblasts cell. The basis of this assay is to compare the potential phototoxic hazard of a compound in the presence and absence of exposure to simulated solar light at non-cytotoxic concentrations. The 3T3 cell viability is determined by measuring neutral red uptake after incubation with the test article. The assay for neutral red uptake requires washing, fixing, and solubilizing cells to measure the amount of neutral red present in the cell extract. If this assay were to be applied for early screening of compounds that absorb light, increased throughput and efficiency of this assay is required. The purpose of this study was to evaluate a more rapid viability endpoint (intracellular ATP) as an alternative to the neutral red uptake assay. A double-blinded study was performed with twelve known phototoxins and four non-phototoxic compounds to validate each method. The results indicated that the ATP assay was equally sensitive with the advantage of fewer preparation steps. These data suggest that throughput could be increased several fold through implementation of ATP as the viability endpoint and further optimization through automation of the assay.

### SUBCHRONIC TOXICITY STUDY OF HEXACHLOROBENZENE (HCB) IN FEMALE HARLAN SPRAGUE-DAWLEY RATS.

J. D. Johnson<sup>1</sup>, D. Vasconcelos<sup>1</sup>, M. Ryan<sup>1</sup>, A. Fuciarelli<sup>2</sup>, S. Graves<sup>1</sup>, M. Hejmancik<sup>1</sup>, A. Braen<sup>3</sup>, M. Vallant<sup>4</sup>, H. Toyoshiba<sup>4</sup>, R. Chhabra<sup>4</sup>, N. Walker<sup>4</sup> and M. Hooth<sup>4</sup>. <sup>1</sup>Health and Life Sciences, Battelle, Columbus, OH, <sup>2</sup>Colorado State University, Fort Collins, CO, <sup>3</sup>Hoffmann-La Roche, Nutley, NJ and <sup>4</sup>NIEHS, NIH, Research Triangle Park, NC.

HCB (cas #118-74-1) is used as a fungicide and an intermediate in the manufacture of dyes, pentachlorophenol, and rubber. HCB has some dioxin-like activity thereby necessitating the need to evaluate it for potential inclusion in the toxic equivalency factor scheme used to assess the risk of dioxin-like compounds. HCB, in corn oil/1% acetone, was administered by gavage (10 rats/group) at dosages of 0 (control), 0.03, 0.1, 0.3, 1, 3, 10, or 25 mg/kg/day, five days a week, for 13 weeks. HCB treatment had no effect on survival. Group mean BW was increased (25 mg/kg/day). Total free T4 was decreased ( $\geq$ 10 and  $\geq$ 1 mg/kg/day), T3 was decreased (25 mg/kg/day), and TSH was similar to control. Dose-related increases in hepatic CYP1A1, CYP2B, and CYP1A2 and pulmonary CYP1A1 activities were observed at dosages equal to and greater than 1, 0.03, 0.3, and at 25 mg/kg/day, respectively. Mean maximal observed CYP1A1 activity was 340 pmol/min/mg (25 mg/kg/day), which is markedly lower than that observed previously for animals treated for 13 weeks with 100 ng TCDD/kg (2130 pmol/min/mg). HCB increased liver cell proliferation ( $\geq$ 10 mg/kg/day). Spleen, liver, and lung absolute and relative organ weights were increased ( $\geq$ 3,  $\geq$ 10, and 25 mg/kg/day, respectively). HCB-related microscopic findings included hepatocellular hypertrophy ( $\geq$ 3 mg/kg/day), pulmonary focal interstitial fibrosis and histiocytic infiltration ( $\geq$ 1 mg/kg/day), mammary gland hyperplasia and thymic atrophy ( $\geq$ 10 mg/kg/day), dermal suppurative inflammation and ulceration (25 mg/kg/day), and splenic hematopoietic cell proliferation ( $\geq$ 3 mg/kg/day) and lymphoid hyperplasia ( $\geq$ 10 mg/kg/day). These data indicate that HCB has only weak dioxin-like activity and also exhibits non dioxin-like effects. (Supported by NIEHS Contract No. N01-ES-65406).

## 1182

### SUBCHRONIC TOXICITY OF ALPHA-METHYL-1,3-BENZODIOXOLE-5-PROPIONALDEHYDE IN RATS.

A. Lapczynski, D. Isola and A. Api. *Research Institute for Fragrance Material, Inc., Woodcliff Lake, NJ*.

alpha-Methyl-1,3-benzodioxole-5-propionaldehyde (MMDHCA), a clear yellowish liquid that is an important fragrance ingredient, was evaluated for its dermal toxicity when applied to the dorsal skin of rats for 13 weeks, followed by a 4-week recovery period. Four groups of male and female rats (15/sex/group) were treated topically with the MMDHCA for at least 90 days at dose levels of 0 (control group; treated with reverse osmosis water), 50, 150 or 300 mg/kg/day. Five animals/sex/group were designated as recovery animals and were observed for approximately 4 weeks post treatment. The animals were sacrificed and necropsied during week 14 (terminal sacrifice) and week 18 (recovery sacrifice). The study evaluations included: clinical observations, dermal irritation observation, body weight, food consumption, estrous cycle, ophthalmology, hematology, serum chemistry, organ weights, macroscopic observations, coagulation, histopathology and male reproductive assessment. There was no material-related mortalities or effects on evaluated parameters. The material-related irritation observed in the skin of treated animals at all dose levels with an increased incidence and severity in animals given 300 mg/kg/day improved to slight or resolved completely during the recovery phase. Based on the findings in this study, the non-observable-adverse-effect level (NOAEL) when applied as a dermal application for at least 90 days is less than 50 mg/kg/day for dermal toxicity and the no-observable-effect-level (NOEL) for systemic toxicity is  $>$  300 mg/kg/day.

## 1183

### SUBCHRONIC TOXICITY OF ACETYL CEDRENE IN RATS.

C. Letizia, D. A. Isola and A. Api. *Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ*.

The subchronic toxicity of acetyl cedrene, a widely used fragrance ingredient, was evaluated in a 13-week dermal toxicity study in rats with a 4-week recovery period. Acetyl cedrene was applied to the intact dorsal skin of male and female rats (15/sex/dose) at dose levels of 0 (control), 50, 150 or 300 mg/kg bodyweight/day. Control animals were treated with reverse osmosis water. Observations included morbidity and mortality assessments, body weights, food consumption, dermal irritation, estrous cycle and ophthalmology. Twenty animals from each group were sacrificed during week 14 and the remaining animals were sacrificed during week 18. A complete necropsy was conducted on all animals. Two females in the control group died on day 33 and one female in the mid-dose group was sacrificed in a moribund condition on day 63. Histopathological examination of this animal revealed a spontaneous fibrosarcoma. Dermal irritation was observed at all doses with higher incidence and severity in higher dose groups. These observations were noted in the recovery group but with lower incidence and severity and had resolved by the recovery sacrifice. There were significant changes in mean body weights, body weight changes and food consumption, but no clear relationship to test material administration. At the terminal sacrifice only, increases in kidney-to-body weight ratios were observed in males in the 2 highest dose groups. In males in the 300 mg/kg group, hyaline droplet formation was noted in the tubular epithelium but this finding had resolved by the recovery sacrifice. This finding was compatible with the diagnosis of alpha-2-micro-globulin nephropathy and was not considered relevant. At the terminal sacrifice, mild chronic inflammation and acanthosis/hyperkeratosis was noted in all dose groups; again, these changes had completely resolved by the recovery sacrifice. Based on these findings, it can be concluded that the no-observable-effect-level (NOEL) for acetyl cedrene when applied as a dermal application for at least 13 weeks is less than 50 mg/kg/day for dermal toxicity and the NOEL for systemic toxicity is 150 mg/kg/day.

## 1184

### CNS AND CARDIORESPIRATORY EFFECTS OF TWO NOVEL BISPYRIDINIUM OXIMES (ICD-39 AND ICD-585).

F. T. Chang, D. Spriggs and S. DeBus. *Applied Pharmacology, USAMRICD, APG-EA, MD*. Sponsor: A. Sciuto.

Inhibition of acetylcholinesterase (AChE) constitutes a critical toxicity component in nerve agent intoxication. Oximes can restore AChE to a functional level and are therefore considered to play a critical role in nerve agent casualty management. As part of a R&D effort in search of a more effective oxime, we evaluated cardiorespiratory and CNS effects of two novel bispyridinium oximes, ICD-39 and ICD-585 (3 doses at 57 umole/kg/45-min, im) in anesthetized and unanesthetized guinea pigs. ICD-39, in a time- and dose-dependent fashion, caused a positive chronotropic effect in unanesthetized animals and a negative chronotropic effect in anesthetized animals. Blood pressure in these animals typically showed a time- and dose-dependent decrease. In unanesthetized animals, respiratory responses after each oxime dose were biphasic (increase/decrease). In anesthetized animals, respiratory frequency invariably increased after ICD-39. No anomalous ECG waveform attributes were noted following ICD-39 in anesthetized or unanesthetized animals. ICD-585 produced no significant change in heart rate and blood pressure. No ab-

normalities were seen in ECG waveform attributes. Respiratory rate showed either no change (anesthetized animals) or a biphasic response pattern (unanesthetized animals). Somewhat unexpected were the findings that 50% of PYR-pretreated animals and 33% of animals without PYR pretreatment displayed aberrant ECoG waveform attributes and neurobehavioral anomalies indicative of seizures following either the first or the second dose of ICD-585. What can be inferred from this study is twofold. First, in addition to their ability in reactivating nerve agent-inhibited AChE, ICD-39 and ICD-585 both appeared to be able to mediate a variety of changes in cardiorespiratory and CNS activities. Second, from the standpoint of safety/toxicity, our data suggest that ICD-39 appears to engender fewer untoward cardiorespiratory and CNS effects than ICD-585.

#### 1185 TOXICOLOGICAL EVALUATION OF CIGARETTES WITH TWO BANDED CIGARETTE PAPER TECHNOLOGIES.

E. H. Theophilus, D. R. Meckley, K. W. Shreve, P. H. Ayres, B. R. Bombick, M. F. Borgerding, C. D. Garner, D. H. Pence and J. E. Swauger. *Research & Development, R. J. Reynolds Tobacco Company, Winston-Salem, NC*.

A tiered testing strategy has been developed to evaluate the potential of tobacco processes, ingredients, or technological developments to change the biological activity resulting from burning cigarette tobacco. The strategy is based on comparative chemical and biological testing. The introduction of banded cigarette papers in cigarettes to meet the New York State Fire Safety Standards for Cigarettes (NYS cigarettes) constitutes an example of a technological development evaluated in a tiered testing strategy that included a comparison of the chemical and biological effects of cigarettes with and without the banded cigarette paper technologies. Specific testing included mainstream cigarette smoke chemistry studies; *in vitro* genotoxicity (Ames and Sister Chromatid Exchange) and cytotoxicity studies (Neutral Red); and *in vivo* 13-week inhalation study in Sprague-Dawley rats and 30-week dermal tumor promotion study in SENCAR mice. The yields of constituents from cigarettes with or without the banded technologies were generally similar and within the range observed for cigarettes in the US market. Collectively, data indicated that cigarettes with and without banded technologies had a similar toxicological profile in this test battery.

#### 1186 TOXICOLOGICAL EVALUATION OF A CIGARETTE PAPER WITH REDUCED IGNITION PROPENSITY: *IN VITRO* AND *IN VIVO* TESTS.

M. Misra<sup>1</sup>, R. D. Leverette<sup>1</sup>, J. T. Hamm<sup>1</sup>, M. B. Bennett<sup>1</sup>, J. D. Heck<sup>1</sup>, R. Morrissey<sup>2</sup> and N. Rajendran<sup>3</sup>. *Lorillard Tobacco Company, Greensboro, NC, <sup>2</sup>PAI, Chicago, IL and <sup>3</sup>IIT Research Institute, Chicago, IL*.

A novel print-banded cigarette paper exhibiting reduced propensity to ignite secondary surfaces in a defined test protocol was compared to a conventional un-banded cigarette paper to assess the potential of the band application to affect the toxicity of cigarette mainstream smoke. Experimental filtered cigarettes made with a nominally realistic quantity or approximate 1.2-fold exaggerated level of the applied banding formulation were compared to a matched control cigarette. The tar, nicotine and CO yields of the cigarette made with the normal-banded paper were moderately higher than those of the control cigarette made with an otherwise identical unbanded paper. An Ames assay using a battery of *Salmonella* tester strains indicated no differences in the mutagenic activity of smoke particulate matter of the banded and control cigarettes. The mammalian cell cytotoxicity (Neutral Red Uptake) of both the particulate and gas/vapor phases of the mainstream smoke of the normal- and heavy-banded cigarettes was indistinguishable from that of the unbanded control cigarette. A 13-week subchronic nose-only smoke inhalation bioassay in rats resulted in no substantive or biologically significant differences in the incidence, severity or reversibility of a variety of measured clinical chemistry, hematologic, histopathologic and physiologic indices of cigarette smoke toxicity. A 26-week SENCAR mouse skin painting bioassay revealed no substantive differences in any indices of tumorigenic potential; including tumor incidence, latency or multiplicity of the cigarette smoke condensates from the test and control cigarettes. It is concluded that the presence of nominally realistic or 1.2-fold exaggerated levels of the applied printed banding material does not meaningfully affect the biological activity in a variety of test systems that have traditionally been employed to evaluate cigarette smoke toxicity.

#### 1187 TOXICOLOGICAL EVALUATION OF DIAMMONIUM PHOSPHATE (DAP) AND UREA AS INGREDIENTS ADDED TO CIGARETTE TOBACCO.

M. S. Stavanya, P. H. Ayres, G. M. Curtin, B. R. Bombick, M. F. Borgerding, C. D. Garner, D. H. Pence and J. E. Swauger. *R.J. Reynolds Tobacco Company, Winston-Salem, NC*.

A tiered testing strategy has been developed to evaluate the potential for new ingredients, tobacco processes, and technological developments to alter the biological activity that results from burning cigarette tobacco. The foundation of this evaluation

strategy is comparative testing, typically including chemical and biological components. In the manufacture of cigarettes, DAP and urea have been used as ingredients added to tobacco, to reconstituted tobacco sheet, and to other processed tobaccos. As part of ongoing stewardship efforts, a toxicological assessment of cigarettes with and without DAP and urea was conducted. Chemical and biological analyses were conducted for test cigarettes containing 0.5% DAP and 0.2% urea in the final blend and 1.0% DAP and 0.41% urea in the final blend compared to reference cigarettes containing no DAP or urea. Principal components of this evaluation included a determination of selected mainstream smoke constituent yields, an Ames assay in *Salmonella typhimurium* strains TA98 and TA100, sister chromatid exchange assays in Chinese hamster ovary cells, a 13-week inhalation study of mainstream cigarette smoke in Sprague-Dawley rats, and a 30-week dermal tumor promotion evaluation of mainstream cigarette smoke condensate in SENCAR mice. Comparative evaluations demonstrated that the addition of DAP and urea to cigarettes at up to 1.0% and 0.41%, respectively, does not alter the biological activity compared to reference cigarettes without DAP or urea.

#### 1188 IN VITRO TOXICITY EVALUATION OF TOOTHPASTES USING RECONSTRUCTED HUMAN ORAL AND GINGIVAL MUCOSA MODELS.

B. De Wever<sup>1</sup>, B. Vande Vannet<sup>2</sup>, P. Bottenberg<sup>2</sup> and M. Cappadoro<sup>1</sup>. *<sup>1</sup>SkinEthic Laboratories, Nice, France and <sup>2</sup>Free University of Brussels, Brussels, Belgium*.

5 different toothpaste formulations (A, B, C, D, E) were evaluated for their toxicity on *in vitro* reconstituted human oral and gingival mucosa (SkinEthic laboratories, Nice, France). Toothpastes A, D and E contained SDS, toothpastes B and C did not. They all did contain fluoride. A 30 % solution was topically applied to triplicate oral and gingival mucosal tissues. H<sub>2</sub>O served as negative control, SDS 0.5% was used as positive control. Tissue viability (MTT), tissue morphology (both LM and TEM) and the release of pro-inflammatory mediator IL-1 $\alpha$  was evaluated after 10 minutes, 1 h and 3 h of exposure. Using gingival mucosa, topical exposure of the toothpastes for 10 min, 1 h or 3 h did not affect MTT values as compared to the negative control. Using oral mucosa however, toothpastes B, E and D induced a significant loss of viability after 1 h (respectively 49.19%, 55.55% and 78.38%). After 3 hours, tissue viability for toothpaste D and E further decreased to 11.12% and 4.53% respectively. Only gingival mucosa tissues exposed to toothpaste D and E show a marked increase of IL-1 $\alpha$  at 1 hour, and to toothpaste A at 3 hours exposure. Oral mucosa tissue exposed for 1 hour resulted in increased levels of IL-1 $\alpha$  for toothpastes A, B, D, & E, which became more important at 3 hours. Morphological analysis of oral mucosa demonstrated partial necrosis after exposure to toothpastes A, B and C, and severe necrosis to D and E. Gingival mucosa exposed to toothpastes D and E showed morphological changes undetected by MTT, indicating that MTT cannot be used as single toxicity parameter and should be confirmed by histology. Both *in vitro* oral and gingival mucosa models are suitable to evaluate the toxicity of toothpaste formulations but show a different sensitivity. The presence of SDS in toothpastes A, D, and E could be responsible for the observed toxicity *in vitro*. These *in vitro* results confirm the clinical inflammatory effects of SDS containing oral care products reported in the literature.

#### 1189 IN VITRO SAFETY EVALUATION STUDIES OF LUTEIN AND ZEAXANTHIN.

X. Chen<sup>1</sup>, B. A. Fowler<sup>2</sup> and F. Khachik<sup>3</sup>. *<sup>1</sup>Program in Toxicology, Department of Epidemiology & Preventive Medicine, University of Maryland, Baltimore, Baltimore, MD, <sup>2</sup>Division of Toxicology, Agency for toxic Substances and Disease Registry, Atlanta, GA and <sup>3</sup>Chemistry and Biochemistry, University of Maryland, College Park, MD*.

Lutein is a carotenoid found in vegetables and fruits. Dietary lutein and zeaxanthin accumulate in human retina and have been implicated in the prevention of age-related macular degeneration (AMD). Some studies have also indicated that lutein and zeaxanthin inhibit human breast cancer cell proliferation and contribute to protection against UV light. Lutein supplementation for the treatment of AMD is currently under way at some hospitals. For evaluation of the safety of chronic supplementation of lutein and zeaxanthin in primates, dose response studies of lutein and zeaxanthin toxicity were conducted using different available cell lines: normal human epidermal keratinocyte (NHEK) cells and normal rat kidney epithelial (NRK52E) cells. DMSO was used as the dissolving vehicle as well as the vehicle control. The cells were exposed to 0.001 to 0.1 mmol/L lutein and zeaxanthin for 24, 48 and 72 hours. The alamar blue assay was used to assess cellular metabolic toxicity. The results of this study indicate that there is no effect on the viability of NHEK cells with DMSO at concentrations lower than 1.0 %. Lutein at 0.05 mM and 0.1 mM reduced NHEK cell viability to 87 ? 1% and 69 ? 4% respectively after 24 h exposure. Decreases of 10 - 20% of cellular metabolism were found only at the highest concentration zeaxanthin groups (0.10 mM). The same results were found in NRK52E cells. Zeaxanthin at 0.05 mM reduced NRK52E cell viability to 90 ?

9% after 48 h exposure and at 0.1 mM, it reduced the viability to 88 ? 5% and 85 ? 5% after 24 and 48 h exposure respectively. Collecting the data suggests that low dosage lutein and zeaxanthin do not cause toxicity in NHEK and NRK52E cells. (Supported by NEI grant EY 12658-02)

#### 1190 AEROSOL CHARACTERIZATION FOR CONSUMER LAUNDRY ENZYME-CONTAINING STAIN REMOVERS.

E. Ayala-Fierro<sup>1</sup>, D. P. Davis<sup>1</sup>, J. Billman<sup>2</sup>, C. Jeng<sup>3</sup>, R. E. Rogers<sup>3</sup> and A. Lefebvre<sup>3</sup>. <sup>1</sup>Clinical Studies and Toxicology, The Dial Corporation, Scottsdale, AZ, <sup>2</sup>Research and Development, The Dial Corporation, Scottsdale, AZ and <sup>3</sup>Toxcon HSRC, Edmonton, AB, Canada.

The use of enzymes in laundry trigger-spray stain removers has been common practice for a number of years. These products use different sprayer nozzles that may produce droplets with different size, mass, decay patterns, and enzyme content. Understanding these parameters is important to prevent consumer over-exposure by inhalation and the potential for sensitization of atopic individuals. The objective of this study was to measure the impact of test substance application on airborne aerosol characteristics as well as enzyme levels. Exposure to commercial stain removers was measured by simulating a heavy use scenario in an environmentally controlled simulated residential exposure chamber. The product was applied 6 inches from fabric targets mounted vertically (horizontal application) over a standard washing machine. The tests were conducted in eight replicates for each test substance. Each replicate applied the test substance sequentially on 8 fabric targets with 5 sprays for each. The characteristics of trigger sprayers were evaluated in the adult breathing zone by determining aerosol mass levels, airborne particle and mass distribution, and enzyme concentration. Aerosol concentrations were high in the first 1-3 minutes and returned to baseline within 10 minutes, during which the average mass concentration was in the range of 4.0-67.3  $\mu\text{g}/\text{m}^3$  and the observed enzyme concentration in air was 12.0-46.7  $\text{ng}/\text{m}^3$ . Large particles were deposited in the fabric with particles < 1 micron remaining in the breathing zone. The variation on these parameters was influenced mainly by the trigger type and product physical characteristics (e.g. viscosity range). In general, a normal use of these products does not produce airborne enzyme levels that exceed common industrial practice SDA guidelines or ACGIH workplace limits.

#### 1191 ENHANCING EFFECT OF CHLORINATED ORGANIC SOLVENTS ON INFLAMMATORY MEDIATOR PRODUCTION.

M. Seo, M. Satoh and H. Nagase. Department of Hygienics, Gifu Pharmaceutical University, Gifu, Japan.

The prevalence rate of allergic diseases such as bronchial asthma and rhinitis is increasing in industrial areas and countries. There are some reports on epidemiological studies that may suggest a link between the incidence of allergic disease and environmental pollutants, such as diesel exhaust particles (DEPs), formaldehyde and volatile organic compounds (VOC). Chlorinated organic solvents are classified into VOC, and recently have become major environmental pollutants. Previously we observed the enhancing effects of some chlorinated organic solvents, such as tetrachloroethylene (PCE) and trichloroethylene (TCE), on histamine release from rat mast cells *in vitro*, and on passive cutaneous anaphylaxis (PCA) *in vivo*. In the present study, we investigated the effects of low concentration of PCE and TCE on antigen-induced inflammatory mediator production from rat mast cell line RBL-2H3. Cells were incubated with anti-dinitrophenol (DNP) monoclonal IgE antibody, and then stimulated by DNP-BSA in the presence of PCE (0.01, 0.1 and 1 mg/L) or TCE (0.03, 0.3 and 3 mg/L). The conditioned medium and cell lysate were collected, and measured IL-4, TNF- $\alpha$  and MCP-1 by ELISA. Each inflammatory mediator production was increased in a dose-dependent manner. Furthermore, mRNA expression of them was evaluated by semi-quantitative RT-PCR, these mRNA expressions were found to be up-regulated by the exposure of PCE and TCE. Thus, this overexpression of inflammatory mediator from RBL-2H3 exposed to PCE and TCE is associated with inflammatory response in late phase. These results suggest that PCE and TCE, even in a low concentration, may affect the immune response via the modulation of cytokine production in the mast cells, and lead to the augmentation of allergic diseases.

#### 1192 RELATIONSHIP BETWEEN CD86/CD54 EXPRESSION AND CELL VIABILITY IN *IN VITRO* SKIN SENSITIZATION TEST OF WATER-SOLUBLE CHEMICALS USING THP-1 CELLS.

T. Ashikaga<sup>1</sup>, H. Sakaguchi<sup>2</sup>, K. Yoneyama<sup>1</sup>, S. Sono<sup>1</sup>, M. Miyazawa<sup>2</sup>, Y. Yoshida<sup>2</sup>, Y. Ito<sup>2</sup>, H. Suzuki<sup>2</sup>, H. Itagaki<sup>1</sup> and H. Toyoda<sup>1</sup>. <sup>1</sup>Shiseido Co., Ltd., Kanagawa, Japan and <sup>2</sup>Kao Corporation, Tochiga, Japan.

We have reported that the human monocytic leukemia cell line, THP-1, which shows enhanced CD86 and/or CD54 expression when treated with allergens, can be used as an *in vitro* skin sensitization test to predict the allergenic potential of

chemicals. In our previous study, we optimized our human cell line activation test (h-CLAT) and performed an inter-laboratory study of the protocol between two laboratories. The results suggested that partial cytotoxicity may be necessary for augmentation of CD86/CD54 expression in allergen-treated THP-1 cells. A similar phenomenon has already been reported in dendritic cells. The aim of this study is to clarify the relationship between CD86/CD54 expression and viability of allergen-treated THP-1 cells. Several water-soluble chemicals (nickel sulfate (Ni), p-phenylenediamine (pPD), ammonium tetrachloroplatinate (Pt) and sodium lauryl sulfate (SLS)) were evaluated at multiple doses that covered the range of concentrations with strong cytotoxicity to almost no-cytotoxicity. In the case of Ni (allergen), enhancement of CD86 expression was observed at about 70-80% cell viability and enhancement of CD54 expression was observed at 40-90% cell viability. For Pt and pPD (allergens), enhancement of both CD86 and CD54 expression was seen when the cell viability was in the range of about 50-90%. The concentration which caused maximum induction of these cell surface antigens varied from chemical to chemical. On the other hand, SLS (non-allergen) did not enhance either CD86 or CD54 expression at any concentration in the range giving 30-90% cell viability. These results suggest that partial cytotoxicity is necessary for induction of CD86/CD54 expression in water-soluble allergen-treated THP-1. Furthermore, two or more measurement points at subtoxic concentrations are necessary for accurate evaluation. These findings should be helpful for dose setting in h-CLAT.

#### 1193 THE RELATIONSHIP BETWEEN CD86/CD54 EXPRESSION AND THP-1 CELL VIABILITY IN AN *IN VITRO* SKIN SENSITIZATION TEST FOR WATER-INSOLUBLE CHEMICALS.

H. SAKAGUCHI<sup>1</sup>, T. Ashikaga<sup>2</sup>, M. Miyazawa<sup>1</sup>, Y. Yoshida<sup>1</sup>, Y. Ito<sup>1</sup>, K. Yoneyama<sup>2</sup>, S. Sono<sup>2</sup>, H. Itagaki<sup>2</sup>, H. Toyoda<sup>2</sup> and H. Suzuki<sup>1</sup>. <sup>1</sup>Kao Corporation, Tochigi, Japan and <sup>2</sup>Shiseido Co., Ltd., Kanagawa, Japan.

Several *in vitro* skin sensitization methods using human cell lines have been reported. In our previous study, we optimized our human cell line activation test (h-CLAT) using THP-1 cells (monocytic leukemia cell line) and conducted an inter-laboratory study. We found that measuring CD86/CD54 expression may be useful for predicting skin sensitization *in vitro*. Also we showed that a certain level of cytotoxicity may be necessary for up-regulation of CD86/CD54 expression. The aim of this study was to confirm the relationship between CD86/CD54 expression and viability of THP-1 cells in the h-CLAT, especially for water insoluble chemicals. In this study, four allergens (DNCB, Propyl gallate, Isoeugenol, Eugenol) were evaluated. For each chemical, more than 10 concentrations that gave a predicted cell viability range of 20-95% were used to determine the relationship between cell viability and surface marker expression. An up-regulation of CD86 and/or CD54 expression at the 70-90% cell viability range was observed. For DNCB, maximum CD86 and CD54 expression was observed at about 85% and 70% cell viability, respectively, whereas for Eugenol, it was at about 70% and 80% cell viability, respectively. Expression patterns of CD86/CD54 differed depending on chemical. The data suggest that: 1. Some cytotoxicity is needed for enhancement of CD86/CD54 expression in the h-CLAT using THP-1 cells for water insoluble chemicals. 2. Two or more concentrations covering the 70-90% cell viability range would increase reliability in the evaluation of various chemicals. 3. A narrow dose setting range is needed for chemicals with a sharp cell survival decline. These findings seem to be helpful for dose setting in the h-CLAT, which should result in a more robust *in vitro* skin sensitization test.

#### 1194 PHENOTYPIC ALTERATIONS AND CYTOKINE PRODUCTION IN THP-1 CELLS IN RESPONSE TO ALLERGENS.

M. MIYAZAWA, Y. Ito, Y. Yoshida, H. Sakaguchi and H. Suzuki. Kao Corporation, TOCHIGI, Japan. Sponsor: J. Avalos.

Dendritic cells (DC), including Langerhans cells (LC) present in epidermis, play a crucial role in the induction phase of allergic contact hypersensitivity. It has been known that DCs express several surface molecules and produce cytokines in response to an allergen. We have previously shown that THP-1 cells, human acute monocytic leukemia cell line, can discriminate allergens and irritants by measuring expression of surface molecules, CD86 and CD54. At the same time, we have also reported that production of IL-1 $\beta$  was up-regulated in THP-1 cells when treated with an allergen, dinitrochlorobenzene (DNCB). The aim of our present study is to further address phenotypic changes and cytokine production in THP-1 cells when treated with chemicals. THP-1 cells were treated with two known allergens (DNCB and NiSO<sub>4</sub>), an irritant (sodium lauryl sulfate (SLS)) and an immunostimulant (lipopolysaccharide (LPS)) for 24 hours at the concentration that exhibited 70-95% viability. Exposure to DNCB, NiSO<sub>4</sub> and LPS induced significant augmentation of CD40 and CD83 expression as well as CD86 and CD54. On the contrary, SLS did not change or slightly decreased expression of these molecules. Also,

DNCB, NiSO<sub>4</sub> and LPS induced marked increase of TNF-alpha secretion in a dose-dependent manner while SLS did not. In addition, THP-1 cells showed augmented production of IL-6 following incubation with only NiSO<sub>4</sub> and LPS. These results revealed that THP-1 cells, with their wide variety of responses to allergens, may emulate allergen-induced maturation processes as those of immature LCs in epidermis. It has been suggested that THP-1 cells, which could develop several LC-like properties, are capable of identifying sensitizing potential of chemicals based on mechanism of sensitization development.

## 1195

### EVALUATION OF CYTOKINES RELEASE FROM THP-1 CELLS AS PREDICTIVE MARKERS OF CONTACT SENSITIZATION.

R. Slim, R. Petty, M. S. LaGattuta and J. R. Piccotti. *Worldwide Safety Sciences, Pfizer Global Research & Development, Ann Arbor, MI.*

The assays currently recommended for evaluating contact hypersensitivity such as the murine local lymph node assay (LLNA) have inherent limitations such as low throughput, and require the use of animals. The development of a predictive high throughput *in vitro* assay as an alternative to the use of animals may prove useful in hazard assessment, especially for the preliminary screening of new molecules. Our primary goal in this study was to identify specific and sensitive marker(s) to predict the potential of compounds to induce immune-mediated hypersensitivity reactions, using THP-1 cells, a human histiocytic lymphoma cell lines. THP-1 cells were incubated for up to 72 hours with the respiratory allergen trimellitic anhydride (TMA) at 2 and 20 mg/mL, contact allergen 2, 4-dinitrofluorobenzene (DNFB) at 1.25 and 2.5 µg/mL, irritant sodium dodecyl sulfate (SDS) at 35 and 70 mg/mL or vehicle control dimethyl sulfoxide (DMSO). Changes in multiple inflammatory cytokines/chemokines including interleukin-1 alpha (IL-1 $\alpha$ ), interleukin-1 beta (IL-1 $\beta$ ), interleukin-2 (IL-2), interleukin-10 (IL-10), interferon-gamma (IFN $\gamma$ ), tumor necrosis factor-alpha (TNF $\alpha$ ), interleukin-8 (IL-8) and macrophage inflammatory protein-1 beta (MIP-1 $\beta$ ) were evaluated in the media of THP-1 cultures using chemiluminescent-based proteome arrays. Treatment of THP-1 cells with non-toxic concentrations of DNFB for up to 72 hours induced significant increases (1.6- to 10.8-fold) in the levels of IL-1 $\alpha$ , IL-1 $\beta$ , IL-10, IFN $\gamma$ , MIP-1 $\beta$  and TNF $\alpha$ . Interestingly, the concentration of IL-8 was increased by greater than 37-fold in the media of THP-1 cells treated with DNFB for up to 24 hours. Changes in these cytokines/chemokines were not seen at non-toxic doses of SDS or TMA. Our data suggest that measurement of inflammatory cytokines/chemokines and in particular soluble levels of IL-8 in this *in vitro* model may provide a sensitive method for assessing the contact sensitization potential of a chemical.

### USE OF HISTORICAL LOCAL LYMPH NODE DATA IN THE DEVELOPMENT OF ALTERNATIVE TEST METHODS FOR SKIN SENSITIZATION.

C. Ryan<sup>1</sup>, P. Kern<sup>2</sup>, D. Basketter<sup>3</sup>, G. Patlewicz<sup>3</sup>, R. Dearman<sup>4</sup>, I. Kimber<sup>4</sup> and F. Gerberick<sup>1</sup>. <sup>1</sup>*Procter & Gamble Company, Cincinnati, OH*, <sup>2</sup>*Procter & Gamble Company, Brussels, Belgium*, <sup>3</sup>*SEAC, Unilever, Sharnbrook, United Kingdom* and <sup>4</sup>*Central Toxicology Laboratory, Syngenta, Macclesfield, United Kingdom*.

In developing new alternative toxicological test methods, the availability of high quality, relevant and reliable *in vivo* data for the endpoint of interest is essential. Ideally, data derived in humans would be the most appropriate as the test methods are attempting to predict a toxicological effect in man. However, a sufficient quantity of such data is most likely not available, so data derived from animal studies usually serves as the basis for comparison. In recent years, the local lymph node assay (LLNA) has emerged as a practical option for assessing the skin sensitization potential of chemicals. In addition to accurately identifying skin sensitizers, the LLNA has also been shown to provide a reliable measure of relative sensitization potency; information that is critical in successful management of human health risks. Therefore, for use in evaluating new alternative test methods for skin sensitization and the development of quantitative structure-activity relationship models, a database of historical LLNA data for 232 different chemicals has been created. This extensive chemical dataset encompasses both the chemical and biological diversity of known chemical allergens. To cover the range of relative allergenic potency, the dataset includes 18 extreme, 31 strong, 76 moderate, 65 weak contact allergens as well as 42 chemicals that are considered to be non-sensitizers. In terms of chemical diversity, aldehydes, ketones, aromatic amines, quinones and acrylates are among the classes represented in the dataset. In addition to 2D chemical structures, the physicochemical parameters included are logK<sub>p</sub>, LogK and molecular weight. It is hoped that this database will accelerate the development, evaluation and eventual validation of new approaches to skin sensitization testing.

## 1197

### DEVELOPMENT OF A PEPTIDE REACTIVITY MODEL FOR SCREENING THE SKIN SENSITIZATION POTENTIAL OF CONTACT ALLERGENS.

J. D. Vassallo<sup>1</sup>, J. G. Chaney<sup>1</sup>, R. E. Bailey<sup>1</sup>, S. W. Morrall<sup>1</sup>, B. B. Price<sup>1</sup>, J. Lepoittevin<sup>2</sup> and F. G. Gerberick<sup>1</sup>. <sup>1</sup>*Central Product Safety, Procter & Gamble, Cincinnati, OH* and <sup>2</sup>*Laboratoire de Dermatochimie, Université Louis Pasteur, Strasbourg, France*.

In order for a chemical to function as a sensitizer it must penetrate the skin, react with protein and be recognized as antigenic by immune cells. Protein reactivity correlates with skin sensitization potential and this relationship is attributed to the fact that chemical allergens, either directly or following biotransformation have electrophilic properties that enable them to form covalent bonds with nucleophilic amino acids, like cysteine and lysine. An *in vitro* assay using peptides containing cysteine or lysine, or glutathione as surrogate nucleophiles was developed. More than sixty different chemicals with sensitization potencies ranging from weak to extreme, and nonsensitizers were reacted with the peptide at various concentrations and incubation times, and peptide depletion, which indicated chemical adduction, was measured by HPLC. The average depletion using the cysteine peptide at a ratio of 1:10 (peptide:chemical), and an incubation time of 24 hours at 25°C was 79, 60, 26 and 4% for chemicals in the strong, moderate, weak and nonsensitizer groups, respectively. The correlation between the reactivity of this peptide and sensitization potential was found to be statistically significant (rank correlation = 0.75, p < 0.0001). Similar results were obtained with the lysine peptide and glutathione. These peptide reactivity data were used to develop a prediction model based on classification tree methodology. Additional chemicals with known sensitization potential were analyzed and the peptide reactivity data were used to assess the robustness of the prediction model and to refine it. Collectively, these data support the use of a peptide reactivity prediction model to screen the sensitization potential of new chemicals. This model may lead to a reduction or replacement of animal use in skin sensitization testing.

## 1198

### IDENTIFICATION OF POTENTIAL MARKERS FOR THE PREDICTION OF SKIN SENSITIZATION: REAL-TIME PCR ANALYSIS OF ALLERGEN-TREATED DENDRITIC CELLS.

L. Gildea<sup>1</sup>, C. A. Ryan<sup>1</sup>, B. C. Hulette<sup>1</sup>, L. Foertsch<sup>1</sup>, R. J. Dearman<sup>2</sup>, I. Kimber<sup>2</sup> and F. Gerberick<sup>1</sup>. <sup>1</sup>*Procter & Gamble Company, Cincinnati, OH* and <sup>2</sup>*Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom*.

Cellular changes within resident skin dendritic cells after allergen uptake and presentation are ideal events to model for study of the allergic immune response. Previous microarray analysis of human peripheral blood-derived dendritic cells (PBMC-DC) revealed many changes in gene expression following dinitrobenzene sulfonic acid (DNBS)-allergen treatment. Analysis of the sensitivity, selectivity, and dynamic range of these genes were evaluated previously by quantitative PCR using a select group of chemicals to determine their usefulness as markers for contact allergy. In this study we developed criteria to select a focused candidate gene list. Per those criteria, subsequent validation of the target genes using an expanded chemical dataset was performed. PBMC-DC were treated for 24 hours with various doses of chemicals and RNA was extracted for use in real-time PCR reactions. Specific primers were designed for selected genes and mean relative fluorescence units (RFU) were calculated and then converted to mean fold changes comparing mean RFU in control (vehicle-treated) samples versus mean RFU in treated samples. Allergen-induced changes in the expression of numerous genes associated with immune function, such as CD43, CCL4, CCL23, SLAM, and the Lectin Receptor, were observed. The dynamic range and sensitivity of these genes were examined using multiple doses of allergens that have various potency classifications such as hydroxycitronellal and dicyclyphenylpropenone. Further prioritization of the targets was carried out by analysis of the same candidate gene list on irritant-treated PBMC-DC to determine their specificity for skin sensitization. Real-time PCR analysis of multiple chemical studies has identified 27 potential genes that fit the selection criteria for sensitivity, dynamic range, and reproducibility and thus will be analyzed further for their usefulness as an endpoint measure for the prediction of contact allergy.

## 1199

### EFFECTS OF LIPOPHILICITY AND VISCOSITY OF SOLVENTS ON DPM/LN BACKGROUND LEVEL IN MURINE LOCAL LYMPH NODE ASSAY (LLNA).

W. Wang-Fan, L. G. Ullmann and G. Arcelin. *Toxicology, RCC Ltd., Fuellinsdorf, Switzerland*. Sponsor: K. Sachse.

This poster is the third part of our positive- and vehicle-control validation studies in murine local lymph node assay (LLNA). Based on our vehicle-control tests results, (the results have been presented as two posters at the Society of Toxicology

43rd Annual Meeting, Baltimore, March 21-25, 2004 and 10th International Congress of Toxicology, Tampere, July 11-16, 2004, separately), ethanol-water systems were found to be suitable for LLNA tests. One of the most useful vehicles is the ethanol-water (70/30, v/v) (EtOH 70%) solution. In order to provide sufficient scientific rationale, a further investigation and comparison of the allergenic potency and local clinical signs caused by the positive control substance alpha-hexylcinnamaldehyde (HCA) have been made. In six parallel LLNA validation studies with 96 CBA/CaOlaHsd mice performed at RCC, six different solvent systems, five of them are recommended by OECD Guideline 429, have been assayed. In order to rationalize and quantitatively analyze the tests results, some relevant physicochemical properties of the six organic solvents have been compared, and some statistic analyses have also been performed with the data obtained from six different vehicles systems. In the experimental studies, the EC3 value of HCA in EtOH70% system is lower than that in AOO (11.72), PG (7.35) and DMSO (16.21). The EC3 values of HCA in 2-butanone (1.76) and DMF (5.71) are lower than that in EtOH70%, but there are some clinical signs observed in both tests with 2-butanone and DMF. Based on the tests results and statistical analyses on dose-response relationship, including comparison of the allergenic potential of the positive control substance HCA in the six vehicles, it has been improved and rationalized that EtOH70% is a very suitable vehicle and may be widely used in LLNA st

## 1200 INFLUENCE OF AGEING ON LOCAL LYMPH NODE ASSAY RESPONSES TO HEXYL CINNAMIC ALDEHYDE.

C. Betts, A. Banyard, L. Beresford, R. J. Dearman and I. Kimber. *Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

The murine local lymph node assay (LLNA) is an established method for the identification of chemicals that have the potential to cause skin sensitisation and allergic contact dermatitis. This assay relies on the measurement of induced proliferative responses in draining lymph node cells (LNC) as measured by incorporation *in vivo* of radiolabelled thymidine. In the LLNA, skin sensitizers are defined as materials that provoke a 3-fold or greater increase in proliferation compared with concurrent vehicle treated controls. It has been reported previously that immune responses, including some aspects of allergen-induced lymph node activation, may be affected by age. In the current investigations we have examined the impact of age of CBA mice (the recommended strain for use in the LLNA) on proliferative responses stimulated by exposure to hexyl cinnamic aldehyde (HCA); a recommended positive control for skin sensitisation testing. Mice (n=4 per group) of average age of 8, 15 or 21 weeks were exposed to 25%w/v HCA in acetone:olive oil vehicle (AOO; 4:1 ratio), or to AOO vehicle alone, in 2 or 3 independent experiments. Stimulation indices (SI) were derived for each experiment. These values were very consistent within and between age groups of mice, with SI values of 4.9, 6.9, and 6.6 achieved for 8 week, 15 week and 21 week old mice, respectively (representative data). Dose responses were performed (using 5, 10 and 25% HCA) in order to determine mathematically using linear interpolation the estimated concentration of chemical necessary to induce an SI of 3 (EC3 value). Values obtained for 8, 15 and 21 week old animals were 13.0, 10.7 and 13.6, respectively. These data are consistent with previous publications for this chemical using animals in the age range of 8-12 weeks (EC3 of 10.3 +/- 0.6). The conclusion is that, at least with respect to HCA, a mild to moderate skin sensitiser, responses in the LLNA assay are stable across mice with age ranges differing by 13 weeks.

## 1201 CORRELATION OF LLNA AND HUMAN SKIN SENSITISATION THRESHOLDS.

D. A. Basketter<sup>1</sup>, C. Clapp<sup>1</sup>, B. Safford<sup>1</sup>, D. Jefferies<sup>1</sup>, I. Kimber<sup>2</sup>, R. Dearman<sup>2</sup>, C. A. Ryan<sup>3</sup> and F. Gerberick<sup>3</sup>. <sup>1</sup>SEAC, Unilever, Sharnbrook, United Kingdom, <sup>2</sup>Syngenta CTL, Macclesfield, United Kingdom and <sup>3</sup>Procter & Gamble, Cincinnati, OH.

For years, methods have been available for the predictive identification of chemicals that possess the intrinsic potential to cause skin sensitization. However, many of these methods have proven less capable in terms of the determination of relative sensitizing potency. In this respect, the local lymph node assay (LLNA) has been shown to have a number of advantages. Through interpolation of LLNA dose response data, the concentration of a chemical required to produce a threshold positive response (the EC3 value) can be measured. The robustness of this measure has been thoroughly demonstrated in terms of inter and intra laboratory reproducibility. Additionally, the relationship between potency estimates from the LLNA and an appreciation of human potency has been reported. In the present work, we have sought to enhance this by undertaking a thorough and extensive analysis of existing human predictive assays, particularly where dose response information is available from historic human repeated insult patch tests (HRIPTs). From this human data, information on the approximate threshold for the induction of skin sensitization in the HRIPT was characterised for 24 chemicals. This was compared to LLNA EC3

values. The results from each assay, (expressed in terms of dose per unit area) showed a clear correlation, substantiating the utility of LLNA EC3 values for prediction of the relative human sensitizing potency of newly identified skin sensitizers.

## 1202 POTENCEY ESTIMATIONS FOR SEVERAL FRAGRANCE MATERIALS IN THE LOCAL LYMPH NODE ASSAY AND THEIR CORRELATION TO HUMAN STUDIES.

J. Lalko and A. Api. *Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ.*

In addition to its application as a method to identify potential contact allergens, the murine Local Lymph Node Assay (LLNA) presents the opportunity for the objective and quantitative measure of relative skin sensitizing potency. These potency estimations are typically based on linear interpolation of the dose response data, which yields an estimated concentration (EC3) required to elicit a positive response. In the present study, the LLNA potency estimations of 29 fragrance materials were compared to those derived from human NOELs for induction determined by the Human Repeated Insult Patch Test (HRIPT) and/or the Human Maximization Test (MAX). For each material the human NOELs and EC3 values were converted to their dose per unit area ( $\mu\text{g}/\text{cm}^2$ ) equivalents to allow for direct comparison. Each value was then used to independently assign both human and murine potency based on an expert classification scheme which groups materials as non-sensitizing, extremely weak, weak, moderate, strong and potent. A good correlation existed between the calculated EC3 values and the NOELs for induction of sensitization in humans. The EC3 values were observed to predict and in some cases slightly over predict the potency classes determined from the human NOELs for approximately 80% of the materials tested. Recently there has been a great deal of attention given to the estimation of potency in the LLNA and its correlation to humans with the aim of utilizing the EC3 value as an important data source for dermal sensitization risk assessments. The results observed show that the EC3 value can provide a useful estimate for contact allergenic potential in humans. The data demonstrate that these estimates can be applied to the risk assessment process in the determination of weight of evidence NOELs for the induction of sensitization. Further, the data show that information obtained in the LLNA can be useful in the design of human studies, where ethics dictate that the design act to confirm a calculated NOEL, rather than identify sensitization potential.

## 1203 ASSESSMENT OF THE LOCAL LYMPH NODE ASSAY USING A MODIFIED LOATS AUTOMATED MICRONUCLEUS ASSAY SYSTEM.

J. Kerzee, Y. Xu and J. W. Parton. *MicaGenix, Inc., Greenfield, IN.*

During sensitization, such as in allergic contact dermatitis, antigen-presenting cells are formed and migrate to the local draining lymph nodes (LN) to activate CD4+ T-cells resulting in lymphocyte proliferation. This is the principle of the local lymph node assay (LLNA) that detects DNA synthesis of lymphocytes in the draining auricular LN. The current study was designed to investigate using a modified Loats Automated Micronucleus Assay System (LAMS) for the LLNA. The modified LAMS distinguishes the proliferative phenotype of the cells by color based on 5-bromo-2-deoxyuridine (BrdU) incorporation; red for proliferating cells or blue for non-proliferating cells. Two trials were conducted in female CD-1 mice sensitized with mercaptobenzothiazole (MBT). In the first trial, Animals were administered BrdU intraperitoneally once-a-day for two days following three consecutive days of topical MBT treatment (7.5%). At the end of the trial, the auricular LNs were excised, lymphocytes were isolated, placed on glass slides, and immunostained against BrdU. As expected, MBT increased LN weight and number of lymphocytes compared to controls. BrdU incorporation (proliferation index) was significantly greater in sensitized animals than in control animals; however the Stimulation Index (SI) was less than 3. In the second trial, each animal served as its own control, such that the right ear was sensitized with MBT, and the left ear was challenged with vehicle. One animal was challenged with vehicle only as a negative control. In 4/5 sensitized animals, there was an increased LN weight and lymphocyte number in the sensitized LNs compared to controls. In addition, BrdU incorporation was significantly greater in the sensitized LNs compared to controls. These data indicate that the modified LAMS can quantitatively measure cell proliferation induced by sensitizers, such as MBT, in the LLNA, thereby reducing the number of animals needed, as well as the assay cost.

## 1204 CYTOKINE EXPRESSION PROFILES OF CD4 AND CD8 CELLS FROM PEANUT ALLERGEN-PRIMED MICE.

P. Wachholz, R. J. Dearman and I. Kimber. *Immunology, Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom.*

There is a growing interest in the development of approaches for assessing the allergenic potential of proteins. Although most foreign proteins are immunogenic (stimulate IgG antibody responses), relatively few are important food allergens. In

the UK and the USA, peanuts are a common cause of food allergy associated usually with high titer IgE antibody and consistent with the preferential activation of T helper (Th) 2 type cells. We have shown previously that sensitization of BALB/c mice to peanut agglutinin (a minor peanut allergen) results in IgE production and elevated type 2 cytokine expression. We have now examined the relative contributions of CD4 (Th) and CD8 (T cytotoxic; Tc) cells to this cytokine phenotype. Mice were immunized by intradermal injection of 1 mg/ml peanut agglutinin and 14 days following the initiation of exposure, draining auricular lymph nodes were excised and single cell suspensions prepared. Cells were labelled with carboxyfluorescein succinimidyl ester (CFSE) to identify proliferating cells, and restimulated *in vitro* with allergen, or with the T cell mitogen concanavalin A (con A). Cells were subsequently stained with fluorescein-labelled anti-CD8 or anti-CD4 antibodies and intracellular cytokine production was measured after saponin permeabilization using fluorescein-labelled anti-cytokine antibodies. Stimulation of cells from peanut-primed mice with either con A or specific allergen resulted in vigorous proliferation of CD4 and CD8 cells, whereas cells from naive mice responded only to con A. Moreover, the proliferating allergen-specific CD4 population was skewed towards a type 2 phenotype, whereas CD8 cells preferentially expressed a Tc1 phenotype (Interleukin-4 and Interferon- $\gamma$  expressing cells 3.5:1 and 1:0.1, respectively). In contrast, con A-activated CD4 and CD8 cells from both peanut primed and naive mice exhibited a heterogeneous cytokine profile. These data suggest that allergen-specific CD4 cells are the major contributors to the Th2 cytokine profile associated with allergic responses induced in mice by peanut agglutinin.

## 1205

### ORAL AND SUBCUTANEOUS EXPOSURE TO PURIFIED PEANUT ALLERGENS AND PEANUT EXTRACT: THE FOOD MATRIX EFFECT.

F. van Wijk<sup>1,2</sup>, R. Pieters<sup>1</sup>, S. Nierkens<sup>1</sup>, S. Koppelman<sup>2</sup> and L. Knijpels<sup>2</sup>.  
<sup>1</sup>Immunotoxicology, IRAS, Utrecht, Netherlands and <sup>2</sup>TNO, Zeist, Netherlands.

There has been a growing interest in the development of experimental animal models to predict allergenicity of food proteins, but at present no definitive test is available. One of the issues that remains to be elucidated is the effect of the food matrix on immune responses to food proteins. To study the intrinsic immunogenicity of purified allergens, and the influence of the food matrix, purified peanut allergens (Ara h 1, Ara h 2, Ara h 3 or Ara h 6) and a whole peanut extract (PE) were tested in both the murine popliteal lymph node assay (PLNA) and in an established oral model of peanut hypersensitivity. In the PLNA, PE or one of the purified allergens were injected into the hind footpad of BALB/c mice and specific responses were measured on day 7. In the oral exposure experiments, PE (1 or 6 mg/mouse) or allergens (0.1 or 1 mg/mouse) in combination with cholera toxin (10  $\mu$ g) as adjuvant were given by gavage to C3H/HeJ mice on three consecutive days followed by weekly dosing. Specific antibody responses were determined weekly. Upon food injection, none of the Ara h proteins did induce significant changes in cell proliferation, cytokine production, or activation of antigen presenting cells (APCs). In contrast, PE induced a 4-fold increase in cell number and high levels of IL-4, IFN- $\gamma$  and IL-10 upon ex-vivo restimulation with PE or the purified allergens. Furthermore PE induced an increase in expression of costimulatory molecules (CD80, CD86, CD54) on APCs. Oral exposure to PE or the Ara h's induced specific IgG and IgE responses in all cases, and Ara h-specific responses were comparable with those observed following exposure to PE. The results obtained using the subcutaneous route of exposure suggest that purified peanut allergens do not possess intrinsic immunogenicity in contrast to a whole PE. However, oral exposure data imply that in this model allergenicity of individual peanut antigens can be revealed with or without the presence of a food matrix.

## 1206

### INFLUENCE OF BACTERIAL ENDOTOXIN ON IGE ANTIBODY RESPONSES PROVOKED IN MICE BY PROTEIN ALLERGENS.

R. J. Dearman<sup>1</sup>, D. Fox<sup>2</sup>, S. Attenborough<sup>2</sup> and I. Kimber<sup>1</sup>. <sup>1</sup>Syngenta CTL, Macclesfield, United Kingdom and <sup>2</sup>Syngenta Jealotts Hill, Bracknell, United Kingdom.

Immediate type hypersensitivity reactions including food allergy and asthma are mediated by specific IgE antibody. The endotoxin content of protein allergen preparations has been suggested recently to influence the quality of immune responses. Thus, intranasal exposure of mice to the common allergen ovalbumin (OVA) with low levels of endotoxin (0.1  $\mu$ g/mouse) enhanced type 2 responses, including the production of IgE, whereas high dose endotoxin (100  $\mu$ g/mouse) resulted in a selective type 1 response. We have investigated the impact of endotoxin on IgE antibody responses induced by intraperitoneal (ip) exposure of BALB/c strain mice to a range of allergens under conditions where variable amounts of specific IgE are produced. The proteins comprised OVA, and the major Brazil nut and potato allergens, Ber e 1 and Sol t 1, respectively. Animals (n=5) received 1% of protein supplemented with endotoxin (lipopolysaccharide from *E. coli* serotype 055

B5; 0.25 or 25  $\mu$ g/mouse) by ip injection on days 0 and 7. Seven days later, serum samples were analyzed for specific IgE antibody by homologous passive cutaneous anaphylaxis assay. The majority of animals were IgE responders following administration of OVA or Sol t 1, although considerably higher titers (1 in 8 to 1 in 32) were recorded for OVA compared with Sol t 1 exposure (1 in 2). In both cases, IgE responses were unaffected by exogenous endotoxin (0.25 or 25  $\mu$ g/mouse). Treatment with Ber e 1 failed to stimulate detectable IgE antibody. However, high dose endotoxin provoked a marked increase in anti-Ber e 1 IgE antibody production with a titer of 1 in 8 recorded. These data demonstrate that the influence of bacterial endotoxin on IgE antibody is allergen-dependent, but is not associated with the vigor of the IgE response.

## 1207

### CYTOKINE FINGERPRINTING OF CHEMICAL ALLERGENS: COMPARISONS OF MESSAGE VERSUS PROTEIN.

B. Flanagan<sup>1</sup>, C. J. Betts<sup>2</sup>, H. T. Caddick<sup>2</sup>, R. J. Dearman<sup>2</sup> and I. Kimber<sup>2</sup>.

<sup>1</sup>Liverpool University Liverpool, United Kingdom and <sup>2</sup>Syngenta CTL, Macclesfield, United Kingdom.

Topical exposure of BALB/c strain mice to the contact allergen 2, 4-dinitrochlorobenzene (DNCB), or to the respiratory allergen trimellitic anhydride (TMA) induces selective type 1 or type 2 cytokine secretion profiles, respectively. We have now examined whether these cytokine expression patterns are regulated at the level of mRNA and/or protein production. Thirteen days after the initiation of topical exposure, a single cell suspension of auricular lymph node cells (LNC) was prepared. Total RNA was prepared from freshly isolated cells and cytokine gene expression was analyzed by ribonuclease protection assay (RPA). Cells were cultured for 120 h and supernatants analyzed for cytokine protein by ELISA. DNCB-activated LNC secreted high levels of the type 1 cytokine interferon (IFN)- $\gamma$ , compared with TMA-stimulated LNC, reaching maximal levels after culture for 96–120 h. The converse type 2 pattern was observed following treatment with TMA; with secretion of most type 2 cell products (including interleukins [IL]-5, 10 and 13) reaching maximal levels after 96–120 h of culture. LNC from TMA-treated mice displayed a type 2 cytokine mRNA profile, with high levels of transcripts for IL-4, IL-10 and IL-13 detected and relatively low levels of IFN- $\gamma$ . In contrast, RNA isolated from DNCB-activated LNC displayed a mixed cytokine phenotype with relatively low levels of transcripts for both type 1 and type 2 cell products. The observation that IFN- $\gamma$  mRNA expression is not increased despite robust secretion of this cytokine indicates that production of IFN- $\gamma$  by draining LNC is controlled mainly at the level of secretion or translation of previously transcribed mRNA. Furthermore, the preferential cytokine profile recorded following TMA exposure was more clearly contrasting when measured at the level of protein secretion rather than at the level of mRNA expression. These data suggest that cytokine profiling by RPA is not appropriate for the prospective characterization of chemical respiratory and contact allergens.

## 1208

### IMPACT OF ROUTE AND INTENSITY OF EXPOSURE DURING SENSITIZATION IN BN RATS.

J. H. Arts<sup>1</sup>, N. Bloksma<sup>2,3</sup>, A. H. Penninks<sup>1</sup> and F. Kuper<sup>1</sup>. <sup>1</sup>TAP, TNO Nutrition and Food Research, Zeist, Netherlands, <sup>2</sup>Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands and <sup>3</sup>Faculty of Biology, Utrecht University, Utrecht, Netherlands. Sponsor: V. Feron.

There are good indications that skin exposure can act as a route for respiratory tract sensitization but less is known about effects of the route on the type of immune reaction evoked and on dose-response relationships. In the present study, both the inhalation and dermal route were used to examine whether allergen-induced effects were dose-related or route-of-induction related. The respiratory allergen trimellitic anhydride (TMA) was given at various concentrations topically to male Brown Norway (BN) rats on days 0 and 7, or by inhalation for 3 h/d on days 0 to 4. Dose levels were comparable on a mg/kg BW basis. All animals were challenged by inhalation to TMA on day 21 and lung function was assessed before, during, shortly and 24 h after challenge. At necropsy on day 23, blood was sampled, bronchoalveolar lavage was performed and the respiratory tract was collected. Lung function changes and an inflammatory reaction predominantly associated with a delayed type, cell-mediated immune reaction were observed following sensitization and challenge by inhalation. Increases in total serum IgE were seen at high TMA concentrations only. Sensitization by the dermal route resulted in an immediate, antibody-mediated type of inflammation, altered lung function changes and increased serum IgE levels at all effective doses. Because changes in lung function were seen at comparable (external) doses it could be concluded that these reactions occurred dose-dependently, independent from the route of sensitization. However, the inflammatory reaction and serum IgE levels appeared predominantly influenced by the sensitization route. This research is funded by the Dutch Ministry of SZW and CEFIC-LRI (Brussels, Belgium).

**1209****TOPICAL EXPOSURE OF MICE TO PHTHALATE IS WITHOUT ADJUVANT EFFECT.**

D. Shaw, R. J. Dearman and I. Kimber. *Syngenta CTL, Macclesfield, United Kingdom.*

It has been suggested that one possible contributor to the increasing prevalence of IgE-mediated allergic diseases (including respiratory allergy and asthma) in Western Europe and the US is the presence in the environment of chemicals that may act as adjuvants. It has been reported previously that certain commonly used phthalate plasticizers, including that used most widely worldwide, di-(2-ethylhexyl) phthalate (DEHP), are able under some circumstances to modify immune responses induced in mice by the common allergen ovalbumin (OVA). Thus, it was reported that subcutaneous administration of DEHP (at 2mg/ml) in the presence of OVA resulted in an increase in anti-OVA IgG1 antibody production compared with mice exposed to OVA alone. Murine IgG1 antibody can be considered a surrogate of IgE antibody as cytokine regulation of this subclass of antibody parallels that of IgE. However, the significance of these observations for human health, and for the development of allergic disease is unclear; not least because the studies have been conducted exclusively using subcutaneous administration of phthalates. We have therefore investigated the ability of DEHP when applied topically to affect anti-OVA IgG1 antibody responses induced by subcutaneous exposure to OVA in BALB/c strain mice. Concentrations of DEHP (500mg/ml) were used that resulted in a marked (approximately 30%) increase in liver weight. Under conditions where anti-OVA IgG1 antibody responses were sub-optimal (immunization with 1mg OVA) topical administration of DEHP was without impact on anti-OVA antibody responses, regardless of whether DEHP was applied local or distant to the site of OVA immunization. These data suggest that the reported adjuvant effect of DEHP is a feature of the subcutaneous route of exposure as topical application of concentrations of DEHP that provoked marked systemic effects were without effect on the induction of immune responses.

**1210****AUGMENTATION OF OVALBUMIN-INDUCED IGE AND AIRWAY HYPERREACTIVITY RESPONSE BY PERFLUOROOCTANOIC ACID (PFOA).**

K. J. Fairley<sup>1</sup>, S. Kearns<sup>1</sup>, L. P. Myers<sup>1</sup>, R. Purdy<sup>2</sup> and B. J. Meade<sup>1</sup>. <sup>1</sup>*Agriculture and Immunotoxicology Group, NIOSH, Morgantown, WV and*<sup>2</sup>*Independent Toxicologist, River Falls, WI.*

Studies were conducted to investigate the role of dermal exposure to Perfluorooctanoic acid (PFOA), an immunosuppressant with widespread use as a carpet and fabric protectant, on the hypersensitivity response to ovalbumin in a murine model. BALB/c mice were exposed dermally to concentrations of PFOA ranging from 0.01-2.0% (0.25-50mg/kg) for 4 days. In hypersensitivity studies, mice were also intraperitoneally injected with 7.5µg ovalbumin and 2mg alum on days 1 and 10 and in some studies, intratracheally challenged with 250µg ovalbumin on days 17 and 26. Endpoints for studies included body and organ weights and cellularities, IgE, airway hyperreactivity, and lung histopathology. Following exposure to PFOA, an increase in liver weights and a decrease in thymus and spleen weights and cellularities were observed. Similar immunomodulatory trends were demonstrated in mice co-administered PFOA and ovalbumin. Greater than a 2-fold increase in total IgE was demonstrated when mice were co-exposed with concentrations of PFOA ranging from 0.75-1.5%, while the ovalbumin-specific IgE response peaked after a 3-fold increase ( $p<0.01$ ) in 0.75% PFOA co-exposed animals as compared to the ovalbumin alone exposed animals. Antigen-specific airway hyperreactivity was increased ( $p<0.05$ ) in the 1.0% PFOA co-exposed group, with a dose-responsive pleiotropic cell response characterized by eosinophilia and mucin production, in animals co-exposed to concentrations of PFOA up to 1.0%, as compared to the ovalbumin alone exposed animals. PFOA was demonstrated to be immunotoxic in a murine model following dermal exposure, with an enhancement of the hypersensitivity response to ovalbumin, suggesting that PFOA exposure may augment the IgE response to environmental allergens.

**1211****EVALUATION OF DERMAL SENSITIZATION TO WESTERN RED CEDAR EXTRACT AND ABIETIC ACID USING THE LOCAL LYMPH NODE ASSAY.**

R. A. Brundage, S. Azadi, B. J. Meade, P. D. Siegel and D. N. Weissman. *HELD/ASB, NIOSH, Morgantown, WV.*

Western Red Cedar (WRC, *Thuja plicata*) induces sensitization and asthma after occupational exposure. Plicatic acid, a low molecular weight (LMW) compound present at high concentrations in WRC wood has been implicated as the active agent. Another wood product, abietic acid (ABA), a terpenoid present in the resin of conifer species, has also been identified as a LMW agent causing occupational sensitization and asthma. We used the mouse local lymph node assay to address the question of whether these agents could induce sensitization via the dermal route.

WRC was extracted in water and the extract was lyophilized (WRC Extract). Mass spectrometry was consistent with plicatic acid being a major, but not the only, component of WRC extract. WRC extract and ABA were applied in concentrations of 12.5, 25, and 50% (w/v) to the ears of Balb/C mice. Vehicle treatment was used as a negative control and 30% -hexylcinnamaldehyde was used as a positive control. Neither WRC nor ABA caused increases in ear thickness, suggesting that neither was a dermal irritant. *In vivo* cell proliferation in draining lymph nodes was measured as 3H-thymidine incorporation following 3 days of exposure. Lymph node cell populations were evaluated for the presence of B220+ IgE+ B cells by flow cytometry on day 10, following 4 days of exposure. 3H-thymidine incorporation in draining lymph nodes was significantly increased by exposure to all three concentrations of WRC extract and the highest concentration of ABA (50%). Stimulation indices were: 3.4, 6.9, and 11.0 for 12.5%, 25%, and 50% WRC extract; and 3.0 for 50% ABA. Only the 50% WRC extract caused significant increases in B220+ IgE+ B cell percentage in draining nodes. Serum total IgE was increased 2 weeks after dermal exposure every other day to 25% and 50% WRC extract. Our results show that both WRC extract and ABA can induce sensitization by the dermal route and that WRC extract and ABA are weak dermal sensitizers (EC3 10% and 50%, respectively).

**1212****INDUCTION OF CONTACT SENSITIZATION BY ANNATTO EXTRACT BIXIN BUT NOT BY NORBIXIN IN FEMALE BALB/C MICE.**

W. Auttachao<sup>1</sup>, D. R. Germolec<sup>2</sup>, K. L. White Jr<sup>1</sup> and T. L. Guo<sup>1</sup>. <sup>1</sup>*Virginia Commonwealth University, Richmond, VA and*<sup>2</sup>*NIEHS, Research Triangle Park, NC.*

Annatto seeds, also known as 'achiote seeds', are commonly used in South American cooking. Annatto dye is an orange-yellow food coloring extracted from the seeds of the tree *Bixa orellana*. It has been used to color butter, margarine, cheese, smoked fish, snack foods, beverages, and cereals. Reported adverse reactions associated with annatto dye ingestion include urticaria and angioedema. The present studies were carried out to examine a possible contact allergenic effect of two purified carotenoid pigments from annatto extract: bixin (BIX: C25H30O4) and norbixin (NOR: C24H28O4). The experiments were conducted in female BALB/c mice by applying BIX (1-25% w/v) and NOR (1-20% w/v) in acetone topically, and assays performed including the local lymph node assay (LLNA), the irritation assay, the mouse ear swelling test (MEST) and flow cytometric analysis. There was no treatment-related adverse effect on the body weights. However, a three-fold increase in the proliferation of auricular lymph node cells was observed at BIX concentrations of 5%-25% ( $p\leq 0.01$ ). A significant increase in percent ear swelling was also produced in mice treated with BIX (5-10%) at 24 hr after challenge as measured in MEST assay. Further study indicated that BIX was not an irritant at the concentrations tested. Additional study demonstrated that exposure to BIX induced a significant increase in the percentage of B cells (Ig+) in the draining lymph node. In contrast, the results from studies on NOR showed that exposure to NOR at concentration levels of 1-20% did not alter the lymph node cell proliferation in the LLNA assay. Taken together, these results suggested that in annatto extract bixin but not norbixin is a contact sensitizer in female BALB/c mice (Supported by the NIEHS Contract ES 05454).

**1213****DIFFERENTIAL ALLERGIC AND NEUROTROPHIN RESPONSES TO FUNGAL COMPONENT EXTRACTS IN MICE.**

M. Ward<sup>1</sup>, N. Haykal-Coates<sup>1</sup>, Y. Chung<sup>2</sup>, L. Copeland<sup>1</sup> and M. Selgrade<sup>1</sup>.

<sup>1</sup>*NHEERL, USEPA, Research Triangle Park, NC and*<sup>2</sup>*SPH, UNC, Chapel Hill, NC.*

*Metarhizium anisopliae* mycelium (MYC), conidia (CON) and inducible protease (IND) extracts were combined to produce the antigen MACA to screen for allergenic potential. Involuntary aspiration (IA) exposure to MACA in BALB/c mice has caused immune, inflammatory and physiological responses characteristic of allergic lung disease. Our objective here was to determine if the component extracts have similar allergenic potential. BALB/c mice received 4 IA of 10 µg of MACA, CON, MYC, IND, or BSA (negative control) in 50 µl HBSS, or HBSS alone (vehicle control) over a 4-week period. Additional mice received 1 exposure to agents as non-allergic controls. Serum and bronchoalveolar lavage fluid (BALF) were collected 3 days (D3) after the final exposure. Mice were assessed for immediate responses following IA exposure and airway hyperresponsiveness to methacholine (MCH; D1 & D3) by whole-body plethysmography, an index of pulmonary resistance and bronchoconstriction (PenH). All fungal extract exposures resulted in elevated BALF total protein, LDH, total cell counts, total IgE and IgA and serum IgE compared to HBSS and BSA controls. These responses were highest in MYC exposed mice, but their PenH was significantly lower compared to the other fungal treatments. To investigate this dichotomy, the level of BALF neurotrophins (NGF, NT-3, NT-4) that have been associated with allergic lung disease were evaluated. All extract exposures resulted in increased levels of the neurotrophins compared to controls. The IND treated mice had the lowest levels of the neurotrophins and significantly higher PenH compared to the other fungal treatments. The rank order of

airway responses to the fungal extracts was the inverse of the other endpoints. These data show differences in the magnitude of responses by the *M. anisopliae* extracts. Additionally, the data suggest that the neurotrophins are not the sole source of the airway responses induced by these extracts. (Supported by UNC/EPA Agreement CT826513. This abstract does not reflect EPA policy)

EFFECTS OF DIESEL EXHAUST ON PULMONARY RESPONSES DURING ALLERGIC SENSITIZATION TO AEROSOLIZED OVALBUMIN IN BALB/C MICE.

P. Singh<sup>1</sup>, M. J. Daniels<sup>1</sup>, D. L. Andrews<sup>1</sup>, E. H. Boykin<sup>1</sup>, T. Krantz<sup>1</sup>, W. P. Linak<sup>2</sup> and L. Gilmour<sup>1</sup>. <sup>1</sup>NHEERL, USEPA, Research Triangle Park, NC and <sup>2</sup>NRMRL, USEPA, Research Triangle Park, NC.

Inhalation of diesel exhaust (DE) is associated with the development of asthma. Studies have also demonstrated that DE induces pulmonary changes that worsen asthmatic responses to respiratory allergens. We have established a DE inhalation-exposure system with the capability of adjusting from whole exhaust to gas-only exposures and that provides time-of-flight measurements of both size-fractionated particle concentrations and gaseous constituents such as NOX, SOX, O<sub>2</sub>, and CO<sub>2</sub>. In order to understand the effects of DE on early development of allergic airway responses *in vivo*, female BALB/c mice were exposed for 4 hours on a single day to either air or DE (particle concentrations of 0.2 mg/m<sup>3</sup> and 2.0 mg/m<sup>3</sup>) or each day for 5 days followed by a daily 40 min exposure to aerosolized ovalbumin (OVA). Responses were measured in the bronchoalveolar lavage fluid (BALF) and in lung tissue homogenates on days 1 and 5. On day 1, DE exposed mice had increased inflammatory cell influx and raised levels of NF-κB in lung tissues, which correlated with some increases in cytokine release, but no increases in cytotoxicity or pulmonary edema compared to air-exposed mice. Five days of DE exposure followed by OVA did not affect cellular inflammation, but cytotoxicity and pulmonary edema were increased compared to air/OVA exposures. Inhalation of OVA increased MIP-2 levels in the BALF and induced both NF-κB and phosphorylated p38MAP kinase signaling proteins in lung cell lysates. Five days of DE exposure had a synergistic effect on lung injury in OVA sensitized mice but did not potentiate the cytokine response. We conclude that this system will be useful for tracking qualitative and kinetic changes in cellular responses during allergic sensitization with controlled modifications of inhalation exposure conditions. Further studies using this system will make it possible to correlate specific biological responses to individual particulate and gaseous components of DE emissions. (This abstract does not reflect EPA policy.)

**1215**

GLABRIDIN INHIBITS INDUCIBLE NITRIC OXIDE SYNTHASE EXPRESSION BY BLOCKING NUCLEAR FACTOR-κB ACTIVATION IN MURINE MACROPHAGES.

J. Kang, Y. Yoon, I. Cho, M. Han, C. Lee, S. Park and H. Kim. *Bioevaluation Center, Korea Research Institute of Bioscience and Biotechnology, Taejon, South Korea.*

Glabridin, a flavonoid present in licorice extract, is known to have antimicrobial, anti-inflammatory and cardiovascular protective activities. In the present study, we report the inhibitory effect of glabridin on nitric oxide (NO) production and inducible nitric oxide (iNOS) gene expression in murine macrophages. Glabridin attenuated lipopolysaccharide (LPS)-induced NO production in isolated mouse peritoneal macrophages and RAW 264.7 cells, a mouse macrophage-like cell line. Moreover, iNOS mRNA expression was also blocked by glabridin treatment in LPS-stimulated RAW 264.7 cells. Further study demonstrated that the LPS-induced NF-κB/Rel DNA binding activity and NF-κB/Rel-dependent reporter gene activity were significantly inhibited by glabridin in RAW 264.7 cells and that this effect was mediated through the inhibition of inhibitory factor-κB degradation and p65 nuclear translocation. In animal model, *in vivo* administration of glabridin increased the rate of survival of LPS-treated mice and inhibited LPS-induced increase in plasma concentrations of nitrite/nitrate and tumor necrosis factor-α. Collectively, these data suggest that glabridin inhibits NO production and iNOS gene expression by blocking NF-κB/Rel activation and that this effect was mediated, at least in part, by inhibiting reactive oxygen species generation. Furthermore, *in vivo* anti-inflammatory effect of glabridin suggests a possible therapeutic application of this agent in inflammatory diseases.

RHOA/ROCK SIGNALING NEGATIVELY REGULATES NUCLEAR FACTOR KAPPA B (NF-κB) ACTIVATION VIA MODULATION OF IκBα LEVELS IN KIDNEY EPITHELIAL CELLS.

M. E. Ellis, W. W. Polk, J. V. Kushleika, P. L. Simmonds and J. S. Woods. *Environmental Health, University of Washington, Seattle, WA.*

The transcriptional activator, NF-κB, controls the expression of genes involved in inflammation, proliferation and survival in a variety of cell types. We previously described NF-κB activation in normal rat kidney epithelial (NRK52E) cells by

lipopolysaccharide (LPS) and other agents, and showed that this involves phosphorylation and degradation of the inhibitor protein, IκBα. However, the specific mechanisms mediating this response were not defined. Here, we report findings suggesting the involvement of the Rho family GTPases, RhoA, and its associated kinase, ROCK, in the control of NF-κB activation in kidney cells. Treatment of NRK cells with LPS (1 μg/ml) induced maximal NF-κB-DNA binding intensity within 30 min, which dissipated within 2 hrs. Pretreatment of cells with Y27632 (30 μM), a specific ROCK inhibitor, doubled the maximal intensity of LPS-induced NF-κB-DNA binding and prolonged the binding intensity for up to 4 hrs. Y27 pretreatment also doubled the intensity of LPS-induced NF-κB-dependent transcriptional activity in cells transfected with a 4xNF-κB-luciferase reporter plasmid. Consistent with these observations, nuclear IκBα content declined to <10% of untreated levels by 10 min after LPS treatment but recovered to 100% by 3 hrs. In contrast, when Y27 was administered before LPS, nuclear IκBα declined and remained at <10% of untreated levels with no recovery for up to 4 hrs. Finally, Y27 pretreatment dramatically increased both the amount and duration of IκBα phosphorylation, compared with that seen after LPS alone. Similar effects were observed when cells were pretreated with GGI, an inhibitor of RhoA activation. These findings suggest that Rho/ROCK signaling negatively affects NF-κB activation in kidney epithelial cells by modulating both cytoplasmic and nuclear levels of the NFκB inhibitor, IκBα. **1217**

INDUCTION OF NUCLEAR FACTOR-KB ACTIVATION THROUGH TAK1 AND NIK BY DIESEL EXHAUST PARTICLES IN L2 CELL LINES.

J. Lee<sup>2</sup>, K. Lee<sup>2</sup>, Y. Lim<sup>1</sup>, H. Kim<sup>3</sup> and H. Sohn<sup>4</sup>. <sup>1</sup>Occ. & Env. Med., St. Mary's Hospital, Seoul, South Korea, <sup>2</sup>Pharmacology, The Catholic University of Korea, Seoul, South Korea, <sup>3</sup>Internal Med., Youngdong Severance Hospital, Seoul, South Korea and <sup>4</sup>Preventive Med., Inje University, Busan, South Korea. Sponsor: L. Yu.

Diesel exhaust particles (DEPs) are known to induce allergic responses in airway epithelial cells such as the production of various cytokines via nuclear factor-kappa B (NF-κB). However, the intracellular signal transduction pathways underlying this phenomenon have not been fully examined. This study showed that the DEP induced NF-κB activity via transforming growth factor-β activated kinase 1 (TAK1) and NF-κB-inducing kinase (NIK) in L2 rat lung epithelial cells. DEP induced the NF-κB dependent reporter activity approximately 2-3 fold in L2 cells. However, this effect was abolished by the expression of the dominant negative forms of TAK1 or NIK. Furthermore, it was shown that DEP induced TAK1 phosphorylation in the L2 cells. These results suggest that TAK1 and NIK are important mediators of DEP-induced NF-κB activation.

**1218**

APPLICATION OF A HIGH-COVERAGE, FUNCTIONAL GENOMIC SCREEN TO DISSECT THE NFκB SIGNALING PATHWAY.

T. A. Halsey, T. J. Page, L. Pluta and R. S. Thomas. *CIIT Centers for Health Research, Research Triangle Park, NC.*

While the organization of numerous signal transduction pathways has been extensively studied, the composition of the majority of pathways is still not completely understood. Current estimates indicate that greater than 40% of the predicted human genes do not have a putative molecular function or known role within a signaling network. Closing the knowledge gap by assigning functions to these genes and placing them contextually into signaling pathways will be critical for understanding cellular responses to toxic agents and disease. The NFκB signaling pathway was chosen due to its role in the cellular response to inflammation and acute toxicity. To identify the components of the NFκB signaling pathway, HEK 293T cells were transduced with a lentivirus containing a NFκB luciferase reporter creating a stable cell line with a high level of signal-to-noise (>30-fold induction with TNFα). Using the stable cell line, a high-coverage gain-of-function (GOF) screen was performed by individually expressing approximately 14, 500 full-length mammalian genes and evaluating what genes when added to cells alter NFκB signaling. More than 30 high confidence genes were identified in the preliminary analysis with several of the genes previously shown to play a role in NFκB signaling including lymphotxin α, TNFR10A, and TNFR10B. However, most of the genes identified are not currently known to play a role in NFκB signaling. The results are presently being confirmed in follow-up assays. The results of the GOF screen were stored in a relational database and bioinformatic tools were used to construct an interactive signal transduction network. The structure of the signaling network was refined using known biomolecular interactions and additional signaling information from the literature. The results demonstrate that application of large-scale genomic screens can identify genes that play a functional role in signaling pathways and reveal previously unknown targets of toxicity.

TRPV1 ANTAGONISTS INDUCE TRANSLOCATION OF INTRACELLULAR TRPV1 TO THE PLASMA MEMBRANE ENHANCING VANILLOID-INDUCED TOXICITIES.

M. E. Johansen<sup>1</sup>, C. A. Reilly<sup>1</sup>, D. L. Lanza<sup>1</sup>, J. Lee<sup>2</sup> and G. S. Yost<sup>1</sup>.

<sup>1</sup>Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT and <sup>2</sup>College of Pharmacy, Seoul National University, Shinlim-Dong, South Korea.

Functional regulation of TRPV1 influences the relative sensitivity of lung epithelial cells to toxicities induced by vanilloid receptor agonists, such as capsaicin. An understanding of how TRPV1 is regulated in lung epithelial cells will provide essential information that could facilitate the identification of drug therapies to remediate lung disorders (e.g., asthma, COPD), that are caused and/or aggravated by xenobiotics interacting with TRPV1. Preliminary results have shown that TRPV1 over-expressing BEAS 2B cells preexposed to various TRPV1 antagonists exhibited increased sensitivity to prototypical TRPV1 agonists, as measured by enhanced calcium flux and cytotoxicity. Incubation (4 hrs) with LJO-328 (1  $\mu$ M), a potent and selective TRPV1 antagonist, caused a >250-fold decrease in the LD50 and a doubling in calcium flux following nonivamide administration. In contrast, LJO-328 co-incubated with TRPV1 agonists (i.e. RTX or nonivamide) prevents TRPV1-mediated calcium flux and cell death. Attenuation of the antagonist-induced enhancement of TRPV1-mediated toxicities with brefeldin A (a golgi transport inhibitor), but not cycloheximide (a protein synthesis inhibitor), suggested that exposure to TRPV1 antagonists induced translocation of existing intracellular stores of TRPV1 to the plasma membrane, augmenting TRPV1 agonist sensitivity in these cells. These data indicate an intracellular receptor trafficking mechanism for the regulation of TRPV1 distribution and function to maintain an operative plasma membrane population of TRPV1 in these cells. Supported by: The National Heart, Lung, and Blood Institute (HL069813).

INDUCTION OF ORGANIC ANION TRANSPORTING POLYPEPTIDE 2 EXPRESSION BY CYCLIC AMP-DEPENDENT SIGNALING PATHWAY IN MOUSE HEPA-1 CELLS.

C. Chen, X. G. Cheng and C. D. Klaassen. University of Kansas Medical Center, Kansas City, KS.

Cyclic AMP (cAMP) is a ubiquitous second messenger involved in many signal transduction pathways. The expression of a number of genes is modulated in response to hormones and other environmental signals via variations in intracellular cAMP. The aim of this study was to determine whether a cAMP-dependent signaling pathway is involved in the regulation of mouse organic anion transporting polypeptide 2 (Oatp2), a hepatic uptake transporter for organic anions, such as cardiac glycosides. Hepa-1 cells (a mouse hepatoma cell line) were treated with four different concentrations of the adenylate cyclase activator forskolin (0.5-10  $\mu$ M) or two cellular membrane-permeable cAMP analogs, dibutyryl cAMP and 8-bromo-cAMP (0.01-1 mM). Mouse Oatp2 mRNA was quantified using the branched DNA signal amplification assay. All four concentrations of forskolin, as well as dibutyryl cAMP and 8-bromo-cAMP induced mouse Oatp2 expression. The Oatp2 mRNA expression was increased at least 3 fold in cells treated with 10  $\mu$ M forskolin, 1 mM dibutyryl cAMP, or 1 mM 8-bromo-cAMP. A luciferase reporter gene construct containing 7.8-kb of the 5'-flanking region of mouse Oatp2 was engineered. Luciferase activity in response to treatment with 5  $\mu$ M forskolin was assayed in Hepa-1 cells transiently transfected with the mouse Oatp2 promoter reporter gene construct. Forskolin treatment induced reporter gene activity by approximately 3 fold. In conclusion, Oatp2 expression is induced by a cAMP-dependent signaling pathway in mouse Hepa-1 cells. (Supported by NIH grants ES-09649)

TOBACCO SMOKE-INDUCED EPITHELIAL CELL PROLIFERATION AND SQUAMOUS METAPLASIA IN THE LUNGS OF RATS: ROLE OF MAPK/AP-1 PATHWAY.

C. Zhong, Y. Zhou and K. E. Pinkerton. CHE, University of California, Davis, CA.

Epidemiological and experimental evidence has demonstrated tobacco smoke (TS) is causally associated with various types of cancers including lung cancer. However, the cellular and molecular mechanisms remain unclear. Sustained epithelial cell hyperplasia and squamous metaplasia are considered as preneoplastic lesions during the formation of lung tumors. Mitogen-activated protein kinases (MAPKs)/activator protein -1 (AP-1) pathway plays central role in the control of cell proliferation and differentiation, and can be activated by various stimuli such as carcinogens, oxidants and inflammatory cytokines, all factors that are produced by TS. To date, information on the response of MAPK/AP-1 pathway during TS-induced hyperplasia and squamous metaplasia is virtually absent. The present study investigated the effects of TS on the development of epithelial hyperplasia and squamous metaplasia, activation of MAPK/AP-1, and expression of AP-1 target genes including cell cycle

regulators and differentiation markers in rats. Exposure to TS (30 mg/m3 and 80 mg/m3, 6h/day x 3days/ week) for 14 weeks dramatically induced epithelial cell proliferation and squamous metaplasia in a dose-dependent manner, effects that paralleled the activation of AP-1 - DNA binding activity. TS significantly increased the levels of phosphorylated ERK1/2, JNK, p38 and ERK5, indicating the activation of these MAPK pathways. Expression of jun and fos proteins were differentially regulated following TS exposure. Moreover, TS upregulated AP-1 -dependent cell cycle proteins including cyclin D1 and PCNA, while AP-1 -dependent cell differentiation markers including keratin 5, 14, loricrin, and filaggrin were altered correspondingly. These findings provide the first report that demonstrated the role of MAPK/AP-1 pathway in TS-induced preneoplastic lesions such as epithelial hyperplasia and squamous metaplasia.

MAPPING GENE EXPRESSION NETWORKS: USING WHOLE GENOME EXPRESSION ANALYSIS WITH RNAI TO DEFINE THE HEAT SHOCK SIGNAL TRANSDUCTION CASCADE.

T. Page, T. Halsey, L. Pluta and R. S. Thomas. CIIT, Research Triangle Park, NC.

Gene expression networks (GENs) are collections of linked signal transduction pathways that convert input signals into complex gene expression cascades. In a well known example, exposure of cells to steroid hormones results in a primary wave of gene expression that is regulated by the corresponding ligand-dependent transcription factor. The primary wave of gene expression is enriched in transcription factors that, in turn, activate a secondary wave of gene expression. This cycle is repeated to form the GEN associated with the specific steroid hormone. In this work, we present an approach to "reverse engineer" GENs using a combination of time-course microarray analysis coupled with RNAi-mediated inhibition of key transcription factors in the GEN. Our model for this approach is the heat shock treatment of HeLa cells since it is a general stress response in cells and is present following exposure to chemical toxicants. When HeLa cells are pretreated with an siRNA for the HSF1 transcription factor (siHSF1) we observe a five-fold decrease in the induction of HSP70, indicating that HSP70 is regulated by HSF1. Although this observation has been previously reported, it validates the underlying approach. In the presence of siHSF1, we also detected a significant alteration in a number of other genes such as placental growth factor and PZDK3. Additionally, we have identified two transcription factors that are induced in the primary wave of gene expression, KLF2 and EGRI. Expression of KLF2 was then blocked via siRNA treatment and downstream signaling was compared to both siHSF1 treated cells and untreated cells. Additional genes were identified as KLF2-dependent, allowing a separate branch of the heat shock GEN to be mapped. These results demonstrate that the coupling of whole-genome expression analysis with RNAi can be a powerful tool for clarifying existing signaling branches, and identifying previously unknown branches that play a role in a given network or toxicological endpoint.

IDENTIFICATION OF SIGNALING PATHWAYS ACTIVATING REACTIVE GLIOSIS IN MULTIPLE MODELS OF BRAIN INJURY: A GENOMIC, PROTEOMIC AND PROTEIN PHOSPHORYLATION ANALYSIS.

K. Sriram and J. P. O'Callaghan. Centers for Disease Control & Prevention (CDC)-NIOSH, Morgantown, WV.

Reactive gliosis (gliosis, glial activation) is a hallmark of disease-, trauma- and chemical-induced damage to the CNS. This response is characterized by activation of microglia and astrocytes at sites of damage. Despite the regional- and cell-type specific targets of individual nervous system insults, reactive gliosis represents a feature common to all types of neural injury. This implies that there are common 'signals' responsible for its induction, signals that remain to be elucidated. Discovery and characterization of the signaling events that lead to this common response to brain damage would enhance our ability to detect early signatures of the neurotoxic condition. To achieve this, we used various brain injury models [1-Methyl-4-phenyl-1, 2, 3, 6, -tetrahydropyridine (MPTP), methamphetamine (METH), kainic acid (KA), and traumatic brain injury (Stab)] as denervating tools to damage distinct areas of mouse brain and elicit a glial response. Applying genomic (cDNA microarray, real-time PCR) and proteomic (antibody microarray, Ciphergen ProteinChip<sup>®</sup> platform, phosphoprotein immunoblots) analysis, we identified the early induction of several ligands of the gp130 signal transducer family (IL-6, CNTF, LIF, OSM) and other cytokines and chemokines (TNF- $\alpha$ , MCP-1) known to activate the Janus kinase-signal transducer and activator of transcription (JAK-STAT) pathway. The temporal expression of these ligands and the specific activation of JAK2-STAT3 was selective to the target region and preceded the induction of GFAP and astrocyte hypertrophy across all brain injury models examined. Pharmacological inhibition of JAK2 with tyrophostin B42 (AG490) attenuated STAT3 activation and GFAP expression in the MPTP model. Taken together, our

results suggest that the JAK2-STAT3 pathway is activated prior to induction of astrogliosis in multiple models of brain injury. Ligands and effectors associated with activation of this pathway may serve as early 'biomarkers' of neurological/neurotoxic hazards.

## 1224

### CHANGES IN EXPRESSION OF TOTAL AND PHOSPHORYLATED ERK1/2 IN TCDD-EXPOSED EMBRYONIC MOUSE PALATES.

C. J. Wolf and B. Abbott. *Reproductive Toxicology Division, USEPA, ORD, NHEERL, Research Triangle Park, NC.*

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) induces cleft palate in mice by preventing fusion of the palatal shelves. TCDD maintains EGF and EGF receptor (EGFR) expression levels in medial epithelial cells of the palate at a time when EGFR levels fall in those of controls. EGFR activates the MAPK - ERK pathway; therefore, MAPK signaling may play a critical role in mediating TCDD-induced cleft palate. In this study, we examined whether TCDD exposure alters MAPK signaling by monitoring the ratio of phosphorylated ERK (pERK) to total ERK (tERK) in embryonic mouse palates. Pregnant mice were dosed with 24 ug/kg TCDD or corn oil (control, CO) on gestational day (GD) 12 and embryos were collected on GD 14. Embryonic palates from 5 control and 5 treated litters were isolated and pooled by litter. Expression of pERK and tERK protein were quantitated by densitometric analysis of Western blots and by ELISA, and the ratio of pERK/tERK was determined. On Western blots, all bands were normalized to Bactin, and ERK appears as 2 bands, ERK1 and ERK2. Western analysis revealed that the pERK/tERK ratio was reduced in the TCDD (0.25 ± 0.05) compared to CO (0.41 ± 0.08; p < 0.01) group for ERK1 but not for ERK2 (0.25 ± 0.09 TCDD vs. 0.33 ± 0.10 CO). There was more tERK1 in the TCDD group compared to CO. ELISA analysis showed the ratio of pERK/tERK was not different between the TCDD and CO groups. However, ELISA analysis does not separate ERKs 1 and 2 and may not be able to detect changes in one isoform. When data from both bands were added together in the Western analysis, no significant difference was found in the ratio of pERK/tERK ratio between TCDD and CO groups. These preliminary results suggest tERK1 is more abundant compared to controls but kinase activity is not high enough to maintain the pERK/tERK ratio in palates exposed to TCDD. Additional data on pERK/tERK at other time points and in specific areas of the palate may more fully illustrate the pathway for TCDD-induced cleft palate. [This abstract does not necessarily reflect EPA policy].

## 1225

### INTERACTIONS WITH THE TGF- $\beta$ SIGNALING PATHWAY: A KEY MECHANISM OF DEVELOPMENTAL TOXICITY?

T. W. Thomas<sup>1,2</sup> and C. A. Kimmel<sup>2</sup>. <sup>1</sup>AAAS Risk Policy Fellow, Washington, DC and <sup>2</sup>NCEA, USEPA, Washington, DC.

The TGF- $\beta$  signaling pathway is responsible for regulation of several cellular processes, including pattern formation and tissue specification during embryo development. Mutations in components of the TGF- $\beta$  pathway at later development stages often result in patterning defects and malformation of embryonic organs in vertebrate animals; similarly, mutations in these components have been linked to several human birth defects. However, interference with this pathway by environmental agents has yet to be defined as a key mechanism of toxicity. To determine if interactions between environmental toxicants and this signaling pathway represent a key mechanism of toxicity, we searched the literature for interactions between agents that cause developmental toxicity and initiating events of the TGF- $\beta$  signaling pathway. These events were then linked to adverse outcomes through a cascade of biochemical and physiological changes that resulted from the initial interactions between the toxicants and the signaling pathway. We found that environmental tobacco smoke, retinoic acid, cyclophosphamide and alcohol all interact with the TGF- $\beta$  signaling pathway in a similar manner to cause adverse outcomes. Moreover, these agents all interact with the pathway to cause a change in either the expression of TGF- $\beta$  or its receptor or the localization pattern of TGF- $\beta$  or its receptor. These results demonstrate that interactions between these agents and the TGF- $\beta$  signaling pathway may constitute a fundamental pathway for developmental toxicity. Defining mechanisms of toxicity will be important for reducing uncertainties and for animal to human data extrapolation in human health risk assessment. Disclaimer: The views expressed are those of the authors and do not necessarily reflect the views or policies of the USEPA.

### DIABETES-INDUCED NEPHROPATHY ASSOCIATES WITH AKT AND P38 KINASE ACTIVATION.

Y. Song, R. Wu, M. Barati, M. Rane and L. Cai. *Medicine, University of Louisville, Louisville, KY.*

Diabetic nephropathy is related to tubulointerstitial accumulation of extracellular matrix (ECM). Tubular atrophy, initiated from renal tubular epithelial cell (RTC) apoptosis, has repeatedly been shown to be one of the best histological predictors of

renal ECM accumulation in biopsies. The present study tested the hypothesis that alterations of renal signaling pathways under diabetic condition are causative factor for the development of diabetic nephropathy. Firstly, diabetic mice were produced by single dose of streptozotocin (STZ) and were sacrificed at one, three, and six months after hyperglycemia. Results showed that six months of STZ-induced diabetic mice significantly presented renal fibrosis, shown by increases in serum BUN and renal PAS staining. Western blot analysis demonstrated significant increases in renal Akt phosphorylation at one and three months, followed by a decrease at six months after hyperglycemia. Increased Akt phosphorylation at 3 months, resulted in enhanced association of Akt and p38 MAPK as demonstrated by immunoprecipitation studies. These results suggest a cross-talk between Akt/p38 kinase pathways. Immunohistochemical staining of control and 3 months diabetic kidney sections showed enhanced phosphoS<sup>473</sup>-Akt in the RTC. Therefore, we have further studied the effect of high levels of glucose (22 mM) on human RTCs (HCK11 cell line) on the Akt signaling and apoptotic cell death. Exposure of RTCs to 22 mM glucose significantly increased Akt Ser<sup>473</sup> phosphorylation at three and nine hours, and decreasing thereafter. Additionally, hyperglycemia induced p38 phosphorylation at six to twelve hours. Under the same experimental condition, apoptotic cell death, detected by TUNEL positive cells, was significantly increased after 12 hrs. These results suggest that diabetes-induced nephropathy may associate with diabetes-induced RTC cell death through down-regulation of Akt/p38 MAPK pathways, resulting in a tubular atrophy and consequently tubulointerstitial fibrosis (Supported, in part, by ADA and AHA grants).

## 1227

### DISPOSITION OF TCDD IN A MOUSE MODEL OF OBESITY AND TYPE II DIABETES.

J. J. Diliberto, M. J. DeVito, D. G. Ross, V. M. Richardson and L. S. Birnbaum. *NHEERL, USEPA, Research Triangle Park, NC.*

Recent epidemiology studies have shown an association between type II diabetes and exposure to TCDD (2, 3, 7, 8-tetrachlorodibenzo-p-dioxin). A possible explanation is that diabetics have a slower elimination of TCDD than non-diabetics. The objective of the present study was to examine the influence of diabetes and body fat mass on the disposition of TCDD using a mouse model of obesity and Type II diabetes. Male C57BL/6J (C57) and AJ/6 (AJ) mice were placed on a normal diet or a high fat, high simple carbohydrate (HFHSC) diet for 13 wks before the start of the study. The HFHSC diet was used to induce obesity and signs of type II diabetes in C57 mice; while AJ mice on a HFHSC diet became fatter than AJ/6 on a normal diet, but not obese nor hyperglycemic. Mice were then housed in metabolism cages, maintained on their respective diets throughout the study, and given a single po dose of 5  $\mu$ g [ $^3$ H]TCDD/kg. After 40 days, mice (singly housed in metabolism cages with separate collection of urine and feces every 24h) were killed and tissues collected. Disposition in excreta and tissues was quantified. Percentages ( $\pm$ SD) of cumulative administered dose excreted were: in feces 50±5.4, 32±3.6, 48±2.3, 33±3.8; and in urine 22±2.0, 27±5.7, 15±1.5, 21±5.0 for C57 normal diet, C57 fat diet, AJ normal diet, and AJ fat diet, respectively. Percentages ( $\pm$ SD) of administered dose at 40 days post-dosing were: in liver 2.9±0.3, 6.7±1.2, 5.0±0.5, 5.5±1.3; and in adipose tissue 4.7±0.6, 28.3±4.1, 7.6±0.8, 21.7±3.2 for C57 normal diet, C57 fat diet, AJ normal diet, and AJ fat diet, respectively. Data from this study made clear the effects of body fat and diabetes on the deposition of TCDD in excreta and tissues, and showed that a high body fat mass slowed the elimination of TCDD. (This work was funded in part by an Interagency Agreement with the US Air Force #FQ7624-00YA085. This abstract does not represent USEPA policy.)

## 1228

### MATERNAL AND FETAL DISPOSITION OF GENISTEIN GLUCURONIDE AND SULFATE CONJUGATES FOLLOWING 14-DAY *IN UTERO* EXPOSURE TO GENISTEIN.

N. V. Soucy, H. D. Parkinson, M. A. Sochaski and S. J. Borghoff. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Diets high in soy-based products are well known for their estrogenic activity. Genistein, the predominant phytoestrogen present in soy, is known to interact with both estrogen receptor (ER)  $\alpha$  and  $\beta$ . Genistein has been shown to elicit reproductive effects in developing rodents. In the rat, genistein is metabolized predominantly to glucuronide and sulfate conjugates. Neither the glucuronide nor the sulfate conjugate are capable of activating ER. Therefore it is critical to understand how much unconjugated genistein is delivered to the fetus following maternal exposure, and how much remains unconjugated once in the fetus. Genistein (4 and 40 mg/kg) was administered to pregnant Sprague-Dawley rats by oral gavage daily from GD 5-19. Maternal and fetal plasma along with placenta were collected at various time points (0.5, 1, 2, 4, 6, 8, 12 and 24 h) following administration of the final dose on GD 19. Concentrations of genistein, genistein glucuronide and genistein sulfate were quantitated by LC-MS/MS. For both maternal and fetal plasma,

the genistein glucuronide and genistein sulfate were predominant, with unconjugated genistein levels much lower. The ratio of genistein glucuronide to genistein sulfate was higher in the fetal plasma compared to maternal plasma. There was a linear increase in genistein glucuronide and genistein sulfate in fetal plasma with time, while unconjugated genistein concentrations remained relatively constant after an initial appearance in fetal plasma within 1 hour of *in utero* exposure. In the placenta, the concentration of genistein was present at higher levels than the conjugates. It is unclear from these data whether it is maternal transfer, placental formation or fetal liver formation that contributes to the concentrations of conjugates observed in fetal plasma. These data suggest that the concentration of unconjugated genistein available for ER interaction in the fetus is relatively low following maternal exposure to genistein. (Supported by the American Chemistry Council).

THE CANALICULAR TRANSPORTER MULTIDRUG RESISTANCE-ASSOCIATED PROTEIN 2 FACILITATES BILIARY EXCRETION OF DIETHYLSТИLBESTROL.

**M. Z. Dieter**, T. L. Callaghan and **C. D. Klaassen**. *University of Kansas Medical Center, Kansas City, KS.*

Diethylstilbestrol (DES) is a synthetic estrogen that is metabolized in liver primarily by conjugation with UDP-glucuronic acid. The multidrug resistance-associated protein 2 (Mrp2) transporter is localized to the canalicular membrane of hepatocytes and is responsible for export of glucuronide conjugates into bile. The purpose of this work was to test the hypothesis that Mrp2 is responsible for the biliary excretion of DES by studying DES excretion in TR(-) rats, which lack functional Mrp2 protein. The femoral artery, femoral vein, and common bile duct of male control Wistar rats and TR(-) rats were cannulated, after which rats received an intravenous dose of 100 µg/kg (25 µCi/kg) of radiolabeled DES. Blood and bile samples were collected over the course of one hour. Chloroform extraction of samples was performed to separate parent lipophilic DES from its water-soluble conjugates, after which DES was quantified by scintillation counting. Plasma disappearance of parent DES was similar in both Wistar and TR(-) rats. In Wistar rats, serum levels of conjugated DES remained low, however, in TR(-) rats, serum levels of conjugated DES increased over the course of one hour. Within 15 min of administration, Wistar rats excreted approximately 12.5 µg of DES per kg body weight into bile; nearly 78% of this DES was in conjugated form. In contrast, in TR(-) rats, only 0.1 µg/kg (63% conjugated) of DES was excreted into bile within 15 min. After 1 hour, 30.3 µg/kg of DES (83% conjugated) was excreted into bile of Wistar rats, whereas in TR(-) rats, only 0.85 µg/kg (84% conjugated) of DES was excreted. Total DES was quantified in liver and kidney 1 hr after administration. TR(-) rats had 3.6- and 3.9- fold more DES in liver and kidney, respectively, compared to Wistar rats. In summary, impaired biliary excretion of DES, increased serum levels of DES conjugates, and accumulation of DES in tissues in TR(-) rats, collectively indicate that Mrp2 is principally responsible for biliary excretion of DES. (Supported by ES-08156, ES-09716 and ES-07079)

**1230**

DISPOSITION OF 2, 2', 4, 4', 5, 5'-HEXBROMODIPHENYL ETHER IN F344 RATS AND B6C3F1 MICE.

**E. H. Lebetkin**<sup>1</sup>, **J. M. Sanders**<sup>1,2</sup>, **A. C. Creech**<sup>1,3</sup> and **L. T. Burk**<sup>1</sup>. <sup>1</sup>*LPC, NIEHS, Research Triangle Park, NC*, <sup>2</sup>*Department of Toxicology, NCSU, Raleigh, NC* and <sup>3</sup>*NCSU, Raleigh, NC.*

2, 2', 4, 4', 5, 5'-Hexabromodiphenyl ether (BDE-153) is a major congener in the polybrominated diphenyl ether (PBDE) Great Lakes DE-71®. DE-71 is used as a flame retardant in plastics, electronic equipment, textiles, and building materials. DE-71 congeners are present in the environment and have been shown to accumulate in mammalian tissues and fluids. PBDE's are of toxicological interest because of their reported neonatal neurotoxicity in rodents. Toxicity studies on DE-71 are being designed by the National Toxicology Program. The disposition of individual congeners in DE-71 is being determined to investigate possible interactions among them. Thus the disposition of <sup>14</sup>C-BDE-153 was studied in male and female F344 rats and B6C3F1 mice for comparison to similar studies of BDE-99 and 47 conducted in our lab. Results of iv and oral administration of 1 µmol/kg doses, indicate that ca. 70% of a single oral dose is absorbed in rats in contrast to 85% of BDE-99 and 70% of BDE-47 being absorbed. After an oral dose, BDE-153 concentrates in fat (17% of the total dose after 24 hours in rats and 21-27% in mice) and is excreted in the feces (25-30%), with less than 1% in urine. The liver/fat ratio is 0.88 in rats and 0.29 in mice in comparison to 0.22 and 0.14 for BDE-99 and BDE-47 respectively in rats. BDE-153 concentration after an oral dose was higher in all tissues than in blood, with tissue/blood ratios (TBR) over 6 in liver, fat, thymus, and adrenal glands. The adrenal gland TBR ranged from 48 to 244 with the concentration twice as high in female rats and mice as in males. The amount of BDE-153-derived radioactivity in thyroid is not significantly different from other tissues in the rat but is 3 to 4 times higher in mice than rats. The thyroid concentration in rats

was similar to that found in BDE-99 treated rats and 10-fold lower than after BDE-47 treatment. In summary, the tissue distribution of BDE-153 is typical of a lipophilic, polyhalogenated, aromatic chemical and is not as well absorbed as BDE-99, but similar to BDE-47.

METABOLISM AND TISSUE DOSIMETRY OF PENTAVALENT AND TRIVALENT MONOMETHYLATED ARSENIC AFTER ORAL ADMINISTRATION IN MICE.

**M. F. Hughes**<sup>1</sup>, **V. Devesa**<sup>2</sup>, **B. M. Adair**<sup>1</sup>, **M. Styblo**<sup>2</sup>, **E. M. Kenyon**<sup>1</sup> and **D. J. Thomas**<sup>1</sup>. <sup>1</sup>*ORD/NHEERL, USEPA, Research Triangle Park, NC* and <sup>2</sup>*CEMALB, University of North Carolina, Chapel Hill, NC.*

Humans are exposed to monomethylarsonic acid (MMA(V)) and monomethylarsonous acid (MMA(III)), which are formed as metabolites of inorganic arsenic. The sodium salts of MMA(V) are also used as herbicides. This study examined the metabolism and tissue dosimetry of MMA(V) and MMA(III). Adult female B6C3F1 mice were oral gavaged with either MMA(V) (0.4 or 40 mg As/kg; <sup>14</sup>C or unlabeled) or MMA(III) (0.4 mg As/kg, unlabeled). Mice were sacrificed over 24 hr and tissues (blood, bladder, kidney, liver, lung) were removed and analyzed either for radioactivity or for MMA or dimethylarsinic acid (DMA) by hydride generation-atomic absorption spectrometry. MMA(V)-derived radioactivity (<sup>14</sup>C) was rapidly absorbed and distributed among all tissues examined. Peak tissue concentrations of <sup>14</sup>C were observed between 1 and 4 hr post-dosing. Terminal tissue half-lives of <sup>14</sup>C ranged from 4 (liver) to 15 hr (kidney). For the two dosage levels, differences between the area under the curves (AUC) of the concentration-time profiles of <sup>14</sup>C in the blood and organs were less than 100-fold. Only carcass, which consisted of tissues not removed and intestinal contents, had a 100-fold difference in AUC. These findings suggest that absorption of MMA(V) was dose-dependent. Speciation of arsenicals in mice found levels of DMA that were five-fold more or greater in tissues of MMA(III)-treated mice than in MMA(V)-treated mice. Thus, dose and oxidation state of monomethylated arsenic can affect its disposition. (This abstract does not necessarily reflect EPA policy.)

PHARMACOKINETIC EVALUATION OF PERFLUOROOCTANOIC ACID IN THE MOUSE.

**C. Lau**<sup>1</sup>, **M. J. Strynar**<sup>2</sup>, **A. B. Lindstrom**<sup>2</sup>, **R. G. Hanson**<sup>1</sup>, **J. R. Thibodeaux**<sup>1</sup> and **H. A. Barton**<sup>3</sup>. <sup>1</sup>*Reproductive Toxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC*, <sup>2</sup>*Human Exposure and Atmospheric Sciences Division, NERL, ORD, USEPA, Research Triangle Park, NC* and <sup>3</sup>*Experimental Toxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Perfluorooctanoic acid (PFOA) is a stable chemical surfactant with wide industrial and consumer applications. Because PFOA has been detected in both human and wildlife populations, its potential adverse health effects are under active investigation. The pharmacokinetic properties of PFOA are unique: in the rat, there is a pronounced gender difference in its renal clearance such that half-life in females is estimated as 3 h and that in males as 5 days; however, such a major gender difference is absent in humans. The present study is designed to examine the pharmacokinetic properties of PFOA in another rodent species. Young male and female CD-1 mice received a single gavage administration of PFOA at either 1 or 10 mg/kg. Three animals from each group were sacrificed at 4 h, 8 h, 12 h, or 1, 3, 6, 9, 13, 20, 27, 34, 42, 48 days after treatment. Serum was prepared from trunk blood collected from the descending aorta and analyzed for PFOA by HPLC-MS-MS. PFOA was absorbed readily, reaching Cmax between 4-8 h. In contrast to the rat, no discernable sex difference in the disposition of PFOA was observed in the mouse. The terminal serum half-life of PFOA was estimated in the range of 15-20 days. A similar pharmacokinetic profile was seen in both dose groups, suggesting linearity between body burden of the fluorocarbon and administered doses up to 10 mg/kg. These results thus indicate a significant difference in the pharmacokinetic disposition of PFOA between the rat and the mouse, with the profile of the latter species resembling the lack of an apparent sex-dependent elimination in humans. This abstract does not necessarily reflect USEPA policy.

**1233**

INITIAL SKIN PENETRATION STUDY FOR DETERMINING BIS-(2-CHLOROETHOXY)METHANE (CEM) TOXICOKINETICS AFTER A SINGLE DERMAL APPLICATION IN RODENTS.

**S. HONG**<sup>1</sup>, **J. D. Johnson**<sup>1</sup>, **S. W. Graves**<sup>1</sup>, **B. Burbank**<sup>1</sup>, **J. Merrill**<sup>1</sup> and **C. Smith**<sup>2</sup>. <sup>1</sup>*Battelle Memorial Institute, Columbus, OH* and <sup>2</sup>*NIEHS, NIH, Research Triangle Park, NC.*

CEM is a colorless, liquid, haloethane substance used in manufacturing processes, e.g. polysulfide elastomers. It is not a naturally occurring substance but is found in the environment because of volatilization during manufacturing, translocation in

plants, uptake by animals, and industrial waste from plastic and metal finishing processes. Human exposure to CEM occurs primarily via inhalation and dermal routes and, since CEM-rodent studies identified target organs (heart, thymus, liver, kidney, skin), it is potentially toxic to humans. For these reasons, the present study was conducted to obtain initial information about the time course of CEM's dermal penetration into the systemic circulation, generate biological samples for quantifying blood and tissue concentration ranges, and determine appropriate doses and time points for a definitive TK study. The subscapular dorsal skin, clipped of fur, was used as the application site. Single application dosages were 75 or 300 mg/kg for F344 rats (M/F) and 150 or 600 mg/kg (M) and 100 or 400 mg/kg (F) for B6C3F1 mice. Dosing volumes were 0.5 (r) and 2 (m) mL/kg. Plasma concentration-time point profiles were biphasic, except for the mouse low dose (<LOQ, 2.5 ng/mL). Cmax, ke, and AUCinf values were 1.3 ug/mL, 0.216 hr<sup>-1</sup>, and 1.8 hr.ug/mL at 75 mg/kg for male rats; 10 ug/mL, 0.204 hr<sup>-1</sup>, and 17 hr.ug/mL at 300 mg/kg for male rats; and 1.7 ug/mL, 1.8 hr<sup>-1</sup>, and 2.2 hr.ug/mL at 600 mg/kg for male mice, respectively. Females had similar values. Heart and thymus values were similar to plasma results, except thymus AUC values were elevated. Rat plasma AUC values increased disproportionately with dosage suggesting saturation of elimination. These results indicate that a single dermal application of CEM at 100, 200, or 400 mg/kg (rats) and 400 or 600 mg/kg (mice) will produce plasma/tissue concentrations sufficient to characterize CEM TK parameters within and outside the dose proportional range. [Supported by NIEHS N01-ES-05456]

## 1234

### RODENT PLASMA AND TISSUE CONCENTRATION TIME COURSE DATA FOR BIS (2-CHLOROETHOXY)METHANE: A PRELIMINARY IV STUDY.

J. W. Merrill<sup>1</sup>, J. D. Johnson<sup>1</sup>, S. Hong<sup>1</sup>, S. W. Graves<sup>1</sup>, B. Burbank<sup>1</sup> and C. Smith<sup>2</sup>. <sup>1</sup>Battelle, Columbus, OH and <sup>2</sup>NIEHS, NIH, Research Triangle Park, NC.

bis-(2-Chloroethoxy)methane (CEM) is used extensively in a variety of manufacturing processes and is a potentially toxic substance to humans based on rodent-study target organs (heart, thymus, liver, and kidney). A metabolite of CEM, thiodyglycolic acid (TGA), inhibits mitochondrial function, thereby possibly contributing to the mechanism of CEM-induced toxicity. For these reasons, generation of time-course data for CEM and TGA are being developed for use in a PBPK-model for the evaluation of dose matrices and characterization of tumor-dose response relationships. The present study was conducted to obtain preliminary TK parameters, generate biological samples for analytical method development and validation, and determine appropriate doses and time points for a definitive TK study. F344 rats and B6C3F<sub>1</sub> mice were given a single intravenous (IV) administration of CEM in cremophor:ethanol:water (1:1:8) at 10 mg/kg (2 mL/kg). Plasma, heart, and thymus CEM concentration time profiles were biphasic (rats) and monophasic (mice). (Profiles following dermal application suggest CEM may be triphasic for rats and biphasic for mice.) The CEM plasma concentration-time profile resulted in C<sub>5 min</sub>, k<sub>e</sub>, and AUC<sub>inf</sub> values of 8.0 ug/mL, 0.0131 min<sup>-1</sup>, and 211 min.ug/mL for male rats and 3.8 ug/mL, 0.118 min<sup>-1</sup>, and 66.6 min.ug/mL for male mice, respectively. Females had similar values. AUC values were increased for the thymus and heart when compared to the plasma AUC. TGA concentrations were below the LOQ (200 ng/mL), thereby precluding construction of plasma/tissue profiles following a single IV CEM administration. These results indicated that a single IV administration of CEM at 10 mg/kg will allow TK parameters to be determined but a higher dosage (non-toxic) or lower LOQ (2.5 ng/mL) are necessary to characterize a gamma phase. Also, a single IV administration of TGA is needed to determine TK parameters of the metabolite. [This study supported by NIEHS Contract No. N01-ES-04546.]

## 1235

### EFFECTS OF PARTICLE SIZE ON THE SYSTEMIC BIOAVAILABILITY IN RATS FOLLOWING INHALATION EXPOSURE.

S. Hu<sup>1</sup>, B. Naumann<sup>2</sup>, M. Cwik<sup>1</sup> and N. Rajendran<sup>1</sup>. <sup>1</sup>IIT Research Institute, Chicago, IL and <sup>2</sup>Merck & Co., Inc., Whitehouse Station, NJ.

Risk assessment of occupational exposure to airborne pollutants encountered in the workplace is commonly extrapolated from results of inhalation toxicology studies using experimental animals. Though such studies provide a linkage between exposure and its associated biological effect, there is not much information provided regarding the absorption of inhaled particles deposited into various regions of the lung. In this study we hypothesized that altering the regional deposition dose within the respiratory tract by inhaling two distinct sizes of particles may result in subsequent changes of their pharmacokinetics following a single nose-only inhalation exposure to test drug MK-0679. Specifically, two groups of young, adult rats were exposed to a test atmosphere containing either 1.4 or 3.5  $\mu$ m MMAD particles of MK-0679 at the target exposure dose level of 6 mg/KgBW for 1 hour. Upon exposure termination, blood samples were collected at six discrete time points (5 rats/time/group), via cardiac puncture, from rats anesthetized with CO<sub>2</sub>. Drug

concentrations in plasma were measured by HPLC for the determination of bioavailability of drug. Area under the curve (AUC), peak plasma concentration (Cmax) and its corresponding time point (Tmax), and plasma elimination half-life (T1/2) were determined for both exposure groups. The results showed that for both groups post-exposure plasma drug levels increased initially, reached to Cmax at approximate 1-hr post-exposure, decreased rapidly to less than 40% of Cmax at 2-hrs post-exposure, and gradually decreased to approximate 10-20% of Cmax at 6-hrs post-exposure. There was a good agreement of Cmax, Tmax, T1/2, and AUC between the two exposure groups, indicating that there was no statistically significant difference in the systemic absorption between the two exposure groups, despite the expected greater fractional deposition of the 3.5  $\mu$ m particles in the upper respiratory tract. The results suggest that the systemic absorption of MK-0679 via inhalation exposure is influenced the most by the dose deposited in the lungs.

## 1236

### EVALUATION OF THE HALF-LIFE (T<sub>1/2</sub>) OF ELIMINATION OF PERFLUOROOCTANOATE (PFOA) FROM HUMAN SERUM.

D. Ehresman<sup>1</sup>, G. Olsen<sup>1</sup>, J. Burris<sup>1</sup>, J. Froehlich<sup>2</sup>, A. Seacat<sup>1</sup> and J. Butenhoff<sup>1</sup>. <sup>1</sup>Medical Department, 3M Company, St. Paul, MN and <sup>2</sup>Pace Analytical, St. Paul, MN.

The ammonium salt of perfluorooctanoate (C<sub>8</sub>F<sub>15</sub>O<sub>2</sub><sup>-</sup>) is used as an emulsifier and surfactant. PFOA is readily absorbed, distributes primarily to extracellular space (liver and blood), is highly protein (albumin) bound in serum, has no known metabolic conversion and undergoes enterohepatic circulation. Marked sex and species differences occur in the elimination of PFOA. Urine is the primary route of excretion. The T<sub>1/2</sub> of serum elimination in male and female rats is 4-6 days and 2-4 hours and is approximately 21 and 30 days in male and female monkeys, respectively. Sex hormones may modulate differential expression of organic anion transporters involved in the urine elimination of PFOA. To investigate the T<sub>1/2</sub> of serum elimination in humans, 27 retirees (25 males, 2 females) from two fluorocarbon manufacturing plants were followed for 5.5 years for periodic blood collections. The analysis for PFOA used a primary acid extraction in combination with an alkaline back extraction technique. A 5  $\mu$ L injection was introduced to the mass spectrometer through a high performance liquid chromatography system. All quantitative calculations were based on the ion ratios between PFOA and the internal standard (dual substituted <sup>13</sup>C-PFOA). The primary standard was a mixture of linear and branched chain isomers of PFOA. A total of 464 serum samples were analyzed. One retiree's samples were excluded due to the likelihood of occupational exposure to PFOA during follow-up. Initial serum concentrations of PFOA for the remaining 26 retirees ranged between 0.07 to 5.10 mg/mL. Only linear chain PFOA was observed. Individual serum elimination rates were calculated with Pharsight WinNonlin® software. The mean T<sub>1/2</sub> of serum elimination was 1378 days (SD 609) and ranged between 561 and 3334 days. Median was 1257 days (3.5 years). The T<sub>1/2</sub> of serum elimination was not associated with initial PFOA concentrations, age or sex of retiree, years worked at manufacturing facility or the time between retirement and first blood collection.

## 1237

### DISPOSITION OF [<sup>14</sup>C] DECAMETHYLCYCLOPENTASILOXANE ([<sup>14</sup>C]D<sub>5</sub>) IN FISCHER 344 RATS FOLLOWING SINGLE AND MULTIPLE INHALATION EXPOSURE.

J. M. Tobin, D. A. McNett, J. A. Durham and K. P. Plotzke. *Health and Environmental Sciences, Dow Corning Corporation, Auburn, MI.*

The disposition of D<sub>5</sub> in male and female Fischer 344 rats following single or multiple inhalation exposures was evaluated. Animals were administered a single 6 hour nose-only exposure to 7 or 160 ppm [<sup>14</sup>C]D<sub>5</sub> or fourteen 6-hour nose only exposures to unlabeled D<sub>5</sub> followed on the 15th day by a 6 hour exposure to [<sup>14</sup>C]D<sub>5</sub>. Subgroups of exposed animals were established to evaluate body burden, distribution, and elimination. Samples of blood, fat, liver, lung, feces and expired air were also processed for parent D<sub>5</sub> analysis. Retention of D<sub>5</sub> following single exposures was relatively low (~4-5% of inhaled D<sub>5</sub>), with ~8-10% retained following multiple exposures. Approximately 50-80% of this retained dose was attributed to deposition on the fur for males and ~60-70% for the females. Parent and radioactivity was widely distributed to tissues of both males and females, with maximum concentrations observed in the majority of the tissues by 3 hours post-exposure. D<sub>5</sub> was distributed to fat, with elimination of parent and radioactivity occurring slower than observed for plasma and other tissues. Elimination of retained radioactivity was similar in urine (~12%) and feces (~16%) of both sexes following all exposures. Expired air was similar for both sexes following multiple exposures and females following single exposure (~45%) with significantly higher amounts for the males following a single exposure (~72%). In the plasma, liver and lung, the majority of radioactivity immediately following exposure could be attributed to parent, with this decreasing over time to a small fraction attributable to parent from 24 to 168 hours

post exposure. In the urine samples, several peaks were present, but none corresponded to the retention time of parent D<sub>5</sub>. In contrast, the major peak for the feces corresponded to the retention time for parent D<sub>5</sub>. Supported in part by the Silicones Environmental, Health and Safety Council of North America.

## 1238 TOXICOKINETICS OF 14C-RDX IN MINIATURE PIGS.

G. Reddy<sup>1</sup>, M. A. Major<sup>1</sup>, M. A. Berge<sup>2</sup> and S. Patzer<sup>2</sup>. <sup>1</sup>Directorate Toxicology, U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD and <sup>2</sup>Covance Laboratories Inc., Madison, WI.

Cyclotrimethylenetrinitramine (RDX), a nitramine compound, has been used extensively as an explosive in military munitions since World War II. The toxicokinetic data in animals are limited. In this study, the toxicokinetics of 14C-RDX-derived radioactivity was examined following administration of a single oral dose formulated as an aqueous suspension in 0.1% carboxymethylcellulose at a target dose level of 43 mg/kg (53  $\mu$ Ci/kg) to male and female Yucatan minipigs. Blood was collected at 1, 6, 12 and 24 hours postdose from each animal. Urine and feces were collected through 24 hours postdose. Animals were sacrificed at 24 hours postdose and selected tissues collected. Blood, plasma, tissues, and excreta were analyzed for total radioactivity. Female minipigs vomited and experienced tremors and convulsions within 1 hour postdose. Only vomiting was observed in male minipigs, occurring within 2 hours postdose. Animals appeared normal by 2.5 hours postdose. Urine was the major route for elimination of 14C-RDX-derived radioactivity, with 17.3 and 17.6% of the radioactive dose, respectively, in males and females. RDX was well absorbed. Feces accounted for less than 1% of administered dose and gastrointestinal contents for about 5.6% of the dose. The distribution of 14C-RDX-derived radioactivity was extensive, with radioactivity observed in all collected tissues. The highest concentrations of radioactivity were observed in liver and kidney. The calculated percent of radioactive dose was high in liver (3.5 to 5.8%) and muscle (2.5 to 4.7%). Profiling and metabolite identification in urine, plasma, and selected tissues are in progress. (Abstract does not reflect US Army policy)

## 1239 TOXICOKINETICS OF TETRABROMOBISPHENOL A IN HUMAN SUBJECTS.

W. Dekant, W. Voelkel and U. Schauer. Department of toxicology, University of Wuerzburg, Wuerzburg, Germany.

Tetrabromobisphenol A (TBPA) is a widely used as a flame retardant and is suspected to be stable in the environment with possible widespread human exposures. This study reports the characterization of the toxicokinetics of a low dose of tetrabromobisphenol A in human subjects. A single oral dose of 0.1 mg/kg TBPA was administered to 3 male and 2 female human subjects in a gel capsule. The study was performed with informed consent by the human subjects and approved by the local institutional review board. Urine and blood concentrations of TBPA and its metabolites were determined by LC/MS-MS at different time points. TBPA glucuronide and TBPA sulfate were identified as metabolites of TBPA present in blood or urine of the exposed human subject. TBPA glucuronide was formed as a metabolite in all individuals, whereas TBPA sulfate was only detected in two of the five individuals. Maximum plasma concentrations of TBPA glucuronide (10-15 pmol/mL) were obtained within two hours after administration, the glucuronide was cleared from blood with an apparent half-life of 26 h. In the two individuals where TBPA sulfate was present in blood, maximum concentrations were obtained at the 4 hour sampling point, the concentrations rapidly declined to reach the limit of detection after 8 hours. Parent TBPA was not present in detectable concentrations in any of the plasma samples. In urine of all participating individuals, only TBPA glucuronide was detected. This metabolite was slowly eliminated to reach the limit of detection 96 hours after administration. Only a part (approx. 25 %) of the administered dose was recovered in urine. The obtained result suggest absorption of TBPA from the gastrointestinal tract, rapid metabolism of the absorbed TBPA by glucuronide formation, and a possible involvement of polymorphic sulfotransferase in TBPA biotransformation. Due to the high molecular weight of the TBPA-glucuronide, most of the TBPA-glucuronide is likely excreted with feces. This work was supported by the European Commission in context of the FIRE-project

## 1240 TISSUE DISTRIBUTION OF <sup>14</sup>C-ACETAMINOPHEN IN THE MONKEY USING QUANTITATIVE AUTORADIOGRAPHY OR LIQUID SCINTILLATION COUNTING.

O. Boutherin-Falson<sup>1</sup>, L. Faure<sup>1</sup>, A. Raynard<sup>1</sup>, M. Maynaud<sup>1</sup> and J. Descotes<sup>2</sup>. <sup>1</sup>MDS Pharmacology Services, St Germain s/ L'Arbresle, France and <sup>2</sup>Poison Center, Lyon, France.

Distribution studies are an important part of preclinical drug development programs. They also support GLP compliant safety studies, for which both rodents and larger animals are required. In this study, quantitative autoradioluminography

(RLG) and liquid scintillation counting (LSC) were compared in one cynomolgus monkey given a single dose of 20 mg/3.7 MBq/kg of <sup>14</sup>C-acetaminophen intravenously. Forty-five minutes after treatment, the animal was cryopreserved and bisected along its length. One half was sectioned at 30  $\mu$ m with a 3600 Leica cryomacrotome. The evaluation of the sections was performed using a Fuji BAS-2500 scanner linked to AIDA Raytest software, which had previously been validated in accordance with FDA 21 CFR, part 11 guidelines. Quantification was achieved using blood calibration samples processed together with the sections. The other half of the animal was defrosted and 23 tissues/organs were collected, homogenized, combusted using a 307 Packard Oxidizer and counted for total radioactivity. When comparing results obtained with either method, the slope and  $r^2$  values of the linear regression analysis of paired concentrations were 0.9999 and 0.9995, respectively. In addition, 19 out of 23 RLG results ranged between -10.6% and +13.8 % of the reference LSC values. The other 4 results were within -26.1% and +18.4% of the reference LSC values. The organ to blood ratios, a standard parameter for the evaluation of accumulation, were very similar whatever the method used. In conclusion, quantification with RLG gave comparable results to those obtained with LSC. RLG is a reliable method applicable to large animals which allows the collection of data in a GLP-compliant manner.

## 1241 ETHYLENE GLYCOL UPTAKE IN VOLUNTEERS EXPOSED BY INHALATION AND BY THE DERMAL ROUTE.

S. Upadhyay, J. Carstens, T. H. Faller, H. Greim, G. A. Csanady and J. G. Filser. Toxicology, GSF Neuherberg, Germany.

Four healthy, non-smoking male volunteers (between 30 and 56 years old) inhaled over 4 h a defined quantity of 13C2-ethylene glycol (13C2-EG) vapor. Separately, the same volunteers were exclusively exposed up to 6 h to liquid 13C2-EG (0.8 ml), applied to 66 cm<sup>2</sup> of the inner forearm skin. Plasma samples and urine were collected up to 30 h after starting the exposures and analyzed by GC/MS for labeled and unlabeled (endogenous) EG, glycolic acid (GA) and oxalic acid (OA). The amounts of inhaled EG (1.34-1.61 mmol) corresponded to inhalation exposures ranging from 7.0-8.4 ppm (4 h; alveolar ventilation 20 l/min). Maximum plasma concentrations ranged from 10-16  $\mu$ mol/l 13C2-EG and from 0.9-2.6  $\mu$ mol/l 13C2-GA. The amounts excreted ranged from 44-130  $\mu$ mol 13C2-EG, from 9.5-13  $\mu$ mol 13C2-GA, and from 0.2-3.8  $\mu$ mol 13C2-OA, corresponding to 3.0-9.3% 13C2-EG, 0.59-0.92% 13C2-GA, and 0.02-0.28% 13C2-OA of the amounts of 13C2-EG inhaled. In the dermal experiments, maximum plasma concentrations of 13C2-EG were 0.5-2.0  $\mu$ mol/l (n=3) and below the quantitation limit (QL=0.5  $\mu$ mol/l; n=1). Neither 13C2-GA (QL=2.9  $\mu$ mol/l) nor 13C2-OA (QL=0.2  $\mu$ mol/l) was quantifiable. The amounts excreted (adjusted for 4-h exposures) ranged from 7.9-15  $\mu$ mol 13C2-EG (n=4). 13C2-GA was 1 and 4  $\mu$ mol in two volunteers and not quantifiable in the two others. 13C2-OA was not detected. Plasma concentration of endogenous GA ranged from 25-55  $\mu$ mol/l and the amounts excreted within 24 h were 90-870  $\mu$ mol GA and 120-240  $\mu$ mol OA. From the urinary 13C2-EG and 13C2-GA analyses it is calculated that systemic EG uptake from continuous dipping of both hands (hand skin area 910 cm<sup>2</sup>) in liquid EG for 4 h and longer is similar to that absorbed during inhalation of 10-30 ppm EG over the same time period. The calculated GA excretion resulting from an 8-h exposure to 30 ppm EG ranges from (70-110  $\mu$ mol) being comparable with that of endogenous GA in 24 h. Financial support by the Ethylene Oxide and Derivatives Sector Group of CEFIC (Brussels, Belgium) is gratefully acknowledged.

## 1242 STRATEGIES TO ASSESS SYSTEMIC EXPOSURE OF TEST MATERIAL IN SUBCHRONIC STUDIES.

S. A. Saghir, A. L. Mendlala, M. J. Bartels, S. J. Day, S. C. Hansen, J. M. Sushynski and J. S. Bus. Toxicology & Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.

Strategies were developed to estimate systemic bioavailability of test materials, their diurnal variations in blood levels and elimination in subchronic feeding/drinking studies after reaching steady-state levels utilizing minimum number of blood samples. Systemic bioavailability of test materials was determined by calculating area under the blood/plasma concentration curve over 24 h (AUC-24 h) using complete sets of data (5-8 samples) and 3, 2 and 1 selected time-points. Twenty-one sets of data (17 from literature) were analyzed for AUC-24 h. Chemicals included short t<sub>1/2</sub> drinking water disinfectant by-products to intermediate t<sub>1/2</sub> pharmaceutical drugs and pesticides. The best predictions of AUC-24 h were made when three time points were used corresponding to C<sup>max</sup>, a mid-morning sample, and C<sup>min</sup>. These values were 103±10% of the original AUC-24 h, with 13 of 17 values between 96 and 105% of the original. Calculation of AUC-24 h from two samples (C<sup>max</sup> and C<sup>min</sup>) or one mid-morning sample afforded slightly larger variations in the calculated AUC-24 h (69-135% of the original). Following drinking water exposure, prediction of AUC-24 h using 3 time-points (C<sup>max</sup>, mid-morning and C<sup>min</sup>) was very close to actual values (80-100%) among mice. Collection and analysis of 1-3 blood samples per dose level provide insight into dose proportional or non-dose proportional differences in systemic bioavailability that may point towards saturation of absorption or elimination or some other phenomenon, which may need further investigation. In addition, collection of the terminal blood samples from rats which is usually conducted 16 hours after removing

the fortified diet/water be helpful in estimating the blood/plasma half-life of the compound. Amount of the test materials and/or metabolite(s) in excreta and their possible use as biomarkers in predicting the daily systemic exposure evaluated. Determining these parameters in the early stages of the development is critical for appropriate design of other, longer-term toxicity studies.

#### 1243 THE EFFECT OF DOSE ON THE METABOLIC PROFILE OF TRICHLOROETHYLENE.

C. Hines<sup>2</sup>, S. Muralidhara<sup>2</sup>, C. A. White<sup>2</sup> and J. V. Bruckner<sup>2</sup>. <sup>1</sup>University Of Georgia, Athens, GA, <sup>2</sup>Pharmaceutical and Biomedical Sciences, UGA, Athens, GA, <sup>3</sup>UGA, Athens, GA and <sup>4</sup>UGA, Athens, GA.

The purpose of these experiments is to characterize the effect of dose on the metabolic profile of trichloroethylene (TCE) by monitoring the major metabolites: trichloroacetic acid (TCA), trichloroethanol (TCOH), and chloral hydrate (CH). Fasted male Sprague-Dawley rats received either 10 or 50 mg/kg of TCE as an aqueous Alkumuls emulsion by gavage. Serial blood samples were obtained via a carotid artery cannula. TCE, CH, TCA, and TCOH were quantitated by headspace gas chromatography. The Cmax of TCE increased 15-fold with the 5-fold increase in dose suggesting saturation of first pass metabolism of TCE. The half-lives of CH, TCA, and TCE increased 3-, 2-, and 3- fold with the increase in dose, indicating saturation of metabolism (CH, TCA, and TCE) or renal clearance (TCA). The half-life of TCOH did not change with the dose. The half-lives of TCA and TCOH are significantly longer than that of TCE at both doses indicating that the elimination of TCA and TCOH is the rate-limiting step in their disposition. The half-life of CH is approximately equal to the half-life of TCE indicating it is a formation rate-limited metabolite. Cmaxs for CH and TCA increased 4-fold with the 5-fold increase in dose; whereas, Cmax of TCOH increased 8-fold. These changes in Cmax coupled with the changes in half-life resulted in 16-, 10-, and 12-fold increases in AUC for CH, TCA, and TCOH with a 5-fold increase in TCE dose. The changes in the metabolic profile of TCE as a function of dose suggest nonlinear elimination of TCE as well as the metabolites. These changes in TCA toxicokinetics may significantly impact the carcinogenic potential of TCA. (Supported by EPA STAR Grant R830800).

#### 1244 MATERNAL AND FETAL DISPOSITION OF LAMIVUDINE, ZIDOVUDINE, AND LAMIVUDINE-ZIDOVUDINE IN THE PREGNANT RAT.

S. Lewis<sup>1</sup>, Y. Alnouti<sup>2</sup>, M. Bartlett<sup>1</sup> and C. White<sup>1</sup>. <sup>1</sup>Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA and <sup>2</sup>University of Kansas Medical Center, Kansas City, KS. Sponsor: J. Bruckner.

The pharmacokinetics and fetal disposition of lamivudine (3TC) and zidovudine (AZT) monotherapies and lamivudine-zidovudine combination therapy were compared in the pregnant rat. Pregnant Sprague-Dawley rats were anesthetized with ketamine: acepromazine: xylazine (50:3:3:3.4 mg/kg, IM) on day 19 of pregnancy. A jugular catheter was implanted and laparotomy performed. Rats were dosed with 3TC alone, AZT alone, or 3TC-AZT combination at 25mg/kg, IV bolus (n=6). Serial blood, placenta, fetus and amniotic fluid (AF) samples were obtained. 3TC and AZT levels were quantitated by HPLC-MS-MS. Pharmacokinetic parameters and relative exposures (AUC<sub>tissue</sub>/AUC<sub>maternal plasma</sub>) were determined by WinNonlin. The plasma pharmacokinetic parameters for 3TC in combination with AZT were consistent with 3TC monotherapy. For AZT, a decrease in half-life (82.2 ± 12 min to 51.3 ± 2.3 min) and volume of distribution (1.13 ± .15 L/kg to 0.78 ± 0.1 L/kg) was noted when 3TC was coadministered, while no differences were noted in the clearance or AUC. The fetal exposure of amniotic fluid, fetal, and placental tissues to 3TC when AZT was coadministered increased from 0.38 ± 0.07 to 0.84 ± 0.4, 0.19 ± 0.06 to 0.39 ± 0.1, and 0.14 ± 0.08 to 0.19 ± 0.03, respectively. This suggests that the placental transport of 3TC to the fetal compartment was increased by the presence of AZT or that the efflux transport of 3TC out of the fetal compartment was blocked. The relative exposure of amniotic fluid, fetal and placental tissues to AZT when 3TC was coadministered decreased from 0.44 ± 0.06 to 0.37 ± 0.1, 0.48 ± 0.05 to 0.30 ± 0.07, and 0.53 ± 0.05 to 0.43 ± 0.1, respectively. The changes noted in the placenta, fetus, and amniotic fluid suggest that transporters play a complex role in the uptake of 3TC and AZT in these tissues. Thus, combinations of nucleoside drugs can dramatically influence fetal exposure resulting in changes in fetal toxicity.

#### 1245 TOXICOKINETICS OF DELTAMETHRIN IN DIFFERENT VEHICLES IN RATS.

H. J. Kim, K. Kim, S. Muralidhara and J. V. Bruckner. Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.

Deltamethrin (DLM) is a relatively potent neurotoxin and a type II pyrethroid. Crofton et al. (1995) and several reports revealed that DLM administered in methylcellulose or in Emulphor® (EM) was not toxic, whereas DLM in corn oil or

in glycerol formal (GF) produced severe hypomotility, convulsions and motor incoordination. In order to determine if the effects of different vehicles on neurotoxicity might be due to toxicokinetic differences, we characterized the toxicokinetics of DLM in GF or suspended in 5% EM. Male adult Sprague-Dawley rats were given 10 mg DLM/kg by gavage. One mg DLM/kg in GF or 10 mg/kg in EM was delivered intravenously. Serial plasma and tissue samples were collected over 96 hr and analyzed for DLM content by high performance liquid chromatography. Relevant pharmacokinetic parameters were calculated. DLM was trapped in the lung following intravenous doses in both vehicles. The concentrations of DLM in fat and spleen remained quite high over time following oral administration. The absolute bioavailability in GF and EM were  $0.17 \pm 0.05$  (mean ± SD) and  $0.12 \pm 0.04$ . Apparent absorption rate constants for GF and EM were 1.38 and 1.60 hr<sup>-1</sup>, respectively. DLM was absorbed 6-fold more from GF in the GI tract; a peak concentration in plasma of  $0.46 \pm 0.03$  µg/ml was reached within 1.3 hr after oral dosing in GF, whereas a Cmax of  $0.072 \pm 0.020$  µg/ml was reached within 1 hr in EM. Average areas under the curve (AUC) for plasma were  $3.88 \pm 1.05$  and  $0.59 \pm 0.19$  µg·hr/ml, respectively. Therefore, it appears that the greater neurotoxicity of DLM in GF can largely be attributed to its greater bioavailability in that vehicle. (Supported by EPA STAR Grant R830800)

#### 1246 PHARMACOKINETICS AND TOXICOKINETICS OF PHOSPHORODIAMIDATE MORPHOLINO OLIGOMERS AGAINST HEPATITIS C VIRUS AFTER SINGLE INTRAVENOUS INJECTION.

A. Amantana, M. Cate, M. Reddy, D. Weller and P. Iversen. *Toxicology*, AVIBioPharma, Inc., Corvallis, OR.

Modulation of gene expression via nucleic acid sequence-specific intervention represents a new approach for drug discovery and development. Phosphorodiamidate morpholino oligomers (PMOs) represent third generation antisense agents, with translational inhibition as the mechanism of action. The objective of this study was to examine the toxicokinetics and bioavailability of HCV-IRES and HCV-AUG designed against the IRES region and the translational start site of HCV RNA. PMO concentrations were measured by the "HPLC duplex assay" following single, bolus intravenous administration of 15, 50 and 150 mg/kg. Serum chemistry data indicated no significant difference between treated and control group. Complete blood count data showed decreased hematocrit in both the HCV-IRES and HCV-AUG treated groups and a decrease in leukocyte and platelet count only in the group that received the 150mg/kg dose of HCV-AUG. Plasma and tissue disposition of both compounds were characterized by a rapid distribution into all tissues examined; distribution half-life of 8-15 min. The apparent elimination half-life increased with dose to over 48 hrs. The kidney had the highest concentration followed by the liver, with lower concentrations observed in the spleen, lung, heart, brain and skeletal muscle. Plasma and tissue concentration generally increased linearly with increased dose. No degraded PMO was observed in any blood, tissue or urine. Overall, maximal urinary excretion of both compounds occurred within 4 hours following administration. Excretion of intact HCV-IRES increased as a function of dose from 0.06mg to 20mg over a 10-fold increase in dose (15mg/kg to 150 mg/kg). HCV-AUG excretion increased from 0.83mg to 6mg from 15mg/kg to 50mg/kg. The study provides new and unique data regarding pharmacokinetic and toxicokinetics of phosphorodiamidate morpholino oligomers targeting hepatitis C virus.

#### 1247 TOXICOKINETIC STUDY FOR DELTAMETHRIN AND ITS METABOLITE, 3-PHENOXYBENZOIC ACID, IN IMMATURE AND ADULT RATS.

K. Kim, J. V. Bruckner and H. Kim. Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.

Deltamethrin (DLM) is a widely-used type II pyrethroid insecticide with relatively potent neurotoxicity. Previous studies have shown that immature rats are more susceptible to acute DLM neurotoxicity than adults. The primary objective of this investigation was to determine whether the susceptibility of immature rats to acute DLM neurotoxicity was due to age-dependent toxicokinetics of DLM. Male adult Sprague-Dawley (S-D) rats with an indwelling arterial cannula were dosed with 1 mg DLM/kg intravenously in glycerol formal or with 10 mg/kg by gavage. Serial blood and tissue samples were collected over 96 hr and analyzed for DLM and 3-phenoxybenzoic acid (PBA) content by high performance liquid chromatography. Ten-day-old (D10) male S-D rats received 10 mg/kg by gavage. Salivation was observed in adult rats, but this sign disappeared within 15 – 30 min. All immature pups treated with 10 mg/kg showed serious tremors and choreoathetosis and died within 6 hr. Relevant pharmacokinetic parameters were calculated. The maximum plasma concentration of DLM in pups was  $3.30 \pm 0.95$  (mean ± SD) µg/mL, while that in adult rats was  $0.46 \pm 0.026$  µg/mL. The AUC<sub>06 hr</sub> of DLM in immature pups (12.30 mg·hr/L) was about 6.7-times greater than that in adult rats (1.85 mg·hr/L). Conversely, the AUC<sub>06 hr</sub> of PBA, a major DLM metabolite, in adult rats (4.00 mg·hr/L) was about 3.5-times greater than that in immature pups (1.14

mg·hr/L). These results indicate that the increased susceptibility of immature rats to acute DLM neurotoxicity is due to the higher systemic levels of DLM. The PBA data indicate that the immature rats' metabolic capacity is limited. Increased gastrointestinal absorption of DLM may also contribute to the higher blood levels of parent compound in this age-group. (Supported by EPA STAR Grant R830800)

UPTAKE AND DISPOSITION OF INHALED METHANOL VAPORS IN HUMANS.

L. Ernstgard<sup>1</sup>, G. Johanson<sup>1</sup> and E. Shibata<sup>2</sup>. <sup>1</sup>*Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden* and <sup>2</sup>*Department of Health and Psychosocial Medicine, Aichi Medical University School of Medicine, Nagakute-cho, Japan.*

Methanol is a widely used solvent and a potential fuel for motor vehicles. Human kinetic data of methanol are sparse. As a basis for biological exposure monitoring and risk assessment, we studied the inhalation toxicokinetics of methanol vapors in human volunteers. In addition sex differences and the suitability of bio-monitoring via saliva sampling were investigated. Four females and four males were exposed by inhalation to 0 (control exposure), 100, and 200 ppm methanol vapour for 2 h during light physical exercise (50 W) in an exposure chamber. Capillary blood, urine, saliva and exhaled air were sampled before, during, and after exposure and analyzed for methanol by head space gas chromatography. The exposures were performed according to the Helsinki declaration and after approval by the regional ethical committee. Methanol in blood increased from a background level of about 20 to 116 and 244  $\mu$ M at 0, 100 and 200 ppm, respectively. Saliva showed substantially higher concentration of methanol than blood the first several minutes after exposure. This difference disappeared within a few minutes, thereafter the levels in blood, urine and saliva closely followed one another. The concentration in all three media had returned to background levels later in the evening the same day. The half time of methanol in blood was about 110 minutes and the apparent total clearance 0.44 L/min. In blood, urine, saliva and exhaled air the AUC was about twice as high after exposure to 200 ppm of methanol compared to 100 ppm suggesting linear kinetics. No sex differences in the toxicokinetics of methanol could be detected. In conclusion the experimental results showed non-saturated metabolism of methanol and consistent patterns of methanol in blood, urine and saliva following a 2-h inhalation exposure.

PERCUTANEOUS ABSORPTION OF WATER SOLUTION OF TRICHLOROETHYLENE IN VOLUNTEERS DURING PRE-STEADY AND STEADY STATE.

I. Jakasa<sup>1</sup>, J. Kruse<sup>2</sup> and S. Kezic<sup>1</sup>. <sup>1</sup>*Coronel Institute, Academic Medical Centre, Amsterdam, Netherlands* and <sup>2</sup>*Kinetox, Vleuten, Netherlands*. Sponsor: P. Boogaard.

To study dermal absorption of trichloroethylene (TRI) six volunteers (3 female and 3 male) were dermally exposed to 0.05% TRI water solution for 10, 20, 40, 90 and 120 min on the volar forearm over an area of 21 cm<sup>2</sup>. The internal exposure was assessed by measuring the concentration of TRI in exhaled air. An inhalation exposure with a known input rate and duration served as a reference dosage. The permeation rate courses were determined from exhaled air after both inhalation and dermal exposure using mathematical de-convolution. To determine permeability coefficient from non-steady state permeation data a mechanistic skin model of Kruse (2004) was used. The concentration of TRI in dosing solution decreased from 8 (10 min exposure) to 60 % (120 min exposure) revealing finite dose exposures. The average skin flux into the skin amounted to 0.0156, 0.0215, 0.0263, 0.0269 and 0.0323 mg cm<sup>-2</sup> h<sup>-1</sup> for 10, 20, 40, 90 and 120 min exposure durations, respectively. The respective maximal fluxes into the blood obtained from the slope of the cumulative permeation curve amounted to 0.0041, 0.0207, 0.0205, 0.0199 and 0.0351 mg cm<sup>-2</sup> h<sup>-1</sup>. The estimated K<sub>p</sub> amounted to 0.085 cm h<sup>-1</sup>. In contrast to theoretical considerations, the average skin fluxes after short exposures were smaller than those after longer exposures. This can be explained by relatively higher contribution of TRI evaporation from the skin after the end of exposure to the systemically absorbed amount. Incorporation of the loss of TRI from the skin due to evaporation into the skin model improved the goodness of the fit of the experimental data. The skin model used in the study showed to be feasible in estimation of steady state permeability from short term exposures and finite dose data. In addition, the model helps in the interpretation of experimental data of well described dermal permeation studies.

INFLUENCE OF HEPATIC CLEARANCE ON THE TOXICITY OF THE TYPE I PYRETHROIDS BIFENTHRIN AND PERMETHRIN.

E. J. Scollon<sup>1</sup>, R. Tornero-Velez<sup>2</sup>, S. J. Godin<sup>3</sup>, M. F. Hughes<sup>1</sup> and M. J. DeVito<sup>1</sup>. <sup>1</sup>*ORD/NHEERL, USEPA, Research Triangle Park, NC*, <sup>2</sup>*ORD/NERL, USEPA, Research Triangle Park, NC* and <sup>3</sup>*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC.*

Pyrethroids are a class of neurotoxic insecticides that are used in a variety of agricultural and household activities. Hepatic intrinsic clearance (CL<sub>int</sub>) of the Type I pyrethroids permethrin and bifenthrin may be a critical determinant of their toxic

effect. Rat LD<sub>50</sub>s reported in the literature for permethrin and bifenthrin are 1200 and 70 mg/kg, respectively. We determined *in vitro* metabolic parameters in adult male rat liver microsomes for permethrin and bifenthrin using a parent depletion approach. K<sub>m</sub> (3.82  $\mu$ M  $\pm$  0.07 and 5.41  $\mu$ M  $\pm$  7.26), V<sub>max</sub> (309.32  $\pm$  66.69 and 206.67 pmoles/min/mg protein  $\pm$  86.96) and hepatic CL<sub>int</sub> (9.7E-3 and 4.59E-3 L/hr/mg protein) were determined for the cis and trans isomers of permethrin, respectively. The *in vitro* parameters for the metabolism of bifenthrin were: K<sub>m</sub> = 34.75  $\mu$ M  $\pm$  41.94; V<sub>max</sub> = 845 pmoles/min/mg protein  $\pm$  479; hepatic CL<sub>int</sub> = 2.93E-3 L/hr/mg protein. The 3 to 4-fold difference in hepatic clearance rates between the permethrin isomers and bifenthrin do not account for their disparity in toxicity. This suggests that metabolism at other sites as well as pharmacodynamic effects are critical determinants of the toxicity of permethrin and bifenthrin. Hepatic clearance alone does not appear to fully explain the differences in the toxicity between bifenthrin and permethrin. (SJG supported by CT826513. This abstract does not represent USEPA policy.)

METABOLISM OF DI(2-ETHYLHEXYL) PHTHALATE (DEHP) IN JUVENILE AND FETAL MARMOSET AND RAT.

Y. Kurata, F. Makinodan, N. Shimamura, M. Okada and M. Katoh. *Mitsubishi Chemical Safety Institute Ltd., Ibaraki, Japan*. Sponsor: M. Tsuchitani.

DEHP induces testicular lesion in juvenile rats, but not in marmosets (Kurata et al., SOT 2003). Since MEHP and its metabolites were suspected to be a cause of testicular lesions, we compared the metabolic profile of DEHP in juvenile and fetal marmoset with that of rats. STUDY-I: 14C-DEHP (100 mg/kg) was singly dosed to juveniles by gavage. Then the radioactivities in the plasma (2, 4, 8, 24hr after dosing), urine, feces (0 to 24hr), and tissues (24hr) were measured together with metabolite contents. The plasma radioactivity in rats was 20 to 100 times higher than that in marmosets. Three types of metabolites such as MEHP, conjugates of MEHP and MEHP-metabolites, or unconjugated MEHP-metabolites such as 5-Oxo, 5-OH, and 6 or 8-COOH MEHP were detected in rat plasma. However, unconjugated MEHP-metabolites were not detected in marmosets. About 60 % of the dose was excreted into the urine in rats. As for marmoset, although the bioavailability was presumed to be about 20 to 30%, the majority of the dose was excreted into the feces. As for rats, large amount of unconjugated MEHP-metabolites (about 35% of dose), which were the same kinds of plasma, were detected in the urine. However, as for marmosets, the majority was conjugated MEHP and its metabolites. Specific accumulation in the testes was noted neither in rats nor in marmosets, radioactivities in marmoset liver, kidney, or testes was much lower than those of rats. STUDY-II: we determined the tissue distribution (24hr) in fetuses when 14C-DEHP (100 mg/kg) was singly dosed to dams on gestation day of 130 for marmosets and day of 20 for rats. High radioactivity was observed in the digestive tract, liver, and kidney, and specific accumulation in the testis was noted in neither rats nor in marmosets. However, the radioactivity in rat testis was about 20-times higher than that in marmosets. Clear species differences in plasma and tissue radioactivity concentrations, and in the content of metabolites were demonstrated, and that might be the causes of species difference in testicular lesions.

TRANSPLACENTAL TOXICOKINETICS OF 3'-AZIDO-3'-DEOXYTHYMIDINE (AZT) IN MICE.

B. Collins<sup>2</sup>, S. Black<sup>1</sup>, P. Patel<sup>1</sup>, J. Demeter<sup>1</sup>, J. Blake<sup>1</sup>, S. Cooper<sup>1</sup>, R. Fernando<sup>1</sup>, M. Veselica<sup>1</sup> and C. Garner<sup>1</sup>. <sup>1</sup>*DMPK, RTI International, Research Triangle Park, NC* and <sup>2</sup>*NIEHS, Research Triangle Park, NC*.

The anti-HIV drug 3'-azido-3'-deoxythymidine (AZT) has been demonstrated to be a perinatal carcinogen in mice, causing lung, liver, and mammary tumors in offspring. In these studies transplacental pharmacokinetics of AZT was determined in mice and both maternal and fetal exposures were estimated at doses that bridged effect and no effect doses in support of risk assessment. AZT was administered orally by gavage to pregnant CD-1 female mice at 50, 100, 200, and 300 mg/kg/day on GD 10-17 as 2 equal doses 6 hr apart. On the last day of dosing blood and fetuses from 3 mice per timepoint were sampled at 0.083, 0.17, 0.33, 0.5, 1, 2, 6.083, 6.17, 6.33, 6.5, 7, 8, 12, and 24 hours following the day's first dose. For determination of bioavailability and linearity of clearance, single IV doses of 50 and 100 mg/kg were administered to gravid females on GD 17. Plasma was collected at 0.083, 0.17, 0.33, 0.5, 1, 1.5, 2, 2.5, 3, 5, 7, 8, 12 and 24 hours post dose. Both parent compound and its metabolite AZT-glucuronide (GAZT) were determined in maternal plasma and whole fetuses using validated analytical methods. The plasma method was validated over the concentration range from 0.200 to 500  $\mu$ g AZT/mL plasma and 0.200 to 10.0  $\mu$ g GAZT/mL plasma. The method was validated from 0.1 to 100  $\mu$ g of AZT of pup tissue. The limit of detection (LOD) for the assays was estimated to be 0.04 and 0.014  $\mu$ g/g for fetus and dam plasma respectively. In the dams, plasma concentrations of AZT reached maximal levels within 15 minutes following oral doses, suggesting rapid absorption. Bioavailability was high in the dams. In fetal tissues, AZT concentrations reached maximal levels

at later times, suggesting that the placenta delayed absorption. Fetal maximal concentrations were generally lower than in dam plasma. Ratios of AZT exposure between fetus and dam plasma suggest that at doses of 50 mg/kg/day or higher fetal exposures were similar to that of dams. Overall the data suggests that in the mouse fetal AZT exposure mirrors that of the dam, though the profile differs.

### 1253 DISPOSITION OF BDE 99 AND BDE 153 IN FEMALE MICE.

D. Bauer<sup>1</sup>, D. F. Staskal<sup>1</sup>, J. J. Dileberto<sup>2</sup> and L. S. Birnbaum<sup>2</sup>. <sup>1</sup>*Curriculum in Toxicology, University of North Carolina - Chapel Hill, Chapel Hill, NC* and <sup>2</sup>*Experimental Toxicology Division, USEPA, Research Triangle Park, NC*.

Polybrominated diphenylethers (PBDEs) represent a novel class of compounds typically used as flame retardants in electrical and household consumer goods. Recently, increased bioaccumulation of PBDE congeners has raised concern over the potential toxicity of these compounds in humans. Of particular interest are the congener profiles found in biota as they do not parallel profiles of commercial mixtures; a phenomenon that may be due to differential exposure and/or differences in metabolic capacity. Previous studies in our laboratory have shown major differences in excretion patterns of BDE 47 in rats and mice. In this study, the distribution and excretion of two other prominent BDE congeners were examined. Female C57/BL6 mice were given [<sup>14</sup>C] 2', 2', 4, 4'-pentaBDE (BDE 99) or [<sup>14</sup>C] 2', 4, 4', 5, 5'-hexaBDE (BDE 153) via intravenous administration (1mg/kg). The results indicate that BDEs 99 and 153 are not as rapidly excreted in the urine of mice as BDE 47. 21% of BDE 47 was excreted in the urine 24 hours following exposure, in contrast to 6% of BDE99 and <1% of BDE 153. A total of 42% BDE 47 was excreted in the urine over a five day period, versus 11% of BDE 99. Preliminary metabolite analyses reveal a majority of parent compound in the urine, a result analogous to BDE 47. Remaining BDE 99 and 153 were found primarily in adipose and other lipophilic tissues. Excretion and retention of PBDEs in mice appears to be dependent on the degree of bromination; the dominance of lower brominated congeners in biota despite the rapid excretion patterns demonstrated in mice raise questions as to the animal model that should be used in human health risk assessment. ### 1254 DEVELOPMENT OF AN *IN VITRO* BLOOD-BRAIN BARRIER MODEL FOR BRAIN DISPOSITION SCREENING OF PHARMACEUTICALS.

G. Stolper, M. Klausner, J. E. Sheasgreen and P. J. Hayden. *MatTek Corp., Ashland, MA*.

Solute distribution between blood and brain is strictly regulated by the blood-brain barrier (BBB). While the BBB performs an important function in keeping unnecessary or harmful molecules from the brain, it poses a challenging problem in delivering therapeutics, including anticancer, antibiotic or antipsychotic drugs into the brain. Conversely, preventing potentially damaging molecules from overcoming the BBB is also an increasing problem, especially when combinations of therapeutics are encountered. Medical and pharmaceutical scientists therefore have a growing need for rapid, reliable *in vitro* models of the BBB for preclinical screening of pharmaceutical BBB transport properties. The current presentation describes initial results in development of an *in vitro* BBB model derived from bovine brain capillary endothelial cells (BCEC). Capillary vessels were first isolated from bovine brains. Individual BCECs were then released by further enzymatic digestion of the capillaries. BCEC thus obtained were cryopreserved. The isolation procedure produced a highly pure population of BCECs, as demonstrated by immunocytochemical staining for the endothelial cell marker von Willebrand factor. After recovery from cryopreservation, BCECs were cultured on microporous membrane culture inserts to produce the BBB model. Transmission electron microscopy and H&E stained light microscopy of the cultures show uniform endothelial cell monolayers with evidence of tight junction formation. Immunocytochemical staining also demonstrated uniform expression of the tight junction protein ZO-1 localized along the BCEC borders. Permeation of Lucifer yellow across the BBB culture was low, further demonstrating development of barrier function. Finally, Western blotting experiments were conducted to reveal the presence of the important BBB efflux transporter p-glycoprotein. These results show significant progress in development of a reliable *in vitro* BBB model that will be useful for preclinical screening of candidate pharmaceutical compounds. This work was supported by NCI Grant # R43 CA101703-02.

### 1255 PHARMACOKINETICS OF TAFA93, A NOVEL PRO-DRUG OF THE mTOR INHIBITOR RAPAMYCIN.

D. G. Freitag, M. D. Abel, L. J. Aspeslet, P. R. Mayo, R. S. Barber, D. J. Trepianier, D. Ure, R. T. Foster and R. W. Yatscoff. *Isotechnika, Edmonton, AB, Canada*. Sponsor: J. Daniels.

**Introduction:** TAFA93, a novel mTOR inhibitor, is intended for use in the prevention of organ graft rejection and the treatment of autoimmune diseases. It was developed as an orally administered pro-drug of rapamycin that will maintain efficacy

while altering the pharmacokinetics (PK) in such a way as to decrease clinical adverse effects. It has been proposed that some drug related adverse effects are due to the rapid rise in whole blood rapamycin levels after dosing. TAFA93, upon hydrolysis to rapamycin, attenuates the rapid rise in rapamycin concentrations thereby potentially improving the safety profile. **Methods:** Pharmacokinetics were investigated in rats, dogs and primates. Hyperlipidemia was studied in a rat model. Efficacy was investigated in a rat heterotopic heart transplant model. **Results:** PK studies demonstrated that TAFA93 displayed a significantly different PK profile than rapamycin. Specifically, Cmax was blunted and Tmax was significantly increased. In the rat TAFA93 shifted the Tmax for rapamycin from approximately 0.5 hours to approximately 3 hours and reduced the Cmax for rapamycin by approximately 70% with only a 30% reduction in AUC. The altered PK in TAFA93 treated rats was associated with cholesterol levels that were significantly lower ( $p < 0.01$ ) than the levels measured in rapamycin treated animals. In addition, transplant data indicated that TAFA93 prolonged graft survival, compared to control at doses of 2.5 and 10 mg/kg/day, and was equally efficacious to rapamycin at 2.5 mg/kg/day despite a 1/3 decrease in AUC. Graft survival times of 41±4 and 39±4 days were obtained for TAFA93 and rapamycin respectively. **Conclusions:** TAFA93 is a novel pro-drug of rapamycin which in preclinical trials alters the PK of rapamycin in such a way as to decrease some of the known side effects while maintaining efficacy.

### 1256 RAT STRAIN DIFFERENCES IN ETHYLENE GLYCOL RENAL TOXICITY IS DRIVEN BY THE RENAL CLEARANCE OF OXALIC ACID.

W. M. Snellings<sup>1</sup>, M. Bartels<sup>2</sup>, R. Corley<sup>3</sup>, M. Dryzga<sup>2</sup>, D. Wilson<sup>2</sup> and J. Domoradzki<sup>4</sup>. <sup>1</sup>*Global Environmental, Health & Safety, Dow Chemical, Danbury, CT*, <sup>2</sup>*Toxicology, Dow Chemical, Midland, MI*, <sup>3</sup>*Battelle Northwest, Richland, WA* and <sup>4</sup>*Toxicology, Dow Corning, Midland, MI*.

The kidney has been identified as a primary target organ in toxicity studies with ethylene glycol (EG), with rats being more sensitive than mice and males more sensitive than females. The male Wistar rat also appears to be more sensitive than male rats from other strains. Kidney toxicity results from a build up of the terminal metabolite, oxalic acid (OX), which can precipitate with calcium to form crystals. In this study, the renal clearance of OX as well as inulin (IN), a marker for glomerular filtration, was evaluated in young and old male Wistar rats and in rats that have been exposed for one year to 0, 50, 150 or 300 mg/kg/day EG via the diet. Age had a slight affect on the ability of male Wistar rats to clear OX, as the ratio of OX to IN clearance increased from ~0.6 to ~0.9. No effects were observed following chronic dietary exposures to ethylene glycol as the ratio of OX to IN clearance remained ~0.9. In all other rat strains and species studied (F344 rats, SD rats, dogs, sheep and humans), the clearance of OX was shown to be slightly higher than inulin (1.2-2.1), indicating the presence of an active transport process. In male Wistar rats, the net clearance of OX suggests that reabsorption processes are more important than active secretion, which likely contributes to the enhanced sensitivity of male Wistar rats. When OX and IN clearances are related to body weight, all species, with the exception of the male Wistar rat, have glomerular filtration and OX clearance rates that can be scaled allometrically. Since human risk assessments for renal toxicity may be driven by results from chronic studies in male Wistar rats, this quantitative assessment will be critical to determinations of human equivalent exposures and internal dose-response assessments. (Sponsored by the Ethylene Glycol Panel of the American Chemistry Council).

### 1257 DBDPO METABOLISM IN FISH AND MAMMALS: CONTRIBUTION TO LOWER BROMINATED DIPHENYL ETHERS.

M. Hardy. *Albemarle Corporation, Baton Rouge, LA*.

The flame retardant decabromodiphenyl oxide/ether (DBDPO) represents >80% of global polybrominated diphenyl ether (PBDE) use. PBDE typically detected in biota, tetra (BDE47), penta (BDE99, 100) and hexa (BDE153, 154), appear to originate from use of PentaBDE product. DBDPO metabolism has been questioned as a contributor; the evidence is reviewed. DBDPO is poorly absorbed. Its fish BCF<sub>water</sub> was < 50.<sup>1,2</sup> Trout absorbed 0.005% of 7.5 or 10 mg DBDPO/kg/d administered in food over 120 d.<sup>3</sup> DBDPO was not detected in carp fed treated food for 90 d (940 ng/fish/d); 0.4% uptake was estimated based on presumed metabolites.<sup>4</sup> PBDE typically reported in wild-caught fish were not detected. The test article purity was not stated by either, but one<sup>5</sup> used a former product whose only known composition was 77% DBDPO, ~23% nona- and octa-BDE, and concluded "no evidence of debromination to these congeners [e.g. BDE-47, 99 and 100] was found". Rats absorbed DBDPO to a limited extent (0.28–2%, oral dose) with 98% eliminated in feces as parent.<sup>5,6</sup> Production of metabolites was limited (2% @ 277ppm, diet) and thought to occur in the gut, not systemically. A rat study using a DBDPO formulation to enhance/maximize absorption/metabolite production reported trace amounts of 3 nonaBDE and perhaps OH-BDE.<sup>7</sup> The test article was 98% DBDPO; nonaBDE are typical impurities. Similar results were found

in a 2nd study with an absorption enhancing formulation.<sup>8</sup> The existing data indicate DBDPO metabolism does not contribute to the PBDE typically detected in biological samples. <sup>1</sup>Biodegradation and Bioaccumulation Data of Existing Chemicals. 1992. **1258** BIO-PHYSICO CHEMICAL DETERMINANTS OF TIME-TO-STeady STATE FOR VOLATILE ORGANIC COMPOUNDS (VOCS).

**D. A. Manca**, G. Balagopal and P. Welsh. *Standards Development Branch, Ontario Ministry of the Environment, Toronto, ON, Canada.*

Human exposure to VOCs encountered in the environment is generally irregular and/or intermittent. However, steady state toxicokinetic (SST) conditions may be attained even under these circumstances, and often within shorter exposure durations for VOCs than many persistent organic pollutants. Therefore, it is relevant to characterize and optimize the biochemical and physical variables that control time-to-steady state for a given VOC. We used a physiologically-based toxicokinetic (PBT) human model constructed on an Excel spreadsheet and performed TK simulations. The end-point, time-to-steady state for arterial blood concentration (C<sub>ass</sub>), was evaluated for each VOC by varying the biochemical and physical variables. The biochemical and physical properties assessed in the model (blood: air partition coefficient (Pb), intrinsic clearance (Clint; V<sub>max</sub>/K<sub>m</sub>), and tissue: blood partition coefficient (Pt)) were varied from 1 to 10, 000. Pb was the major factor in attaining SST conditions. When all the variables (including Pb) were set at 1, 5.5 hours were required to reach SST conditions, whereas a Pb value of 1000 required 350 hours. Varying the Pt from 1 to 10, 000 gradually increased the biphasic character of the relationship, which is attributed to the redistribution of VOCs in different tissue compartments. Clint had a minimal effect on the time-to-steady state due to flow and Pt limitations in the liver compartment. The major single limiting factor to achieving time-to-steady state was alveolar absorption and elimination. We classified and validated several VOCs based on Pb. This classification can be useful for assessing internal dosimetry under various exposure conditions.

**1259** RELATIONSHIP BETWEEN CYP1A1 GENOTYPE AND BENZO(A)PYRENE (BP) HEMOGLOBIN (HB) ADDUCTS IN MATERNAL AND FETAL BLOOD.

**T. Wright, C. Cunningham and S. R. Myers.** *Pharmacology and Toxicology, Center for Environmental and Occupational Health Sciences, University of Louisville, Louisville, KY.*

The cytochrome P450 isoform CYP1A1 has been widely studied because of its interactions with the PAH substrates such as BP. In addition to being a substrate for CYP1A1, BP is also a potent inducer of the enzyme. Because CYP1A1 plays such a pivotal role in the metabolism of BP, as well as several other PAH found in tobacco smoke, we deemed it justifiable to measure the levels of BP Hb adducts in cord blood samples with regards to CYP1A1 genetic polymorphisms of Msp I (T6235C) and Hinc II (A4889G). Matched maternal and fetal blood samples were obtained from smokers at delivery and stratified based on cotinine determinations. Subjects were divided into three groups based on CYP1A1 Msp I genotype: wild type (TT), heterozygous (TC), homozygous variant (CC). Subjects were divided into two groups based on CYP1A1 Hinc II genotype (AA) and heterozygous (AG). There were no homozygous variants for Hinc II. BP diol epoxide Hb adduct levels were highest in the cord blood samples with the CYP1A1 Msp I wild type (TT) genotype and lowest in the cord blood samples with the CYP1A1 Msp I homozygous variant (CC) genotype ( $\alpha = 0.05$ ,  $P < 0.39$ ). This was also the trend with BP-7, 8-oxide Hb adduct levels ( $\alpha = 0.05$ ,  $P < 0.61$ ) and BP-4, 5-oxide Hb adduct levels ( $\alpha = 0.05$ ,  $P < 0.13$ ). BP diol epoxide Hb adduct levels were slightly higher in cord blood samples with the CYP1A1 Hinc II heterozygous genotype than in the wild type ( $\alpha = 0.05$ ,  $P < 0.75$ ). Cord blood subjects with the CYP1A1 Hinc II wildtype genotype had higher BP-7, 8-oxide Hb adduct levels than those with the heterozygous genotype ( $\alpha = 0.05$ ,  $P < 0.21$ ). BP-4, 5-oxide Hb adduct levels were slightly higher in the cord subjects with the CYP1A1 Hinc II heterozygous genotype than in subjects with the wild type genotype ( $\alpha = 0.05$ ,  $P < 0.62$ ). These results suggest that polymorphisms of the CYP1A1 genotype may play a role in formation of hemoglobin adducts.

ASSOCIATION BETWEEN GENETIC POLYMORPHISMS IN CYP1A1 AND CYP17, RACE, AND TAMOXIFEN SIDE EFFECTS IN BREAST CANCER PATIENTS.

**M. M. Diawara<sup>1</sup>, J. B. Babus<sup>2</sup>, L. M. Lewis<sup>2</sup> and J. A. Flaws<sup>2</sup>.** *<sup>1</sup>Biology, Colorado State University-Pueblo, Pueblo, CO and <sup>2</sup>Epidemiology and Prev. Medicine, University of Maryland School of Medicine, Baltimore, MD.*

Despite the widely accepted use of tamoxifen to treat estrogen receptor positive (ER+) breast cancer patients, there are clear indications that this drug is not the optimal breast cancer treatment for all women. About 50% of women taking tamoxifen experience serious side effects. The nature of these side effects sometimes varies between African American women and Caucasian women. The reasons for the lack of optimal response to tamoxifen are unknown. Since genetic polymorphisms in metabolic enzymes are racially distributed and have been associated with suboptimal responses to some drug therapies, it is our hypothesis that racial disparities in tamoxifen-related side effects may be associated with genetic polymorphisms in selected cytochrome P450 enzymes (CYP1A1 and CYP17). We tested our hypothesis by conducting a cross-sectional study of 123 breast cancer patients (53 African Americans and 70 Caucasians). Each patient completed a questionnaire and provided a blood sample for evaluation of polymorphisms in CYP1A1 and CYP17 using polymerase chain reaction and enzyme digests. African American women had four times greater odds of having a CYP1A1 polymorphism compared with Caucasian women (odds ratio: 4.65; 95% confidence interval: 1.17 - 18.51). No differences were observed between the two ethnic groups for polymorphisms in CYP17 (odds ratio: 1.01; 95% confidence interval: 0.43 - 2.34). CYP1A1 polymorphisms were associated with an increased risk of one side effect from tamoxifen (migraines), but not with other side effects from the drug (nausea, migraines, depression, vaginal discharge, vaginal dryness, insomnia, or hot flashes). These data suggest that the risk of polymorphisms in CYP1A1 differs by race, and that the risk of at least one side effect from tamoxifen may be associated with genetic polymorphisms in CYP1A1. STRUCTURAL HETEROGENEITY AT THE UDP-GLUCURONOSYLTRANSFERASE 1A LOCUS IN A KOREAN POPULATION.

**S. Yea<sup>1,2</sup>, W. Kim<sup>2</sup>, S. Lee<sup>2</sup>, J. Sohn<sup>2</sup>, S. Oh<sup>2</sup>, Y. Park<sup>1</sup> and J. Shin<sup>2</sup>.**

*<sup>1</sup>Department of Biochemistry, Inje University, Pusan, Korea, South Korea and*

*<sup>2</sup>Pharmacogenomics Research Center, Inje University, Pusan, South Korea. Sponsor: H. Kim.*

Glucuronidation catalyzed by UDP-glucuronosyltransferases (UGTs) is one of the most important mechanisms for a host defense against xenobiotics and endobiotics. UGT1A family is derived from a single gene locus (UGT1A) coding for nine functional proteins (UGT1A1, UGT1A3-UGT1A10) and three pseudogenes (UGT1A2, UGT1A11-UGT1A12). The N-terminal end of UGT1A isoforms is coded by distinct exon 1s located upstream of the common exons 2 through 5. Although genetic polymorphisms of several UGT1A isoforms have been reported separately, the haplotypes in all functional exons are not identified and little information is available regarding SNPs in Koreans. In the present study, genetic polymorphisms at all functional exons of UGT1A locus were analyzed by direct sequencing of genomic DNA in fifty healthy Korean subjects and their haplotypes were inferred from genotype data using an expectation-maximization algorithm. We identified forty-four SNPs at exon 1s and one SNP at exon 5 (1-39% of allelic frequencies). Eleven SNPs at exon 1 were novel, and the frequencies of known variants also showed significant differences between Koreans and other ethnic groups reported. For example, allelic frequencies of UGT1A7\*3 (N129K, R131K, and W208R) were 31.6% in Caucasian and 25.5% in Japanese, while it was 18.0% in Korean population. Haplotypes were estimated only for individuals with allelic frequency over 15%. Five major haplotypes that occur at frequency over 5% were identified, which together accounted for 78% of all haplotypes. Haplotype I, the reference sequence, was the most common (0.435), from which haplotype II (0.132) differed at positions in exon 1 of UGT1A4, UGT1A5, UGT1A7. These results suggest that genetic polymorphisms of UGT1A locus seem to be different between Korean and other ethnic populations.

ROLE OF ALCOHOL DEHYDROGENASE GENOTYPE IN PREDICTING DEVELOPMENT OF FETAL ALCOHOL SYNDROME (FAS).

**N. M. Spiegl<sup>1</sup>, J. L. Powell<sup>1</sup>, K. S. Squibb<sup>1</sup>, K. A. Strauss<sup>1</sup>, J. O'Kane<sup>2</sup> and J. D. Cook<sup>2</sup>.** *<sup>1</sup>Epidemiology and Preventive Medicine, University of Maryland School of Medicine, Baltimore, MD and <sup>2</sup>Medical and Research Technology, University of Maryland School of Medicine, Baltimore, MD.*

Women who drink alcohol during pregnancy are at increased risk of delivering an infant with Fetal Alcohol Spectrum Disorders (FASD) or Fetal Alcohol Syndrome (FAS). However, not all women who drink while pregnant will have an affected

baby, suggesting that maternal or infant genes involved in alcohol metabolism play a role in disease susceptibility. Alcohol is principally metabolized to acetaldehyde via the enzyme Alcohol Dehydrogenase (ADH). Polymorphisms at ADH2 result in altered ADH kinetics therefore modulating individual metabolism of ethanol. Prior animal studies have linked metabolic changes in this locus to negative fetal outcomes in ethanol-exposed fetuses. Due to inconsistent human studies, this study was designed to further examine the ADH2 genotype of mother/infant pairs and determine the influence of genotype on risk of developing FAS/FASD. Peripheral blood samples from 69 mothers and cord blood from 60 infants have been collected, and the genomic DNA purified using a commercial kit. ADH2 genotype was determined using restriction fragment length polymorphism PCR (RFLP-PCR). Maternal ethanol use was estimated by AUDIT questionnaire and interview. Infant outcomes included weight, length, head circumference and gestational age at birth. In examining AUDIT scores, women expressing an ADH2\*3 allele drank less than ADH2\*1 homozygotes. In addition, ADH2\*1 homozygous mothers with the heaviest alcohol use gave birth to smaller infants with lower gestational ages at delivery. Infants requiring intensive care hospitalization postnatally were also seen predominantly in mothers who were ADH2\*1 homozygotes. To date, our data suggest a role for ADH genotype affecting maternal drinking patterns and infant outcomes. Showing ADH genotype to be a biomarker indicative of potential maternal alcohol use, as well as an accurate predictor of fetal outcome, is paramount to developing interventions for high-risk pregnancies.

## 1263 CHARACTERIZATION OF THE VAL108MET COMT POLYMORPHISM.

A. E. Doyle<sup>1</sup>, B. L. McAtee<sup>1</sup>, J. P. Bressler<sup>1,2</sup>, P. M. Silber<sup>3</sup> and J. D. Yager<sup>1</sup>. <sup>1</sup>Environmental Health Sciences, Johns Hopkins University, Baltimore, MD, <sup>2</sup>Kennedy-Krieger Institute, Baltimore, MD and <sup>3</sup>In Vitro Technologies, Inc., Baltimore, MD.

A major detoxification pathway for the carcinogenic catechol estrogens is *O*-methylation by catechol-*O*-methyltransferase (COMT). The val108met polymorphism in the COMT gene has been positively associated with breast cancer and a number of neuropsychiatric conditions. Recently we found that human hepatocytes homozygous for the met108 allele (low activity genotype, COMT<sup>LL</sup>) had lower levels of cytosolic COMT protein and activity. In addition, cytosolic COMT activity levels correlated with cytosolic COMT protein levels. Thus, we hypothesized that the lower levels of COMT protein observed in cells with the COMT<sup>LL</sup> genotype may be due to an increased rate of degradation of the low activity COMT protein, COMT<sup>L</sup>. To investigate this hypothesis, COMT<sup>HH</sup> and COMT<sup>LL</sup> human breast cell lines were incubated with cycloheximide, to inhibit protein synthesis, for varying lengths of time before harvesting and preparing cytosolic fractions. Western blotting was performed to determine COMT protein half-life in each cell line. To date, our results indicate that the half-life of COMT protein in COMT<sup>HH</sup> and COMT<sup>LL</sup> cell lines is greater than 24 hours. In addition, we are investigating whether there is an association between the val108met COMT polymorphism and COMT mRNA levels. We hypothesized that the lower levels of cytosolic COMT protein in COMT<sup>LL</sup> cells may also be due to decreased levels of COMT mRNA. Northern blots to detect COMT mRNA were conducted on total RNA isolated from COMT<sup>HH</sup> and COMT<sup>LL</sup> human breast cell lines. Thus far, no clear trend or association between total COMT mRNA levels (normalized to actin mRNA levels) and the val108met COMT genotype has been observed. We are currently confirming the Northern blot results using the TaqMan™ real-time reverse transcription PCR assay. In addition we plan to confirm and extend our findings in cell lines by measuring COMT mRNA levels in cryopreserved COMT<sup>HH</sup> and COMT<sup>LL</sup> human hepatocytes. Support from R01CA77550 and T32ES07141

## 1264 POLYMORPHISM IN N-ACETYLTRANSFERASE 1 ALLELES NAT1\*10 AND NAT1\*14A IN BENZIDINE-EXPOSED WORKERS IN THE CHINESE DYESTUFF INDUSTRY: LACK OF ASSOCIATION WITH CYTOLOGICAL GRADING OF EXFOLIATED UROTHELIAL CELLS.

W. Guo<sup>1</sup>, G. Lin<sup>1</sup>, J. Chen<sup>2</sup>, K. Golka<sup>3</sup> and J. Shen<sup>1</sup>. <sup>1</sup>Institute of Plant Physiology and Ecology, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences, Shanghai, China, <sup>2</sup>Municipal Center for Disease Prevention and Control, Shanghai, China and <sup>3</sup>Institute for Occupational Physiology at the University of Dortmund, Dortmund, Germany.

N-Acetyltransferase 1 (NAT1) modifies bladder cancer risk in Caucasians formerly exposed to small amounts of aromatic amines in cigarette smoke. Thus, the present study was performed to investigate an association between NAT1\*10 and NAT1\*14A genotypes and bladder cancer risk in benzidine-exposed Chinese workers. Based on the cytological grading of exfoliated urothelial cells according to Papanicolaou ("Pap test"), members of our research cohort were stratified into dif-

ferent subgroups. An allele-specific PCR-based procedure was used to detect the polymorphism in polyadenylation signal at the locus of NAT1 T1088A. A nested-PCR-RFLP procedure was conducted to differentiate NAT1\*14A (T1088A, C1095A, and G560A) from NAT1\*10 (T1088A, C1095A). No significantly different frequencies of homozygous and heterozygous NAT1\*10 alleles were found among the subgroups with gradings according to Papanicolaou  $\leq$ II (18.3% and 40.2%, respect.), higher gradings according to Papanicolaou ( $>$ II; 28.0% and 34.1%, respect.), and with bladder cancer (26.3% and 34.2%, respect.). The present data show that NAT1\*10 neither displayed an association with an elevated grading of urothelial cells nor a clear impact on the risk for bladder cancer in benzidine-exposed Chinese workers.

## 1265 INDIRECT EVIDENCE FOR EXTRAGENIC AND/OR ENVIRONMENTAL INFLUENCE ON HUMAN NAT1 EXPRESSION: ANALYSIS OF PRIMARY HEPATOCYTES BY ALLELE-SPECIFIC QUANTITATIVE REAL-TIME RT-PCR.

J. M. Walraven, D. F. Barker, M. A. Doll and D. W. Hein. *Pharmacology & Toxicology, University of Louisville, Louisville, KY.*

Arylamine N-acetyltransferase (NAT) isozymes play an important role in metabolizing environmental carcinogens and other xenobiotics through N-acetylation or O-acetylation reactions, thereby modifying individual cancer risk and individual drug response or toxicity. Two genetic loci, NAT1 and NAT2, exhibit single nucleotide polymorphisms that define genotype. We analyzed cryopreserved human hepatocytes for NAT1 genotype and acetylator phenotype. Genotyping individuals for known NAT1 polymorphisms did not predict their measured enzyme activity. To distinguish the possible involvement of cis-acting genetic factors versus environmental or genetic trans-acting factors in the regulation of hepatocyte NAT1 expression, we designed a real-time RT-PCR Taqman assay for quantitative measurement of allele-specific mRNA expression in NAT1\*4/\*10 heterozygotes. Genomic DNA from NAT1\*4/\*10 heterozygotes, with a defined allele ratio of 1, was used as a control for differences in allele-specific probe characteristics, PCR amplification and overall variability of the assay. NAT1\*4/\*4 and NAT1\*10/\*10 genomic DNAs were also mixed in different ratios and analyzed to create a standard curve. We established that NAT1\*4/NAT1\*10 ratio measurements outside of the range of 0.5 to 1.5 could be considered significantly different from 1.0 (equal expression of each allele). Analysis of the mRNA expression ratios from individual hepatocytes using the standard curve revealed that functionally significant cis-acting genetic factors do not appear to account for the discrepancy between NAT1 enzyme activity and NAT1 genotype in these hepatocytes. Although NAT1\*4/\*10 ratios ranged from 3.3 to 0.5, overall enzyme levels varied over 350-fold. These results suggest that environmental and/or genetic trans-acting factors influence the expression of NAT1 in human hepatocytes, and experiments have been designed to test this hypothesis. Partially supported by NCI grant CA34627 and NIEHS Training Grant T32-ES011564.

## 1266 FUNCTIONAL CHARACTERIZATION OF MOUSE N-ACETYLTRANSFERASES IN A NAT2 KNOCKOUT MODEL.

J. A. Loehle<sup>1</sup>, L. Wakefield<sup>2</sup>, H. Long<sup>2</sup>, M. A. Doll<sup>1</sup>, J. R. Neale<sup>1</sup>, E. Sim<sup>2</sup> and D. W. Hein<sup>1</sup>. <sup>1</sup>Pharmacology/Toxicology, University of Louisville, Louisville, KY and <sup>2</sup>Pharmacology, University of Oxford, Oxford, United Kingdom.

Arylamine N-acetyltransferase (NAT) isozymes are linked to cancer susceptibility in multiple tissues. Three NAT isozymes have been identified in mice, with NAT1 and NAT2 being most abundant. Functional characterization of NAT1 and NAT2 was investigated in a Nat2 knockout (KO) model (Pharmacogenomics Journal 3: 169-177, 2003) and a Nat2 wild type (WT) strain for comparison. NAT1 and NAT2 catalytic activity, protein, and mRNA levels were determined in cytosols from liver, gut, pancreas, bladder, mammary, and prostate of both male and female adult mice. NAT2 and NAT1 catalytic activities were assessed using p-aminobenzoic acid (PABA) and isoniazid (INH), respectively. NAT1 and NAT2 protein was determined using NAT1- and NAT2-specific antisera. Nat1 and Nat2-specific mRNA levels were determined by qRT-PCR using Nat1- and Nat2-specific primers. PABA acetylating activity was undetectable in all KO mice in all tissues from both males and females, except for mammary tissue where very low levels of PABA acetylation were detected. In contrast, NAT2 catalytic activity was readily detected in all tissues from male and female WT mice. NAT1 catalytic activity levels were similar in KO and WT mice in all tissues. Nat1 and Nat2 protein expression levels were consistent with these results. However, no significant differences in Nat1- or Nat2-mRNA levels were observed between KO and WT mice, indicating that insertion of the LacZ ablation cassette eliminates NAT2 acetylating activity via disruption of the NAT2 protein, without significantly affecting transcription rates or transcript stability. Some gender effects were observed in the pancreas as both NAT1 and NAT2 catalytic activities were higher in males than females. In conclusion, NAT2 catalytic activity is substantially reduced in the KO mice. In contrast, NAT1 acetylation activity is detectable in all tissues tested and is not influenced by the Nat2 knockout. Partially supported by the Wellcome Trust, Summer Res. Scholars Prog. (University Louisville) & NCI grant CA34627.

MECHANISTIC STUDY OF THE A<sup>411</sup>T (L137F) GENETIC POLYMORPHISM IN HUMAN N-ACETYLTRANSFERASE 2.

**Y. Zang, S. Zhao, J. States and D. W. Hein.** *Pharmacology & Toxicology, University of Louisville, Louisville, KY.*

Human N-acetyltransferase 2 (NAT2) genetic polymorphisms may modify individual cancer susceptibility from carcinogen exposure. A<sup>411</sup>T (L137F) is a recently identified single nucleotide polymorphism (SNP) in the NAT2 coding region that coexists with three other SNPs T<sup>341</sup>C (I<sup>114</sup>T), C<sup>481</sup>T (silent) and A<sup>803</sup>G (K268R) in allele NAT2\*5I. cDNA cloning followed by transient expression in COS-1 cells showed that NAT2\*5I encoded an NAT2 isozyme with very low activity resulting from the combined effects of L137F and I114T. A<sup>411</sup>T reduced NAT2 immunoreactive protein to an undetectable level by western blot, whereas neither A<sup>411</sup>T alone nor in combination with other SNPs caused a change in mRNA level measured by real time RT-PCR. However, RNA distribution in polyosome profile indicated no change in translation initiation efficiency. Missense mutants displayed different effects on N-acetylation activity: (wild-type L137: 70.2±5.2; L137F: 1.34±0.03; L137W: non-detectable; L137I: 34.2±2.0; L137G: 0.52±0.04). To further test our hypothesis that A<sup>411</sup>T (L137F) destabilizes NAT2 and accelerates protein degradation induced by protein misfolding, various NAT2 alleles were cloned and recombinantly expressed in E.coli, which do not possess the ubiquitin-mediated degradation pathway. In contrast to mammalian cells, NAT2 possessing the A<sup>411</sup>T SNP recombinantly expressed in E.coli showed no reduction in immunoreactive NAT2 protein, though its catalytic activity was very low. These findings, suggest that the A<sup>411</sup>T(L137F) SNP confers slow acetylator phenotype resulting from enhanced ubiquitin-mediated degradation. Supported by a dissertation research grant from the Susan G. Komen Breast Cancer Foundation; NCI grant CA34627, and the Kentucky Lung Cancer Research Program.

PARAOXONASE POLYMORPHISM LEU-MET55 AND ITS RELATIONSHIP TO DIABETIC COMPLICATIONS IN PATIENTS WITH NON-INSULIN-DEPENDENT DIABETES MELLITUS.

**A. KARAKAYA.** *Toxicology, Ankara University, Ankara, Turkey. Sponsor: A. Ankara University.*

Serum paraoxonase (PON1) is an esterase that hydrolyses organophosphates such as paraoxon and sarin. On the other hand, this enzyme is located on HDL. It is proposed to have responsibility for the antioxidative activity of HDL and decreases the oxidative modification of LDL *in vitro*. The human PON1 gene contains two coding region polymorphisms leading to two different PON1 isoforms: one at position 192 and a second at position 55 [leucine (L) to methionine (M) substitution]. The polymorphisms affect the hydrolytic activity of the PON1 isoenzymes with respect to certain substrates, such as paraoxon and lipid peroxides. Several studies have shown that PON1 could be involved in the pathogenesis micro and macroangiopathy in diabetic late complications. A low PON1 activity in diabetes may contribute to this increased susceptibility by reducing its ability to retard LDL-oxidation. We investigated the effects of the PON1 L/M55 polymorphism on serum PON1 activity, glycaemic control and plasma lipoproteins in NIDDM patients with complications and without complications and in non-diabetic control subjects. Serum PON1 activity in the group with complications was significantly reduced by 23.5% than in the group with no complications and by 26.3% than in non-diabetic control group ( $P<0.05$ ). The distribution of PON1 activity for the PON1 L/M55 polymorphism was the same for three groups ; MM homozygotes have the lowest activity and LL homozygotes the highest, with LM heterozygotes having intermediate activity (LL > LM > MM). The frequency of PON1 M genotype for the group with complications was found higher compared with those of the group without complications and controls (0.37; 0.33; 0.33 respectively). In conclusion, PON1 M homozygosity and low serum PON1 activity in NIDDM patients with complications may be related to an increased tendency for lipid peroxidation (Supported by Research Fund of Ankara University).

GSTM1, GSTM3 AND SMOKING HABITS IN BLADDER CANCER CASES FROM TWO DIFFERENT INDUSTRIAL AREAS.

**K. Golka<sup>1</sup>, T. Schmidt<sup>1</sup>, T. Seidel<sup>2</sup>, H. Dietrich<sup>2</sup>, H. Roemer<sup>1,3</sup>, D. Loehlein<sup>3</sup>, T. Reckwitz<sup>4</sup>, J. Soekeland<sup>1,4</sup>, R. Thier<sup>1</sup> and S. Selinski<sup>5</sup>.** <sup>1</sup>*Institute for Occupational Physiology at the University of Dortmund, Dortmund, Germany*, <sup>2</sup>*Department of Urology, Lutherstadt Wittenberg, Germany*, <sup>3</sup>*Department of Surgery, Klinikum, Dortmund, Germany*, <sup>4</sup>*Department of Urology, Klinikum, Dortmund, Germany* and <sup>5</sup>*Department of Statistics, University of Dortmund, Dortmund, Germany*.

Smoking is the most important risk factor of transitional cell carcinoma of the urinary bladder. Many, but not all publications report an association between the glutathione S-transferase M1 (GSTM1) negative genotype and smoking habits in

bladder cancer cases. Thus we investigated 210 bladder cancer cases from an area of the former chemical and rubber industry in Lutherstadt Wittenberg, 83 bladder cancer cases and 210 surgical controls without a history of malignancies from a hospital in Dortmund, located in a former area of coal, iron and steel industries. Genotyping for GSTM1 and GSTM3 was performed on nuclear DNA according to standard PCR/RFLP methods. Smoking habits were qualified by a standardized interview. Smokers and ex-smokers showed higher percentages in cases from Dortmund (43%/40%) and Lutherstadt Wittenberg (33%/45%) compared with controls (27%/35%). The percentage of GSTM1 negative cases was 63% in the entire bladder cancer patient group compared to 50% in the control group. The percentages of GSTM1 negative smokers in the two case groups were 67% and 67%, respectively, compared with 71% and 55% in non-smokers with bladder cancer. No relevant association between age at beginning of smoking, number of pack years and tumour classification or grading could be observed. The percentage of GSTM1 negative non-smoking controls was 50% and thus within the percentages commonly observed in healthy Caucasian populations. GSTM3 \*A/\*A was 76% in the entire group of bladder cancer cases and 74% in controls. No association between age at beginning of smoking, number of pack years and tumour classification or grading could be observed. Thus the elevated percentage of GSTM1 negative bladder cancer cases in the investigated industrial areas is, if at all, only in part due to smoking habits.

GST-T1, P53, AND CASPASE-8 POLYMORPHISMS AND COLON CANCER RISK.

**J. Goodman<sup>1,2</sup> and C. C. Harris<sup>2</sup>.** <sup>1</sup>*Gradient Corporation, Cambridge, MA* and <sup>2</sup>*Laboratory of Human Carcinogenesis, National Cancer Institute, Bethesda, MD.*

Glutathione-S-transferase T1 (GST-T1) detoxifies mutagenic compounds via conjugation with glutathione. p53 acts through various mechanisms to repair DNA damage and/or induce apoptosis. Caspase-8 plays a major contributing role in p53-mediated apoptosis. As such, polymorphisms in any of these genes could affect cancer risk. As no one has yet examined this, we were interested in whether there were interactions among these functional polymorphisms, independent of their main effects, that could alter colon cancer risk. We hypothesized that a C to G polymorphism 429 bp 3' of the stop codon in *GST-T1*, p53 Arg72Pro, and *caspase-8* Asp302His alone or in combination leads to an increased colon cancer risk. This hypothesis was tested in a case-control study of 830 subjects from the greater Baltimore area. Logistic regression analysis adjusted for age, race, and gender revealed an increased risk of colon cancer (OR=1.82, 95% CI: 1.19-2.80) in individuals homozygous for the *caspase-8* 302His allele carrying at least one G allele of *GST-T1* (vs. *GST-T1* C/C homozygotes). In contrast, a decreased colon cancer risk (OR=0.41, 95% CI: 0.19-0.89) was observed in individuals with at least one 302Asp *caspase-8* allele, who had at least one G allele of *GST-T1* (vs. *GST-T1* C/C homozygotes). Interestingly, the 72Pro allele of *p53* decreased cancer risk alone (OR (Pro/Arg vs. Arg/Arg)=0.90, 95% CI: 0.58-1.40; OR(Pro/Pro vs. Arg/Arg)=0.63, 95% CI: 0.39-1.00;  $P_{trend}=0.02$ ) and had a slight interaction with *GST-T1* ( $P_{interaction}=0.06$ ). There were no apparent interactions between p53 and caspase-8 polymorphisms. These results suggest that the effects of the *GST-T1* polymorphism on colon cancer risk vary according to one's *caspase-8* genotype but are not very dependent on *p53* genotype. We have also shown for the first time that the *p53* 72Arg allele is protective against colon cancer. These results should be cross-validated in other populations.

THE GLUTAMATE CYSTEINE LIGASE CATALYTIC SUBUNIT -129 C/T SINGLE NUCLEOTIDE POLYMORPHISM IS ASSOCIATED WITH THE LEVEL OF GAD65 AUTOANTIBODIES IN TYPE 1 DIABETES PATIENTS WITH A DELAYED AGE-AT-ONSET.

**L. M. Bekris<sup>1</sup>, M. Janer<sup>2</sup>, T. J. Kavanagh<sup>1</sup> and A. Lernmark<sup>3</sup>.** <sup>1</sup>*Environmental and Occupational Health Sciences, University of Washington, Seattle, WA*, <sup>2</sup>*Institute for Systems Biology, Seattle, WA* and <sup>3</sup>*Medicine, University of Washington, Seattle, WA.*

GSH protects against reactive oxygen species (ROS) mediated cell injury in response to a variety of toxicants, and plays a role in the immune response and cytokine production. Type 1 diabetes mellitus (T1D) is an autoimmune disease involving auto-reactive T-cells and ROS, both of which are thought to lead to pancreatic beta-cell destruction. Peripheral blood GSH levels are depleted in many diseases including diabetes. In this investigation we hypothesized that GCLC expression may be a susceptibility factor for T1D. A polymorphic -129 C/T single nucleotide polymorphism (SNP) exists in the promoter region of the GCLC gene and the T allele is associated with lower GCL activity than the C allele. An association with the GCLC -129 C/T SNP and myocardial infarction has recently been reported in a Japanese population. The specific aim of this investigation was to determine the frequency of the GCLC -129 C/T polymorphism and its association

with T1D age-at-onset and T1D autoantibodies in T1D patients (n=761; ages 0-34 years) and in age-matched control subjects (n=551) from Sweden. There was no association between GCLC -129 C/T SNP and T1D age-at-onset. However, patients with an age-at-onset of 15-34 years who possess the GCLC -129 SNP T/T genotype and who are positive for glutamate decarboxylase autoantibodies (GAD65 Ab+) have a higher GAD65 Ab index than GAD65 Ab+ T1D patients with the C/C genotype (Kruskal-Wallis test p-value = 0.0405, Dunn's Multiple Comparison test, p-value < 0.05). Since the GCLC -129 SNP T/T genotype has been shown to result in lower GCL activity, these results suggest that lower GCL activity may be associated with increased GAD65 autoantibody levels in delayed age-at-onset T1D patients.

**1272 BIOLOGICAL CHARACTERIZATION OF THE MANGANESE SUPEROXIDE DISMUTASE (MNSOD) VAL-9ALA POLYMORPHISM.**

B. L. McAtee, A. E. Doyle and J. D. Yager. *Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

A val-9ala polymorphism, found in the mitochondrial targeting signal of MnSOD, has been associated with a number of diseases, including breast cancer in several epidemiology studies. MnSOD functions in the mitochondrial matrix to dismutate superoxide to hydrogen peroxide. Previous studies have reported that the polymorphism may cause an increase in import of MnSOD to the mitochondrial matrix *in vitro*. Altered levels of MnSOD due to the polymorphism are hypothesized to disrupt the oxidative balance in the cell, making the cell more susceptible to oxidative stress. This study aimed to determine if the polymorphism is functional in breast epithelial cancer cell lines. We examined 4 breast epithelial cancer cell lines to evaluate MnSOD activity, protein, and mRNA expression levels. Two cell lines were genotyped as homozygous for the alanine allele, while two others were homozygous for the valine allele. Semi-quantitative western blots were used to evaluate MnSOD protein levels. Preliminary results suggest that 1 ala/ala cell line had significantly higher amounts of MnSOD protein versus the other 3 cell lines (p<0.001) when corrected for mitochondrial mass. MnSOD activity assays revealed that all 4 lines had very low levels of MnSOD activity and did not show any significant difference between the cell lines. MnSOD mRNA expression was analyzed using the TaqMan™ real-time reverse transcription PCR system. Preliminary results suggest that there is no difference in mRNA expression levels among the cell lines. We are currently adding 4 additional cell lines to our study to further investigate the functionality of this polymorphism. (Supported by NIH grants R01CA94747 and T32ES07141).

**1273 MOLECULAR ANALYSIS OF DIHYDROPYRIMIDINE DEHYDROGENASE AND THYMIDYLATE SYNTHASE GENE POLYMORPHISMS IN A TURKISH POPULATION.**

S. Suzen, N. Yuce, G. Guvenc and Y. Duydu. *Toxicology, Ankara University, Ankara, Turkey.* Sponsor: S. Suzen.

Suzen HS, Yuce NN, Guvenc G, Duydu Y Ankara University, Faculty of Pharmacy, Department of Toxicology, Tandoğan, Ankara, Turkey. 5-Fluorouracil (5-FU) is a widely used chemotherapeutic agent to treat various malignancies. 5-FU is converted to a metabolite that inhibits thymidylate synthase (TS) which is a critical target in cancer chemotherapy. The detoxification of 5-FU *in vivo* is mainly due to cytosolic enzyme dihydropyrimidine dehydrogenase (DPD). Among other mutations in the DPYD gene, the most prominent one resulting in severe DPD deficiencies is G to A transition in 5-splice recognition site of intron 14 (IVS14+1G A). A genetic polymorphism that is characterized by a VNTR in the enhancer/promoter region of TS gene might also affect the outcome of 5-FU therapy. Together, the assessment of polymorphisms in genes that encode DPD and TS might be useful in selecting patients who are likely to tolerate and to respond adequately to 5-FU. The aim of this study was to identify IVS14+1G A and VNTR polymorphisms in a Turkish population and to make a comparison with the other populations. In this purpose, PCR-RFLP technique was used to identify frequency of the polymorphic DPYD and TS genes in 120 healthy unrelated individuals. Our preliminary results showed that no splice mutation in the DPYD gene was detected among 120 Turkish individuals. The frequencies of the allele TS (2R) and TS (3R) in Turkey were 0.415 and 0.585, respectively. Our results revealed that, compared with other populations, the molecular profile of polymorphism at DPYD gene loci is similar to many Asian and European populations. On the other hand Turkish population TS allele frequency data is very similar to Caucasian populations. Further studies in different populations will be contributed for prediction of the efficacy and toxicity of using 5-FU based chemotherapy. (Supported by Ankara University, Biotechnology Institute, Project No: 2001-K-120-240)

**1274 TWO POLYMORPHISMS IN THE DNA REPAIR GENE MGMT INCREASE HUMAN SENSITIVITY TO THE TOBACCO-SPECIFIC NITROSAMINE NNK.**

C. E. Hill, A. A. Affatato, K. J. Wolfe, J. K. Wickliffe and S. Z. Abdel-Rahman. *PMCH- Environmental Toxicology, University of Texas Medical Branch, Galveston, TX.*

Efficient DNA repair is critical for the protection of cells from carcinogenic agents present in tobacco smoke. Many polymorphisms in several DNA repair genes have been associated with increased risk of cancer. O6-Methylguanine-DNA-Methyltransferase (MGMT) is a direct reversal DNA-repair protein that plays an important role in protecting the cell from mutations resulting from exposure to alkylating mutagens. We propose that inherited polymorphisms in the coding region of MGMT, which result in amino acid substitutions, may significantly influence the level of smoking-induced genetic damage, a critical step in the cascade of events leading to cancer. We tested the hypothesis that the inheritance of the Leu84Phe or the Ile143Val polymorphism in MGMT is associated with increased genetic damage resulting from exposure to alkylating agents found in tobacco smoke. We used the mutagen sensitivity assay, with the tobacco-specific nitrosamine NNK as a model alkylating mutagen, to test this hypothesis. Lymphocytes obtained from healthy volunteers were exposed *in vitro* to NNK and the genotoxic response was measured by assessing the increase in chromosome aberration (CA) frequency. A significant increase in NNK-induced CA was observed in cells from individuals with the Phe allele compared to cells from individuals homozygous for the wild-type Leu allele. This was true especially for smokers, males and younger individuals. A significant increase in NNK-induced CA was observed for males or younger individuals with the Val allele compared to individuals homozygous for the Ile allele. These data suggest that the inheritance of the Phe allele and/or the Ile allele may affect the repair efficiency of genetic damage induced by NNK. It may also provide a partial mechanistic explanation for previously reported findings that indicate an association between MGMT polymorphism and increased risk of cancer. (Supported by an External Research Program grant from Philip Morris Inc. and by an NIEHS T32-07454 grant).

**1275 ASSOCIATIONS BETWEEN MERCURY, BDNF POLYMORPHISM, AND ATTENTIONAL ATTRIBUTES OF MOTOR FUNCTION.**

D. echeverria<sup>1,2</sup>, J. S. Woods<sup>1,2</sup>, N. J. Heyer<sup>1</sup>, F. M. Farin<sup>2</sup>, A. C. Bittner<sup>1</sup>, T. Li<sup>2</sup> and C. Garabedian<sup>1</sup>. *Battelle CPHRE, Seattle, WA and<sup>2</sup>ENHV, U of Washington, Seattle, WA.*

We evaluated whether BDNF polymorphism (BDNF) is associated with attentional attributes of reduced motor function in mercury-exposed subjects. Behavioral scores, urine and buccal cell samples were collected for 194 male dentists (DDS) and 233 female dental assistants (DAs) who were exposed to mercury for 19 and 10 yrs. Spot urinary levels were respectively 3.32 (4.87) and 1.98 (2.29) ug/l. BDNF status was respectively 68% or 66% Wild Type, 26% and 30% single substitution, and 5% and 4% full mutation. Analyzing genders separately, multiple regression controlled for age, vocabulary, alcohol, medications, injury, repetitive trauma, and visual acuity. Performance on Digit Span, Finger Tap, and Hand Steadiness were adversely affected by joint exposure to mercury and BDNF in an additive manner in both groups. However, the dominant and non dominant factor for finger speed had no association with BDNF. But when we co-varied out the effect of both hands from Finger Tap Alternate, the resultant residual term, Finger Tap Alternate<sup>partial</sup> remained associated with BDNF. Further, the correlation between BDNF and the sequence of Hits and Contact Time for Hand Steadiness showed a significant decay in correlation from Hole 3 to Hole 9 (the largest to smallest hole) where only Hits and Time for Hole 3 were associated with the BDNF. [Hits 3-9: correlations were 0.27, 0.24, 0.03, 0.00, 0.02, 0.00, 0.01; Time 3-9: correlations were 0.45, 0.17, 0.06, 0.02, 0.04, 0.01, 0.01]. This observation is consistent for both groups. The results suggest that deficits in attention necessary to alternate finger taps or first learn to position a probe without touching the sides of a hole, is adversely affected by the polymorphism. Further, our methods are particularly useful when exposure levels approach that of the general population because identifying a vulnerable group with a BDNF polymorphism reveals the additive effect of a personal genetic factor with a more precise attentional deficit attributable to exposure to elemental mercury.

**1276 IDENTIFICATION OF A NOVEL VARIANT OF THE PREGNANE X RECEPTOR IN HEPATIC ADVERSE DRUG REACTION PATIENTS.**

J. D. Tugwood<sup>1</sup>, D. F. Carr<sup>2</sup> and H. Pringle<sup>2</sup>. *<sup>1</sup>Safety Assessment, AstraZeneca Pharmaceuticals, Macclesfield, United Kingdom and <sup>2</sup>University of Leicester, Leicester, United Kingdom.* Sponsor: E. Pognan.

The incidence and economic impact of idiosyncratic drug-induced hepatotoxicity has been a longstanding concern for the pharmaceutical industry and regulatory bodies. Problems arise in the analysis of genetic variation in adverse drug reactions

(ADRs) due to the very low frequency of occurrence and thus the ability to acquire a significant patient cohort. In this study, access to an archive of 1900 clinical liver biopsies has enabled the identification of a cohort of 53 individuals displaying histological and biochemical evidence of ADRs. The Pregnen X Receptor (PXR) is a ligand-activated transcription factor known to regulate the transcription of a number of genes involved in hepatic xenobiotic metabolism and bile acid homeostasis. The PXR gene is a candidate for altered functionality in patients with ADRs, in particular drug-induced cholestasis. Sequence analysis of the PXR protein-coding region revealed the presence of a novel non-synonymous single nucleotide polymorphism within the ligand-binding domain. This resulted in a cysteine to arginine change at residue 301 (C301R), identified in 2 of the 53 ADR patients as a heterozygote. The variant has not been found in a cohort of over 300 non-ADR individuals of various ethnic origins. Electrophoretic Mobility Shift Assays using the CYP3A-DR3 response element show that the C301R variant binds to DNA with approximately the same affinity as the wild-type PXR. However, transfection studies using a CYP3A-DR3 reporter plasmid show that C301R has reduced basal transcriptional activity, and impaired responses to the PXR ligands rifampicin and hyperforin, compared to wild-type receptor. Since hepatic ADRs occur at such low frequency, and given that they appear to be multifactorial in their aetiology, it is possible that having enriched for a population of ADRs, one single genetic factor among a large number may have been identified. In the general population this may have such a low occurrence as to have remained undetected without such "enrichment".

#### MEASURING CHOLINESTERASE ACTIVITY IN HUMAN SALIVA.

B. Claus Henn<sup>1,2,3</sup>, S. Padilla<sup>2</sup> and S. McMaster<sup>3</sup>. <sup>1</sup>ASPH Research Fellow, Research Triangle Park, NC, <sup>2</sup>NTD, USEPA, Research Triangle Park, NC and <sup>3</sup>HSD, USEPA, Research Triangle Park, NC.

Biomonitoring of organophosphorous and carbamate pesticides has focused primarily on the inhibition of blood cholinesterase. Blood biomonitoring, however, can be invasive, time-consuming, and costly, especially in young children and infants. Therefore, saliva biomonitoring has recently been explored as a practical and feasible alternative to blood. To determine whether an individual's salivary cholinesterase was consistent over time and which of two methods was more accurate and preferable, saliva samples were collected once per week for five consecutive weeks from 20 adults using a Salivette (cotton swab) and pipette. To measure cholinesterase activity, the radiometric method developed by Johnson and Russell (1975) was modified for human saliva by increasing tissue volume, substrate volume, incubation time, and incubation temperature. Using this method, cholinesterase was found to be present and measurable, with good repeatability (2.2% average difference between duplicate samples). Activity in pipette-collected samples ranged from 0 to 153.7 nmol hydrolyzed/min/ml saliva, while activity in Salivette-collected samples was slightly higher: 3.4 to 264.7 nmol hydrolyzed/min/ml saliva. The activity for some individuals was very consistent during the five weeks, whereas for others it was variable, and, in general, variability in activity for the two collection methods was comparable (mean coefficient of variation [CV] for pipette=34.8%; Salivette=35.6%). Cholinesterase levels from the two collection methods were significantly correlated ( $r=0.41$ ,  $n=100$ ,  $p<0.05$ , two tails). In terms of participant preference, the Salivette was preferred to the pipette method at the majority (86%) of visits. Results from this study demonstrate that (1) cholinesterase is measurable in saliva, (2) in some people (about 50% of our population) the activity is consistent from week to week, and (3) the collection methods yield comparable results, though participants prefer the Salivette. This is an abstract of a proposed presentation and does not reflect Agency policy.

**1278**

#### A CONVERSION FACTOR BETWEEN TWO CHOLINESTERASE ASSAYS AND ITS APPLICATION IN ESTABLISHING A NORMAL RANGE FOR HUMAN RBC AChE.

D. E. Arrieta<sup>1</sup>, V. M. Nihart<sup>1</sup>, J. D. Henderson<sup>1</sup>, S. A. McCurdy<sup>2</sup>, L. J. Lefkowitz<sup>3</sup> and B. W. Wilson<sup>1</sup>. <sup>1</sup>Environmental Toxicology and Animal Science, University of California, Davis, CA, <sup>2</sup>Epidemiology and Preventive Medicine, University of California, Davis, CA and <sup>3</sup>US Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD.

The Cholinesterase (ChE) Reference Laboratory (CRL) at the US Army Center for Health Promotion and Preventive Medicine (USACHPPM) uses a modification of the delta pH method of Michel to annually analyze over 15,000 blood specimens from personnel that predominantly work at chemical agent storage sites and chemical demilitarization facilities. UC Davis and CRL are collaborating to derive a conversion factor between the delta pH and the colorimetric Ellman ChE assays. The factor is used to estimate a normal range of Ellman determined human blood acetylcholinesterase (AChE) levels based on CHPPM's data. Human red blood cells

(RBCs) from three volunteers were assayed at UCD by the delta pH and Ellman methods according to standard procedures. Both assays were carried out at 25 °C, and with optimal final substrate concentrations: 10 mM acetylcholine bromide for the delta pH assay and 1 mM acetylthiocholine iodide for the Ellman assay. RBCs were treated with diisopropyl fluorophosphate to generate a dose/response curve of inhibition. This yielded an approximate conversion factor: delta pH = 0.091 Ellman + 0.052 with an  $r^2$  of 0.96. This approach permits converting the extensive CRL database of baseline (presumably unexposed) delta pH AChE values into a normal range of Ellman AChE activities, assays used to evaluate occupational exposure to pesticides. The estimated normal 95% range of human AChE for the Ellman assay was 7.12 to 9.10  $\mu$ mol/min/mL with a mean value of  $8.23 \pm 0.62$  SD  $\mu$ mol/min/mL. This work was supported by the US Army Medical Research and Materiel Command under Grant Project Order DAMD17-01-1-0772, NIOSH (#CDC U07/CCU906162-06) and NIEHS (#ES05707).

#### PESTICIDE EXPOSURE ASSESSMENT: CONCURRENT PASSIVE DOSIMETRY AND BIOLOGICAL MONITORING OF TRICLOPYR AND 2, 4-D EXPOSURES OF A BACKPACK APPLICATOR CREW.

X. Zhang<sup>1,2</sup>, S. P. Acevedo<sup>1</sup>, Y. Chao<sup>1</sup>, T. M. Dinoff<sup>1</sup>, R. L. Williams<sup>1,2</sup> and R. I. Krieger<sup>1,2</sup>. <sup>1</sup>Personal Chemical Exposure Program, Department of Entomology, University of California, Riverside, CA and <sup>2</sup>Environmental Toxicology Graduate Program, University of California, Riverside, CA.

Strategies for pesticide exposure assessment represent different levels of quantitative certainty. This study concerned the consistency of exposure monitoring of workers using backpack sprayers. A crew of 8 applicators, a mixer/loader, and a supervisor applied two herbicides, triclopyr and 2, 4-D, as a tank mix for weed control in forestry. When coveralls were used as a passive dosimeter, the average residues recovered were  $2.50 \pm 1.55$  mg equiv/d for triclopyr and  $0.75 \pm 0.52$  mg equiv/d for 2, 4-D. When the herbicides were collected on cotton whole body dosimeters worn beneath the coveralls, measurements were reduced to  $0.22 \pm 0.23$  mg equiv/d and  $0.14 \pm 0.17$  mg equiv/d ( $n=5$ ) respectively. Cotton gloves (under nitrile gloves) and socks, and face/neck skin wipes were included in each case but they contributed less than 1% to the exposure estimate. Urine specimens (24 h) were analyzed for triclopyr and 2, 4-D, the biomarkers. The excreted doses of triclopyr and 2, 4-D were  $5.2 \pm 4.3$   $\mu$ g equiv/d and  $3.8 \pm 3.4$   $\mu$ g equiv/d respectively. Their corresponding excreted daily dosage was  $0.072 \pm 0.057$  and  $0.052 \pm 0.044$   $\mu$ g equiv/kg-d respectively. Based upon these results, the estimated clothing penetration was 11% for triclopyr and 20% for 2, 4-D. Their respective dermal absorption rates were 3.6%/d and 4.2%/d. For backpack application of triclopyr and 2, 4-D, worker dose based upon external pesticide deposition on coveralls was nearly 340-times and 180-times more than the dose determined by biomonitoring. Although external measures predicted excessive applicator exposures, use of backpack sprayers in a rugged forest terrain minimized releases to the forest environment and resulted in worker exposures far below toxic levels.

#### ENVIRONMENTAL INDUCTION OF CYP1A-, CYP2M1- AND CYP2K1-LIKE PROTEINS IN TROPICAL FISH SPECIES BY PRODUCED FORMATION WATER ON THE NORTHWEST SHELF OF AUSTRALIA.

S. Zhu<sup>1</sup>, S. CodiKing<sup>2</sup> and M. L. Haasch<sup>1</sup>. <sup>1</sup>Pharmacology, Environmental Toxicology Research Program, NCNPR, University of Mississippi, University, MS and <sup>2</sup>Australian Institute of Marine Science, Townsville, QLD, Australia.

Normal operation of oil well platforms results in the discharge of produced formation water (PFW). The expression of CYP1A, CYP2M1- and 2K1-like proteins was examined in Gold-Spotted Trevally (Carangoides fulvoguttatus) and Bar-Cheeked Coral Trout (Plectropomus maculatus) as possible biomarkers of PFW impact. The results of this pilot study indicated PFW contamination near the Harriet A platform may contribute to induction of CYP1A- and 2M1-like proteins in Trevally, while other contaminants associated with PFW may induce a CYP2K1-like protein. In a 2003 caged fish study, Stripey seaperch (Lutjanus carponotatus) were caught at a clean site, then distributed to three caging sites: A (near field), B (far field) and C (a non-impacted reference site). Fish were sampled at time (T) zero, T=3 and T=10 days. Significant increases of CYP1A, one CYP2K1- and two CYP2M1-like proteins were noted at Site A at T=10. For the other CYP2K1-like protein, a significant increase was observed at site A only at T=3, but not at T=10. Prevailing winds switched between day 6 and day 10 of sampling, moving the surface water due west, therefore exposing the fish to different components of PFW that may possibly induce this CYP2K1-like protein. These results indicate that CYP1A protein is sensitive to PFW exposure and may act as a good biomarker. Importantly, statistically significant environmental induction of both CYP2M1- and CYP2K1-like proteins in tropical fish due to PFW exposure has not previously been described and represents possible new biomarkers (other than CYP1A) of PFW fraction-specific contamination. (Supported by Apache Energy Party Ltd., Australian Institute of Marine Science and the Environmental Toxicology Research Program of University of Mississippi)

## ANALYSIS OF ENVIRONMENTAL POLLUTANTS IN BREAST MILK AND DNA DAMAGE IN BREAST-MILK CELLS.

K. F. Arcaro<sup>1,2</sup>, J. W. Staudenmayer<sup>3</sup>, A. P. DeCaprio<sup>3</sup>, J. Wang<sup>1</sup> and M. T. Reece<sup>3</sup>. <sup>1</sup>Environmental Sciences, University of Massachusetts, Amherst, MA, <sup>2</sup>Veterinary & Animal Sciences, University of Massachusetts, Amherst, MA and <sup>3</sup>University of Massachusetts, Amherst, MA.

It has been hypothesized that increased genetic instability, resulting from exposure to environmental toxicants, may increase an individual's risk of developing breast cancer. It is important, therefore, to determine the extent to which exposure to environmental pollutants results in increased genetic instability. We have addressed this issue by examining both the levels of pollutants in breast milk, and DNA damage in breast-milk cells. Breast milk samples collected from twenty-one women living in the Springfield, MA and Albany, NY areas, were analyzed for levels of 101 polychlorinated biphenyl (PCB) congeners and 8 organochlorine pesticides/metabolites (Hexachlorobenzene, oxychlordane, pp'-DDE, op'-DDE, -Chlordane, trans-Nonachlor, Mirex, and cis-Nonachlor). Cells in the milk were separated by centrifugation within one hour of milk collection, and DNA damage was assessed using the single cell gel electrophoresis assay. Each woman completed a questionnaire providing information on her age, age of her nursing child, her cigarette smoking history and current exposure, and number of children she previously nursed. Mother's age ranged from 21 to 40 years, and child's age ranged from 3.5 to 67 weeks. PCBs and pesticides were detected in all 21 milk samples. Among women who had not previously nursed a child (n = 15), there were significant positive correlations between age of the woman and 1) total PCB level, 2) Hexachlorobenzene level, and 3) pp'-DDE level. None of these correlations were significant in women who had previously nursed a child (n = 6). All samples contained cells with detectable levels of DNA damage, but no significant correlations between levels of pollutants and DNA damage were observed.

## AMBIENT AND BIOLOGICAL MONITORING OF EXPOSURE TO AROMATIC AMINES IN THE RUBBER INDUSTRY.

T. Weiss<sup>1,2</sup>, H. U. Kaefferlein<sup>2</sup>, T. Bruening<sup>2</sup> and J. Angerer<sup>1</sup>. <sup>1</sup>Institute of Occupational Medicine, Friedrich-Alexander University, Erlangen, Germany and <sup>2</sup>Institute of Occupational Medicine - Center of Toxicology, Ruhr-University, Bochum, Germany.

Diphenylguanidine and di-*o*-toluylguanidine are important vulcanization accelerators and are suspected to release aniline (A) and *o*-toluidine (*o*-T) during the manufacture process of automotive rubber parts. Both, A and *o*-T, are confirmed animal carcinogens. Recent studies also suggest at least a 6.5-fold increase in bladder cancer incidence of workers exposed to *o*-T [Ward *et al.* 1996, *J National Cancer Inst* 88: 1046; Markowitz and Levin 2004, *Occup Environ Health* 46: 154]. The purpose of this investigation was to determine exposure to A and *o*-T in 69 healthy workers of the rubber industry. For this purpose ambient monitoring by personal air sampling and biological monitoring of the internal dose (A and *o*-T in urine) and the effective dose (Hb adducts) was carried out by GC/MS analysis. Two known bladder carcinogens in humans, 4-aminodiphenyl (4-ADP) and 2-naphthylamine (2-NA) were included in the study. Urine and blood samples were collected post-shift and results were compared to those derived from 200 non-exposed individuals and those published in the cohorts of Ward *et al.* and Markowitz and Levin. A and *o*-T levels in the air were lower 0.11 ppm (TWA: 2 ppm). Urinary levels of A and *o*-T were higher compared to non-exposed individuals (A: 9.4 vs. 3.7 µg/L; *o*-T: 10.5 vs. 0.1 µg/L). Hb adducts were also higher in the exposed persons (A: 821 vs. 488 ng/L; *o*-T: 563 vs. 23 ng/L). No difference could be determined for Hb adduct levels of 4-ADP and 2-NA between exposed workers and controls. Hb adduct levels of *o*-T were only ~10-fold lower than those, which were reported in the cohort studies by Ward *et al.* and Markowitz and Levin. The results show that diphenylguanidine and di-*o*-toluylguanidine can release A and *o*-T during regular manufacturing processes of automotive rubber parts. The comparison between ambient and biological monitoring also shows that A and *o*-T are primarily taken up via the skin. Therefore, exposure is underestimated by ambient monitoring.

## SINGLE NUCLEOTIDE POLYMORPHISM AT EXON 4 IN THE MICROSOMAL EPOXIDE HYDROLASE GENE IS ASSOCIATED WITH INCREASED AFLATOXIN ALBUMIN ADDUCTS IN THE BLOOD OF HUMANS IN GHANA.

B. Dash<sup>1</sup>, E. Afriyie-Gyawu<sup>1</sup>, H. J. Huebner<sup>1</sup>, J. Wang<sup>2</sup>, P. E. Jolly<sup>3</sup> and T. D. Phillips<sup>1</sup>. <sup>1</sup>Faculty of Toxicology, Texas A&M University, College Station, TX, <sup>2</sup>Texas Tech University, Lubbock, TX and <sup>3</sup>University of Alabama, Birmingham, AL.

Hepatocellular carcinoma (HCC) is a multifactorial disease with various host and environmental factors involved in its etiology. Of these, aflatoxin exposure has been established as an important risk factor in the development of HCC and the pres-

ence of aflatoxin-albumin adducts in the blood serves as a valuable indicator of human exposure. In this research, the relationship between a variety of different HCC host factors and the incidence of aflatoxin-albumin adduct levels was studied in a Ghanaian population at risk for HCC. These factors included age, sex, HBV and HCV status and genetic polymorphisms in both microsomal epoxide hydrolase (mEH) and glutathione S-transferases (GSTs). Blood samples were analyzed for aflatoxin-albumin adducts, HBV and HCV status. GSTM1 and GSTT1 deletion polymorphisms and mEH exon 3 and exon 4 single nucleotide polymorphisms (SNP) were determined from urine samples. In univariate analysis, age, HBV and HCV status, GSTT1 and mEH exon 3 genotypes were not associated with aflatoxin-albumin adduct levels. However, mean adduct levels were significantly higher in both females and individuals typed heterozygous for mEH exon 4 (vs. wild types). Stratification analysis also showed that gender along with mEH exon 4 genotype and HBV status had a significant effect on adduct levels. Both females typed HBsAg+ and males with mEH exon 4 heterozygote genotypes showed significantly higher adduct levels as compared to the HBsAg- and wild types, respectively. Understanding the relationships between these host factors and the variability in aflatoxin-adduct levels may help in identifying susceptible populations and targeting aflatoxin-specific interventions for humans at high risk for HCC and chronic liver diseases (NIEHS P42 ES04917, USAID LAG-G-00-96-90013-00).

## CORRELATION OF MATERNAL HEMOGLOBIN (HB) 4-AMINOBIPHENYL ADDUCT LEVELS WITH RESPECT TO COTININE LEVELS AND MATERNAL GENOTYPES.

S. R. Myers, C. Cunningham and T. Wright. *Pharmacology and Toxicology, Center for Environmental and Occupational Health Sciences, University of Louisville, Louisville, KY.*

Of all the avoidable risks for adverse pregnancy outcomes, cigarette smoking is the most important and obvious. Cigarette smoke affects the primary user, the mother, but also, the fragile fetus. It has been estimated that between fifteen and thirty percent of pregnant women in the United States smoke during pregnancy. Furthermore, Kentucky regularly ranks among the states with the highest percentage of pregnant smokers with twenty-three percent, a close second to West Virginia while Utah ranks the lowest at approximately fourteen percent. These extremes may be attributable to cultural and agricultural differences between the populations of these states. In the current study, we correlated the level of hemoglobin adducts to 4-aminobiphenyl found in tobacco smoke. Maternal hemoglobin adduct levels were measured in subjects based on cotinine concentrations and specific genotypes of interest. Maternal subjects with cotinine levels  $\geq$  50 ng/ml who possessed a NAT1\*10 allele had higher 4-aminobiphenyl hemoglobin adduct levels than subjects with the same cotinine levels who did not possess a NAT1\*10 allele ( $\alpha = 0.05$ ,  $P < 0.13$ ). Maternal subject with cotinine levels  $\geq$  50 ng/ml who were NAT2 slow acetylators had slightly higher 4-aminobiphenyl hemoglobin adduct levels than subjects with the same cotinine levels who were NAT2 rapid or intermediate acetylators ( $\alpha = 0.05$ ,  $P < 0.52$ ). Maternal subject with cotinine levels  $< 5$  ng/ml who were NAT2 slow acetylators had slightly lower 4-aminobiphenyl hemoglobin adduct levels than subjects with the same cotinine levels who were NAT2 rapid or intermediate acetylators ( $\alpha = 0.05$ ,  $P < 0.30$ ). These data suggest that the genetic polymorphisms of N-acetyltransferase may contribute to the variations in hemoglobin adduct levels seen in smokers, especially among the aromatic amines.

## CORRELATION OF MATERNAL AND FETAL HEMOGLOBIN (HB) ADDUCTS IN SMOKERS WITH RESPECT TO GENOTYPE.

C. Cunningham, T. Wright and S. R. Myers. *Pharmacology and Toxicology, Center for Environmental and Occupational Health Sciences, University of Louisville, Louisville, KY.*

Hb adducts have been suggested as biochemical monitors of carcinogen exposure and measures of genotoxic risk. Studies have demonstrated that carcinogenic compounds, especially those present in cigarette smoke bind covalently to Hb. To further elucidate the relationship between maternal and fetal Hb adducts as a measure of tobacco smoke exposure, matched maternal/cord blood samples were obtained and 4-aminobiphenyl and benzo(a)pyrene adducts characterized. The results were graphed and linear regressions were performed for each of the adducts determined. Correlations between Hb adducts of paired maternal and fetal samples were assessed and Pearson's correlation coefficient (*r*) was used to determine the tightness of the data. In order to account for deviations from the regression line, individual data points were examined with regard to the genotypes of the maternal and fetal samples. A positive correlation was found to exist among both maternal and fetal samples for both 4-aminobiphenyl (*r* = .536,  $\alpha = 0.05$ ,  $P < 0.0001$ ) and benzo(a)pyrene (*r* = .346,  $\alpha = 0.05$ ,  $P < 0.0001$ ). Based on the inferred NAT1, NAT2, GSTM1 and GSTT1 genotypes for each of the maternal/fetal data points, no trend in hemoglobin adduct levels could be established. Genotypes appeared to

be distributed evenly across the scatter plot. NAT2 slow acetylators were slightly more common in pairs who had low levels of 4-aminobiphenyl hemoglobin adducts for both maternal and fetal samples. In addition, no trend in genotype was observed when considering CYP1A1 Msp I, CYP1A1 Hinc II, GSTM1 or GSTT1 polymorphisms, suggesting that either additional genotype polymorphisms or combinations of genotype may play an important role in the overall level of tobacco smoke carcinogen Hb adducts

### LEVELS OF POLYCYCLIC AROMATIC HYDROCARBONS IN AMNIOTIC FLUID SAMPLES FROM SMOKERS AND NONSMOKERS.

J. Weeks and S. R. Myers. *Pharmacology and Toxicology, Center for Environmental and Occupational Health Sciences, University of Louisville, Louisville, KY.*

Previous studies from this laboratory have focused on the characterization of blood protein adducts formed *in utero* as a result of maternal smoking during pregnancy. These biological samples, obtained during the third trimester of pregnancy, at delivery, have clearly shown a correlation between maternal smoking and exposure of the fetus to tobacco smoke carcinogens, including 4-aminobiphenyl and benzo(a)pyrene. In the present study, we examined exposure of the fetus during the first trimester of development to various environmental carcinogens, particularly those found in tobacco smoke. Amniotic fluid samples were obtained from women undergoing routine amniocentesis at between 16 and 20 weeks gestational age. Amniotic fluid, produced by the fetal lungs and kidneys, is an important part of pregnancy and fetal development and this fluid surrounds the fetus throughout pregnancy. In these studies, samples of amniotic fluid were obtained from non-smokers as well as 0.5 pk/da smokers through >2pk/da smokers. Amniotic fluid samples were extracted and analyzed by HPLC and GC/MS for the presence of polycyclic aromatic hydrocarbons (PAHs). Amniotic fluid levels of PAHs were found in almost all samples analyzed. However, there was a clear correlation between levels of maternal smoking and PAHs in the amniotic fluid. 1-hydroxypyrene levels ranged from  $1.54 \pm 0.12 \mu\text{g/L}$  in nonsmokers to  $11.72 \pm 0.67 \mu\text{g/L}$  in women smoking >2 pk/da, indicating approximately a 10X increase over non-smokers. Similar results were found with more widely established carcinogens, including hydroxylated benzo(a)pyrene derivatives, which ranged from  $1.41 \pm 0.13 \mu\text{g/L}$  in nonsmokers to  $11.56 \pm 0.59 \mu\text{g/L}$  in >2pk/da smokers. These results indicate that exposure to harmful environmental carcinogens can occur during early gestational periods and may place the fetus at a risk of genotoxic as well as teratogenic events.

### INVESTIGATIONS OF VARIATION IN URINARY PROFILES BETWEEN SMOKERS AND NON-SMOKERS USING METABONOMIC (NMR SPECTROSCOPIC) URINALYSIS.

M. Ogden. *R&D, R. J. Reynolds, Winston-Salem, NC.* Sponsor: D. Doolittle.

Development and evaluation of potentially reduced exposure tobacco products (PREPs) requires knowledge of smoke constituent uptake in smokers. Since smoke is a complex mixture, altering product specifications often results in conflicting yield and uptake estimates. Alternatives to developing and measuring countless constituent-specific biomarkers are needed. Metabonomics has the potential to provide this holistic approach for PREP assessment; however, initial exploratory research is required to demonstrate the potential. In this study, the hypothesis was tested that the metabolic profiles of smokers differ from those of non-smokers, and these differences can be mapped and quantified by metabonomic (NMR spectroscopic) urinalysis. Urine samples (24-h) were collected from smokers (N=24) and non-smokers (N=9) of mixed gender and varying ages on a controlled low mutagenicity diet. Samples were analyzed using 600 MHz  $^1\text{H}$  NMR spectroscopy. The resulting NMR spectra were interpreted using pattern recognition methods to characterize metabonomic alterations between the two groups. An initial principal component analysis (PCA) showed that several sources of variation existed in the data other than smoking. This resulted in the two sets of data overlapping in a plot of the first two components. However, when a supervised approach (PLS-DA) was applied to the data, the resulting plot showed that the majority of smokers could be separated from non-smokers. A number of urine samples contained a series of unknown compounds, mostly from smokers, but also in a small number of samples from non-smokers. These compounds were unrelated to nicotine and its major metabolites. No correlations were noted between NMR spectral data and demographic data, but the NMR data correlated with Ames urinary mutagenicity assays (both TA98 and YG1024;  $R^2=0.6$ ). Interestingly, no correlations were noted with tobacco-selective biomarker data (major nicotine and NNK metabolites). Reducing the conflicting sources of variation (as seen by PCA) may improve the predictive quality of the NMR spectral data.

## 1288

### RACE/ETHNICITY, INCOME AND PERCHLOROETHYLENE (PERC) EXPOSURES AMONG ADULT AND CHILD RESIDENTS OF BUILDINGS WITH DRY CLEANERS.

J. E. Storm<sup>1</sup>, M. J. McDermott<sup>1</sup>, K. M. Aldous<sup>1</sup>, B. C. Blount<sup>2</sup>, J. Serle<sup>3</sup> and S. J. Shost<sup>1</sup>. <sup>1</sup>*Department of Health, New York State, Troy, NY*, <sup>2</sup>*US Centers for Disease Control and Prevention, Atlanta, GA* and <sup>3</sup>*Mt. Sinai School of Medicine, New York, NY*.

Residential indoor air levels of perc were documented in 65 apartments in 24 New York City multifamily buildings where dry cleaners using perc were operating. Alveolar breath and blood perc level for adult (20-55 yrs old) - child (5-14 yrs old) pairs residing in each sampled apartment were also determined. Mean indoor air perc levels were significantly higher in buildings located in minority (population < 48.9% White) ( $72 \mu\text{g/m}^3$ ) or low-income (>23.6% households below poverty threshold) ( $230 \mu\text{g/m}^3$ ) census block groups than in buildings located in non-minority (18  $\mu\text{g/m}^3$ ) or higher income (23  $\mu\text{g/m}^3$ ) census block groups. Mean indoor air perc levels were also significantly higher in households identifying themselves as minority (African-American or Hispanic alone or in combination with any other race) (82  $\mu\text{g/m}^3$ ) than in households identifying themselves as non-minority (White) (16  $\mu\text{g/m}^3$ ) and significantly higher in low-income households (annual income <\$30,000) (106  $\mu\text{g/m}^3$ ) compared to higher income households (annual income >\$60,000) (18  $\mu\text{g/m}^3$ ). Individual adult and child blood and breath perc levels were significantly correlated with indoor air perc levels ( $R^2$  range 0.55-0.68). Not surprisingly then, blood perc levels in minority (1.07-1.96 ng/mL) or low income (1.17-2.16 ng/mL) residents were significantly higher than in non-minority (0.54 ng/mL) or low income residents (0.50-0.51 ng/mL). Alveolar breath perc levels were also higher in minority or low-income residents than in non-minority or higher income residents but not significantly so. These findings suggest that minority and low income residents of multifamily buildings with co-located dry cleaners constitute a subpopulation in New York City with exposure to perc greater than non-minority and higher income residents of buildings with co-located dry cleaners. Funded through USEPA STAR Grant R827446010.

### HEALTH EVALUATION OF MARINE FISHES FROM JOHNSTON ATOLL NATIONAL WILDLIFE REFUGE, A FORMER MILITARY INSTALLATION.

D. M. Papoulias<sup>1</sup>, J. L. Zajicek<sup>1</sup>, M. L. Annis<sup>1</sup>, D. K. Nicks<sup>1</sup>, J. S. Candrl<sup>1</sup>, L. Woodward<sup>12</sup> and D. E. Tillitt<sup>1</sup>. <sup>1</sup>*USGS, Columbia Environmental Research Center, Columbia, MO* and <sup>2</sup>*USFWS, Honolulu, HI.* Sponsor: C. Richter.

The JANWR was recognized as an important seabird refuge in 1926. Over decades, defense activities in the area have resulted in contamination with radioisotopes, pesticides, dioxins, metals, PCBs, and PAHs. At the request of the USFWS, the USGS evaluated the extent of contamination and fish health at 3 areas on Johnston Island (JI) and a reference site. The assessment was designed to determine if adverse effects were present in fishes from contaminated sites, not to determine causality. Dioxins and PCBs were measured in sediments along pre-defined transects; while fish collected along these transects were examined through gross, histological (blood, liver, kidney, spleen, gonad), and biochemical (EROD) metrics. Dioxins ( $\leq 40\text{pg TCDD-equiv/g dry wt.}$ ) and PCBs ( $\leq 20-10, 600\text{ng tPCB/g dry wt.}$ ) in the near-shore sediments off JI were an order of magnitude or 300-fold greater, respectively, than concentrations in reference sediments collected off another island at the atoll. *Chaetodon auriga*, *Acanthurus triostegus*, *Mulloidichthys flavolineatus*, *Parupeneus multifasciatus*, and *Gymnothorax javanicus* dominated the 233 fish examined. Fish from JI tended to have larger livers, smaller spleens, and a higher incidence and severity of lesions. Gross lesions included: fin erosions and deformities, eye cataracts, epidermal papilloma, head and pigmentation abnormalities. Microscopic lesions in tissues of fish from JI were moderate, yet generally greater in severity and incidence than lesions in fish from the reference site. Anomalies identified included: granulomas, macrophage aggregates, reduced fat/glycogen, inflammation, and necrosis. Micronuclei were up to 3-fold higher in fish from some JI sites. EROD was generally elevated in JI fish, but results were variable due to inter-species differences and numbers of individuals tested. Overall, results of the health assessment indicated that fish collected off JI were in poorer health than those from the reference site.

### EXPOSURE ASSESSMENT IN CONTAMINATED ENVIRONMENTS.

R. A. Lingenfelter<sup>1</sup>, L. Cizmas<sup>1</sup>, Z. Naufal<sup>1</sup>, C. Naspinski<sup>1</sup>, L. He<sup>1</sup>, G. Zhou<sup>1</sup>, T. McDonald<sup>1</sup>, G. Denoux<sup>1</sup>, R. Autenrieth<sup>1</sup>, A. Mekhtiev<sup>3</sup>, A. Islamzadeh<sup>2</sup> and K. Donnelly<sup>1</sup>. <sup>1</sup>*Texas A&M University, College Station, TX*, <sup>2</sup>*Institute of Physiology n.a. A.I. Karaev, Baku, Azerbaijan* and <sup>3</sup>*Sumgayit Centre For Environmental Rehabilitation, Sumgayit, Azerbaijan*.

Humans are frequently exposed to complex mixtures of polycyclic aromatic hydrocarbons and other compounds. These include exposures due to chemically contaminated, or Superfund, sites, as well as exposures to combustion by-products.

Human populations in contact with these chemicals may experience adverse health effects if the exposures are of a sufficient dose and duration. However, limited information is available to understand the relationship between environmental concentrations and absorbed dose. Studies have been conducted at a contaminated and control site in Azerbaijan to investigate the relationship between environmental concentrations and biomarkers of exposure. Data have been collected to measure environmental concentrations, and biomarkers of exposure in human populations. The biomarkers being investigated include blood plasma concentrations of PAHs, and DNA adduct formation in lymphocytes. The results indicate that concentrations of total polycyclic aromatic hydrocarbons (tPAHs) range from 2, 300 ng/m<sup>2</sup> for a window swipe to 40, 400 ng/m<sup>2</sup> for a floor swipe sample. The model carcinogen, benzo(a)pyrene, was detected in house dust at concentrations ranging from 178 ng/m<sup>2</sup> to 483 ng/m<sup>2</sup>. Analysis of human blood plasma of all exposed individuals for PAH residues found mean total PAH levels of 303 ng/ml blood and mean carcinogenic PAH levels of 5.6 ng/ml blood. DNA adducts were significantly higher in the total exposed population than in the total control population. However adducts in lymphocytes from men in the control region were comparable to those in men from the exposed region. Overall, the results indicate there is a correlation between PAHs in environmental samples and PAH adducts in an exposed population.

## 1291 INTEGRATION OF BIOMONITORING DATA INTO THE RISK ASSESSMENT PROCESS.

S. H. Robison<sup>1</sup>, L. Needham<sup>2</sup>, E. Faustman<sup>3</sup>, H. Zenick<sup>4</sup> and L. Sheldon<sup>5</sup>. <sup>1</sup>Procter & Gamble, Cincinnati, OH, <sup>2</sup>CDC, Atlanta, GA, <sup>3</sup>University of Washington, Seattle, WA, <sup>4</sup>NHEERL, USEPA, Research Triangle Park, NC and <sup>5</sup>NERL, USEPA, Research Triangle Park, NC.

Improved biomonitoring (BM) technologies are being used to measure very low levels of environmental chemicals in the tissues of adults, children and developing fetuses. These measurements can show that people have been exposed to chemicals and that these chemicals have been absorbed into the body. However, linkages to exposure on the one hand and linkages to human health on the other are not always clear. The ILSI Biomonitoring workshop explored the process and information needed to put BM information into perspective by associating these data with exposure and potential health outcomes. Key questions associated with the use of BM data were discussed, these included How can BM data be used more widely?, What other data is needed to use BM data in risk assessment?, How might BM data be used inappropriately? Case studies of arsenic, phthalates, perfluorooctane sulfonic acid, polycyclic aromatic hydrocarbons and organophosphates were conducted to evaluate BM data for different classes of chemicals against these questions. The case-studies identified specific scientific issues and developed perspective on broader scientific questions. An overarching need is for the development of consensus criteria similar to the Bradford-Hill criteria that are commonly applied to epidemiology studies for application and interpretation of BM data. In general it was determined that in many cases there is an absence of human toxicokinetic data that are essential when evaluating human exposure relative to animal toxicology data. Furthermore, PBPK and exposure models should be developed along with gaining a clearer understanding of dose metrics are needed. In addition, there is a lack of information on how to identify appropriate biomarkers that reflect low level exposure at or near the threshold for effect. There is also a need to carefully examine the risk assessment paradigm in the context of BM data and to develop a risk communication strategy.

## 1292 A FLEXIBLE APPROACH FOR EVALUATING FIXED RATIO MIXTURES OF FULL AND PARTIAL AGONISTS FOR MIXTURES OF MANY CHEMICALS.

C. Gennings<sup>1,2</sup>, H. Carter<sup>1,2</sup>, R. A. Carchman<sup>2</sup>, M. J. DeVito<sup>3</sup>, J. Simmons<sup>3</sup> and K. M. Crofton<sup>3</sup>. <sup>1</sup>Biostatistics, Virginia Commonwealth University, Richmond, VA, <sup>2</sup>Solveritas, LLC, Richmond, VA and <sup>3</sup>NHEERL, ORD, USEPA, Research Triangle Park, NC.

Detecting interaction in chemical mixtures can be complicated by differences in the shapes of the dose-response curves of the individual components (e.g. mixtures of full and partial agonists with differing response maxima). We present an analysis scheme where flexible single chemical dose-response curves are combined in an 'additivity model' with prediction for the mixture based on a constraint of additivity. Iterative algorithms are used to estimate mean responses for this model at observed mixture combinations using only single chemical parameters. A 'full model' is also fit to the data with additional mixture parameters included. A likelihood-ratio test is used to test the hypothesis of additivity by comparing the full and additivity model predictions in the likelihood functions. When interaction is detected, an interaction threshold model may be estimated along the mixture ray. This model has two components: an implicit additivity region and an explicit part that describes the departure from additivity; the interaction threshold is the boundary between the two regions. The methods are illustrated with resulting data from a study of a mixture of 18 PHAHs in female Long Evans rats exposed by oral gavage for four

consecutive days with serum thyroxine (T4) as the response variable. The mixing ratio was selected based on the ratios found in breast milk, fish and other sources of human exposure. The methods demonstrated three plateau levels for the maximum effects of the single chemicals and allowed for dose threshold effects for each single chemical and the fixed-ratio mixture. The likelihood-ratio test of additivity was rejected due to evidence of greater than additive interaction in the high dose region. Estimation of the interaction threshold within the observed experimental region suggested evidence of additivity in the low dose region. (This abstract does not reflect USEPA policy.)

## 1293 A BAYESIAN NETWORK MODEL TO PREDICT HAZARD POTENCY FOR SKIN SENSITISATION.

D. Jefferies, L. J. Aspinall, R. J. Safford, C. J. Clapp, A. Madrigal, M. Chamberlain and D. A. Baskett. *Safety and Environmental Assurance Centre, Unilever, Bedford, United Kingdom.*

When assessing the skin sensitisation potency of a chemical, a risk assessor is often faced with information from a range of tests and/or predictive models. Under these circumstances the implicit approach is to take a weight of evidence approach, where the value assigned to each piece of evidence depends on its type and quality. In this present work, we have built a Bayesian Belief Network model to make this process explicit. The model provides a framework for assessing the relative contribution of different sources and for quantifying uncertainty, and ultimately facilitates prediction for new substances with limited data. It combines test results from Buehler, Guinea Pig Maximisation (GPMT), Human Repeat Insult Patch (HRIP), Human Maximisation (HMT) and Local Lymph Node (LLNA) tests and also incorporates Quantitative Structure Activity Relationship (QSAR) predictions for sensitisation and penetration. The methodology combines prior knowledge provided by experts, with evidence on the relationships between tests that is learnt from data. The output of the model is a prediction of the concentration that will give sensitisation at a defined level (typically 5% and 1%) in an HRIP, with a measure of uncertainty. The model has been built on a training set of 30 chemicals chosen to cover a range of chemical classes and sensitisation potencies, and then has been tested on a further nine. Initial results are promising; within the training set there is good correlation between model predictions and HRIP estimates from data, and the model predicts well for the additional evaluation set.

## 1294 TOXICITY-RELATED MOLECULAR PARAMETERS CALCULATED FOR ALDEHYDES AND KETONES FOUND IN DIESEL EXHAUST.

P. Martin<sup>1</sup>, R. Garg<sup>2</sup>, M. C. Madden<sup>3</sup> and C. J. Smith<sup>1</sup>. <sup>1</sup>Lorillard Tobacco Co., Greensboro, NC, <sup>2</sup>Chemistry, Clarkson University, Potsdam, NY and <sup>3</sup>USEPA NHEERL, Research Triangle Park, NC.

Quantitative structure activity relationship (QSAR) studies can help elucidate toxicological mechanisms of complex mixtures, e.g., vehicle emissions. Some of the aldehydes and ketones found in vehicle emissions have been identified as irritants, mutagens and carcinogens. Several are listed as Hazardous Air Pollutants regulated by the 1990 Clean Air Act. Environmental sources of these carbonyls are numerous with automobile and truck emissions a major source in outdoor air. Diesel engine exhaust (DE) is a complex mixture of gases, vapors, liquid aerosol and particulate matter. This mixture contains combustion products such as carbon (soot), nitrogen, water, carbon monoxide, nitrogen dioxide, sulfur dioxide, polycyclic aromatic hydrocarbons and aldehydes. Historically, the soot fraction of DE has received the most attention as its compositional fraction can vary from 60%-80% of the total depending on the fuel, engine types and load. More recently, gas and vapor phase constituents, e.g., aldehydes and ketones, have been considered. Toward understanding this complex mixture, 75 DE carbonyls have been identified from the literature. A number of molecular parameters related to biological activity have been calculated for these 75 carbonyls, including calculated base ten logarithm of the octanol-water partition coefficient (Clog P), molecular volume (MgVol), calculated molar refractivity (CMR) and number of valence electrons (NVE). These calculations suggest that DE carbonyls tend to be hydrophobic, with 48 of the 75 compounds (64%) being either hydrophobic or strongly hydrophobic (0.5 < Clog P >2), 8% being weakly hydrophobic (0 < Clog P < 0.5) and only 28% being hydrophilic (Clog P <0). [This abstract may not represent official EPA policy.]

## 1295 THREE-DIMENSIONAL ANATOMICAL RECONSTRUCTION OF THE UPPER RESPIRATORY TRACT OF B6C3F1 MICE.

E. A. Gross<sup>1</sup>, D. R. Joyner<sup>1</sup>, A. M. Jarabek<sup>1,2</sup> and J. S. Kimbell<sup>1</sup>. <sup>1</sup>CIIT Centers for Health Research, Research Triangle Park, NC and <sup>2</sup>National Center for Environmental Assessment, USEPA, Washington, DC.

The influence of the anatomy of the upper respiratory tract (URT) on airflow distribution and ventilation rate is a critical factor determining uptake of inhaled agents and interspecies differences in lesion location. Computational fluid dynamics (CFD) models based on three-dimensional anatomical reconstructions of the

URT have been used in rats, monkeys and humans to improve the accuracy of the descriptions of uptake of inhaled gases and particles for use in risk assessment. Because most bioassays are conducted in both rats and mice and since the mouse serves as the species on which many genomic platforms are based, a CFD model of the URT of the B6C3F1 mouse was undertaken. The methods used to develop the specimens for other CFD models were modified to reduce artifacts and improve the fidelity of the *in vivo* architecture. A male B6C3F1 mouse was killed without exsanguination. The head was fixed for 2 hr in Bouin's fluid rather than formalin to minimize shrinkage. The nasal airways of the specimen were filled with cryo-embedding medium that was saturated with Xerox copy toner to enhance the contrast between the airways and tissue structures and to provide support during sectioning. The head was embedded nose tip down and sectioned in frozen carboxymethylcellulose rather than paraffin to eliminate distortion and facilitate realignment. High quality digital photography was used to capture images of the block face. Images (412 total) were collected at sectioning intervals ranging from 10 to 50 $\mu$ . The three-dimensional image processing software, Mimics (Materialise, Ann Arbor, MI), was used to convert the series of digital photographs to a three-dimensional reconstruction using operator controlled thresholding criteria. This reconstruction will form the basis for a CFD model of airflow and inhaled material transport in the mouse nasal passages and is expected to improve the accuracy of uptake estimates for this important species, facilitating quantitative interspecies comparative risk assessment.

### A PHARMACOKINETIC-PHARMACODYNAMIC MODEL FOR GENE-REGULATED PROSTATE MAINTENANCE: COMPARING THE EFFECTS OF CASTRATION WITH ANTIANDROGEN EXPOSURE IN THE RAT.

**M. G. Zager**<sup>1,2</sup>, **L. K. Potter**<sup>1,2</sup> and **H. A. Barton**<sup>2</sup>. <sup>1</sup>*Toxicology, University of North Carolina, Research Triangle Park, NC* and <sup>2</sup>*ORD, NHEERL, USEPA, Research Triangle Park, NC*.

Antiandrogens affect prostate maintenance in two ways. Androgen antagonists, such as the fungicide vinclozolin, act as competitive ligands for the androgen receptor (AR). Enzyme inhibitors, such as the therapeutic drug Finasteride, inhibit the enzyme 5 $\alpha$ -reductase (5 $\alpha$ R) from metabolizing testosterone (T) to the more potent dihydrotestosterone (DHT). Each mode of action results in decreased DHT levels and hence decreased prostate size. Castration leads to nearly total removal of T and DHT from the body, resulting in acute, significant prostate regression. A model describing the pharmacokinetics (PK) of T, DHT, luteinizing hormone (LH), and antiandrogens was linked to a pharmacodynamic (PD) model describing the androgen-controlled gene regulation of the prostate in the adult male rat. The resulting PK-PD model is able to simulate the prostatic effects of castration and antiandrogen exposure. The model describes the metabolism of T to DHT by 5 $\alpha$ R with feedback loops for the positive regulation of T synthesis by LH and negative regulation of LH by T and DHT. The gene-regulated processes involved in prostate maintenance, including cell proliferation, apoptosis, fluid production, and 5 $\alpha$ R activity, are each controlled in the model by the occupancy of a single gene by androgen-AR dimerized complexes. The model accurately captures the dynamics of the prostate after castration vs. daily doses of Finasteride, compared with experimental data. Daily dosing of Finasteride results in significantly decreased levels of DHT and raised levels of T due to the feedback loop. The result is approximately 60 percent prostate regression after 21 days compared to over 90 percent regression due to castration. This modeling effort provides a framework for extension from the adult to the more sensitive pubertal developmental period by including growth and changes in hormone synthesis and metabolism. (Funded by EPA/UNC Training Agreement CT827206. This abstract does not reflect EPA policy.)

## 1297

### PHYSIOLOGICALLY BASED PHARMACOKINETIC/PHARMACODYNAMIC MODELING FOR THE N-METHYL CARBAMATE PESTICIDE CARBARYL: INSIGHT INTO MECHANISM AND RISK ASSESSMENT.

**J. Wang**<sup>1</sup>, **Y. Tan**<sup>1</sup>, **A. Tobia**<sup>2</sup>, **C. Lunchick**<sup>2</sup>, **M. Krolski**<sup>2</sup> and **R. B. Conolly**<sup>1</sup>. <sup>1</sup>*CIICT Centers for Health Research, Research Triangle Park, NC* and <sup>2</sup>*Bayer CropScience, Research Triangle Park, NC*.

A physiologically based whole body pharmacokinetic/pharmacodynamic (PBPK/PD) model was developed for the N-methyl carbamate pesticide carbaryl (1-naphthyl N-methylcarbamate) as well as its major metabolites naphthol and hydroxylated carbaryl in rats and humans. The model consists of liver, blood, brain, fat, lumped slowly perfused and rapidly perfused compartments, with blood circulation linking the compartments for compound distribution. Intravenous (IV), oral, and dermal exposures as well as fecal and urinary elimination were described. The model simulates inhibition of acetylcholinesterase (AChE) in blood and brain based on tissue dosimetry. Tissue concentration and AChE inhibition data from

Sprague-Dawley rats, as well as fecal and urinary elimination data, were used for model calibration. Model simulations were consistent with experimental data and highlighted that the key pharmacokinetic characteristics of carbaryl are quick absorption, quick metabolism, and quick excretion. In the case of oral gavage, about 85-90% of a dose goes into urine through blood circulation while the half-life of compounds in circulation is less than 0.75 hour. PBPK modeling indicated that whole body pharmacokinetic model has the advantage for such a case in gaining insight to pharmacokinetic reality over those models which only consider concentration-time profiles in blood or specific tissues. The model was scaled up from rats to human toddlers and used to predict AChE inhibition associated with lawn care application of carbaryl. The predicted level of AChE inhibition in toddlers was about 1%, a level that is not clinically detectable. This predicted low level of AChE inhibition reflects its rapid clearance from target tissues and its reversible interaction with AChE.

## 1298

### USE OF EXPOSURE RELATED DOSE ESTIMATING MODEL (ERDEM) FOR ASSESSMENT OF AGGREGATE EXPOSURE OF INFANTS AND CHILDREN TO N-METHYL CARBAMATE INSECTICIDES.

**F. W. Power**<sup>1</sup>, **M. Okino**<sup>1</sup>, **J. B. Knaak**<sup>4</sup>, **R. Tornero-Velez**<sup>2</sup>, **A. Lowit**<sup>3</sup>, **J. N. Blancato**<sup>4</sup> and **C. C. Dary**<sup>1</sup>. <sup>1</sup>*NERL/EDRB, USEPA, Las Vegas, NV*, <sup>2</sup>*NERL, USEPA, Research Triangle Park, NC*, <sup>3</sup>*Office of Pesticide Programs, USEPA, Washington, DC* and <sup>4</sup>*Pharmacology and Toxicology, SUNY, Buffalo, Buffalo, NY*.

A physiologically based pharmacokinetic (PBPK) model was developed within the Exposure Related Dose Estimating Model (ERDEM) framework to investigate selected exposure inputs related to recognized exposure scenarios of infants and children to N-methyl carbamate pesticides as specified under the Food Quality Protection Act (FQPA). Conservative assumptions underlying residential exposure and cumulative risk were examined as inputs for particular exposure scenarios using residential dermal transfer coefficients, ambient air concentrations, and dietary intake. Physiological, pharmacokinetic and pharmacodynamic parameters describing the fate and effects of carbaryl, aldicarb, and propoxur in rats were scaled to establish the model structure for exposure to humans. Adjustments were made for differences in metabolism and physiology between children and adults. Michaelis-Menten kinetics were used to describe metabolism, where the chemical species compete for the catalytic enzymes. Bimolecular rate constants,  $k_i$  (pM-1 hr-1), were used to describe inhibition of acetylcholinesterase by the parent compounds, where the effects are assumed to be additive. The simulation results over a day reveal the effects of residential exposure on cholinesterase activity, and highlight the scenarios and biological pathways where chemical interactions are important. The interactions are a cause for differences in risk between cumulative and single-chemical exposures. Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

## 1299

### SPATIAL/TEMPORAL MODELING OF CYTOCHROME P450-MEDIATED PHOSPHOROTHIONATE INSECTICIDE METABOLISM IN THE RAT LIVER ACINUS.

**J. E. Chambers**<sup>1</sup>, **J. G. Baravik**<sup>1</sup>, **S. C. Burgess**<sup>1</sup>, **D. E. MaryBeth**<sup>1</sup>, **E. C. Meek**<sup>1</sup>, **S. F. Oppenheimer**<sup>2</sup> and **E. B. Shows**<sup>1</sup>. <sup>1</sup>*Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS* and <sup>2</sup>*Department of Mathematics and Statistics, Mississippi State University, Mississippi State, MS*.

In order to be effective anticholinesterases, the phosphorothionate insecticides (e.g., parathion) containing a P=S group, require CYP-mediated bioactivation (desulfuration) to their oxon metabolites which contain a P=O group (e.g., paraoxon). The spatial patterns of parathion desulfuration in the rat liver acinus were investigated by measuring the cellular content of CYP mRNA and performing mathematical modeling of the transport of the insecticide and its metabolite, as well as the rate of formation of the oxon. Adult male rats were treated i.p. with 80 mg/kg phenobarbital (PB) to induce CYP 2B1/2. Laser capture microdissection was used to determine the regional distribution of mRNA for CYP 2B1/2 in livers of control and treated rats. Real time PCR was used to quantify mRNA, and indicated higher levels of CYP 2B1/2 mRNA from the PB treated rats. The levels of CYP-mediated desulfuration were determined in hepatic microsomes by monitoring the amount of paraoxon (the active metabolite) produced by paraoxon's ability to inhibit an exogenous source of acetylcholinesterase. The spatial dimensions of the hepatic sinusoids were determined microscopically. The data were used to create predictive mathematical models for the spatial metabolism of insecticides through the hepatic acinus. The modeling involves partial differential equations using estimates of diffusion rates for the insecticide and its oxon through cell membranes, sinusoidal blood flow rates, P450 content and P450 rates of desulfuration. The desulfuration modeling is the initial model to more realistically predict the spatial/temporal metabolism of phosphorothionates. (Supported by NIH P20 RR 017661)

**1300****BIOTRANS: A NEW TOOL FOR PREDICTING THE METABOLISM OF CHEMICAL MIXTURES.**

A. N. Mayeno, R. S. Yang and B. Reisfeld. *Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Colorado State University, Fort Collins, CO.*

Metabolism of a single xenobiotic may produce one or more reactive species via complex pathways. Metabolism of a mixture of compounds is more complicated, as metabolites shared among the pathways can be formed, as well as species not seen using each constituent chemical alone. Experimental studies of chemical mixtures to determine toxic intermediates and understand the interconnected metabolic pathways can be resource prohibitive; hence, novel, alternative approaches are needed. Here we describe the structure and use of a computer-assisted modeling tool for "predictive metabolomics" that we call BioTRaNS (Biochemical Tool for Reaction Network Simulation). This tool simulates metabolism *in silico* by using "virtual enzymes" (each comprising reaction rules and binding feasibility predictors) and "virtual agents" (that perform non-enzymatic reactions) to mediate the transformation of "virtual molecules". The simulation generates a rich, time-dependent inventory of metabolites interlinked by specific reactions, thus forming a biochemical reaction network. As a test case, we selected a mixture of four VOCs: trichloroethylene, perchloroethylene, methyl chloroform, and chloroform. These VOCs are common groundwater contaminants, and each can exert harmful health effects. Using BioTRaNS to create a system containing a number of Phase I and Phase II virtual enzymes, as well as appropriate virtual agents, we were able to predict the metabolites of the four pollutants, describe their metabolic pathways, and identify metabolites in common and intermediates expected to be unstable or reactive, including epoxides, acid chlorides, ketenes, and radicals. We were also able to predict and highlight species based on mechanism-based rules, such as cytochrome P450 heme-oxo-substrate complexes. Our work represents the first steps in using this technology to describe and understand the interwoven and complex metabolic pathways of chemical mixtures. (This study was supported, in part, by NIEHS grants K25 ES11146 and T32 ES 07321.)

**1301****INTER-INDIVIDUAL VARIABILITY IN BENZENE METABOLITES.**

S. Kim<sup>1</sup>, R. Vermeulen<sup>2</sup>, S. Waidyanatha<sup>1</sup>, Q. Lan<sup>2</sup>, M. T. Smith<sup>3</sup>, G. L. Li<sup>4</sup>, L. Zhang<sup>3</sup>, M. Shen<sup>2</sup>, S. Yin<sup>4</sup>, N. Rothman<sup>2</sup> and S. M. Rappaport<sup>1</sup>. <sup>1</sup>SPH, UNC, Chapel Hill, NC, <sup>2</sup>NCI/NIH/DHHS, Bethesda, MD, <sup>3</sup>SPH, UC, Berkeley, CA and <sup>4</sup>Chinese CDC, Beijing, China. Sponsor: I. Rusyn.

The deleterious effects of benzene exposure are thought to be caused by the production of cytotoxic and genotoxic metabolites. Since metabolism varies among individuals, we investigated interindividual variability in the production of benzene metabolites among 116 workers exposed to benzene in China (mean exposure = 4.8 ppm; 10th-90th percentiles 0.40-10 ppm). Each worker had repeated measurements of both personal airborne exposure to benzene and toluene and urinary benzene metabolites (tt-muconic acid, S-phenylmercapturic acid, phenol, catechol, and hydroquinone), as well as of unmetabolized benzene in urine. We used mixed effects statistical models that incorporated random slope and intercept terms for each worker to evaluate interindividual variability. In this context, the random slope explains the subject-specific relationship between each metabolite (or unmetabolized benzene) and benzene exposure, while the random intercept relates to the background metabolite level for each subject (due to the presence of non-benzene sources of the metabolites, particularly the phenolic compounds). Significant interindividual variability was detected for each benzene metabolite and for unmetabolized benzene in urine. Fixed effects were included in the models to investigate the influence of potential covariates on benzene metabolite levels, notably co-exposure to toluene, lifestyle factors, and smoking. Several of these covariates were significantly associated with the production of benzene metabolites. \* Supported by grant P42ES05948 from NIEHS/NIH.

**1302****USING OBSERVED VARIABILITY AS A CRITERION FOR CELLULAR KINETICS MODELS AFTER FURAN EXPOSURE.**

M. V. Smith<sup>1</sup>, R. R. Maronpot<sup>2</sup>, T. L. Goldsworthy<sup>3</sup>, R. W. Morris<sup>4</sup> and C. J. Portier<sup>5</sup>. <sup>1</sup>Constella Health Sciences, Constella Group, Durham, NC, NC, <sup>2</sup>Experimental Pathology, NIEHS, Research Triangle Park, NC, <sup>3</sup>Integrated Laboratory Systems, Inc., Research Triangle Park, NC, <sup>4</sup>Anesthesiology, Duke University Medical Center, Durham, NC and <sup>5</sup>Computational Biology and Risk Assessment, NIEHS, Research Triangle Park, NC.

Potential carcinogens are frequently examined by investigating their effect on the balance between the replication and apoptosis rates of cells. Observations on cell replication (by BrdU labeling) cover the entire period of BrdU exposure (usually several days), while observations on apoptosis are restricted to the brief period (sev-

eral hours) that apoptotic cells are identifiable; thus the data are difficult to compare directly. Additionally it is difficult to take into account the effect of the experimental treatment on the length of the time interval of apoptotic identifiability. Dynamic models linking cellular replication and apoptosis may be stochastic (linked birth and death models) or statistical (differential equation system with covariance structure determined by the data). The data from a furan exposure experiment (Fransson-Steen, R. et al.(1997)) are re-analyzed to address the above concerns. Four groups of mice were exposed to 4 levels of furan (0, 4, 8 and 15 mg/kg) for 3 weeks. BrdU was supplied for the last 7 days. Using a derived expression for the variability of the fraction of unlabeled cells, the statistical model was found to be more appropriate for this data. Hypothesis tests showed a significant increase in cell replication and apoptotic rates at the highest dose level as well as an increase in the apoptotic duration at the highest 2 dose levels.

**1303****QUANTITATIVE MODELS OF BYSTANDER EFFECTS FROM IONIZING RADIATION IN NON-TARGETED CELLS.**

W. C. Griffith, E. Vigoren and E. Faustman, *University of Washington, Seattle, WA.*

Major revisions of our understanding of the mechanisms of how ionizing radiation causes effects such as cytotoxicity and mutations have occurred in the last decade. This is due to accumulating evidence that these effects, called bystander effects, can occur in cells distant from those being irradiated (see J.B. Little, *Oncogene*, 2003). Observations made in many types of systems suggest these effects are due to secreted factors, although no specific factor has been identified. The secreted factors have been shown to be transmissible through both gap junctions and extra cellular media. Secreted transmissible factors through gap junctions can cause cytotoxicity and mutations, whereas factors in extra cellular appear to only cause cytotoxicity. In this work we integrate many of these observations in quantitative models of the secreted factors to better understand how the secreted factors may operate and how to better extrapolate *in vitro* observations to *in vivo* systems. We examine a number of possible assumptions that are consistent with the observations. One type of model used for gap junctions treats each cell as a separate compartment connected by first order rates in a two dimensional geometry, and within cells the secreted factor is deactivated at a constant rate. Exposure to ionizing radiation is simulated as an initial amount of the factor being deposited in the central compartment. Variations on this model describe the deactivation of the secreted factor as a saturable mechanism. Other types of models describe transmission across cells as involving a variable time delay. These models are extrapolated to three dimensional geometries to describe tissues. The models are shown to potentially provide a method for classifying diverse *in vitro* systems in terms of the rate of transmission of secreted factors, and how to estimate these rates from mutation rates or cytotoxicity fractions. We also suggest the types of experiments that might be performed to distinguish between the types of proposed models. This work was supported by a research grant from the Department of Energy Low-Dose Program.

**1304****A MECHANISTIC MODEL OF LIFETIME CANCER RISK FOR INHALATION EXPOSURES TO REACTIVE GASES.**

J. Kimball<sup>1</sup>, D. L. Kalisak<sup>1</sup>, R. B. Conolly<sup>1</sup>, F. J. Miller<sup>1</sup> and A. M. Jarabek<sup>1,2</sup>.

<sup>1</sup>CIIT Centers for Health Research, Research Triangle Park, NC and <sup>2</sup>National Center for Environmental Assessment, USEPA, Washington, DC.

Quantitative cancer dose-response analyses typically estimate lifetime risk using adult human parameter values (i.e., 70 kg, 70 years, 20 m<sup>3</sup> of air/day). Despite recent regulatory emphasis, children's risk is often relegated to a qualitative discussion of intrahuman variability or use of an uncertainty factor. Mechanistic models of dosimetry and cancer using age-specific parameters can increase the accuracy of lifetime risk estimates. Previously, a clonal growth (CG) model predicted cancer risks from inhaled formaldehyde (HCHO) based in part on estimates of (1) regional HCHO flux to respiratory tissues and (2) numbers of cells at risk. In this model, the number of cells at risk was estimated for the adult and assumed to vary in proportion to age-specific body weight. The CG model used regional HCHO fluxes from adult computational fluid dynamics (CFD) and typical-path models of the nasal passages and lung, respectively, and adult ventilation rates and activity patterns throughout life. Here, age-specific flux predictions and childhood ventilation rates and activity patterns are used to test the hypothesis that these factors affect risk estimates using HCHO as representative reactive gas. Age-specific HCHO fluxes were estimated for the human respiratory tract using a CFD model of HCHO uptake in the nasal passages and a single-path model of HCHO uptake in the lower respiratory tract isotropically scaled to estimates of nasal and lung volumes, respectively, in children aged 3 months and 1, 5, 10, and 15 years. Surface areas for each lung generation and 20 levels of flux in the nasal passages were estimated for each age group and used to calculate age-specific numbers of respiratory cells at risk. These values are input sequentially by age group to the CG model to develop lifetime cancer risk estimates. This information helps determine the importance of incorporating age-specific parameters during childhood in risk estimates for lifetime exposures to inhaled reactive gases.

## PRELIMINARY DEVELOPMENT OF A MECHANISTIC THYROID HORMONE MODEL.

E. A. Merrill<sup>1</sup>, J. M. Gearhart<sup>2</sup>, P. J. Robinson<sup>2</sup>, T. R. Sterner<sup>3</sup> and D. R. Mattie<sup>4</sup>. <sup>1</sup>Geo-Centers, Inc., Wright-Patterson AFB, OH, <sup>2</sup>ManTech, Inc., Wright-Patterson AFB, OH, <sup>3</sup>OpTech, Corp., Dayton, OH and <sup>4</sup>AFRL/HEPB, Wright-Patterson AFB, OH.

An existing model for free iodide (I<sup>-</sup>) kinetics in the adult rat was expanded into a pharmacodynamic thyroid hormone feedback model. Portions of Kohn *et al.*'s model were incorporated to account for processes such as hormone production, storage and secretion in the thyroid, deiodination of thyroxine (T<sub>4</sub>) to triiodothyronine (T<sub>3</sub>) to less active forms, and the feedback mechanisms between free hormone levels, TSH and sodium iodide symporter (NIS) up-regulation and down-regulation. The previously developed iodide model successfully described iodide kinetics and the inhibition of iodide uptake at the thyroid NIS by a competitive inhibitor, perchlorate (ClO<sub>4</sub><sup>-</sup>), but did not predict subsequent blood hormone perturbations. The new model uses first order hormone production rates from the thyroid and M-M kinetics to describe deiodination of T<sub>4</sub> by Type I deiodinase in the kidney and liver, Type II T<sub>4</sub> 5'deiodinase in other lumped tissues, and T<sub>3</sub> deiodination by Type III deiodinase and its inhibition by free T<sub>4</sub>. Transport of thyroid hormones bound to thyroxin-binding prealbumin and albumin are described as flow limited. While the preliminary model structure and parameters established here are intended to describe normal thyroid conditions and early upregulation, future modifications of parameter values may allow hormone predictions based on a disrupted thyroid status. Ultimately, the improved rat model may be extrapolated to a human PBPD model and validated against published human data.

## BIOLOGICALLY-BASED MODELING OF THE SPONTANEOUS TRANSFORMATION OF HUMAN KERATINOCTYES, RHEK-1.

E. E. Perrigo, O. Lohitnavy, J. A. Campain, B. Reisfeld and R. Yang. *Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO.*

Neoplastic transformation of an immortalized human keratinocyte cell line, RHEK-1, by various carcinogens and chemical mixtures has been investigated in our laboratory and elsewhere. This human cell line, though useful for studying multi-stage carcinogenesis, exhibits certain tendency for spontaneous transformation, particularly after multiple passages. In the present study, computational models of cellular growth and the step-wise process of spontaneous malignant transformation are developed for the RHEK-1 cell line. Cellular growth and time-course acquisition of transformation-associated characteristics such as anchorage independent growth (AIG) in methylcellulose and tumor formation in immunocompromised mice were incorporated in the model. Normal cell growth is described logically with a carrying capacity estimated by saturation density analysis. Conceptually, three compartments are included in the transformation model: normal RHEK-1 cells which can die, divide, or mutate, AIG positive cells which can die, divide, or further mutate, and finally, malignant cells capable of forming tumors in nude mice. Distinct division and death rates, estimated from experimental data, are used for cells in each compartment. Furthermore, cell growth and cell death is assumed to be deterministic, while mutation is assumed to be a stochastic process. Accurate model simulations of RHEK-1 cells under negative control experimental conditions formulate a basis for chemically-induced neoplastic transformation. Thus, further development includes the integration of extensive time-course cell and molecular biology data from chemically treated keratinocytes to establish the carcinogenic potential of chemicals (polycyclic aromatic hydrocarbons) and chemical mixtures (marine diesel fuel and Jet A). (This study is supported, in part, by ATSDR Cooperative Agreement #U61/ATU881475 and NIEHS Training Grant 1 T32 ES 07321).

## EVALUATION OF MOUSE MODELS FOR ASSESSING THE ALLERGENIC POTENTIAL OF PROTEINS.

K. Thomas<sup>1</sup>, C. Herouet<sup>2</sup>, G. Bannon<sup>3</sup>, G. Ladics<sup>4</sup>, S. MacIntosh<sup>5</sup>, L. Privalle<sup>6</sup> and M. Woolhiser<sup>7</sup>. <sup>1</sup>ILSI Health and Environmental Sciences Institute, Washington, DC, <sup>2</sup>Bayer CropScience, Sophia Antipolis, France, <sup>3</sup>Monsanto, St. Louis, MO, <sup>4</sup>DuPont Company, Newark, DE, <sup>5</sup>Bayer BioScience, Research Triangle Park, NC, <sup>6</sup>BASF, Research Triangle Park, NC and <sup>7</sup>The Dow Chemical Company, Midland, MI.

Animal models may prove useful in evaluating the allergenic potential of novel proteins in the context of biotechnology. However, no standardized and validated model currently exists. The objective was to evaluate the utility of mouse models to differentiate between allergens and putative non-allergens. Human allergenic proteins (peanut Ara h 1 and Ara h 2, cows' milk  $\beta$ -lactoglobulin [B-LG]) and putative non-allergenic proteins (spinach RUBISCO and soy lipoxygenase [SLG]) were pu-

rified to > 90%. Each of four labs used the intraperitoneal (ip) route of exposure with the BALB/c, BDF-1, C3H/HeJ, A/J, or C57/Bl6 strains. Other variables included the presence or absence of adjuvant, the number and time between ip injections, protein doses, and the use of homologous or heterologous PCA to assess IgE. One lab also evaluated clinical signs. All labs demonstrated significant PCA responses to RUBISCO in the absence of adjuvant. In two labs, purified Ara h 2 provided poor IgE PCA titers, and the relative response via PCA to RUBISCO was significantly greater than Ara h 2. In another lab, a much higher clinical score was seen with SLG than B-LG. The nature and magnitude of the responses varied between different mouse strains. In general, it was not possible to differentiate between the allergens and putative non-allergens in any lab using the strains and endpoints evaluated. The presence of endotoxin contamination in the putative non-allergenic proteins may, in part, explain the relatively large PCA responses observed with the putative non-allergenic proteins. In conclusion, no ip mouse model evaluated could differentiate between the purified allergens and putative non-allergens. In conclusion, further work will be necessary before mouse models could be utilized to evaluate the potential allergenicity of proteins.

## VALIDATION OF FUMONISIN BIOMARKERS IN F344 RATS.

Q. Cai<sup>1,2</sup>, H. Guan<sup>1,2</sup>, L. Tang<sup>1,2</sup>, H. Luo<sup>1,2</sup>, M. Billam<sup>1,2</sup>, Z. Wang<sup>1,2</sup>, Y. Tang<sup>1,2</sup> and J. Wang<sup>1,2</sup>. <sup>1</sup>Environmental Toxicology, Texas Tech University, Lubbock, TX and <sup>2</sup>The Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX.

Fumonisins are ubiquitous contaminants of cereal grains around the world. Fumonisin B1 (FB1) is a carcinogen and a strong tumor promoter in animal models. Dietary exposure to FB1 has etiologically been linked to human neural tube defect and elevated esophageal and liver cancers in certain areas of the world. Disruption of sphingolipids metabolism and metabolites of sphingolipids, especially ratio of sphinganine (Sa) and sphingosine (So) have been proposed as potential biomarkers for FB1 exposure. To validate FB1 biomarkers for studying human diseases risks, male F344 rats were administrated p.o. with either a single-dose of 0, 10, and 25 mg FB1/kg body weight (b.w.), or multiple-doses of 0, 1.0 or 2.5 mg FB1/kg /day b.w. for 5 weeks. The time course of FB1 induced metabolic alteration of sphingolipids was assessed in serum and urine samples collected from the treated rats at different time interval by a robust HPLC-fluorescence detection with D-erythrosphingosine (C20) as the internal standard. In the single-dose study, urinary Sa/So ratio reaches the maximum in day 8 (30.11 ± 19.40) for 25 mg FB1/kg group and in day 6 (11.48 ± 6.54) for 10 mg FB1/kg group, whereas serum Sa/So ratio shows a similar pattern for the two treatment groups and reaches the maximum around day 3 with the Sa/So ratio of 0.79 ± 0.01 for 10 mg/kg and 1.02 ± 0.05 for 25 mg/kg, respectively. In the multiple-doses study, serum and urinary Sa/So ratio reach the maximum more gradually, and kept at that level more lastingly than those observed in the single-dose study. The dose-response relationship between treatment of FB1 and FB1 metabolites in feces and Sa/So ratio in urine and serum was further examined. (Supported by the NIH grant CA94683)

## SHORT-TERM SAFETY EVALUATION OF NOVASIL IN HUMANS.

J. Wang<sup>1,2</sup>, T. Goldston<sup>3</sup>, H. Luo<sup>1,2</sup>, M. Billam<sup>1,2</sup>, Z. Wang<sup>1,2</sup>, H. Guan<sup>1,2</sup>, L. Tang<sup>1,2</sup>, E. Afriyie-Gyawu<sup>4</sup>, C. Lovett<sup>3</sup>, J. Griswold<sup>3</sup>, B. Brattin<sup>4</sup>, H. J. Huebner<sup>4</sup> and T. D. Phillips<sup>4</sup>. <sup>1</sup>Environmental Toxicology, Texas Tech University, Lubbock, TX, <sup>2</sup>The Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX, <sup>3</sup>Division of Clinical Research, TTUHSC, Lubbock, TX and <sup>4</sup>College of Veterinary Medicine, Texas A&M University, College Station, TX.

Novasil clay (NS) provides significant protection from the adverse effects of aflatoxins (AFs) in multiple animal species by decreasing bioavailability from the GI tract. It is postulated that NS clay can be safely added to human diets to diminish exposure and health risks from AF contaminated food. To determine the safety and tolerance of NS in humans and establish dosimetry protocols for long-term efficacy studies, a randomized and double-blinded phase I clinical trial was conducted. Volunteers (20 - 45 yr in age), were clinically screened for confirmation of their health status. Fifty subjects (23 males and 27 females) were randomly divided into two groups: the low-dose group received 6 capsules containing 1.5 g/day, and the high-dose group received 6 capsules containing 3.0 g/day for a period of 2 wk. NS capsules were manufactured in same color and size and were distributed to each participant 3 times a day at designated sites, where follow-up was taken to record any side effects and complaints. Blood and urine samples were collected before and after the study for laboratory analysis. All participants completed the trial and compliance was 99.1%. Mild GI effects were reported in some participants. Symptoms

included abdominal pain (6%, 3/50), bloating (4%, 2/50), constipation (2%, 1/50), diarrhea (2%, 1/50), and flatulence (8%, 4/50). No statistical significance was found between the two groups for these adverse effects ( $P>0.25$ ). No significant differences were shown in hematology, liver and kidney function, electrolytes, vitamin A & E, and minerals in either group. These results demonstrate relative safety of NS clay in human subjects and will serve as a basis for long-term human trials in populations at high risk for aflatoxicosis (Supported by USAID LAG-G-00-96-90013-00).

#### COMPARISON OF FORMALIN FIXED AND FROZEN TISSUES FOR SPHINGANINE AND SPHINGOSINE DETERMINATION FOLLOWING FUMONISIN B<sub>1</sub> EXPOSURE IN SWINE.

W. M. Haschek<sup>1</sup>, S. Hsiao<sup>1</sup>, M. E. Tumbleson<sup>2</sup>, G. Tyagi<sup>1</sup> and P. D. Constable<sup>3</sup>. <sup>1</sup>*Veterinary Pathobiology, University of Illinois at Urbana-Champaign, Urbana, IL*, <sup>2</sup>*Agricultural and Biological Engineering, University of Illinois at Urbana-Champaign, Urbana, IL* and <sup>3</sup>*Veterinary Clinical Medicine, University of Illinois at Urbana-Champaign, Urbana, IL*.

Fumonisin B<sub>1</sub> (FB1), a mycotoxin produced by *Fusarium verticillioides*, is a contaminant of corn and causes lethal pulmonary edema in swine and leukoencephalomalacia in horses. Since FB1 inhibits sphingolipid metabolism, sphinganine (Sa) and sphingosine (So) can be used as biomarkers of exposure. Serum and fresh tissues (stored at -80°C) are used experimentally to determine Sa and So concentrations following FB1 exposure. However, formalin fixed tissues are more routinely available for diagnostic purposes and would provide multipurpose, low cost, long term preservation for research studies. To determine whether formalin fixed tissues could be used, we quantified Sa and So concentration by reverse-phase high-performance liquid chromatography (HPLC) in kidney, liver, and lung obtained 3 months previously from FB1-treated and control pigs, and compared the results for fresh frozen and formalin fixed tissues. Formalin fixed tissues had lower Sa and So than the corresponding fresh frozen tissues. The Sa:So ratio in formalin fixed tissues was higher because the loss for So was greater than for Sa. The correlation coefficients between fresh frozen and formalin fixed tissues was high ( $>0.95$ ). These results indicate that formalin fixed liver, kidney and lung can be used to determine alterations in Sa and So concentrations, with the Sa:So ratio being the most useful. This information should allow retrospective determination of FB1 as a cause of toxicity in spontaneous diseases. Supported by C-FAR (02E-082-4VR) and the International Life Sciences Institute.

#### INFLUENCE OF THE SOY ISOFLAVONES GENISTEIN AND DAIDZEIN ON THE EXPRESSION OF 17 $\beta$ -ESTRADIOL-METABOLIZING ENZYMES IN CULTURED MCF-7 BUS127 CELLS.

L. Lehmann, L. Jiang, E. W. Lerch and M. Metzler. *Institute of Food Chemistry and Toxicology, University of Karlsruhe, Karlsruhe, Germany*.

The activation of 17 $\beta$ -estradiol (E2) to the catechol estrogens 2-hydroxyestradiol (2-HO-E2) and 4-hydroxyestradiol (4-HO-E2) constitutes an important risk factor in hormonal carcinogenesis. 4-HO-E2 exhibits a stronger genotoxic potential than 2-HO-E2. In human breast tissue, 2-HO-E2 is mainly formed by cytochrome P450 (CYP) 1A1, and 4-HO-E2 is formed by CYP1B1. The catechol estrogens are detoxified by catechol-O-methyltransferase (COMT). Since genistein (GEN) und daidzein (DAI) are believed to exhibit a protective function on hormonal carcinogenesis, we examined the influence of E2, GEN und DAI alone and in combination on the expression of COMT, CYP1A1, and CYP1B1 in cultured MCF-7 BUS127 cells by reverse transcription/competitive polymerase chain reaction. CYP1A1 enzyme activity was determined by measurement of the conversion of ethoxresorufin to the fluorescent dye resorufin. In addition, estrogen-induced cell proliferation was determined by means of the E-screen. E2, GEN, and DAI inhibited the expression of COMT. The maximal effect (reduction by 70% of the original relative mRNA level) was obtained with 100 pM E2, 1 microM GEN, and 1 microM DAI, respectively. The same concentrations also induced the most pronounced cell proliferation in the E-screen. The effects of E2, GEN und DAI were additive up to the maximal effect and could be suppressed by the estrogen receptor antagonist ICI 182, 780. The expression of CYP1B1 was only slightly modulated by E2 and the isoflavones, whereas the expression of CYP1A1 was inhibited by both E2 and the soy isoflavones. CYP1A1 mRNA levels correlated with enzyme activity. These studies indicate that GEN und DAI stimulate the formation of the more genotoxic catechol metabolite of E2 but inhibit the detoxification of both catechol metabolites in estrogen-responsive tumor cells. Supported by Deutsche Forschungsgemeinschaft (Grant Me 574/21-1).

#### MODIFIED METHOD FOR EXTRACTION AND HPLC ANALYSIS OF SPHINGANINE AND SPHINGOSINE FROM BODY FLUIDS, CELLS AND TISSUES.

M. E. Tumbleson<sup>1</sup>, S. Hsiao<sup>2,3</sup>, G. L. Bargren<sup>3</sup>, P. D. Constable<sup>4</sup> and W. M. Haschek<sup>2,3</sup>. <sup>1</sup>*Agricultural and Biological Engineering, University of Illinois at Urbana-Champaign, Urbana, IL*, <sup>2</sup>*Veterinary Pathobiology, University of Illinois at Urbana-Champaign, Urbana, IL*, <sup>3</sup>*Veterinary Diagnostic Laboratory, University of Illinois at Urbana-Champaign, Urbana, IL* and <sup>4</sup>*Veterinary Clinical Medicine, University of Illinois at Urbana-Champaign, Urbana, IL*.

Free sphinganine (Sa) and sphingosine (So) are important biomarkers for fumonisin B<sub>1</sub> exposure. The method for analyzing tissue Sa and So levels was developed by Merrill et al., 1988 (*Anal Biochem* 171:373). Yoo et al., 1996 (*Toxicol in Vitro* 10:77), proposed a more economical method with simplified steps and improved recoveries, as well as allowing the entire extraction to be performed in 1.5 mL microcentrifuge tubes. This method worked well for cells and rodent kidney, but was not recommended for rodent liver and tissues from other species. Norred et al., 1996 (*Toxicol in Vitro* 10:349), proposed dual cycles of extraction for rat liver and kidney. In this study, we reevaluated the methods developed by Yoo and Norred for analyzing Sa and So in a variety of body fluids, cells and tissues. Using Yoo's extraction protocol and modified HPLC conditions, we successfully quantified Sa and So in cells (HepG2 hepatocytes, PK15 renal cells, A10 smooth muscle cells, H9C2[2-1] cardiomyocytes), serum and urine from pigs and calves, as well as fresh frozen swine tissues (liver, kidney, lung and heart). The modified method also worked well for formalin fixed swine liver, kidney and lung but not heart, due to unexplained peaks in the chromatogram interfering with interpretation of Sa and So. Modifications in HPLC conditions included a lower % of potassium phosphate buffer in the mobile phase (8%), a lower flow rate (1 mL/min) and a lower excitation wavelength (230 nm). Norred's method did not work well for our samples. Our modified method provides a relatively rapid and economical method for quantifying Sa and So in a variety of body fluids, cells and tissues. Supported by International Life Sciences Institute.

### 1313

#### EFFECT OF AFLATOXIN B1 ON DRY GRIND ETHANOL PROCESS.

G. S. Murthy<sup>1</sup>, D. E. Townsend<sup>1</sup>, G. L. Meerdink<sup>2</sup>, G. L. Bargren<sup>2</sup>, M. E. Tumbleson<sup>1,2</sup> and V. Singh<sup>1</sup>. <sup>1</sup>*Agricultural and Biological Engineering, University of Illinois at Urbana-Champaign, Urbana, IL* and <sup>2</sup>*Veterinary Diagnostic Laboratory, University of Illinois at Urbana-Champaign, Urbana, IL*. Sponsor: W. Haschek.

Aflatoxins, like all mycotoxins, are toxic fungal metabolites which can have adverse health effects on animals and human beings. Aflatoxins are a major concern for the dry grind corn processing industry as it is believed that aflatoxins affect yeast and reduce its efficacy in producing ethanol. In the present study, aflatoxin B1 (100, 200, 350 or 775 ppb) was added to mycotoxin free (aflatoxin B1, B2, G1, G2; fumonisin B1, B2; ochratoxin A, zearalenone and deoxynivalenol) corn and laboratory scale fermentations were conducted. Fermentation, using *Saccharomyces cerevisiae*, was carried out at 30°C for 72 hr with continuous agitation. Mean ethanol concentrations in the fermenter ranged from 14.01 to 14.51 % (v/v) at 60 hr for all treatments. No effect of aflatoxin B1 was observed on fermentation rates or on final ethanol concentrations. In the dry grind ethanol process, 55% of aflatoxin B1 was detected in wet grains and 45% in thin stillage (supernatant). Aflatoxin B1, up to 775 ppb, had no effect on ethanol.

### 1314

#### SERUM AND URINE SPHINGANINE ARE USEFUL BIOMARKERS OF FUMONISIN B<sub>1</sub> EXPOSURE IN SWINE DUE TO SLOW SYSTEMIC CLEARANCE.

G. Tyagi<sup>1</sup>, S. Hsiao<sup>1</sup>, J. L. Marlatt<sup>2</sup>, M. E. Tumbleson<sup>3</sup>, P. D. Constable<sup>2</sup>, R. M. Eppley<sup>4</sup> and W. M. Haschek<sup>1</sup>. <sup>1</sup>*Veterinary Pathobiology, University of Illinois at Urbana-Champaign, Urbana, IL*, <sup>2</sup>*Veterinary Clinical Medicine, University of Illinois at Urbana-Champaign, Urbana, IL*, <sup>3</sup>*Agricultural and Biological Engineering, University of Illinois at Urbana-Champaign, Urbana, IL* and <sup>4</sup>*CFSAN, USFDA, Laurel, MD*.

We have shown that fumonisin B<sub>1</sub> (FB1) toxicity in swine manifests as cardiogenic pulmonary edema. The mechanism of FB1 toxicity is believed to be inhibition of sphingolipid metabolism, resulting in altered sphinganine (Sa) and sphingosine (So) concentrations. In swine, alterations in Sa and So are found in serum and urine, as well as tissues such as heart, liver, lung and kidney. This study characterized the clearance of Sa and So from blood and urine in pigs in order to determine the usefulness of Sa and So as biomarkers of FB1 exposure. Male castrated pigs (15 kg body wt) were given 1 mg FB1/kg or saline (controls) IV at 0, 24, and 48 hr. Blood and urine were collected from FB1 pigs (n = 4 to 8) and from controls (n = 4) over 144 hr. The serum and urine Sa concentration as well as the serum Sa:So ratio increased in FB1 treated pigs, peaking at 96 hr in serum and 120 hr in urine.

Sa and So concentrations decreased after this time but were still elevated at 144 hr in both serum and urine. The serum and urine So concentrations were also increased, though to a much lesser extent. These results indicate that intracellular sphingolipids continued to be released following termination of FB1 exposure. Therefore, serum and urine Sa and the Sa:So ratio are useful biomarkers of recent FB1 exposure. *Supported by International Life Sciences Institute.*

**1315**

CLINOPATHOLOGY AND TISSUE SPHINGOLIPID CLEARANCE AFTER FUMONISIN B<sub>1</sub> EXPOSURE OF SWINE.

J. L. Marlatt<sup>1</sup>, G. Tyagi<sup>2</sup>, S. Hsiao<sup>2</sup>, M. E. Tumbleson<sup>3</sup>, R. M. Eppley<sup>4</sup>, P. D. Constable<sup>1</sup> and W. M. Haschek<sup>2</sup>. <sup>1</sup>*Veterinary Clinical Medicine, University of Illinois at Urbana-Champaign, Urbana, IL*, <sup>2</sup>*Veterinary Pathobiology, University of Illinois at Urbana-Champaign, Urbana, IL*, <sup>3</sup>*Agricultural and Biological Engineering, University of Illinois at Urbana-Champaign, Urbana, IL* and <sup>4</sup>*CFSAN, USFDA, Laurel, MD.*

Fumonisin B<sub>1</sub> (FB1) inhibits sphingolipid metabolism which is believed to be the mechanism of FB1 toxicity. In pigs, we have shown that FB1 causes cardiotoxicity that results in pulmonary edema and increases sphinganine (Sa) and, often, sphingosine (So) concentrations in serum and urine, as well as heart, liver, lung and kidney. Therefore, Sa and So are considered biomarkers of FB1 exposure. This study characterized the clinopathology and tissue sphingolipid clearance in pigs after FB1 exposure to determine the usefulness of tissue Sa and So as biomarkers. Male castrated pigs (15 kg body wt) were given 1 mg FB1/kg or saline (controls) IV at 0, 24, and 48 hr. FB1 pigs were euthanized at 72 (Group A, n = 4) or 144 hr (Group B n = 4), and controls (Group C, n = 4) at 144 hr. Liver specific serum biochemistry and urinalysis (creatinine, protein and specific gravity) were determined at 0, 72 and 144 hr, and were not significantly different from controls though the values in the FB1 groups were often higher. Two FB1 treated pigs developed respiratory distress with one dying due to pulmonary edema. The Sa and So concentrations and Sa:So ratio in liver, kidney, lung and heart from Groups A and B pigs were significantly increased compared to controls ( $p < 0.05$ ), but there was no difference in values in treated pigs at 72 and 144 hr. These results suggest that accumulated intracellular sphingolipids do not rapidly leave the cell and/or that sphingolipid metabolism continues to be inhibited after cessation of FB1 treatment. Therefore, tissue Sa and So concentration are a useful biomarker for recent FB1 exposure. *Supported by International Life Sciences Institute.*

**1316**

SENSITIVE SCREENING BIOASSAY FOR DEOXYNIVALENOL DETECTION IN FOOD SAMPLES.

C. A. Landgren and S. Hendrich. *Food Science and Human Nutrition, Iowa State University, Ames, IA.*

A bioassay was used to screen for deoxynivalenol (DON) in the range of common contamination in a variety of food samples. Six corn and five wheat foods were acquired from local commercial sources and one naturally contaminated wheat (research) sample was tested. Parallel samples were prepared from extraction of 25 g food samples with acetonitrile: water (84:16), cleanup with an alumina: charcoal SPE column, and evaporation under nitrogen over warm water. One aliquot of each sample was dissolved in complete RPMI-1640 media supplemented with 0.03% ethanol and 1.7% DMSO. Samples were plated to 96-well low-evaporation plates in triplicate and serially diluted 1:1. DON standard controls and blanks were included on each plate. Human K-562 erythroleukemia cells were added at a density of  $2.5 \times 10^4$  cells/well. Plates were incubated for 48 hours at 37° C, 5% CO<sub>2</sub>. Cell proliferation was assessed by the MTS dye reduction assay. A second aliquot of each sample was dissolved in 20% aqueous methanol for HPLC/UV analysis of DON. 3-Acetyl DON and 15-Acetyl DON were not detected in any samples. The experiment was replicated three times. DON was detected in one corn and two wheat samples by both methods. The positive corn sample had DON levels of 368 and 464 ng/g food; the commercial positive wheat sample had 255 and 152 ng/g food; the research wheat sample had DON levels 3893 and 2735 ng/g for HPLC and bioassay methods respectively. The IC50 for DON was 389 ng/ml media and samples negative for DON by HPLC had bioassay responses as percent of controls  $\geq 85\%$ . The correlation between the two methods was 0.87 for the DON-contaminated samples. This sensitive bioassay detected DON in a variety of food matrixes within the range of contamination that could be present in the human food supply.

**1317**

INTEGRATION OF FDA DATABASES TO DEVELOP METHODOLOGIES FOR PREDICTIVE TOXICOLOGY.

M. Cheeseman and M. Twaroski. *CFSAN/OFAS, USFDA, College Park, MD.*

Chemically induced toxicity continues to be one of the major concerns of pharmaceutical, agricultural, and other chemical industries. Toxicology disciplines relevant in these industries are extremely diverse, involving mammalian, environmental, and

ecological systems. Many of these endpoints required by regulatory agencies at FDA and EPA involve costly and lengthy animal testing. These long term studies may, for example, utilize as many as 160 rodents or 32 dogs. The valuable information can be used to: 1) build predictive models based on structure activity relationships; 2) reduce the time required for evaluations; 3) reduce the number of animal studies. In this regard, USFDA has been actively collaborating with the public toxicity database standardization effort, ToxML, to create a set of controlled vocabulary to represent toxicity data. Using the templates based on RedBook, groups in FDA initiated construction of endpoint-specific databases according to the ToxML standard. These databases will greatly assist our reviewers in their evaluations. In addition, non-proprietary portions will be made available so that high quality data from FDA can contribute to the success of predictive toxicology.

**1318**

MATERNAL EXPOSURE TO GENISTEIN DURING PREGNANCY SUPPRESSIVELY EFFECTS ON TUMOR INITIATION INDUCED BY 7, 12-DIMETHYLBENZ[A]ANTHRACENE IN STEROIDOGENIC ORGANS OF F1 OFFSPRING.

J. Watanabe, H. Okamoto, M. Satoh and H. Nagase. *Department of Hygienics, Gifu Pharmaceutical University, Gifu City, Gifu, Japan.*

Recently, much attention has been focused on the protective effects of isoflavones against tumor. However, little is known about an indirect effect of isoflavones on the F1 offspring via maternal exposure during pregnancy. In this study, we examined whether maternal exposure to genistein, a soy isoflavone, during pregnancy was effective to prevent tumor initiation induced by 7, 12-dimethylbenz[a]anthracene (DMBA) on the reproductive organs of the F1 offspring. Twenty-five pregnant ICR mice were used. Genistein dissolved in corn oil (0.1, 1 and 10 mg/kg/day) was subcutaneously injected every day from gestation day 14 to day of birth. On 8 weeks old of the F1 offspring, DMBA (100 mg/kg, i.p.) was injected and after 16 hours of the injection, testis, prostate, ovary and uterus were removed from the F1 offspring, and subjected to single-cell gel electrophoresis assay to examine indirect suppressive effect of genistein on the tumor initiation induced by DMBA. There was no significant difference in the organ weight between control and genistein-treated groups. DNA damage was clearly shown in all of the reproductive organs in non-genistein treated group. In genistein treated group, no suppressive effect for DNA damage was found in prostate and uterus, however, significant suppressive effect was observed in testis and ovary. Generation of fetal reproductive organs has been known to begin gestation day 14 in mice, suggesting a possibility that fatal testis and ovary, which are steroidogenic organs, are affected by genistein under maternal exposure in this study. Since cytochrome P450 (CYP) 1B1 is constitutively expressed in steroidogenic organs and induced by polycyclic aromatic hydrocarbons such as DMBA, induction of CYP1B1 may be suppressed by genistein. To elucidate the underlying mechanism, we further examined induction of CYP1B1 mRNA by semi-quantitative RT-PCR and quantified serum estrogen level. We discuss this possibility based on these results.

**1319**

EFFECTS OF N-6 AND N-3 POLYUNSATURATED FATTY ACIDS ON COLORECTAL CARCINOGENESIS.

G. Alink<sup>1</sup>, B. Ommen<sup>2</sup> and Y. Domnels<sup>1,2</sup>. <sup>1</sup>*Wageningen University, Wageningen, Netherlands* and <sup>2</sup>*TNO, Zeist, Netherlands.* Sponsor: P. van Bladeren.

*In vivo* studies have demonstrated that high fat fish oil (HFFO) diets with high levels of n-3 polyunsaturated fatty acids (PUFAs) can inhibit the formation of chemically-induced colon tumors compared to high fat corn oil (HFCO) diets which are rich in n-6 PUFAs. Our studies show that HFFO diets also protect against the initiation of aberrant crypt foci in F344 rats compared to HFCO diets. Furthermore eicosapentaenoic acid (EPA) also inhibited the proliferation of human colon adenocarcinoma Caco-2 cells compared to linoleic acid (LA). The mechanism responsible for the inhibitory effects of n-3 PUFAs on colorectal tumors may partly be related to inhibition of PGE<sub>2</sub> synthesis from arachidonic acid (AA). Plasma levels of PGE<sub>2</sub> were indeed lower in HFFO fed rats compared to HFCO fed rats. However, reductions in PGE<sub>2</sub> synthesis by EPA compared to AA in Caco-2 cells did not lead to differential effects on cell proliferation, which suggests that PGE<sub>2</sub> is not directly involved in regulation of cell proliferation in colon cancer cells by n-6 and n-3 PUFAs. Our results suggest that lipid peroxidation-induced oxidative stress might be an important mechanism by which n-3 PUFAs possess anticarcinogenic effects. This is supported by the fact that HFFO diets with a high amount of EPA increased the amount of lipid peroxidation in F344 rats compared to HFCO diets with a high amount of LA. Levels of malondialdehyde, which is an end product of lipid peroxidation were also increased after incubation of Caco-2 cells with EPA. Furthermore, transcription of genes involved in oxidative stress is increased in HFFO fed rats, whereas addition of antioxidants diminishes the anticancer effects of n-3 PUFAs in Caco-2 cells, which also suggests that oxidation of n-3 PUFAs underlies their anticancer effects. Overall, the results might imply that n-3 PUFAs

protect against colon carcinogenesis via increased oxidative stress that ultimately leads to inhibition of cell proliferation. Diets enriched with high levels of n-3 PUFAs may thus have beneficial colon cancer inhibiting effects, which may be reduced by high levels of dietary antioxidants

## 1320 BIOMARKERS OF OXIDATIVE STRESS: NEW PROSPECTS AND APPROACHES.

**D. C. Liebler.** *Department of Biochemistry, Vanderbilt University School of Medicine, Nashville, TN.*

Oxidative stress plays a key role in the development of cardiovascular disease, neurodegenerative diseases, and cancer. Many toxic chemicals associated with increased risk of these diseases also induce oxidative stress. Assessment of oxidative stress in clinical studies has been hampered by a dearth of robust, sensitive, and well-validated biomarkers. This symposium will address new opportunities to develop oxidative stress biomarkers for application to human clinical studies. Dr. Maria Kadiiska (NIEHS) will discuss the Biomarkers of Oxidative Stress Study (BOSS), which evaluated several different noninvasive or minimally invasive chemical markers of carbon tetrachloride- or ozone-induced oxidative stress in rats. Dr. Stanley Hazen (Cleveland Clinic Foundation) will describe the development and validation of multiplexed LC-MS-MS assays for specific lipid and protein oxidation products in human serum and the application of these markers to assess oxidative stress endpoints as risk factors for cardiovascular disease. Dr. Ian Blair (University of Pennsylvania) will present recent developments in the identification and LC-MS-MS-based analysis of products of oxidative DNA damage and DNA adducts derived from electrophilic lipid oxidation products. Dr. Lawrence Marnett (Vanderbilt University) will discuss recent findings that DNA adducts derived from electrophilic products of lipid oxidation undergo metabolism to a series of products that can be analyzed as potential urinary biomarkers of oxidative stress. Dr. Daniel Liebler (Vanderbilt University) will discuss the identification of albumin adducts formed by reactive products of lipid oxidation and the potential application of these adducts as serum biomarkers of oxidative stress *in vivo*.

## 1321 PRODUCTS OF OXIDATION AS MEASURABLE INDICATORS OF OXIDATIVE STRESS: VALIDATION OF BIOMARKERS FROM RODENT CCL4 AND OZONE EXPOSURE.

**M. Kadiiska.** *Environmental Toxicology Program, National Institute of Environmental Health Sciences, Research Triangle Park, NC.* Sponsor: D. Liebler.

Oxidation products of lipids, proteins and DNA in plasma and urine of rats were measured as part of a comprehensive, multilaboratory validation study searching for non-invasive biomarkers of oxidative stress. The goal of the study was to find the most sensitive, selective and specific markers of oxidative stress that are applicable to different oxidative insults and stored specimens. Investigators from 24 labs worldwide are participating in this study. The focus of this presentation will be on the findings from measurement of oxidative stress in experimental animal models of CCl<sub>4</sub> poisoning and ozone exposure. The time and dose-dependent effects of CCl<sub>4</sub> and ozone exposure on concentrations of lipid hydroperoxides, TBARS, malondialdehyde (MDA) and isoprostanes were investigated with different techniques. In addition, measures of oxidation products of proteins (protein carbonyls, methionine sulfoxidation, tyrosine oxidation products) and DNA (strand breaks, 8-OHdG, M1G) were carried out as well. The pattern of oxidative stress biomarkers seen in these two exposures will offer insight into the specificity and sensitivity of the markers and will provide evidence that a given product of oxidation may be a marker for some type of oxidative stress but not others.

## 1322 MOLECULAR MECHANISMS OF OXIDANT STRESS IN AT-RISK SUBJECTS UNDERGOING REVASCULARIZATION.

**S. Hazen.** *Department of Molecular Medicine, Cleveland Clinic Foundation, Cleveland, OH.* Sponsor: D. Liebler.

Our group has successfully developed and applied LC/MS/MS assays that permit multiplexed stable isotope dilution quantitative analyses of multiple molecular markers of distinct protein and lipid oxidation products in clinical specimens. This approach permits comprehensive metabolic profiling of clinical and biological specimens, and is equally applicable to clinical and Mechanism-based investigations. For example, in recent clinical studies we have shown that nitrotyrosine, a protein oxidation product of nitric oxide (NO)-generated oxidants, predicts atherosclerotic risks and burden better than current diagnostic laboratory tests employed in clinical practice (Shishehbor et al, (2003) JAMA). Through simultaneous analyses of ni-

trotyrosine and other specific oxidation products of distinct oxidant generating pathways, such as chlorotyrosine for myeloperoxidase (MPO)-catalyzed oxidation, dityrosine for tyrosyl radical-mediated oxidative crosslinking, and ortho-tyrosine for hydroxyl radical-like oxidant damage to proteins, complementary studies have demonstrated the potential clinical utility of select oxidative stress biomarkers as targets for therapy and response to lipid lowering (statins) (Shishehbor et al, (2003) Circulation).

## 1323 NOVEL BIOMARKERS OF OXIDATIVE STRESS-INDUCED DNA DAMAGE.

**I. Blair.** *Department of Pharmacology, University of Pennsylvania, Philadelphia, PA.* Sponsor: D. Liebler.

A major consequence of oxidative stress is increased lipid peroxidation resulting from reactive oxygen species or from the action of oxygenases such as cyclooxygenase or lipoxygenase. Depletion of intracellular reducing equivalents during oxidative stress provides the opportunity for lipid hydroperoxides to undergo homolytic decomposition to a series of bifunctional aldehydic electrophiles. For example, we have shown that omega-6 polyunsaturated fatty acids can decompose to 4-hydroperoxy-2-nonenal, 4-oxo-2-nonenal, 4-hydroxy-2-nonenal, 4, 5-epoxy-2-decenal, and 9, 11-dodecadienoic acid. Each of these bifunctional electrophiles is able to interact with DNA to induce specific lesions that are potential biomarkers of oxidative stress. We have recently identified carboxylate-containing DNA-adducts as specific biomarkers for up-regulation of the cyclooxygenase (COX) or lipoxygenase (LOX) pathways. This presentation will describe the application of stable isotope dilution LC-MS-MS to develop sensitive assays for specific products of DNA damage through these oxidative stress mechanisms.

## 1324 URINARY DNA ADDUCTS AND THEIR METABOLITES AS BIOMARKERS OF OXIDATIVE STRESS.

**L. Marnett.** *Department of Biochemistry, Vanderbilt University School of Medicine, Nashville, TN.*

Oxidizing agents, nitrosating agents, or halogenating agents react directly with DNA to form modified bases or induce strand breaks. In addition, aldehyde, ketone, or epoxide products of lipid, protein, or DNA oxidation react with DNA bases to form stable adducts. These adducts may remain in genomic DNA, allowing quantification in tissue extracts, or they may be removed by repair pathways and excreted allowing quantification in urine. Several products of direct or indirect oxidative damage to DNA have been detected in genomic DNA from human subjects, but attempts to develop biomarkers based on these products have met with uneven success. For large-scale biomarker screening, a urine-based assay is ideal. Yet detection of a biomarker in urine requires that it be excreted intact without prior metabolism. Our recent studies demonstrate that the primary adduct formed from the reaction of malondialdehyde with DNA, M1dG, is metabolized prior to excretion in the rat. This finding indicates that in order to adequately evaluate the usefulness of M1dG as a biomarker *in vivo*, both the parent compound and its metabolite(s) must be considered. Furthermore, these results suggest the likelihood that other DNA adducts undergo a similar metabolic fate. This presentation will address both the *in vivo* analysis of urinary M1dG and the potential metabolism of other DNA adducts as biomarkers for oxidative stress-induced DNA damage.

## 1325 PROTEIN ADDUCTS AS OXIDATIVE STRESS BIOMARKERS.

**D. C. Liebler**<sup>1</sup>, <sup>1</sup>*Department of Biochemistry, Vanderbilt University School of Medicine, Nashville, TN*, <sup>2</sup>*Department of Pharmacology, University of Pennsylvania, Philadelphia, PA*, <sup>3</sup>*Environmental Toxicology Program, National Institute of Environmental Health Sciences, Research Triangle Park, NC* and <sup>4</sup>*Department of Molecular Medicine, Cleveland Clinic Foundation, Cleveland, OH*.

Reactive oxidants modify essentially all biomolecules and nonradical electrophiles produced as byproducts of lipid oxidation also react with proteins and DNA. In contrast to DNA modifications, relatively little is known about protein modifications by reactive endogenous electrophiles associated with oxidative stress. Several examples of protein modifications by electrophilic products of lipid oxidation are known (e.g., modification of apolipoproteinB-100 (ApoB-100) in LDL) and are considered critical steps in disease pathogenesis. However, the reactions of many electrophilic products of lipid peroxidation with proteins have not been explored. New proteomics approaches based on tandem mass spectrometry (MS-MS) now enable the high-throughput characterization of protein adducts, mapping of modification sites and quantitation of adducts. We have characterized adducts formed by reactive electrophilic products of lipid oxidation with human serum albumin and

other proteins and have mapped the adducts at the level of amino acid sequence. This presentation will describe the identification of oxidative stress-derived protein modifications and their application as biomarkers of oxidative stress *in vivo*.

#### **1326** GENETIC BASIS FOR SUSCEPTIBILITY TO METALS: METABOLISM AND MOLECULAR TARGETS.

**E. K. Silbergeld.** *Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

There are substantial individual differences in human susceptibilities to many toxicants, including metals. Understanding these differences in susceptibility is fundamental to identifying factors important in assessing and managing health risks associated with metals such as lead, cadmium, mercury, and arsenic. Genetic factors may play a significant role in the variable human response to metal exposures. The goal of this symposium is to present and discuss information from both epidemiology and basic research that is relevant to refining our knowledge of metal toxicity and the relationships between metal exposures and human diseases.

#### **1327** DO GENETIC POLYMORPHISMS MODIFY THE KINETICS OR TOXICITY OF LEAD? INSIGHTS FROM EPIDEMIOLOGY.

**B. S. Schwartz.** *Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Lead is widely distributed in the body. With its affinity for sulfhydryl and carboxyl groups, it binds to proteins in blood and tissues, including many polymorphic gene products. We evaluated interactions between lead dose and 7 polymorphic genes in 3 large scale epidemiologic studies involving 3, 186 subjects. In studies of former organolead workers (N=1, 109), current and former Korean lead workers (N=937), and Baltimore residents (N=1, 140), we measured lead in blood by AAS and in bone by <sup>109</sup>Cd K-shell X-ray fluorescence. Genotyping was completed for 9 SNPs including those in  $\delta$ -aminolevulinic acid dehydratase (ALAD; G177C), apolipoprotein E (ApoE; C393T and C407T), and vitamin D receptor (VDR; C47T [BsmI] and T1202C [FokI]). Health outcomes included neurobehavioral assessment and blood pressure. Linear regression was used to examine associations of genotypes with dose biomarkers and health outcomes, and interactions of lead dose and genotypes in associations with health outcomes. ALAD genotype was consistently associated with blood lead but not with bone lead in the Korea study. VDR-BsmI genotype was associated with blood lead, DMSA-lead, and tibia lead in the organolead and Korea studies. This genotype was also associated with blood pressure and cognitive function, and modified relations of blood lead with cognitive function in Baltimore residents. ApoE genotype was associated with tibia lead and modified its relations with cognitive function in the organolead study. Our results demonstrate that genetic polymorphisms, especially for ALAD and VDR, modify the kinetics of lead, as evidenced by differences in lead biomarkers by genotype. In contrast, the polymorphisms were inconsistently found to modify relations of lead dose with health outcomes. By comparing and contrasting associations of genotypes with lead dose measures, and of the lead-gene interactions in their associations with health effects, hypotheses can be generated regarding the mechanistic role of the gene products, that is, whether these modify the toxicokinetics or toxicodynamics of lead.

#### **1328** USE OF GENETICALLY ALTERED ANIMALS TO DETERMINE THE ROLE OF CADMIUM IN METALLOTHIONEIN TOXICITY.

**C. D. Klaassen.** *Pharmacology, U Kansas Med. Ctr, Kansas City, KS.*

The role of metallothionein (MT) in Cd toxicology has been studied using MT-I transgenic (MT-TG) and MT-I and II knock-out (MT-null) mice. We have shown that (1) MT-TG and MT-null mice appear to be normal except for altered tissue MT levels; (2) MT does not appear to affect Cd absorption from the gastrointestinal tract, and tissue Cd distribution, but MT plays an important role in the elimination and tissue retention of Cd; (3) MT protects against acute inorganic Cd-induced lethality and hepatotoxicity, and the mechanism of protection appears to be sequestration of Cd in the cytosol, thus reducing the amount of Cd in critical organelles; (4) MT modulates Cd-induced expression of protooncogene (c-jun) and tumor suppressor gene (p53) in mouse liver; (5) MT protects against Cd-induced nephrotoxicity, but does not appear to be a major factor in modulating acute CdMT-induced renal injury and Zn-induced protection; (6) MT protects against chronic Cd-induced hematotoxicity, ameliorates Cd-induced elevation of serum TNF- $\alpha$  and IL-1 $\alpha$  levels, and splenomegaly; (7) MT protects against chronic Cd-induced hepatotoxicity, as evidenced by decreased hepatic inflammation, apoptosis,

and granulomas; and (8) MT-null mice are more susceptible than controls to chronic Cd osteotoxicity. These studies using MT-TG and MT-null mice have been excellent tools in advancing our understanding of the role of MT in Cd toxicology, and suggest that MT plays a major role in protection from Cd toxicity.

#### **1329** ARSENIC METABOLISM: KNOCKOUT MICE AND POLYMORPHISM STUDIES.

**H. V. Aposhian, R. A. Zakharyan, U. K. Chowdhury, M. D. Avram, M. L. Wollenberg, A. Hernandez and M. M. Aposhian.** *Molecular and Cellular Biology, University of Arizona, Tucson, AZ.*

There are at present questions about how inorganic arsenic metabolism is regulated and why is there variability in the metabolic processing of inorganic arsenic in humans as judged by the concentration of arsenic species excreted in the urine. A critical enzyme in this process is MMA(V) reductase, which reduces arsenate, MMA(V), and DMA(V) to more toxic metabolites. The enzyme has an absolute requirement for GSH. The MMA(V) reductase protein is identical to the most recently discovered glutathione S-transferase omega. Our laboratory has given sodium arsenite to MMA(V) reductase knockout mice and to wild mice. Although exon 3 of the MMA(V) reductase gene has been removed, the livers of wild mice still have 20% of the MMA(V) reductase activity of the knockout mice indicating that another protein may have some supplemental MMA(V) reductase activity. No such studies are available for arsenic methyltransferases. The genetics of these mammalian enzymes is lacking. Polymorphism studies are becoming available to help to decipher and correlate changes in the genes responsible for arsenic metabolism and urinary arsenic species. These studies also will be reviewed. (Supported by the Superfund Basic Research Program NIEHS Grant No. ES-04940 from the National Institute of Environmental Health Sciences).

#### **1330** MERCURY-INDUCED AUTOIMMUNITY IN GENETICALLY SUSCEPTIBLE MICE.

**M. Monestier.** *Microbiology & Immunology, Temple University School of Medicine, Philadelphia, PA.* Sponsor: E. Silbergeld.

The incidence of human autoimmune diseases is increased following exposure to various chemical or pollutants. Only a few animal models are available to help us understand the mechanisms of chemically-induced autoimmunity. In susceptible mice, subtoxic doses of mercury elicit a complex autoimmune syndrome with production of highly specific IgG antinucleolar antibodies, a polyclonal increase in serum IgG1 and IgE, and tissue lesions that include a glomerulonephritis and vasculitis. Susceptibility to mercury is conferred by various genetic factors. The production of autoantibodies is under the control of major histocompatibility complex class II molecules (with H2<sup>s</sup> mice being especially susceptible), whereas undetermined polygenic factors control the polyclonal response to mercury. My laboratory has focused on the mechanisms, such as cytokine production and costimulatory molecules expression, which regulate mercury-induced autoimmunity. Our most recent work indicates that resting dendritic cells and CD25+CD4+ regulatory T cells cooperate in maintaining tolerance to mercury. If dendritic cells are activated or if regulatory T cells are depleted, tolerance to mercury is lost even in mice that are normally resistant. Because dendritic cells are best activated by microbial components, these experiments indicate that infectious agents and chemical challenges can conspire to trigger autoimmune manifestations in previously tolerant individuals.

#### **1331** MOLECULAR MECHANISMS OF LEAD-INDUCED CARDIOVASCULAR DISEASES.

**E. K. Silbergeld.** *Environmental Health Sciences, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

There is compelling epidemiological evidence associating lead exposures with increased risks of cardiovascular diseases, including hypertension, stroke, and peripheral arterial disease. We have reported that relatively small increases in blood lead [PbB], on the order of 2 $\mu$ g/dL, increases risks of both prevalent disease and mortality in adult men and women. For peripheral arterial disease, odds of disease were increased 3-5 fold as PbB increased from 1.4 to 2.8  $\mu$ g/dL. These effects are observed at Pb exposures in the range of 1-5  $\mu$ g/dL PbB, well below those associated with altered renal function. The epidemiological studies indicate no biological interactions between Pb and serum cholesterol or calcium. To understand mechanisms by which Pb affects the cardiovascular system, we have examined possible interactions between Pb and polymorphisms in genes that encode proteins known to be involved in both lead metabolism and regulation of vascular function. These candidate genes include endothelial nitric oxide synthase (eNOS), superoxide dismutase (SOD), vitamin D receptor (VDR), and aminolevulinic acid dehydratase (ALAD). These studies utilized a population of lead workers in Korea, who have been followed from 1997 to 2002 under protocols approved by Johns Hopkins, University of Maryland, and the Soonchunhyang University School of Medicine. There was a

significant relationship between both blood Pb and bone Pb levels and increased systolic blood pressure. The G<sup>894</sup>-T<sup>894</sup> polymorphism in eNOS was not associated with either blood pressure or an effect modification of the Pb:blood pressure relationship. However, this eNOS polymorphism did modify the distribution of Pb into bone. These results indicate that gene:environment interactions may be highly complex, involving both toxicokinetics and potential target proteins.

### 1332 PESTICIDE NEUROTOXICITY AT THE INTERSECTION OF EPIDEMIOLOGY AND TOXICOLOGY.

W. K. Boyes<sup>1</sup> and F. Kamel<sup>2</sup>. <sup>1</sup>EPA, Research Triangle Park, NC and <sup>2</sup>NIEHS, Research Triangle Park, NC.

Neurotoxicity of high-level pesticide exposure in adults is well-documented, but less is known about the consequences of chronic exposure to moderate dose levels. Results from human epidemiology studies and animal toxicology studies are not always consistent. Recent human studies suggest that moderate pesticide exposure may be associated with increased risk of an array of neurologic symptoms, particularly affective outcomes including depression and suicide. Laboratory animal studies do not address comparable outcomes, and typically have not identified subtle neurological impairments that persist beyond the exposure period, despite higher dose levels than are typically experienced by humans. Are these apparent species differences real? If so, are they related to pharmacokinetic or pharmacodynamic factors? Alternatively, are differences related to the types of outcomes assessed, duration of exposures, combined exposures to multiple agents, or to other factors? Understanding and predicting human health risks from pesticide exposure requires complex integration of the differing data provided by human and animal studies.

### 1333 NEUROTOXICITY OF CHRONIC PESTICIDE EXPOSURE IN LICENSED PESTICIDE APPLICATORS IN THE AGRICULTURAL HEALTH STUDY (AHS).

F. Kamel<sup>1</sup>, L. S. Engel<sup>2</sup>, B. C. Gladen<sup>1</sup>, J. A. Hoppin<sup>1</sup>, M. R. Alavanja<sup>3</sup> and D. P. Sandler<sup>1</sup>. <sup>1</sup>NIEHS, NIH, DHHS, Research Triangle Park, NC, <sup>2</sup>Memorial Sloan-Kettering Cancer Center, New York, NY and <sup>3</sup>NCI, NIH, DHHS, Rockville, MD. Sponsor: W. Boyes.

Little is known about the neurological consequences of chronic exposure to moderate pesticide levels in the absence of poisoning. We explored this issue in a cross-sectional analysis of data from the AHS, a cohort of licensed pesticide applicators enrolled in 1993-97 in Iowa and North Carolina. At enrollment, ~19,000 applicators reported lifetime pesticide exposure and frequency of 23 neurologic symptoms reflecting cognitive, motor, sensory and nonspecific dysfunction experienced during the prior year. A summary measure indicating greater symptom number (10+ vs <10 symptoms) was associated with lifetime use of any insecticide, showing a significant dose-response trend; adjusted relative risk (RR, 95% confidence interval) for the highest exposure category was 2.5 (2.1-3.0). Weaker relationships were seen for other pesticides - in the highest exposure category, RR was 1.4 (1.2-1.7) for fumigants, 1.3 (1.0-1.7) for herbicides, and 1.2 (1.1-1.4) for fungicides. Among chemical classes of insecticides, the strongest relationships were for organophosphates [RR=2.2 (1.9-2.6)] and organochlorines [RR=2.0 (1.8-2.2)]. Events involving high pesticide exposure were associated with greater symptom number [RR=3.0 (2.7-3.5)], as were physician diagnoses of pesticide poisoning [RR=2.5 (2.0-3.1)]. Increased symptom number was associated with insecticide use even when applicators who had experienced a pesticide poisoning or high-exposure event were excluded from the analysis. Insecticide and fumigant use were also associated with increased prevalence of individual symptoms as well as groups of symptoms defined a priori and reflecting affect, cognition, systemic effects, peripheral neuropathy, motor dysfunction, or vision. These results suggest that, even in the absence of pesticide poisoning, an increase in self-reported neurologic symptoms is associated with lifetime use of pesticides, particularly organophosphate and organochlorine insecticides.

### 1334 ORGANOPHOSPHATE EXPOSURE, DEPRESSION AND SUICIDE: MATCHING EPIDEMIOLOGICAL DATA TO MODELS BASED ON ANIMAL STUDIES AND CASE SERIES.

L. London<sup>1</sup>, A. Flisher<sup>2</sup>, V. Major<sup>3</sup>, H. Kromhout<sup>4</sup> and D. Mergler<sup>5</sup>. <sup>1</sup>School of Public Health and Family Medicine, University of Cape Town, Observatory, South Africa, <sup>2</sup>Department of Psychiatry and Mental Health, University of Cape Town, Observatory, South Africa, <sup>3</sup>Department of Health Sciences, Peninsula Technicon, Cape Town, South Africa, <sup>4</sup>Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands and <sup>5</sup>CINBIOSE, University of Quebec a Montreal, Montreal, QC, Canada. Sponsor: W. Boyes.

The role of organophosphates as agents used in suicide in the developing world is well-documented. However, the potential role of exposure to OPs as a causal factor in suicide has not been explored to date. Animal data have identified the impact of

OP exposure on serotonin, which is known to be an important neurotransmitter implicated in depression amongst humans, and in increasing levels of impulsivity, itself a significant factor in suicide attempts. Ecological studies and case series data provide additional circumstantial evidence to support the hypothesis that humans exposed to OPs may be at increased risk for affective disorders and suicide, although evidence from epidemiological studies is less consistent. Data will be presented from a cross-sectional study conducted in 2002 amongst 813 farm workers in the rural Western Cape Province of South Africa, which examined a range of standardised neuropsychological and psychiatric outcomes in relation to a history of OP exposure. These included the General Health Questionnaire (GHQ), the Beck Depression Inventory (BDI), the Brief Symptom Inventory (BSI), the Refined 12 - Item Four-Factor Measurement Model of the Aggression Questionnaire, the Barrat Impulsiveness Scale, and suicidal ideation. Preliminary analyses indicate important differences in affective outcomes by gender, farm type and spray activities. These differences will be elaborated in presentation, outlining their relevance to better understanding the potential hazards associated with organophosphate pesticides.

### 1335 ANIMAL MODELS OF CHRONIC PESTICIDE TOXICITY.

V. C. Moser, P. J. Bushnell, R. C. MacPhail, D. W. Herr, R. S. Marshall, D. L. Hunter and W. K. Boyes. NTD/NHEERL/ORD, USEPA, Research Triangle Park, NC.

Despite the wealth of literature on acute neurotoxicological effects of organophosphorus (OP) pesticides in laboratory animals, there are relatively few reports of long-term exposure. Reports in the literature describing  $\pm$ chronic $\pm$  exposures to pesticides are, in fact, as short as 7 days and rarely as long as 4 months. Furthermore, routes of administration range from subcutaneous to dietary. Doses used in many of the studies produce signs of acute toxicity and/or significant brain or blood cholinesterase (ChE) inhibition. In contrast, human exposures are often prolonged and without obvious toxic effects. In rats, few neurobehavioral effects have been reported following exposures of 3-4 month duration. Decreased motor activity has been reported occasionally, and one study reported a transient improvement in learning at low doses. Shorter-term exposures, however, appear to produce various neuromotor and cognitive effects; some of these effects were observed at doses producing considerable ChE inhibition. On the other hand, subcutaneous exposure to a few OPs produced cognitive changes even after recovery of enzyme activity. The comparability of these findings to human exposures is limited due to the dose, length, and route of exposures. Data will be presented from a 1-year study of chlorpyrifos, given via the feed with and without intermittent high-dose challenges. Chronic chlorpyrifos produced some neurobehavioral changes, altered the rats $\pm$  response to acute challenges, and caused a mild but persistent cognitive deficit. These subtle changes in behavior may correspond to the relatively vague changes in psychomotor and cognitive function reported in humans. Overall, however, the generally available data are insufficient to assess the ability of chronic animal studies to predict the outcomes in OP-exposed humans. This is an abstract of a proposed presentation and does not reflect EPA policy.

### 1336 DEVELOPMENT OF PHYSIOLOGICALLY BASED PHARMACOKINETIC AND PHARMACODYNAMIC MODELS TO DETERMINE DOSIMETRY, DYNAMIC RESPONSE, AND TO ASSESS RISK FOLLOWING EXPOSURE TO ORGANOPHOSPHORUS INSECTICIDES.

C. Timchalk and T. S. Poet. Pacific Northwest National Laboratory, Richland, WA.

There is an ongoing need to develop approaches for quantitatively assessing risk associated with exposures to a broad-range of organophosphorus insecticides and to determine the potential implications of these exposures to human health. These insecticides share common metabolic activation/detoxification pathways and a common mechanism of neurotoxicity associated with excessive cholinergic stimulation, due to the inhibition of acetylcholinesterase in nerve tissues. Efforts are underway to develop state-of-the-art physiologically based pharmacokinetic and pharmacodynamic (PBPK/PD) modeling approaches to assess dosimetry and biological response following exposure to single organophosphorus insecticides or more complex mixtures. A PBPK/PD model has been developed for the organophosphorus insecticides chlorpyrifos and diazinon utilizing available data from rats and humans. These models have been extended to incorporate age- and polymorphism-dependent changes and have been successfully used to quantitatively determine the dose-dependent impact of insecticide exposure. Secondly, a binary PBPK/PD model has been developed to quantitatively assess dosimetry and response due to mixed exposures. This binary model facilitates understanding the mixture interactions and the potential for additivity, synergism or antagonism from multiple insecticide exposures. These results demonstrate that PBPK/PD modeling can be used to

quantitatively assess exposure and biological response to classes of insecticides involving multiple routes of exposure (i.e. skin, ingestion, inhalation) that are routinely encountered in the environment. In summary, it is envisioned that once fully validated, these modeling approaches will be very useful for assessing exposure and health risk as a component of a broader biomonitoring or epidemiology assessment strategy for a wide range of potentially exposed individuals. Supported by: CDC/NIOSH 1 R01 OH03629-01A2; EPA-STAR R828608.

 **1337** PESTICIDE NEUROTOXICITY IN ADULTS: IMPLICATIONS FOR PESTICIDE SAFETY TESTING AND PUBLIC HEALTH.

W. K. Boyes, *EPA, Research Triangle Park, NC.*

Pesticide safety evaluations depend on the best available scientific information, including data from animal toxicity and human epidemiological studies. Several recent epidemiological studies indicate that chronic pesticide exposure increases the risk of neurologic symptoms and affective disorders. Animal studies, in contrast, do not investigate comparable outcomes and generally have not demonstrated analogous chronic impairments. There are several factors to consider when evaluating the comparability of epidemiological and animal neurotoxicity studies. Regarding the epidemiological literature, issues include co-exposure to other agents, concurrent, chronic or previous exposures, use of appropriate controls, potential confounding factors, methods of exposure assessment, and subjective or objective evaluation of neurological status. In epidemiological studies, it is difficult to attribute health outcomes to specific exposures, and dose levels are difficult to quantify. Animal experiments must be evaluated regarding factors such as dose level and duration, procedures used to assess neurological or behavioral status, and appropriateness of the animal model to human neurotoxicity. Factors which may explain apparent differences between animal and human studies include: animal neurological status is evaluated with different procedures than those used in humans; animal studies may involve shorter exposure durations and higher dose levels; most animal studies evaluate a single pesticide ingredient whereas humans are typically exposed to many agents in product formulations. Since neither type of study can adequately address all issues, an appropriate blend of scientific information is necessary to evaluate potential human risks of chronic pesticide exposure. [This is an abstract of a proposed presentation and does not reflect EPA policy]

 **1338** CURRENT REGULATORY AND SCIENTIFIC VIEWS REGARDING CHEMICAL HAZARDS TO CHILDREN.

D. R. Juberg<sup>1</sup> and D. J. Paustenbach<sup>2</sup>. <sup>1</sup>*Regulatory Laboratories, Dow AgroSciences, Indianapolis, IN* and <sup>2</sup>*ChemRisk, San Francisco, CA.*

The evaluation of the health of children, specifically the estimated risk due to environmental chemical exposures, continues to receive increasing regulatory attention. It has resulted in decision-making that has scientific, policy, and public health impacts. At the center of this discussion is whether children are uniquely susceptible and whether current regulatory approaches are protective of children. This workshop will discuss ongoing initiatives by the EPA and CDC aimed at characterizing children's exposures and evaluating biomonitoring data. Other parameters that are influential in predicting susceptibility, namely, pharmacokinetics and pharmacodynamics, will also be addressed. The use of uncertainty factors in setting environmental criteria and estimating safe doses will be discussed and a case study from the VCCEP program will be presented. A view from the medical community, frequently the first responders to questions and concerns over children's health, will be offered. The scientific questions about whether children are significantly more susceptible to toxicants and the current regulatory response to this concern (e.g., FQPA, testing requirements, basic research, cancer risk assessment guidelines) are the focus of this workshop. An anticipated outcome is the identification of those areas of research that will give the toxicology community the opportunity to be a central figure in properly addressing this important public health question.

 **1339** OVERVIEW OF USEPA RESEARCH ACTIVITIES AIMED AT CHARACTERIZING CHILDREN'S EXPOSURES.

E. A. Cohen Hubal, *USEPA, Research Triangle Park, NC.* Sponsor: D. Juberg.

Given the potential vulnerability of children to the effects of environmental exposures, understanding the relationship between children's health outcomes and environmental exposures is an important research need to reduce uncertainty in risk assessment. Over the past 8 years, significant research activities have been initiated at the USEPA to increase understanding of children's vulnerabilities and to better characterize children's exposures to chemical stressors in the environment. Research efforts include development of models, methods, and data to quantitatively de-

scribe ways that children are exposed to environmental stressors. Current and recently completed studies include large field studies to measure children's exposures to chemicals in their homes and daycare centers as well as targeted studies to better understand the determinants of exposure. CTEPP, a study of 260 preschool-age children, has recently been completed and data are being analyzed to identify important exposure factors and pathways. A longitudinal children's study of 60 infants and toddlers is being implemented over the next couple of years to assess exposures to current-use pesticides, phthalates, and BFRs. As a result of these and other Agency initiatives, important data are being collected and assessment approaches are being developed and used to improve the scientific basis of exposure assessments for children. Despite this significant progress, there are many important gaps associated with how to effectively measure and characterize exposure for health studies and risk assessment. In this presentation, ongoing and recent USEPA initiatives aimed at evaluating children's exposures and health risks will be discussed, including issues associated with characterizing cumulative risks from exposures to multiple environmental stressors. The information and data obtained from these efforts will help identify the most important exposures for children and enable decision to prioritize environmental health related activities. This work has been funded wholly or in part by the USEPA. It has been subjected to Agency review and approved for publication.

 **1340** USING CDC BIOMONITORING DATA FOR ASSESSING CHILDRENS' EXPOSURES TO ENVITONMENTAL CHEMICALS.

L. L. Needham, *NCEH, CDC, Atlanta, GA.* Sponsor: P. Williams.

It has been well documented that children on a kilogram basis are more highly exposed to a variety of environmental chemicals than are adults. In addition, because their body functions are still developing, the impact of these exposures may be greater; thus, they are more susceptible to these exposures than are adults. These early life exposures can not only potentially affect the child near the time of the exposure but in some instances can lead to adverse health outcomes later in life. Thus, it is important to monitor exposures occurring especially *in utero*, infant, toddler, and early childhood life stages. CDC has utilized samples collected from its National Health and Nutrition Examination Survey (NHANES) to estimate background levels for 116 chemicals in the U. S. general population, based on race/ethnicity, gender and age. The biggest limitation on the NHANES was age, specifically the younger ages. For most of the analytes, measurements were made in urine samples only in those aged 6 years and older and in serum samples only in those aged 12 years and older. Exceptions to these age ranges were lead, cadmium, mercury, and cotinine measurements. To obtain more data on exposures occurring early in life, our laboratory has collaborated extensively with other groups to determine levels of environmental chemicals in the younger populations and in some instances we relate these levels to adverse health outcomes. Specific examples will include organophosphorus pesticides, phthalates, and perfluorinated chemicals.

 **1341** EVALUATION OF CHILDHOOD EXPOSURES TO INDUSTRIAL CHEMICALS THROUGH VCCEP.

P. R. Williams, *ChemRisk, Boulder, CO.* Sponsor: D. Paustenbach.

The Voluntary Children's Chemical Evaluation Program (VCCEP) is designed to provide data to enable the public and risk assessors to better understand or evaluate the potential health risks to children associated with certain chemical exposures. Specifically, in response to a request from the USEPA, chemical manufacturers have voluntarily begun to collect and analyze data for 23 different chemicals in the first tier of a pilot of this program. These chemicals were selected for initial evaluation because they have been found to be present as contaminants in either human tissues or fluids (e.g., adipose tissue, blood, breath, breast milk, urine); food and water children may eat and drink; or air children may breathe (including residential or school air). A key question of VCCEP is whether the potential hazards, exposures, and risks to children have been adequately characterized, or whether additional data are needed to evaluate children's unique risks. In this presentation, the tiered testing protocol of VCCEP's pilot program will be discussed, as well as the key findings from the first set of chemicals that have undergone peer consultation. These include: acetone, decabromodiphenylether, methyl ethyl ketone, pentabromodiphenyl ether, octabromodiphenyl ether, and vinylidenechloride. The status of other chemicals currently being evaluated under VCCEP will also be discussed (e.g., benzene, ethylbenzene, xylene, n-dodecane, undecane, decane). Particular focus will be given to the lessons learned and data limitations associated with VCCEP, as well as recommendations for areas of improvement in future evaluations.

### 1342 EVALUATION AND PREDICTION OF DOSIMETRY IN CHILDREN: EMPIRICAL AND MECHANISTIC APPROACHES.

A. M. Jarabek. USEPA Visiting Scientist, CIIT Centers for Health Research, Research Triangle Park, NC.

Susceptibility in children to the adverse health effects of hazardous chemicals is a function of exposure, pharmacokinetics (PK), and pharmacodynamics (PD). This presentation will focus on consideration of the potential susceptibility of various life stages due to differences from adults in PK and PD parameters. Current approaches for dosimetry adjustment and response analysis will be described. These approaches range from empirical descriptions of dose-response at various levels of observation (e.g., at the population versus tissue levels) in different age groups to mechanistically motivated models that attempt to account for mode of action by explicitly incorporating anatomical and physiological determinants of PK and PD on an age-specific basis. Semi-empirical analyses of specific mechanistic parameters (e.g., scaling of metabolic clearance rates) have also been explored to address differences due to life stage. Examples of ingested compounds and inhaled particles or gases will be used to illustrate the range of approaches. Predictions based on empirical versus mechanistic approaches for various dose metrics and response outcomes will be compared, including predictions of lifetime cancer risk constructed with distinct age groups and activity patterns compared to adult daily average simulations. Because of the many challenges in ensuring proper protection of children's health, it is important that the range of approaches for dosimetry and response analysis be described in a context that provides an appreciation of the uncertainty versus accuracy afforded by the empirical versus mechanistic descriptions. Characterization of the context provides a basis for the proper application of data-derived uncertainty factors in health risk assessment and can facilitate an interface with exposure models. The emphasis on empirical versus mechanistic approaches provides a framework that can be used to construct characterization of this context for these critical interfaces. The presentation also readily reveals research needs for various PK and PD parameters.

### 1343 DIFFERENTIAL SENSITIVITY OF CHILDREN AND ADULTS TO CHEMICAL TOXICITY AND THE USE OF UNCERTAINTY FACTORS IN REGULATING RISKS.

G. Charnley<sup>3</sup>, M. L. Dourson<sup>1</sup> and R. Scheuplein<sup>2</sup>. <sup>1</sup>*Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH*, <sup>2</sup>*Keller and Heckman, Stafford, VA* and <sup>3</sup>*HealthRisk Strategies, Washington, WA*.

We investigated the current uses and level of protectiveness of uncertainty factors in determining safe doses for chemical exposures. We found that when experimental animal studies are available in teenage-to-adult animals but not in younger animals, the division of the lowest teenage-to-adult animal NOAEL by an Uncertainty Factor for Database Deficiency (UFD) of 3 or 10 accounts for between ~92% and 98% of the possible occurrences of lower younger-animal NOAELs. Drawing conclusions about the adequacy of an Uncertainty Factor for within Human Variability (UFH) is more challenging, though, based on specific comparisons for newborns, infants, children, adults and those with severe disease, where the population protected is between 60% and 100%. For example, with severe disease, the population protected is closer to 60%; in larger populations that include sensitive individuals a percentage closer to 100% of the population (including children) is protected by using either a 10-fold uncertainty factor for human variability or by using a 3.16-fold factor each for toxicokinetic and toxicodynamic variability. We conclude that an additional factor to limit environmental chemical exposures is unlikely to provide significantly greater protection to children over 6 months of age when compared to the current method. The same conclusion might not always hold true for children younger than 6 months of age, however, in the absence of adequate developmental or systemic toxicity testing.

### 1344 AN EVALUATION OF ENVIRONMENTAL HEALTH TRENDS AMONG CHILDREN BASED ON MEDICAL AND SCIENTIFIC EVIDENCE.

D. A. Goldstein. A2NE, Monsanto Company, St. Louis, MO. Sponsor: P. Williams.

Identification of high priority childrens environmental health issues currently relies heavily upon recognition of broad trends in childrens health outcomes. Widely held beliefs regarding trends in childrens health, frequently described as epidemics of childhood cancer or autism, are often unsubstantiated by or sometimes at odds with existing scientific evidence. In this presentation, a systematic review of the literature regarding child health trends is discussed in order to identify validated trends in child health. For example, although clear evidence exists for increases in childhood asthma in recent years, only suggestive evidence exists for some other allergic disorders (allergic rhinitis, sinusitis). Changes in population adjusted child

cancer rates indicate small alterations in the frequency of major childhood cancers, possible trends for certain rare tumors, and increases in brain tumor diagnosis rates resulting from improvements in diagnostic technology. There is no convincing evidence available regarding trends in neuro-developmental disorders, including autism, ADHD, and learning disabilities. While data document a declining age of puberty in females, evidence for other changes in reproductive function demonstrates wide temporo-spatial variation, but no clearly defined global trends. Some caution is warranted, however, when relying on trends to identify key areas of environmental contribution to disease. Accurate trend data is contingent upon stable diagnostic criteria and disease recognition over time and place in addition to adequate sampling methodologies. Further, while changes in disease rate over time are unlikely to change for purely genetic conditions, environmental contributions to disease burden do not necessarily result in observable trends in the general population. Broad trends may miss large, but static, contributions to disease, or may ignore susceptible sub-populations or locally important environmental factors.

### 1345 TOXICOLOGIC EVALUATION OF INHALED VACCINES.

M. Reed. *Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM*.

Mucosal and systemic immunity stimulated by aerosolized vaccines have been recognized as effective pathways for preventative immunizations and therapies for pathogens and diseases ranging from flu (e.g., FluMist) to measles (World Health Organization) to asthma. Likewise, in the face of an ever-present risk of aerosol delivery of chemical and biological agents, inhaled vaccines make sense by stimulating immunity at the portal of pathogen/ chemical entry. However, several toxicological hurdles exist for those challenged with developing or regulating vaccines, especially those designed for administration to the respiratory tract. General toxicological assessment as are required for all vaccine subtypes are necessary as well as special considerations including safety pharmacology. Adjuvant type and possible transport to the brain via the olfactory pathway are of concern as well. This symposium will bring together experts in the field of inhaled therapeutics and vaccine development, to give insight into the required and perceived toxicology of aerosolized vaccines.

### 1346 AIRWAY DRUG DELIVERY OPTIONS FOR INHALED BIOLOGICS AND VACCINES.

C. Leach. *Preclinical Development, Lovelace Respiratory Research Institute, Albuquerque, NM*.

There is a growing interest among academic, commercial, and government entities in developing vaccines for delivery to the respiratory tract both to the nasal and pulmonary tissues. Over 50 of the currently approved vaccines target respiratory diseases yet only one product actually utilizes the respiratory epithelia as its initial delivery site. Respiratory delivery offers the obvious advantages of being needle-free and eliciting immunity at the port of entry for the pathogen. Thus there may be additional mucosal immunity in addition to humoral immunity, and at lower total doses. There are many ways of achieving drug delivery to the respiratory tract each of which may offer advantages specific to the respective vaccine. Nebulizers offer the advantage of being readily available and easy to use in clinical settings. However they are expensive, time consuming, not portable and not practical in developing nations. In addition, some vaccines may not stand up to the high shear forces generated by some nebulizers. Metered dose inhalers (MDIs) are inexpensive, portable, and provide a semi-sterile, light and moisture-free environment. However MDIs may not be able to deliver high doses of vaccines where required. Dry powder inhalers are perhaps the best option since technology exists whereby low density, respirable, high drug load particles can be generated for use in simple, inexpensive, and portable devices. Devices and/or particles sizes can be adjusted to provide optimum delivery to either the nasal or deep respiratory tissue. Other technology such as piezoelectric aerosol technology may also prove useful for respiratory tract delivery of vaccines. Because of the novelty of aerosolized vaccine delivery, there will most likely be heavy dependence on knowledge of existing aerosol drug technologies and understanding such as insulin, antibiotics and others to lead developers in the proper direction to provide safe, effective, inexpensive and easy to use inhaled vaccine products.

### 1347 IMMUNOGENICITY AND SAFETY TESTING OF VACCINES: A REGULATORY PERSPECTIVE ON GENERAL REQUIREMENTS AND SPECIAL ISSUES OF THE RESPIRATORY TRACT.

K. L. Hastings. *Office of New Drugs, CDER, USFDA, Rockville, MD*.

Nonclinical safety assessment of inhaled therapeutics is a standard component of drug development. Usually, this involves what are generally referred to as "bridging toxicology" studies to determine the potential adverse effects of drugs that were previously administered by the oral or parenteral route. As part of this assessment,

studies to determine the ability of an inhaled drug to induce respiratory hypersensitivity reactions are usually conducted, although the methodologies used are of questionable utility. Safety assessment of vaccines to be administered by inhalation presents several unique issues. Although it is obvious that an immune response should be induced, distinguishing between pharmacodynamic and adverse immunologic reactions can be very difficult. As with other forms of hypersensitivity, it is likely that individual genetic makeup puts individuals at risk for immunologically-mediated adverse reactions, and it is unlikely that nonclinical methods would be useful for risk assessment. However, inhalation toxicology methods are available which could be useful in hazard identification. Adaptations of these methods to assessing the safety of inhaled vaccine products will be discussed.

 **1348** UNIQUE ISSUES ASSOCIATED WITH TOXICOLOGY ASSESSMENT OF VACCINES FOR BIOWARFARE AGENTS.

R. House. *Dynport Vaccine Company, Frederick, MD.*

Recent geopolitical events have resulted in an increased urgency in the development and licensure of vaccines designed to protect against bioterrorist/biowarfare agents. However, development of such vaccines presents the researcher and regulator with multiple scientific and practical challenges. These challenges can be complicated even further when live vaccines are considered. Some of these challenges include choice of the appropriate animal model(s) for toxicology testing and how they relate to the model(s) used for demonstration of efficacy, potential difficulties in locating facilities to perform the work (primarily related to ability to handle certain biological agents and GLP compliance), and physiochemical and biochemical/microbiological characterization. This presentation will discuss the development strategies associated with preventative vaccines for protection against select agent pathogens, with special emphasis on preclinical considerations for inhaled live vaccines.

 **1349** WHO SPONSORED PRECLINICAL TOXICITY TESTS FOR INHALED MEASLES VACCINE.

M. Papania. *Centers for Disease Control and Prevention, Atlanta, GA.* Sponsor: M. Reed.

The goal of the WHO's Measles Aerosol Project is to license at least one method for respiratory delivery of currently licensed measles vaccines. Preclinical toxicity testing is an important component of the regulatory process for licensing the vaccine/device combination. WHO solicited proposals for the study, which was conducted by the Centre International de Toxicologie in cynomolgus macaques. There were 4 groups of 6 male and 6 female, measles-negative animals per group. A control and study group were used for each of two nebulizers studied. One nebulizer delivered particles  $<5\text{ }\mu\text{m}$  and the other  $>10\text{ }\mu\text{m}$ . The test article was lyophilized measles vaccine with measured potency. The control article was vaccine excipients. Two 5x human doses of vaccine or placebo were given, on day 1 and day 21. Exposure estimates were based on breathing rate, lung volumes and aerosol  $\text{J}$ . Three animals per sex per group were sacrificed on day 7 and 42. Endpoints measured were: A) Vital signs and clinical observations: before, during, and 60 min post aerosol exposure (emphasis on respiratory symptoms). B) Serum chemistry, hematology (with coag), and urinalysis C) Serum serology at 7, 14, 21, 28 and 42 days. D) Daily observations: of health, activities, behavior, food and water consumption, etc with special attention to any neurological effects and to observations of the inside of the nose and mouth for local effects. Ophthalmologic observations were also made. E) Gross pathology, lung lavage, organ weight, ophthalmology, and histopathology (emphasis on localized virus staining, cribiform plate, olfactory bulb, and mouth, nasal and throat passages). The study was completed in 2004. Results are pending at the time of this abstract but will be included in the presentation.

 **1350** NONCLINICAL SAFETY EVALUATION OF TLR4 AGONISTS ADMINISTERED BY NASAL SPRAY.

C. M. Lynch. *Nonclinical Development, Corixa Corporation, Seattle, WA.* Sponsor: M. Reed.

Over the past few years, it has become clear that most vaccine adjuvants and immunomodulatory agents act on various members of the Toll-like receptor family. Toll-like receptors recognize structural components of pathogens and, through this interaction, activate the immune system. The first microbial product discovered to be a Toll-like receptor agonist was lipopolysaccharide (LPS), a membrane component of Gram-negative bacteria, which activates Toll-like receptor 4 (TLR4). Although LPS is a potent immunomodulatory agent, its medicinal use is limited by

its extreme toxicity. We have developed a series of natural and synthetic TLR4 agonists that retain many of the immunomodulatory properties of LPS, but have greatly reduced the toxicity. These TLR4 agonists have potent immunomodulatory effects when administered to the airway mucosa. They can induce both nonspecific innate resistance to respiratory pathogens and specific adaptive immunity when used as mucosal adjuvants. These compounds can be potentially used to protect against respiratory infections caused by bacteria and viruses and to modulate immune responses to allergens associated with the development of atopic disorders. We conducted a number of toxicity studies in rodents and dogs to assess the safety and potential toxicity after intranasal administration of TLR4 agonists to support clinical trials in humans. This presentation will discuss the factors affecting successful delivery to the nasal cavity such as, selection of the appropriate animal model, anatomical features of the nasal cavity, administration techniques and delivery devices. Special considerations for toxicity assessment of products administered via the intranasal route, specifically, the potential for retrograde transport along the olfactory nerves to the brain will be discussed. Efforts to expose the olfactory epithelium will be described. The IND-enabling nonclinical safety studies of TLR4 agonists will be presented.

 **1351** TOXICOLOGICAL RESEARCH AND TESTING: BEST PRACTICES AND OPPORTUNITIES FOR LABORATORY ANIMAL REFINEMENT, REDUCTION, AND REPLACEMENT.

S. M. Lasley<sup>1</sup> and W. S. Stokes<sup>2</sup>. <sup>1</sup>*Department of Pharmacology, University of Illinois College of Medicine, Peoria, IL* and <sup>2</sup>*NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC.*

In the performance of toxicology studies, whether for purposes of product safety testing or identifying mechanisms of toxicant action, it is becoming increasingly important to adopt practices and approaches that refine, reduce, and replace the numbers of laboratory animals utilized. Incorporation of best practices into studies will help ensure that animals are used in the most humane and judicious manner consistent with successful attainment of the research or testing objectives. Adoption of these practices is of timely importance because of continually increasing regulatory oversight of animal care and use, and thus consideration of these issues from different viewpoints is of broad interest to toxicologists. Best practices for regulatory testing involves careful consideration and appropriate incorporation of *in vitro* methods, humane endpoints, and tiered testing strategies (Stokes). Current best practices for housing and providing environmental enrichment for study animals should be consistently utilized, and factors considered that might potentially influence study outcomes (Brown). GLP requirements for pre-clinical safety studies are important factors to address, and optimal animal welfare practices consistent with compliance must be ensured (McCormack). Application of toxicogenomics to pre-clinical safety studies involving animals is an emerging concern, and potential opportunities for these methodologies to refine, reduce, and replace animal use are being developed (Schechman). Finally, updating of European Union animal welfare laws continue to evolve, and their potential impact on harmonization of animal care programs and toxicological research is a relevant concern to multinational companies (Donovan).

 **1352** BEST PRACTICES FOR USING HUMANE ENDPOINTS AND TIERED TESTING STRATEGIES TO REFINE, REDUCE, AND REPLACE ANIMAL USE IN TOXICOLOGICAL RESEARCH AND TESTING.

W. S. Stokes. *NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC.*

Animal care and use regulations, guidelines, and policies require consideration of alternatives prior to the use of animals for research and testing. Toxicology studies using animals should therefore incorporate methods and approaches consistent with study objectives that minimize the use of animals and that reduce or avoid potential pain and distress. Several new and recently revised regulatory testing guidelines for acute local and systemic toxicity now recommend the use of humane endpoints and tiered testing strategies. The guidelines allow for hazard identification to be accomplished in some situations with reduced or no animal use. This approach involves an initial review of all available relevant information and data on the test and related substances. If further information is needed, this is generated in a step-wise manner and may include determination of physical/chemical properties, structure-activity relationship evaluations, and *in vitro* studies. A weight-of-evidence evaluation is made at each stage to determine if there is sufficient information for determination of hazard or if additional data is needed. If animal studies are deemed necessary, the use of sequential testing can often reduce the total number required, especially for those chemicals causing severe effects. The establishment of humane endpoints prior to the initiation of animal studies can also provide a basis for appropriate interventions to reduce the severity and/or duration of pain and distress. This involves anticipating possible toxic effects and establishing appropriate criteria that can serve as the basis for ending a procedure before or when pain and

distress become apparent. Appropriate consideration and incorporation of best practices in toxicology studies can be expected to refine, reduce, and/or replace animal use while supporting the attainment of study objectives

 **1353** BEST PRACTICES FOR ENVIRONMENTAL ENRICHMENT AND HOUSING FOR LABORATORY ANIMALS USED IN TOXICOLOGICAL RESEARCH AND TESTING.

M. J. Brown. *Charles River Laboratories, East Thetford, VT.* Sponsor: S. Lasley.

Environmental enrichment (EE) is defined as any measure which promotes expression of natural, species specific behaviors and a decrease in, if not the disappearance of, abnormal behaviors. The importance of environmental enrichment for laboratory animals is recognized in national regulations and guidelines such as the Animal Welfare Act and Guide for the Care and Use of Laboratory Animals, as well as international regulations such as ETS123. However, in animal testing, there has been ever increasing efforts to standardize animal use over the years through control of genetics, hygiene, feeding and housing. EE is viewed by some as potentially decreasing this standardization and thus increasing variability, increasing the numbers of animals which must be used and invalidating the historical database. Concerns are confounded by the numerous published reports with conflicting conclusions - enrichment does, or does not affect body weights; food consumption; organ weights; urine and plasma corticosterone; behavioral tests; endocrine activations; aggressiveness, and the list goes on. The effect of the stress of a non-enriched environment on study results has also been discussed. Science has been a continually evolving field. Standards of housing and handling laboratory animals have continued to improve as we learn more about topics such as laboratory animal disease and housing needs. We are continuing to learn about animal needs as more research is done into the effects of environment. Many toxicology labs have embraced the concept of EE. All those involved in toxicological testing must use this new knowledge to strive to improve animal well being in a manner that is consistent with testing objectives. The diverse types of studies, differing objectives, different regulatory agencies and chemical and toxicological properties of the test substance will all affect the type and extent of EE which can be incorporated into studies. Scientists, veterinarians, IACUCs and regulatory agencies should be working together to enhance animal well being through the use of EE whenever possible.

 **1354** BALANCING ANIMAL WELFARE AND GLP COMPLIANCE IN NONCLINICAL LABORATORY SAFETY STUDIES.

J. F. McCormack. *Office of Regulatory Affairs, US Food and Drug Administration, Rockville, MD.* Sponsor: W. Stokes.

Persons conducting nonclinical laboratory studies frequently face circumstances they perceive as necessitating either a compromise in animal care or compliance with FDA GLP regulations. This presentation will address the objectives of the GLP regulations and the use of the GLP quality management system in balancing adequate veterinary care with the need to acquire critical product safety information. The roles of testing facility management, the study director, and the attending veterinarian and their cooperative interaction in resolving conflicts will be emphasized. Study directors and attending veterinarians often view their respective responsibilities under FDA GLP regulations and animal care regulations as incompatible. The presentation will discuss how a thorough understanding of the GLP regulations can support the compatibility of these responsibilities. The presentation will also discuss the role of testing facility management in establishing procedures and an organizational structure to minimize conflict and ensure the quality and integrity of studies conducted in their facility. A discussion of common misperceptions about GLP requirements related to animal care and use will be conducted. Topics related to facility design, standard operating procedures and protocols, treatment of study animals, record retention, and FDA inspections will be covered. The presentation will also address the objectives of and activities occurring under the interagency agreement among NIH, USFDA, and USDA on animal care and use in nonclinical laboratories. The discussion will cover the responsibilities of the respective regulatory authorities and the type of information they share and how they interact under the Memorandum of Understanding.

 **1355** APPLICATION OF TOXICOGENOMICS TO PRE-CLINICAL SAFETY TESTING: VALIDATION CONSIDERATIONS FOR POTENTIAL LABORATORY ANIMAL REFINEMENT, REDUCTION, AND REPLACEMENT.

L. M. Schechtmann. *FDA/NCTR, Rockville, MD.*

Toxicogenomics offers promise for numerous key areas of research/testing, e.g. identification of early more predictive biomarkers of toxicity, new approaches for human, animal, and environmental safety/hazard/risk assessment, and characteriza-

tion of the biological activity and targets of chemicals/drugs. The technology could also potentially stimulate development of a new generation of alternative predictive testing and screening methods that could ultimately influence reduction, refinement and replacement (3Rs) of animals used for such purposes. Regulatory acceptance of the technology for decision-making purposes will necessitate standardization, validation, and demonstration of biological relevance. Efforts are already underway (e.g. ECVAM-ICCVAM/NICEATM collaboration) to begin to lay groundwork for the eventual standardization and validation of toxicogenomic-based technologies that would render them reproducible and reliable for informed regulatory decision-making. It is recognized that such an evaluation may involve considerable complexity, in that both the technology itself and any predictive alternative test methods derived from it will warrant validation. Thus, a strategy involving parallel and interactive processes of technological advancement and validation considerations will help guide the evolution of, establish confidence in, and promote adoption of this promising research/regulatory tool. Efforts directed at regulatory implementation have been in progress at FDA, e.g. draft guidances on (a) submission of pharmacogenomic data and, and (b) tests/devices that employ multiplex and microarray-based technologies. Initiatives such as these will form the foundation for the appropriate utilization of both the toxicogenomics technology and test methods based on toxicogenomics and will pave the way forward for the use of alternative (e.g. *in vitro*-based) toxicogenomics methods with potential regulatory utility and that are responsive to the 3Rs.

 **1356** REVISIONS TO EUROPEAN ANIMAL WELFARE LEGISLATION: IMPACT ON ANIMAL CARE AND TOXICOLOGY STUDIES.

J. C. Donovan. *BioResources, Wyeth Research, Collegeville, PA.* Sponsor: S. Lasley.

Conventional wisdom holds that the evolution of animal welfare legislation in Europe portends what is likely to follow in the US. Accordingly, animal researchers have for some years now been monitoring the development of new European animal welfare regulations. Since 1997 when the Council of Europe decided to revise ETS 123, the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes, a lengthy and complex process ensued that will eventually lead to a new animal welfare Directive, or law, in the European Union. As the Council of Europe neared completion of revising ETS 123 in 2003, the European Union recognized a need to revise Council Directive 86/609, the European Directive on the Approximation of Laws, Regulations and Administrative Provisions Regarding the Protection of Animals Used for Experimental and other Scientific Purposes. In 2003 the European Commission appointed a Technical Expert Working Group (TEWG) to provide scientific input on the promulgation of new legislation. The TEWG reports were published in mid-2004 and will be used as the basis for a first draft. The reports address the scope of the legislation, how experimentation should be authorized, the function of ethical review committees and pain categorization. Following consultation with stakeholders, including animal welfare groups, the Commission will present a final draft to the European Parliament and Council of Ministers for legislative action. This presentation will review the possible implications of the TEWG reports and ETS 123 for US-based animal research institutions, with an emphasis on toxicology studies. Specific areas of concern include: restrictions on non-human primate usage; enrichment requirements; cage size modifications; protocol authorization procedures; other administrative burdens; and, escalation of animal testing costs. A status report on the progress of the evolving legislation will be provided and, if a draft of the regulations is available, a review and analysis of the document.

**1357** THE ROLE OF THE COOH-TERMINAL TRANSACTIVATION DOMAIN OF THE MOUSE AH RECEPTOR IN LIGAND-DEPENDENT AND INDEPENDENT DEGRADATION.

R. S. Pollenz and J. Popat. *Biology, University of South Florida, Tampa, FL.*

The AHR receptor (AHR) is a ligand activated transcription factor that is a member of the bHLH/PAS family of proteins. Following ligand activation, the AHR is capable of forming a heterodimer with the ARNT protein and binding to DNA to regulate specific genes. Several studies have implicated the degradation of the AHR via the 26S proteasome as one of the mechanism that may attenuate receptor action. In addition, it has been suggested that the COOH-terminal domain of the AHR may be necessary for ligand-mediated degradation. This implies that amino acids within the COOH-terminal region may be modified for degradation, or that induction of specific genes may be required for degradation. To address these questions, two truncated AHRs were produced. A stop codon was placed at nucleotide #1501 to generate an AHR with 500 amino acids (AHR500) or at nucleotide 1294 to generate an AHR with 431 amino acids (AHR431). The truncated AHRs were ligated into retroviral expression vectors and used to generate stable cell lines. Treatment of stable cell lines with TCDD for 0-6 hrs showed that the time course

and magnitude of AHR degradation was not impaired in AHR500 or AHR431 when compared to wild type AHR. Geldanamycin (GA) treatment also resulted in similar levels of degradation in all AHRs. Importantly, ligand activation of AHR431 did not result in detectable levels of CYP1A1, and AHR500 induced reduced levels when compared to wild type AHR. Interestingly, the subcellular localization of the AHR431 was predominantly nuclear when compared to AHR500, and immunoprecipitation studies showed that AHR431 was associated with reduced levels of hsp90 and did not contain XAP2. These studies suggest that the COOH-terminal 374 amino acids of the AHR that include the transactivation domain, is not required for ligand-dependent or independent degradation. This implies that AHR degradation does not require genes induced by the AHR-ARNT heterodimer, and that degradation can occur efficiently when the AHR is nuclear. Supported by ES 10991.

**1358**

KINETIC STUDIES OF ARYL HYDROCARBON RECEPTOR ACTIVATION BY INDOLO[3, 2-B]CARBAZOLES, INDIGOS AND 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN IN HUMAN HEPG2 CELLS.

**A. Rannug**<sup>1</sup>, S. Pettersson<sup>1</sup>, **L. Poellinger**<sup>2</sup> and M. Backlund<sup>1,2</sup>. <sup>1</sup>*Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden and* <sup>2</sup>*Cell and Molecular Biology, Karolinska Institutet, Stockholm, Sweden.*

The arylhydrocarbon receptor (AhR) is considered to be an unusually promiscuous receptor and several candidate endogenous ligands have been suggested. These include indoles as well as fatty acid derived molecules. Among these, the naturally occurring ligand indirubin has been claimed to be most efficient, inducing transcription of cytochrome P4501A1 (CYP1A1) in human HepG2 cells at a concentration of 1pM (Adachi et al., *Toxicology Sciences* 80, 2004, 161-9). Other investigators have reported lower affinity of indirubin as measured by competitive binding to rat and mouse liver cytosolic receptors and in assays of AhR activation in a reporter cell line derived from the human hepatoma HepG2 cell line (Rannug et al., *Mutat Res* 282, 1992, 219-25; Guengerich et al., *Arch Biochem Biophys* 423, 2004, 309-16). In this study, we examined the ligand dependent activation of indigo, indirubin, indolo[3, 2-b]carbazole (ICZ), 6-formyl-indolo[3, 2-b]carbazole (FICZ) and 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) using stably transfected HepG2 cells that express luciferase under the control of one xenobiotic response element from the human CYP1A1 gene. Sub-confluent cells were treated with the compounds dissolved in DMSO, at a final DMSO concentration of 0.1 %. Special care was taken to protect cell culture media from light to avoid formation of FICZ from tryptophan present in the medium. Time-course and dose-response studies were conducted and it was observed that indirubin, ICZ and FICZ were the most potent activators, causing a half maximal induction of luciferase activity at concentrations that were approximately 20-fold lower than those of TCDD. The maximum response was obtained at short incubation times (3-6 h) and this may explain the discrepancies between the earlier reports from studies with HepG2 cells. Therefore we conclude that the indolo[3, 2-b]carbazoles and indirubin are more potent activators of the human AhR than TCDD. (Supported by USPHS Grant ES10337)

**1359**

DRE BINDING IS NOT REQUIRED FOR REPRESSION OF AHR SIGNALING BY AHRR.

**B. R. Evans**<sup>1,2</sup>, **L. L. Allan**<sup>3,4</sup>, **D. H. Sherr**<sup>3</sup> and **M. E. Hahn**<sup>1</sup>. <sup>1</sup>*Biology, Woods Hole Oceanographic Institution, Woods Hole, MA,* <sup>2</sup>*Biology, Boston University, Boston, MA,* <sup>3</sup>*Environmental Health, Boston University School of Public Health, Boston, MA and* <sup>4</sup>*Microbiology, Boston University School of Medicine, Boston, MA.*

TCDD causes a variety of effects including toxicity, alterations in the cell cycle, and developmental defects, and the aryl hydrocarbon receptor (AHR) is required to mediate many of these effects. Once ligand activated, the AHR translocates to the nucleus where it forms a transcriptionally active AHR-ARNT heterodimer that binds to dioxin-response elements (DREs), causing changes in gene expression. The AHR repressor (AHRR) is a TCDD-inducible, AHR-regulated protein that can inhibit AHR action, forming a negative feedback loop with the AHR. It has been proposed that the AHRR acts as a repressor through competition with AHR for binding to ARNT and binding to DREs. We previously cloned a zebrafish AHRR and demonstrated that competition for ARNT2b was not the primary mechanism of repression. To investigate the role of DRE binding in the mechanism of AHRR repression, a point mutation was made at tyrosine 9 of zebrafish AHRR. Previous research has shown that a single mutation at the homologous residue of AHR disrupts DRE binding. Gel shift assays confirmed that DRE binding of the mutant AHRR was disrupted. In transient transfection assays in COS-7 cells, both wild-type and mutant AHRRs were able to repress the AHR2-dependent induction of a luciferase reporter (pGudLuc6.1), although repression by the mutant AHRR was slightly attenuated. Co-transfection of increasing amounts of zebrafish ARNT2b failed to reverse repression caused by either the wild-type or mutant AHRR. These

data indicate that the AHRR can act as a repressor independent of DRE binding and in the presence of excess ARNT. Therefore, additional mechanisms of repression must exist. [NIH ES06272 and NIH ES07831]

**1360**

ERK KINASE ACTIVITY CONTRIBUTES TO AH RECEPTOR TARGETED PROTEIN DEGRADATION AND TRANSCRIPTIONAL POTENTIAL.

**S. CHEN** and **R. H. Tukey**. *Laboratory of Environmental Toxicology, Departments of Chemistry & Biochemistry and Pharmacology, University of California, San Diego, La Jolla, CA.*

Along with the mechanics of ligand binding and nuclear translocation, evidence exists that intracellular signaling pathways play an important role in Ah receptor function. Ah receptor ligands such as 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) are known to activate mitogen activated protein kinases (MAPK), such as the Erk kinases. In this study, we focused on the elucidation of the potential effects of Erk kinases on Ah receptor function. Cotreatment of hepalc1c7 cells with TCDD and Erk kinase inhibitors PD98059, U0126 or SL327 synergized TCDD enhanced nuclear accumulation of the Ah receptor, but also led to a reduced capacity to complement induction of Cyp1a1. This is explained by potential modifications through phosphorylation of the carboxyl region of the receptor, leading to diminished transactivation potential. Coincidentally, inhibition of Erk kinase leads to the induction of cellular Ah receptor levels by altering the steady-state concentrations through delayed degradation of the receptor. Erk kinase activity is directly linked to Ah receptor stabilization as demonstrated by reduction in total Ah receptor levels following the overexpression of constitutively active MEK1. Since overexpression of MEK1 enhanced TCDD initiated transactivation potential of the receptor, the transactivation region could be a target for Erk kinases. Immunoprecipitation experiments of the Ah receptor indicate that Erk kinase activity is directly associated with the receptor. Since the carboxyl region of the receptor is responsible for targeted ubiquitination in addition to controlling transactivation potential, these results indicate that Erk kinase activity promotes ligand initiated transcriptional activation while targeting the Ah receptor for degradation. (Supported by USPHS Grant ES10337)

**1361**

INVOLVEMENT OF KINASE SIGNALING PATHWAYS IN AH-RECEPTOR MEDIATED GENE EXPRESSION IN RAT LIVER CELLS.

**B. V. Madhukar**<sup>1</sup>, **G. Chen**<sup>1</sup>, **C. Sorrentino**<sup>2</sup> and **M. S. Denison**<sup>2</sup>.

<sup>1</sup>*Pediatrics/Human Development, Michigan State University, East Lansing, MI and* <sup>2</sup>*Environmental Toxicology, University of California at Davis, Davis, CA.*

Agonists of aryl hydrocarbon (Ah) receptor such as TCDD and certain PCBs induce the expression of genes containing DREs. Cross-talk with other receptor and non-receptor signaling pathways can alter such gene expression. To identify the interactions of Ah-receptor signaling with other signaling cascades a rat liver cell line WB-F344 that expresses Ah-receptor and ARNT protein was stably transfected with the plasmid containing green fluorescent protein (GFP) gene with four DREs. One clone that expressed high levels of GFP in response to TCDD (0.1 nM) or 3, 3, '4, 4', 5-pentachlorobiphenyl (PeCB, 2.0  $\mu$ M) exposure was used to examine Ah-receptor interactions with other signaling pathways. Cultures of the clone were treated with known pharmacological inhibitors of various signaling pathways prior to exposure to TCDD or (PeCB). GFP expression was examined two days after treatment. Pretreatment of the cultures with a PCB congener 2, 2', 4, 4'-tetrachlorobiphenyl (TCB, 20  $\mu$ M) that activated the mitogen activated protein kinases (MAPK) ERKs inhibited Ah-receptor mediated expression of GFP by more than 90%. Pretreatment of cells with a pharmacological inhibitor of ERK U-0126 (10.0  $\mu$ M) or a protein kinase C inhibitor bis indolylmaleimide (BIS, 5.0  $\mu$ M) did not have significant inhibitory effect on GFP expression. In contrast compound 56, a highly specific inhibitor of EGF receptor tyrosine kinase activity completely abrogated GFP expression. A src tyrosine kinase inhibitor PP2 (10.0  $\mu$ M) partially inhibited GFP expression by 50-60%. Taken together these results suggest that interactions of Ah-receptor signaling with other cell signaling pathways may alter Ah-receptor mediated gene expression and potential biological effects of Ah receptor agonists (supported by NIEHS/Superfund grant ES-04911 and Philip Morris External Research Program).

**1362**

ACTIVATION OF THE ARYL HYDROCARBON RECEPTOR ALTERS IN VIVO HEPATOCYTE PROLIFERATION.

**K. A. Mitchell**<sup>1</sup>, **S. A. Hattenbach**<sup>2</sup> and **C. J. Elferink**<sup>1</sup>. <sup>1</sup>*Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX and* <sup>2</sup>*UTMB Summer Undergraduate Research Program, University of Houston-Downtown, Houston, TX.*

Increasing evidence links the aryl hydrocarbon receptor (AhR) to cell cycle regulation. For instance, AhR-defective mouse hepatoma cells exhibit a prolonged transition through G1 phase. Similarly, treatment with the persistent AhR agonist 2, 3, 7,

8-tetrachlorodibenzo-p-dioxin (TCDD) stalls proliferation in hepatoma cells and primary hepatocyte cultures, presumably by disrupting the normal physiological processes of the AhR, yet the mechanism is unclear. The goal of this study was to determine how the AhR regulates *in vivo* hepatocyte proliferation induced either by partial hepatectomy (PH) or by treatment with the tumor-promoting mitogen 1,4-bis[3, 5-dichloro-pyridyloxy]benzene (TCPOBOP). Whereas liver regeneration following PH depends on the production of a cascade of growth factors that culminate in proliferation, TCPOBOP-induced proliferation depends on activation of the constitutive androstane receptor (CAR) and occurs independently of PH-induced stimuli. To test how AhR activation affects proliferation, mice were gavaged with TCDD (10-20  $\mu$ g/kg) or peanut oil one day prior to 70% PH or TCPOBOP treatment (3 mg/kg, gavage). Mice were sacrificed 18-60 hours later, following a 2-hr pulse with bromodeoxyuridine (BrdU), and liver was fixed for histological analysis or homogenized for western blotting. Whereas exposure to TCDD resulted in a 5-fold decrease in the number of BrdU+ hepatocytes 36 hours after PH, it increased proliferation in TCPOBOP-treated mice. AhR levels were upregulated in hepatocytes following either PH or TCPOBOP treatment, but were not altered by TCDD. Interestingly, exposure to TCDD had not effect on cyclin D1 levels, but consistently increased cyclin E levels in both model systems; however, the ramifications of this are unclear. In summary, these findings indicate that the AhR may play a role in regulating hepatocyte proliferation induced by two separate stimuli comprising distinct pathways.

### 1363

#### TEMPORAL AND DOSE-DEPENDENT HEPATIC GENE EXPRESSION PATTERNS IN MICE PROVIDE NEW INSIGHTS INTO TCDD-MEDIATED HEPATOTOXICITY.

D. R. Boverhof, L. D. Burgoon, C. Tashiro, B. Chittim, J. R. Harkema and T. R. Zacharewski. *Biochemistry & Molecular Biology, National Food Safety & Toxicology Center, and Center for Integrative Toxicology, Michigan State University, East Lansing, MI.*

Many, if not all, of the toxic effects of 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) are due to sustained, inappropriate changes in gene expression mediated via the activation of the aryl hydrocarbon receptor (AhR). Despite years of research the exact mechanisms responsible for its toxic effects remain unknown. In an effort to further characterize the mechanisms of TCDD-mediated toxicity, comprehensive temporal and dose response microarray analyses were performed on hepatic tissue from immature ovariectomized C57BL/6 mice treated with TCDD. For temporal analysis, mice were gavaged with 30  $\mu$ g/kg of TCDD or vehicle and sacrificed after 2, 4, 8, 12, 18, 24, 72 or 168 hours. Dose response mice were gavaged with 0, 0.001, 0.01, 0.1, 1, 10, 100 or 300  $\mu$ g/kg of TCDD and sacrificed after 24 hours. Hepatic gene expression profiles were monitored using custom cDNA microarrays containing 13, 361 cDNA clones. 443 and 315 features exhibited a significant change at one or more doses or time points, respectively, as determined using an empirical Bayes approach. Functional gene annotation extracted from public databases associated gene expression profiles with physiological processes such as oxidative stress and metabolism, differentiation, apoptosis, gluconeogenesis, and fatty acid uptake and metabolism. Complementary H&E examination, Oil Red O staining, clinical chemistry (i.e. ALT, TG, FFA, cholesterol) and high resolution gas chromatography/mass spectrometry assessment of hepatic TCDD levels were also performed in order to phenotypically anchor changes in gene expression to toxicity. Collectively, the data support a proposed mechanism for TCDD mediated hepatotoxicity including fatty liver which involves mobilization of peripheral fat and increased uptake of fatty acids potentially as an alternative energy source due to inhibition of hepatic gluconeogenesis. Supported by grant ES11271

### 1364

#### EXPRESSION OF DOMINANT NEGATIVE N-CADHERIN RESULTS IN AHR-DEPENDENT GENE INDUCTION IN HEPA 1C1C7 WILD-TYPE CELLS.

L. M. Van Pay<sup>1</sup> and B. Allen-Hoffmann<sup>1,2</sup>. <sup>1</sup>*Molecular and Environmental Toxicology, University of Wisconsin, Madison, WI* and <sup>2</sup>*Pathology and Laboratory Medicine, University of Wisconsin, Madison, WI.*

We have established that suspension-mediated disruption of all cell adhesion leads to the AhR-dependent induction of the prototypical XRE-regulated target gene, CYP1A1, in Hepa 1c1c7 wild-type cells. Increases in steady state CYP1A1 mRNA following a cadherin-disrupting shift from high to low calcium medium indicated that adherens junctions, mediators of cell-cell adhesion, may play a role in the suspension-induced AhR/ARNT signaling response. Our hypothesis is that disruption of adherens junctions leads to an increase in  $\beta$ -catenin, a cadherin-binding intracellular adherens junction protein, which promotes the AhR-dependent induction of CYP1A1. In order to further study the mechanism by which suspension induces AhR/ARNT signal transduction, a doxycycline-inducible dominant negative N-cadherin (dn-N-cad) protein was used to specifically disrupt cadherin-mediated cell-cell adhesion in adherent Hepa 1c1c7 wild-type cells. Maximal induction of

the dn-N-cad protein occurred 24-48 hours post treatment with doxycycline and was clone dependent. As predicted, expression of the dn-N-cad transgene decreased endogenous cadherin levels and resulted in increased  $\beta$ -catenin levels as early as 24 hours post treatment. Increases in mRNA levels of CYP1A1 were observed at 32, 48 and 56 hours following treatment with doxycycline. These studies directly demonstrate that in adherent Hepa 1c1c7 wild-type cells disruption of N-cadherin-containing junctions results in the endogenous upregulation of CYP1A1 expression. Our findings suggest a role for  $\beta$ -catenin in endogenous regulation of AhR/ARNT signaling. These data support the overall hypothesis that AhR/ARNT signaling may be endogenously regulated by cell-cell interactions *in vitro*.

#### ER $\alpha$ IS A LIGAND-DEPENDENT MODULATOR OF AHR TRANSCRIPTION: INTERPLAY BETWEEN THE TWO RECEPTOR SYSTEMS.

J. Matthews, B. Whilen and J. Gustafsson. *Department of Biosciences, Karolinska Institute, Huddinge, Sweden.*

Using chromatin immunoprecipitation (ChIP) we have demonstrated the TCDD-mediated recruitment of ER $\alpha$  to AhR target genes, and transient transfection experiments in HuH7 liver cells showed that ER $\alpha$  increased AhR/ARNT complex (AhRC) activity. In this study we used real-time PCR analysis of endogenous CYP1A1 levels to confirm the enhancing effect of ER $\alpha$  on AhR activity, and re-ChIP analysis further demonstrated the presence of ER $\alpha$  in the active AhRC. No oscillatory cycling was apparent; however the use of  $\alpha$ -amanitin pretreatment was effective in dissecting the differential recruitment kinetics between the enhancer and tata-box regions of the CYP1A1 promoter. We also examined the ability of different AhR and ER ligands to influence the recruitment of ER $\alpha$ , and the AhRC to pS2 and CYP1A1 using ChIP followed by real-time PCR. As expected, TCDD induced the recruitment of ER $\alpha$  to the CYP1A1 promoter, but not to the pS2 promoter. Surprisingly, DIM, ICZ, and  $\beta$ -naphthoflavone, induced the recruitment of ER $\alpha$  to both the CYP1A1 and the pS2 promoters, whereas  $\alpha$ -naphthoflavone only induced the recruitment of ER $\alpha$  to pS2 and not CYP1A1. This suggests that diverse AhR ligands can differentially influence ER $\alpha$  activity. Phytoestrogens genistein and coumestrol, as well as 4-t-octylphenyl and BPA caused a similar time-dependent recruitment of ER $\alpha$  to pS2; however preferential recruitment of the p160 coactivators was evident. For instance, E2 caused the recruitment of all three p160 family members to pS2, whereas 4-t-octylphenol preferentially recruited TIF2 as opposed to AIB1 or SRC-1. In cotreatment with TCDD, all estrogenic compounds increased the recruitment of ER $\alpha$  to CYP1A1. Collectively, these data implicate ER $\alpha$  as a modulator of AhR signaling cascades, that different AhR ligands can differential influence ER $\alpha$ , supporting a new mechanism of AhR-ER $\alpha$  cross-talk. In addition, these data also suggest that different ligands can influence the coregulator complex composition during transcription activity.

### 1366

#### THERAPEUTIC CONCENTRATIONS OF HALOPERIDOL DO NOT DIRECTLY AFFECT OVARIAN FUNCTION AND OOCYTE QUALITY AS TESTED IN MOUSE OVARIAN FOLLICLE CULTURE MODEL.

R. Cortvriendt<sup>1,2</sup>, E. Gobbers<sup>1</sup>, V. Van Merris<sup>1</sup> and J. Smitz<sup>1</sup>. <sup>1</sup>*EggCentris NV, Zellik, Belgium* and <sup>2</sup>*Follicle Biology Laboratory, Vrije Universiteit Brussel, Brussels, Belgium.* Sponsor: G. Daston.

Patient plasma concentrations of the neuroleptic drug haloperidol used in antipsychotic and behaviour therapies range between 5  $\eta$ M and 100  $\eta$ M. Several in-vivo animal studies suggested that haloperidol can influence the gonadotrophin and prolactin release and can have an impact on reproduction. It is not clear whether haloperidol can provoke cellular down-stream effects via receptor binding in the ovary, which would create additional disturbances for female fertility. The in-vitro mouse ovarian follicle bioassay was used to investigate the direct effects of haloperidol on the ovarian function and on oocyte quality. Preantral mouse ovarian follicles were cultured individually during 12 days in continuous presence of haloperidol (1, 10, 50, 100, 1000  $\eta$ M). A total of 420 follicles were used in 6 replicates. *In vitro* ovulation was induced by hCG and mature oocytes were harvested for morphological analysis and grading of meiotic maturation. Haloperidol exposed follicle cultures were evaluated for follicle differentiation, oocyte maturation and steroid hormone secretion pattern. Up to a dose of 100  $\eta$ M haloperidol had no effects on follicle survival and differentiation (antrum formation), oocyte maturation or steroid production. But at a dose of 1000  $\eta$ M haloperidol oocyte maturation capacity was significantly decreased: only 64 $\pm$ 17% of the oocytes extruded a polar body, compared to 97 $\pm$ 5% in the control group. Also 17  $\beta$ -estradiol secretion was decreased compared to the control group ( $P=0.05$  in t-test). The mouse in-vitro follicle bioassay reveals that haloperidol doses within the human therapeutic dose window do not alter folliculogenesis, oocyte quality and steroidogenesis by a direct interaction with the ovarian follicle. Doses of haloperidol over 100  $\eta$ M interfere with oocyte maturation perhaps via cellular receptor-mediated pathways in the ovary that bind the compound with a low affinity.

BCL-2 FAMILY MEMBERS PROTECT AGAINST  
METHOXYCHLOR-INDUCED TOXICITY OF MOUSE  
OVARIAN ANTRAL FOLLICLES *IN VITRO*.

K. P. Miller<sup>1</sup>, C. Greenfeld<sup>2</sup> and J. A. Flaws<sup>1</sup>. <sup>1</sup>Program in Toxicology, University of Maryland-School of Medicine, Baltimore, MD and <sup>2</sup>Department of Physiology, University of Maryland-School of Medicine, Baltimore, MD.

The organochlorine pesticide methoxychlor (MXC) is a reproductive toxicant that destroys antral follicles in the mammalian ovary. In response to *in vivo* MXC exposure, mouse antral follicles show increased atresia and altered apoptotic protein expression. Moreover, mice overexpressing the anti-apoptotic protein Bcl-2 (Bcl-2+), and mice deficient in the pro-apoptotic protein Bax (BaxKO) are protected from *in vivo* MXC-induced atresia. Likewise, studies using an *in vitro* culture model indicate that MXC inhibits antral follicle growth and increases atresia over controls. This current study tested the hypothesis that isolated antral follicles from Bcl-2+ and BaxKO mice are protected from MXC-induced atresia and growth inhibition, and that our *in vitro* culture model mimics *in vivo* MXC exposure. Mouse antral follicles were isolated and exposed *in vitro* to vehicle (DMSO) or MXC (1-100 µg/ml) for 96hrs. Follicle diameters were measured at 24hr intervals to assess growth in response to MXC. After 96hrs, follicles were processed for histological analysis of atresia. MXC (10 and 100 µg/ml) significantly inhibited growth of wild type (WT) antral follicles *in vitro* compared to controls at 72 and 96hrs (n=25 follicles/treatment; p≤0.03). In contrast, MXC did not inhibit growth of Bcl-2+ and BaxKO follicles until 96hrs (n=28 follicles/treatment; Bcl-2+ p≤0.004; BaxKO p≤0.001). MXC also increased atresia of small and large WT antral follicles over controls (n=6-11 follicles/treatment; p≤0.03), but did not increase atresia of large Bcl-2+ and BaxKO antral follicles over control levels. These data suggest that Bcl-2 overexpression or Bax deletion provides protection from MXC-induced antral follicle toxicity. These data also indicate that this *in vitro* culture model mimics our findings *in vivo*, supporting the use of this method to evaluate ovarian follicle toxicity. (Supported by NIH HD38955, T32 ES07263-13, T32 HD07170 and a Colgate-Palmolive Postdoctoral Fellowship)

REVERSAL OF BENZO-A-PYRENE EFFECTS ON  
OXYTOCIN-INDUCED  $Ca^{2+}$  OSCILLATIONS IN  
HUMAN MYOMETRIAL PHM1-41 CELLS.

R. Barhoumi, I. Awooda, S. Safe and R. C. Burghardt. Faculty of Toxicology, Texas A&M University, College Station, TX.

Benzo-a-pyrene (BaP) is one of the polycyclic aromatic hydrocarbons that exist as major environmental pollutants. In the present study, we have examined the effect of this carcinogen/mutagen upon human myometrial  $Ca^{2+}$  signaling. Exposure of PHM1-41 cells to BaP did not alter basal calcium levels of these cells or the IP3-releasable  $Ca^{2+}$  pool. However, BaP significantly decreased the oxytocin-induced  $Ca^{2+}$  transient as well as the frequency of oxytocin-induced oscillations. To determine the source of these alterations, a variety of pharmacologic agents such as the endoplasmic reticulum Ca-ATPase inhibitor thapsigargin, an activator and inhibitor of protein kinase C, a K<sup>+</sup> channels blocker, and tyrosine kinase inhibitors and activators were used. Our data revealed that the store operated channels are significantly affected by BaP treatment. The inhibition of myometrial smooth muscle oscillations induced by BaP seems to be mediated, at least in part, via activation of  $Ca^{2+}$  activated K<sup>+</sup> channels, because partial inhibition was eliminated by the K<sup>+</sup> channel blocker tetraethylammonium chloride. The non-specific tyrosine kinase inhibitor genistein and the epidermal growth factor receptor tyrosine kinase inhibitor AG1478 markedly reduced the oxytocin induced  $Ca^{2+}$  oscillations in control cells but not in BaP treated cells. The effect of these inhibitors on the tyrosine kinase pathway in control myometrial cells is similar to the BaP effect suggesting that BaP inhibits tyrosine kinase activity in PHM1-41 cells. The use of FBS or charcoal/dextran treated FBS (1.25%) prior to oxytocin, restimulated the  $Ca^{2+}$  oscillations induced by oxytocin in BaP treated cells to a level similar to control cells. These data suggest that the action of BaP effect on  $Ca^{2+}$  oscillations in myometrial cells can be reversed.

EFFECTS OF ATRAZINE AND AN ATRAZINE  
METABOLITE MIXTURE ON DIFFERENTIATED  
MAMMARY EPITHELIAL CELL MILK PROTEIN  
PRODUCTION IN CULTURE.

E. P. Hines, R. Barbee, M. Blanton, M. S. Pooler and S. E. Fenton. Reproductive Toxicology Division, USEPA, ORD, NHEERL, Research Triangle Park, NC.

Previous studies have shown that prenatal exposure to the commonly used herbicide, atrazine (ATR) can have adverse effects on mammary gland development and function in female rat offspring. To evaluate the effects of ATR on differentiated mammary epithelia, HC11 cells were tested for a dose response to atrazine or an atrazine metabolite mixture (EBM), containing 25% ATR. Cells were grown to

confluence on plastic in growth medium, then induced to differentiate (produce milk proteins) by adding prolactin, dexamethasone, and insulin (lactation media). The cells were simultaneously dosed with 0, 16, 64, or 250 µM ATR or 0.17, 17.4, or 1740 ng/ml EBM. Cells not induced with lactation media and grown concomitantly were the negative control. Following 4 days of differentiation (induces caseins), media were collected and concentrated, and attached cells were lysed in a solution containing protease inhibitors. Western blot analyses were performed for actin, prolactin and caseins using 50 µg total protein per sample. Actin (40 kDa) was detected at similar levels in all cell treatments and was absent in media samples. Prolactin (28 kDa) was detected in all treatment groups in similar amounts, but was absent in negative controls. Cellular prolactin levels were unchanged by treatment (24 kDa band slightly reduced in negative control). Caseins were detected with the antibody, and the use of lactation medium induced a 5- and more than 20-fold induction of caseins of about 28 and 21 kDa, respectively, over that in negative controls. EBM caused a dose dependent decrease in 21 kDa casein (72, 43, and 1% of control, respectively), whereas only the highest dose of EBM affected the 28 kDa species (36% of control). ATR alone had no effect on the 28 kDa casein, but decreased the 21 kDa species 78, 77, and 68% of control, respectively. Studies to discern the effects of these compounds on gene expression of milk proteins are ongoing. (This abstract is of a proposed presentation and does not reflect EPA policy)

NEONATAL EXPOSURE TO THE PHYTOESTROGEN  
GENISTEIN ALTERS REPRODUCTION IN FEMALE CD-  
1 MICE.

W. Jefferson<sup>1,2</sup>, E. Padilla-Banks<sup>1</sup> and R. Newbold<sup>1</sup>. <sup>1</sup>Laboratory of Molecular Toxicology, NIEHS, NIH/DHHS, Research Triangle Park, NC and <sup>2</sup>Molecular and Environmental Toxicology Department, North Carolina State University, Raleigh, NC.

Developmental exposure to estrogenic substances causes adverse effects on the developing reproductive tract. Genistein (Gen), the primary phytoestrogen in soy products, was investigated for potential adverse effects on the developing female reproductive system. Outbred CD-1 mice were treated by subcu. injection on neonatal days 1-5 with Gen 0, 0.5, 5 or 50 mg/kg/day in corn oil. Mice were weaned at 21 days of age and observed daily for vaginal opening (n=16 mice per group). Vaginal opening occurred earlier in Gen 0.5 and 5 mice than controls (3/16 and 2/16, respectively). However, the highest dose of genistein showed a marked delay in vaginal opening with only 6% open at 30 days of age compared to 40% in controls. At 2 mo., daily vaginal smears showed that Gen altered estrus cycle length as well as caused a dose related increase in severity of abnormal cycles. When Gen mice were bred to control males, the 0.5 and 5 group had normal fertility at 2 and 4 mo. of age with similar numbers of mice delivering live pups and similar litter sizes as controls. However, by 6 mo. of age, there was a sharp decrease in the percent of mice delivering live pups in both Gen 0.5 and 5 doses (60% and 40%) compared to controls (100%). Mice treated with the highest dose of Gen did not deliver any live pups at any age examined. To study the infertility at the high dose, mice were bred and uteri collected at various gestational ages to assess pregnancy loss. There were less Gen 50 mice showing signs of pregnancy on day 6, 8 or 10 (62%, 37% and 45%) compared to controls (89%, 95% and 100%). Further, Gen mice that were pregnant had fewer embryos (<50%) than their control counterparts. Reabsorptions were commonly seen in Gen 50 mice. In summary, mice treated neonatally with genistein exhibit altered vaginal opening, abnormal estrus cycles, early reproductive senescence and subfertility/infertility at doses of Gen that are environmentally relevant.

ESTROGEN-INDUCED PATTERN OF GENE  
EXPRESSION AT HIGH AND LOW DOSES IN FETAL  
MALE RAT TESTIS.

J. M. Naciff, K. M. Hess, J. E. Martinez, G. J. Overmann, L. M. Foertsch, S. M. Torontali, G. J. Carr, J. P. Tiesman and G. P. Daston. Procter & Gamble Company, Cincinnati, OH.

Exposure of developing fetal rodents to some estrogenic compounds at relatively high doses induces abnormalities in the male reproductive system and causes a predisposition to abnormal function during adulthood. We hypothesize these latent developmental effects are preceded by immediate changes in the fetal gene expression. High-density oligonucleotide arrays were used to determine the transcriptional program elicited by transplacental exposure to 17 $\alpha$ -ethynodiol (EE), genistein (Ges), or bisphenol A (BPA), in the developing rat testis and epididymis on GD 20, following maternal exposure on GD 11-20. Dosages were: 0.001-10 µg EE/kg/day, 0.001-100 mg Ges/kg/day and 0.002-400 mg BPA/kg/day, none of which induced detectable morphological changes in the developing reproductive system. The gene expression profile of testis and epididymis was modified by exposure to these estrogen receptor (ER) agonists in a consistent way. The highest dosage of each compound produced a significant change in expression level of 141, 46 and 67 genes (out of 8740), respectively. Dose-dependent analysis of the transcript profile revealed that the expression of 56 genes is significantly modified by

EE, while only 28 genes and 15 genes are dose responsive to Ges or BPA, respectively. Global comparison of the effect of EE, Ges or BPA exposure, at the three highest doses, indicated that the expression of 52 genes change in the same direction, although at a different magnitude. The dose-response curve for gene expression was monotonic, with both the magnitude of change and number of genes significantly changed decreasing with decreasing dose. Further, the gene expression changes induced show clear evidence of a variety of cellular pathways affected by estrogen exposure, some of which may have an impact in both gonadal differentiation and subsequent reproductive function. These results indicate that gene expression data are diagnostic of mode of action and can be used to elucidate dose-response characteristics at low dose.

**1372** LOW DOSE CELLULAR RESPONSES IN THE FETAL RAT TESTIS *IN UTERO* EXPOSED TO DI (N-BUTYL) PHTHALATE.

E. Kleymenova, C. Swanson and K. W. Gaido. CIIT CHR, Research Triangle Park, NC.

Di(n-butyl)phthalate (DBP) is used in personal care products and as plasticizer to soften plastics. Adult male rats *in utero* exposed to DBP at 250-500 mg/kg/day dose-levels have malformations of the reproductive tract and testicular atrophy. These dose-levels also cause development of multinucleated gonocytes (MNG), inhibit cell proliferation, alter formation of seminiferous tubules, and disrupt contacts between Sertoli and germ cells in the fetal rat testis. The goal of the study was to determine if exposure *in utero* to low doses of DBP result in these cellular responses in the fetal testis. Timed-pregnant Sprague-Dawley rats were treated with 0.1, 1, 10, 30, 50, 100, and 500 mg/kg/day DBP by oral gavage on gestation days 12 to 20, and euthanized on day 21. Two hours prior to euthanasia, dams were i.p. injected with 50 mg/kg BrdU. Fetal testes were fixed in situ in modified Davidson's fixative, dissected, and embedded in paraffin. Cellular responses were assessed using H&E- or immunostained with P-cadherin tissue slides. The effect of DBP treatment on the size, total cell number, and cordial cross-section number was significant at 50 mg/kg/day dose-level. Although there was a trend indicating that the 50 mg/kg/day dose-level increases the incidence of MNG, statistical significance was achieved only at the 100 mg/kg/day dose-level. Consistent with this trend, fetal rat testes exposed to 30 and 50 mg/kg/day DBP had focal disruption of Sertoli-germ cell contacts as indicated by P-cadherin immunostaining. Our data demonstrate that in the rat, adverse cellular responses in the fetal testis can be detected at lower doses compared to those causing gross pathological changes. The lowest dose that significantly altered size, total cell number, and cordial cross-section number also decreased the concentration of testicular testosterone in the fetal rat testes *in utero* exposed to DBP. Whether reduction in testicular testosterone following *in utero* exposure to DBP is linked with decreased cell proliferation, disruption of Sertoli-germ cell interaction, and increased occurrence of MNG remains to be determined.

**1373** IDENTIFYING CANDIDATES FOR THE CDM GENE, WHICH CONFFERS RESISTANCE TO CADMIUM-INDUCED TESTICULAR DAMAGE IN MICE.

L. Martin<sup>1</sup>, H. Allayee<sup>2</sup>, D. Shih<sup>3</sup>, G. Lee<sup>1</sup>, D. Hovland<sup>4</sup>, R. Hess<sup>5</sup>, K. Carnes<sup>5</sup>, R. M. Cantor<sup>3,6</sup>, A. J. Lusis<sup>3</sup> and M. Collins<sup>1</sup>. <sup>1</sup>*Molecular Toxicology, UCLA, LA, CA*, <sup>2</sup>*Institute for Genetic Medicine, USC, LA, CA*, <sup>3</sup>*Human Genetics, UCLA, LA, CA*, <sup>4</sup>*Toxicology, Amgen, Thousand Oaks, CA*, <sup>5</sup>*Veterinary Biosciences, University of Illinois, Urbana, IL* and <sup>6</sup>*Pediatrics, UCLA, LA, CA*. Sponsor: Q. Hankinson.

Cadmium is an industrial and environmental toxin that damages the testes, prostate, placenta, kidneys, liver, lungs, and pancreas in humans and other mammals. Strain specificity for cadmium-induced testicular damage in mice is due to a single recessive gene, named cdm. Cdm/cdm mice are afforded complete resistance to cadmium-induced testicular damage, while both wildtype and heterozygous mice are susceptible. Of 44 mouse strains, 14 including C57BL/6J are cdm/cdm, and 30 including DBA/2J are wildtype. The cdm gene has been previously mapped to a region between microsatellite markers D3Mit110 and D3Mit255, a 4.7 Mb region on mouse chromosome 3, using C57BL/6J x DBA/2J (BxD) recombinant inbred strains (Dalton et al., 2000). The present study used 1, 850 F2 mice from a BxD F1 cross to narrow this region to 1.8 Mb. Thirty-two mice with a recombination between two cdm flanking markers (D3Nds2 and D3Mit291) which are 4.3 Mb apart were injected with 6 mg/kg CdCl<sub>2</sub> and phenotyped for testicular damage. Additional polymorphic markers were designed to refine the region to 1.8 Mb. RT-PCR has been run on the 30 candidate genes in this region. Preliminary data indicate expression differences in an oxidoreductase, a ubiquitin-conjugating enzyme, Nfcb1, and two predicted but not yet annotated genes. Real time PCR and protein inhibitor experiments are currently underway for these and other candidate genes in the region. Damage to spermatogenesis, Sertoli cells, and endothelial tissue has been quantified via histopathology. The function of the cdm gene has not yet been identified but it is conceivable that elucidation of the cdm pathway will provide insight into the mechanisms for human cadmium toxicity in reproductive and other organs.

**1374** PERIPUBERTAL DEHP EXPOSURE INHIBITS ANDROGEN-DEPENDENT DEVELOPMENT IN SPRAGUE-DAWLEY RATS.

N. Noriega, J. Furr, C. Lambright, V. S. Wilson and L. E. Gray. RTD, USEPA ORD NHEERL, Research Triangle Park, NC.

The plasticizer Di (2-ethylhexyl) phthalate (DEHP) may present reproductive risk by demasculinizing prenatal and juvenile males. The current study was designed to assess DEHP effects throughout pubertal development in Sprague-Dawley rats. Males were dosed with DEHP at 0, 100, 300 and 900 mg/kg-bw/day from PND 23. A "peri-pubertal" group was dosed until mid puberty (euthanized on PND 43/44), and a "post-pubertal" group was dosed throughout puberty (euthanized on PND 63/64). At the time of first necropsy, where half of the male study population was euthanized, there was a dose dependent reduction in the number of males showing complete preputial separation. Females dosed daily from PND 23 with either corn oil or 900 mg/kg-bw/day DEHP showed no differences in time to vaginal opening. In males, weights of androgen dependent tissues (testis, epididymis, ventral prostate, seminal vesicle, Cowper's glands and levator ani + bulbocavernosus muscles were reduced at high doses in peri and post-pubertal groups. Serum testosterone (T) levels and adrenal gland weights showed dose dependent reductions in the peri-pubertal group, but were not significantly affected in the post-pubertal group. *Ex-vivo* testis T production was reduced (with and without gonadotropin stimulation) in a dose-dependent manner in peri and post-pubertal groups. On a per weight basis (T/mg of testis), there was a dose dependent increase in *ex-vivo* testis T production in the post-pubertal group. These findings support the hypothesis that DEHP treatment around early puberty decreases Leydig cell T output, whereas prolonged treatment throughout puberty increases Leydig cell T output. These data do not support the hypothesis that DEHP exposure promotes precocial pubertal development by elevating serum T. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

**1375** GENE ONTOLOGY MAPPING OF EARLY TRANSCRIPTIONAL RESPONSES ASSOCIATED WITH HEPATOCYTE PROLIFERATION IN THE LIVER OF DIETHYLHEXYLPHthalATE-EXPOSED MICE.

R. Currie<sup>1</sup>, V. Bombail<sup>1</sup>, D. J. Moore<sup>1</sup>, F. Lim<sup>1</sup>, J. Oliver<sup>1</sup>, K. Chipman<sup>2</sup>, L. Kimber<sup>1</sup>, G. Orphanides<sup>1</sup> and J. Moggs<sup>1</sup>. <sup>1</sup>*Syngenta CTL, Macclesfield, Cheshire, United Kingdom* and <sup>2</sup>*University of Birmingham, Birmingham, United Kingdom*.

A number of industrial chemicals cause liver tumours in rodents without damaging DNA directly. Previous studies have suggested that these chemicals induce carcinogenesis by controlling cell growth, proliferation and apoptosis. Assessment of the likely risk to humans posed by nongenotoxic carcinogens will be facilitated by identification of the molecular pathways through which these compounds control cell proliferation. We have investigated these pathways using global gene expression profiling and bioinformatic analyses. Mice were dosed with the model rodent nongenotoxic carcinogen and peroxisome proliferator (PP) diethylhexylphthalate (DEHP) to induce liver growth and peroxisome proliferation within 3 days. Gene expression levels at 2, 8, 24 and 72h were measured using Affymetrix GeneChips and 1, 786 DEHP-responsive genes were identified by ANOVA. Gene Ontology (GO) analysis tools were used to identify the predominant Biological Processes and Cellular Components associated with early DEHP-responsive genes. Consistent with previous studies of DEHP-induced liver cell growth and proliferation, our GO analysis of transcript profiling data revealed a striking overrepresentation of genes involved in acyl-CoA and fatty acid metabolism together with genes associated with the peroxisomal cellular component. Furthermore, this GO analysis revealed gene expression changes associated with a variety of biological functions, including in amino acid metabolism, hemostasis, complement activation, the endoplasmic reticulum overload response and circadian rhythm. Together, these data reveal potential new pathways of PP action and may shed new light on the mechanisms by which nongenotoxic carcinogens control hepatocyte growth and proliferation. Furthermore, our data demonstrate that GO mapping is a powerful approach for elucidating modes of toxicity based on Toxicogenomic data.

**1376** COMPARATIVE ANALYSIS OF GENE NETWORKS AT MULTIPLE DOSES AND TIME POINTS IN LIVERS OF RATS EXPOSED TO ACETAMINOPHEN.

H. Sone<sup>1,2</sup>, H. Toyoshiba<sup>1,2</sup>, T. Yamanaka<sup>1</sup>, F. Parham<sup>1</sup>, R. Irwin<sup>1</sup>, G. Boorman<sup>1</sup> and C. J. Portier<sup>1</sup>. <sup>1</sup>*ETP, NIEHS, Research Triangle Park, NC* and <sup>2</sup>*Environmental Health Sciences Division, NIES, Tsukuba, Ibaraki, Japan*.

As a part of systems toxicology, gene interaction network analysis using microarray data has been developed to determine systematic changes of gene expression after chemical exposure. We have developed two algorithms for analyzing gene-expression networks, both based on Bayesian network structures: the TAO-Gen

(Theoretical Algorithm for identifying Optimal Gene interaction networks) algorithms for identifying networks (1) and a statistical algorithm for quantifying network connections (2). In this paper, these methods were further applied to the gene network profiling of a rat liver exposed to acetaminophen (APAP) to compare differentially expressed genes at multiple doses of exposure chemicals and multiple time points after their exposure. APAP is well known for its use in pain relievers and fever reducers. The maximum daily dose is 4 g (66-77 mg/kg b.w.) for adults. Hepatotoxicity of APAP has been considered to be involved in apoptosis and oxidative stress. Therefore, 17 genes related to apoptosis and oxidative stress were chosen based on ontology to determine gene-interaction networks. The behavior of networks that are made up of the 17 genes selected was comparatively analyzed at multiple doses (from a dose equivalent to the human maximum daily dose to a dose 3 times higher) and time points. The results showed that the network structure at the lower doses can be separated from the high dose structure, suggesting that this analysis can detect different gene interactions at lower doses.

### 1377 A SIGNATURE GENE NETWORK APPROACH TO TOXICITY.

S. Ekins<sup>1</sup>, C. Giroux<sup>2</sup>, Y. Nikolsky<sup>1</sup>, A. Bugrim<sup>1</sup> and T. Nikolskaya<sup>1</sup>. <sup>1</sup>GeneGo Inc., St Joseph, MI and <sup>2</sup>Institute of Environmental Health Sciences, Wayne State University, Detroit, MI.

The different physiological responses to toxicant challenge, both protective and pathological, reflect differential activity of the underlying cellular pathways. Although gene expression profiling has been used to classify distinct cellular states, it is still problematic to identify mechanisms of toxicity from these profiles. To address this limitation, we have developed a gene network-based approach that supports identification of the genes and pathways mediating cellular toxicity. Gene expression microarray data is used to identify interacting, differentially expressed genes that are assembled into toxicant-“signature” gene networks. First, using a yeast experimental model, we demonstrate that all of the cellular responses to hydrogen peroxide exposure can be captured by microarray profiling to construct a phenotypic response network for oxidative stress. Next, using data from published mammalian studies, we demonstrate that MetaCoreTM, a computational platform for pathway and gene network analysis, can be used to construct a gene network that identifies the underlying cellular pathways and processes of chemical-induced toxicity. As an example, gene expression microarray data for benzene-induced hematotoxicity has been used to construct static signaling maps that reveal both oxidative stress and of p53 inhibition of apoptosis. To further illustrate our approach, gene network maps have been constructed that distinguish exposure to two hepatotoxins, furan and acetaminophen (APAP), that cause different liver pathologies. For example, the furan-induced network connects up-regulated genes of cell proliferation and cell cycle progression with down-regulated genes for nuclear receptors and several P450s and their transcriptional regulators. In contrast, the regulatory network for APAP includes the energy producing pathways of cellular glycolysis and mitochondrial -hydroxylation. These examples demonstrate the power of signature gene networks to reveal mechanisms of toxicity and represents a novel method for accessing complex tissue-level processes.

### 1378 A GENETIC NETWORK APPROACH TO COMPARATIVE TOXICOGENOMICS AND RISK ASSESSMENT: THE OXIDATIVE STRESS RESPONSE.

Nikolskaya<sup>2</sup>. <sup>1</sup>Institute of Environmental Health Sciences, Wayne State University, Detroit, MI and <sup>2</sup>GeneGo, Inc., St. Joseph, MI.

Although the precise mechanisms of chemically induced cellular toxicity are often unknown, they are presumed to be associated with diagnostic changes in gene expression of the proteins that mediate the toxicant response. Comparison of gene expression profiling data from different species reveals a high degree of evolutionary conservation of the functional modules of the underlying genetic network. We are exploiting this conservation to develop a yeast computational model for the highly conserved phenotypic responses to oxidative stress and to use this model to identify cellular patterns of gene expression that will be predictive for the underlying mechanisms of toxicity. As a proof of concept for our approach, we have modeled the gene expression profiles for both protective and adverse oxidative stress responses that are induced by hydrogen peroxide in yeast, and demonstrate that this computational model can identify genetic pathways that are conserved among yeast, animal models, and the human. We have separately visualized the genetic networks of the mitochondrial versus the cytoplasmic responses to hydrogen peroxide-induced stress and demonstrate an intimate coupling of the pathways for energy production and protein biosynthesis between these two cellular compartments. Loss of mitochondrial function is an early adverse consequence of exposure of yeast cells to hydrogen peroxide. Ortholog mapping of conserved genes identifies oxidative phosphorylation as a key process in the mitochondrial genetic response network that is

also a source of cellular free radical damage in response to oxidant challenge. Using this key pathway as the seed to visualize the human mitochondrial proteome network has allowed us to identify key signaling nodes (genetic hubs) in the mitochondrial response. Thus, our genetic network analysis enables comparative toxicogenomics and the construction of predictive models for human risk assessment.

### 1379 PREDICTION OF HEPATOCARCINOGENICITY OF CHEMICALS USING THE GENE EXPRESSION IN THE 28-DAY REPEAT-DOSE TOXICITY STUDY.

H. Matsumoto<sup>1</sup>, F. Saito<sup>1</sup>, Y. Yoshikuni<sup>1</sup>, Y. Sudo<sup>1</sup>, M. Otsuka<sup>1</sup>, H. Miyaura<sup>1</sup>, I. Fukuda<sup>5</sup>, K. Saito<sup>2</sup>, K. Sumida<sup>2</sup>, M. Sekijima<sup>3</sup>, K. Nakayama<sup>3</sup> and T. Shirai<sup>4</sup>. <sup>1</sup>Chemicals Evaluation and Research Institute, Japan, Tokyo, Japan, <sup>2</sup>Sumitomo Chemical Co., Ltd., Osaka, Japan, <sup>3</sup>Mitsubishi Chemical Safety Institute Ltd., Ibaraki, Japan, <sup>4</sup>Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan and <sup>5</sup>Mitsui Knowledge Industry Co., Ltd., Tokyo, Japan.

We developed a prediction method for hepatocarcinogenicity of chemicals using the microarray techniques. Male Fischer 344 rats aged 5-week old were treated by daily oral gavages with hepatocarcinogenic and non-hepatocarcinogenic compounds at two dose levels for up to 28 days. The gene expression profiles of the livers were analyzed using the in-house microarray (NEDO-ToxArray) and GeneChip (RGU34A, Affymetrix) on Day-1, 3, 7, 14 and 28 after treatment. Several statistical methods were applied to select the characteristic genes that showed a significant increase or decrease in the gene expression levels between the hepatocarcinogens and the non-hepatocarcinogens. Unsupervised and supervised methods were then adopted to verify the validity of this approach for gene selection. First, in cluster analysis with the selected gene sets, the chemicals were classified into two groups of hepatocarcinogens and non-hepatocarcinogens. Next, in Support Vector Machine with the selected gene sets, prediction of hepatocarcinogens showed good values at high dose on Day-14 and Day-28. In this approach, the selected gene sets were found to be effective to predict hepatocarcinogenicity of the chemicals. This study is supported by NEDO (New Energy and Industrial Technology Development Organization).

### 1380 TOXICOGENOMICS FOCUSING ON THE HEMOPOIETIC STEM CELL TOXICOLOGY.

Y. Hirabayashi<sup>1</sup>, B. Yoon<sup>1</sup>, K. Kitada<sup>2</sup>, T. Matsushita<sup>1,3</sup>, K. Kobayashi<sup>2</sup>, K. Igarashi<sup>1</sup>, Y. Kodama<sup>1</sup>, J. Kanno<sup>1</sup> and T. Inoue<sup>4</sup>. <sup>1</sup>Division of Cellular & Molecular Toxicology, National Institute of Health Sciences, Tokyo, Japan, <sup>2</sup>Kamakura Research Labs, Chugai Pharmaceutical, Co., Ltd., Kamakura, Japan, <sup>3</sup>Fuji Gotenba Research Labs, Chugai Pharmaceutical, Co., Ltd., Shizuoka, Japan and <sup>4</sup>Center for Biological Safety & Research, National Institute of Health Sciences, Tokyo, Japan.

The application of toxicogenomics to hematotoxicology should eventually focus on the alteration of the expression profilings of the hematopoietic stem cell/progenitor compartment. Since the hematopoietic system consists of a mixture of heterogeneous cells from the view of not only functionally different cellular lineages, but also different stages in differentiation, an unfractionated blood sample may give different gene expression profiles, and the microarray data from the net tissue may not always provide an efficient and predictable outcome. Specific attention should be paid to the preparation and interpretation of microarray data. As case studies, hematotoxic gene expression profilings after a single dose of 300 cGy irradiation and repeated 300 ppm benzene inhalation, 6 hours a day, 5 days a week, for 2 weeks were introduced as an inductive approach of toxicogenomics, and then, a couple of plausible genes were selected with respect to the “stemness profiling”. In the WT mice, up-regulation of p53 gene was not appeared in 2 weeks after benzene intermittent exposure, but weakly detected in a month after 300 cGy irradiation. Up-regulation of cyclinG1, down stream of p53, was observed after both, benzene inhalation and 300 cGy irradiation, implying that the up-regulation of cyclinG1 should be a relevant reflect to the prolonged DNA damage. When benzene is exposed, down-regulation of caspase 12 and up-regulation of cyclin B1 is seen only when p53 is knocked out (these gene changes may be hidden by p53 gene regulation in the case of WT mice). In the case of benzene exposure, participation of the same gene repertoire is observed even in the WT mice one month after 300cGy irradiation, suggesting the result may be reflect of a possible p53 dysfunction in these irradiated mice.

### 1381 QC METRICS AND THRESHOLDS FOR ASSESSING THE OVERALL QUALITY OF A MICROARRAY STUDY.

L. Shi<sup>1</sup>, W. Tong<sup>1</sup>, F. Goodsaid<sup>2</sup>, F. Frueh<sup>2</sup>, F. C. Fuscoe<sup>1</sup> and D. A. Casciano<sup>3</sup>. <sup>1</sup>Division of Systems Toxicology, NCTR, USFDA, Jefferson, AR, <sup>2</sup>Office of Clinical Pharmacology and Biopharmaceutics, CDER, USFDA, Rockville, MD and <sup>3</sup>Office of the Director, NCTR, USFDA, Jefferson, AR.

The regulatory review of microarray-based pharmacogenomic data submissions is challenged by the complexity of the DNA microarray experimental process, the use of multiple platforms available in the market, and the lack of standardization across

this process. It is difficult to standardize individual microarray steps for regulatory quality control (QC) purposes, but we believe that platform-independent QC metrics and thresholds for assessing the overall quality of a microarray study can and should be established. Cross-lab/platform comparability is required for the transformation of DNA microarray technology from a research tool to clinical practice, and depends on the availability of such platform-independent QC metrics and thresholds. We have re-analyzed several published data sets and have identified broad differences in data quality. Intra-lab/platform quality control problems were evident for studies that claimed a lack of cross-lab/platform comparability. We have demonstrated problems in data quality as well as the lack of QC metrics and thresholds that objectively assess the overall quality of a microarray study. This process was shown to require independent assessments of the quality of the microarray and the study. It also required appropriate approaches to establish QC metrics and thresholds. Three fundamental questions were addressed: (1) QC Metrics (parameters): How should the quality of a microarray study be assessed? (2) QC Thresholds (cutoffs): Is the quality of a microarray study acceptable? (3) Approaches: What should be done to establish microarray QC metrics and thresholds?

### 1382

#### PROTOCOLS FOR THE ASSURANCE OF MICROARRAY DATA QUALITY AND PROCESS CONTROL.

L. D. Burgoon<sup>1,5,6</sup>, J. E. Eckel-Passow<sup>3</sup>, C. Gennings<sup>4</sup>, D. R. Boverhof<sup>2,5,6</sup>, L. W. Burt<sup>2,5,6</sup>, C. J. Fong<sup>2,5,6</sup> and T. R. Zacharewski<sup>2,5,6</sup>. <sup>1</sup>*Pharmacology & Toxicology, Michigan State University, East Lansing, MI*, <sup>2</sup>*Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI*, <sup>3</sup>*Health Sciences Research, Mayo Clinic Cancer Center, Rochester, MN*, <sup>4</sup>*Biostatistics, Virginia Commonwealth University, Richmond, VA*, <sup>5</sup>*National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI* and <sup>6</sup>*Center for Integrative Toxicology, Michigan State University, East Lansing, MI*.

Microarrays represent a powerful technology that provides the ability to simultaneously measure the expression of thousands of genes. However, it is a multi-step process with numerous potential sources of variation that can compromise data analysis and interpretation if left uncontrolled, necessitating the development of quality control protocols to ensure assay consistency and high data quality. In response to emerging standards, such as the Minimum Information About a Microarray Experiment (MIAME) standard, tools are required to ascertain the quality and reproducibility of results within and across studies. To this end, a comprehensive quality control protocol for microarrays was developed using cDNA microarrays from *in vivo* and *in vitro* dose-response and time-course studies. The protocol combines: 1) diagnostic plots monitoring the degree of feature saturation, global feature and background intensities, and feature misalignments with 2) plots monitoring the intensity distributions within arrays with 3) a support vector machine (SVM) model. This work has been supported by NIH grants ES11271, ES12245 and Superfund P42 ES04911. Support for LDB and JEE was provided by T32 ES07255 and NCI grant R25 CA92049, respectively. TRZ is partially supported by the Michigan Agriculture Experiment Station.

### 1383

#### DBZACH: A COMPREHENSIVE TOXICOGENOMIC INFORMATION MANAGEMENT AND KNOWLEDGE DISCOVERY SYSTEM.

R. Aiyar<sup>2,3,4</sup>, L. D. Burgoon<sup>1,3,4</sup>, P. C. Boutros<sup>2,3,4</sup>, E. Dere<sup>2,3,4</sup>, S. Doran<sup>2,3,4</sup>, S. S. Pai<sup>2,3,4</sup>, J. Vakharia<sup>2,3,4</sup>, R. Rotman<sup>2,3,4</sup>, A. Adams<sup>2,3,4</sup>, B. Lau<sup>2,3,4</sup>, R. Patel<sup>2,3,4</sup> and T. R. Zacharewski<sup>2,3,4</sup>. <sup>1</sup>*Pharmacology & Toxicology, Michigan State University, East Lansing, MI*, <sup>2</sup>*Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI*, <sup>3</sup>*National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI* and <sup>4</sup>*Center for Integrative Toxicology, Michigan State University, East Lansing, MI*.

dbZach (<http://dbzach.fst.msu.edu>), a Minimum Information About a Microarray Experiment -Toxicology (MIAME/Toxicology) supportive toxicogenomic relational database, uses Java-based data mining and visualization tools to facilitate toxicogenomic data quality assurance and control, and knowledge discovery. Currently, dbZach contains subsystems for the management of in-life and *in vitro* sample annotation, pathology, and toxicity data, cDNA clones and annotation, microarray images, raw and normalized data, and quantitative real-time PCR results. Knowledge from cDNA and Affymetrix microarray experiments are anchored to data from complementary studies (e.g. pathology, clinical chemistry) to facilitate mechanistic understanding of toxicological responses. By managing multi-species data, and leveraging orthologous mappings through the integration of data from Ensembl, direct cross-species comparisons are made. dbZach also streamlines microarray data submittal to repositories (e.g., Gene Expression Omnibus and ArrayExpress) by formatting data in Microarray Gene Expression (MAGE) Markup Language files (MAGE-ML). Future developments for dbZach include management of biological pathway information, and integrated quality control tools. The dbZach System will be made source-available for local implementation as an inde-

pendently-operated laboratory information management and knowledge discovery system. Supported by NIH grants \*T32 ES07255 ES 04911-12, ES 011271 and ES 011777.

### 1384

#### LEVAMISOLE RESIDUES IN CHICKEN TISSUES AND EGGS.

H. El-Kholy and B. W. Kemppainen. *Anatomy, Physiology, Pharmacology, Auburn University, Auburn, AL*.

Levamisole is currently being used to treat capillaria infection in chickens even though there is no published withdrawal information available for levamisole in chickens. The tissue residue withdrawal of levamisole in chickens was studied in thirty-two healthy broiler breeders at the age of thirty-two weeks (peak of egg production). Levamisole residues in chicken tissues, eggs and plasma were determined by high performance liquid chromatography with ultraviolet (HPLC-UV) detection method at wavelength 225 nm. The highest level of residue and longest withdrawal time after oral administration of 40 mg/kg levamisole to chickens was in the liver. On day 3 the level of levamisole were undetectable in the plasma. On day 9 levamisole residue level in eggs was 0.096 ug/g and on day 18 it was 0.06 ug/g or less in all the analyzed chicken tissues, those levels were lower than the recommended Maximum Residue Limit (MRL). The withdrawal time for levamisole in chickens is longer than for other species tested. This is due in part to the larger dose of levamisole that is recommended in chickens. In conclusion from this research, levamisole needs 9 days for eggs to be under the MRL and 18 withdrawal days before slaughter of medicated birds for their tissues to be safe for human consumption.

### 1385

#### FUMONISIN B-GLUCOSE REACTION PRODUCTS ARE LESS TOXIC WHEN FED TO SWINE.

G. E. Fernandez<sup>1</sup>, G. D. Osweiler<sup>1</sup>, P. A. Murphy<sup>1</sup>, M. Yaeger<sup>1</sup>, G. Rottinghaus<sup>2</sup>, S. Hendrich<sup>1</sup> and L. Buckley<sup>1</sup>. <sup>1</sup>*Toxicology, Iowa State University, Ames, IA* and <sup>2</sup>*Veterinary Diagnostic Lab., University of Missouri, Columbia, MO*.

Reduction of liver toxicity by fumonisin B1 (FB1)-glucose reaction products has been demonstrated in swine via intraperitoneal delivery. The goal of this study was to evaluate this detoxification strategy using a dietary approach. Eighteen 3-week-old pigs divided in 3 treatments (6 pigs/group) were exposed for 15-d to diets containing either 528  $\mu$ mol total FB/kg (FB), FB-glucose products at 528  $\mu$ mol total FB/kg diet containing 23% unreacted FB (122  $\mu$ mol total FB/kg of diet) (FB-G) or 0  $\mu$ mol total FB/kg diet. Data was analyzed by a repeated measurements analysis at  $\alpha=5\%$ . On d 15, aspartate aminotransferase was highest in FB (576 IU/L  $\pm$  83.2) as compared to FB-G (180.7  $\pm$  51.1) and controls (120.2  $\pm$  18.7), which were not different. Levels of  $\gamma$ -glutamyl transferase were highest in FB pigs (250.5 IU/L  $\pm$  48), followed by FB-G (99.3  $\pm$  23.3) and controls (47.3  $\pm$  10.1), which were different. Total bilirubin was highest in FB treated pigs (3.31 mg/dL  $\pm$  1.2), followed by FB-G (0.41  $\pm$  0.3) and control (0.11  $\pm$  0.02) group, which were similar. Serum Sa/So ratio in FB pigs (1.78  $\pm$  0.2) was higher than in FB-G (1.14  $\pm$  0.2) and control (0.5  $\pm$  0.08) pigs, which were different. Liver Sa/So ratio in FB pigs (0.15  $\pm$  0.05) was higher than in controls (0.03  $\pm$  0.009) but similar to FB-G (0.11  $\pm$  0.04). Weight gain in FB pigs (1.75 kg  $\pm$  0.6) was significantly lower than FB-G (5.1  $\pm$  0.5) and controls (4.17  $\pm$  0.6), which correlated with feed intake reduction in FB pigs. At histopathology, FB pigs showed generalized liver necrosis with cellular and nuclear variability and disorganization of tissue. Liver and kidneys in the FB-G and control groups appeared normal. Results suggest that dietary FB-glucose products could substantially protect swine in instances of widespread FB grain contamination.

### 1386

#### THE NATIONAL RESIDUE PROGRAM AS A FOOD SAFETY TOOL.

J. Vodela<sup>1</sup>, P. Zervos<sup>2</sup>, C. Deyrup<sup>3</sup>, R. Sutton<sup>4</sup>, M. O'Keefe<sup>5</sup>, D. Pagan-Rodriguez<sup>6</sup> and H. Walker<sup>7</sup>. <sup>1</sup>*Residue Branch, USDA/FSIS, Washington, DC*, <sup>2</sup>*Residue Branch, USDA, Washington, DC*, <sup>3</sup>*Residue Branch, USDA, Washington, DC*, <sup>4</sup>*Residue Branch, USDA, Washington, DC*, <sup>5</sup>*Residue Branch, USDA, Washington, DC*, <sup>6</sup>*Residue Branch, USDA, Washington, DC* and <sup>7</sup>*Residue Branch, USDA, Washington, DC*.

The National Residue Program (NRP) is a multi-component analytical sampling effort designed to monitor chemical residues in domestic and imported meat, poultry, and egg products. The NRP is administered by the Food Safety and Inspection Service (FSIS), a public health regulatory agency of the USDA. FSIS, USFDA, and EPA are the key developers of the NRP. They work cooperatively with other organizations to achieve mutual food safety objectives with respect to residues. FDA and EPA have statutory authority for setting tolerances and action levels for chemical residues and for enforcing compliance with those tolerances. This authority is

granted under the FFDCA(FDA) and the FIFRA (EPA). FSIS protects consumers by testing meat, poultry, and egg products for chemical residues and preventing adulterated products from entering the food supply. This testing also allows FDA and EPA to enforce compliance with the tolerances and action levels that they set. In 2003, the FSIS Domestic Monitoring Plan sampled and tested 12 compound classes of drugs and pesticides, comprising approximately 59 residues. Of the 26, 214 Domestic Monitoring Plan samples analyzed, 85 residue violations were found in 85 animals. The residue violations consisted of 36 antibiotics, 20 zeranol, 14 sulfonamides, nine avermectins/milbemycins, four chlorinated hydrocarbon/chlorinated organophosphate, three arsenicals, and two flunixin. No residue violations were found in the testing for arsenicals, chloramphenicol, ractopamine, beta-agonists, melengestrol acetate, and diethylstilbestrol. The most common cause of violations with approved drugs in livestock, poultry, and egg products is a failure to allow an adequate withdrawal time. FSIS sampling focuses on analyzing kidney and liver tissues, since most FDA limits are established for these tissues

**1387 ASSESSMENT OF METALS CONCENTRATIONS IN SALMONBERRIES AND SOURDOCK COLLECTED NEAR A MINING TRANSPORT ROAD IN NORTHWEST ALASKA.**

M. Garry<sup>1,2</sup>, S. S. Shock<sup>2</sup>, L. J. Yost<sup>2</sup>, J. Kulas<sup>3</sup> and W. J. Shields<sup>2</sup>. <sup>1</sup>*U of Wash., Seattle, WA*, <sup>2</sup>*Exponent, Bellevue, WA* and <sup>3</sup>*Teck Cominco, Anchorage, AK*.

Historical transport of ore concentrate over a 50-mile haul road from the Red Dog lead/zinc mine in northwest Alaska to a seaport has been associated with elevated lead levels on moss growing near the road, and with concerns regarding subsistence foods. Initial studies of berries and sourdock, which are part of the local subsistence diet, suggested little impact from mine related activities but results were inconclusive. As part of a comprehensive assessment of potential impacts to human health and the environment associated with metals released during overland transport of ore concentrate, salmonberries and sourdock were evaluated for their potential contribution to dietary metals exposure during subsistence use. In summer 2004, salmonberry and sourdock samples were collected from three traditional harvesting locations, at increasing distance from the port facilities: Site A (1.5 miles NW), Site B (12 miles NW), and Site C (17 miles NW). Washed and unwashed samples were analyzed for lead and cadmium, two metals that had previously been identified as chemicals of concern for the site. Metals concentrations were compared between sites, and to samples collected in 2001 from Site A and from a reference location. Site A salmonberry lead was lower in 2004 than in 2001 ( $p \leq 0.001$ ). Sites B and C berry lead were similar to each other, but slightly lower than in Site A ( $p \leq 0.001$ ). Nevertheless, 2004 berry lead concentrations from all sites were similar to reference conditions. 2004 cadmium concentrations were similar at Sites A, B, and C, and were similar to 2001 Site A and reference concentrations. Sourdock lead and cadmium concentrations were similar at Sites A, B, and C, and in 2001 Site A samples. However, while sourdock lead concentrations at each of the three sites were similar to reference conditions, cadmium concentrations were lower than reference concentrations at all three sites ( $p \leq 0.01$ ). These results suggest that no limitations on subsistence harvest are necessary at any of the sites studied.

**1388 LACK OF EFFECTS OF BETA-CAROTENE DERIVED FROM BLAKESLEA TRISPORA, A NATURAL FOOD COLOR, IN A THIRTEEN-WEEK ORAL TOXICITY STUDY IN F344 RATS.**

K. Nabae<sup>1</sup>, T. Ichihara<sup>1,2</sup>, A. Hagiwara<sup>1</sup>, M. Kawabe<sup>1</sup>, M. Nishino<sup>3</sup>, T. Ogasawara<sup>3</sup>, Y. Sasaki<sup>3</sup>, M. Nakamura<sup>3</sup> and T. Shirai<sup>2</sup>. <sup>1</sup>*Dayu-Kai Institute of Medical Science, Inc., Ichinomiya, Japan*, <sup>2</sup>*Department of Experimental Pathology and Tumor Biology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan* and <sup>3</sup>*San-Ei Gen FFI, Inc., Toyonaka, Japan*.

Beta-Carotene derived from Blakeslea trispora is considered equivalent to chemically synthesized beta-carotene. A group Acceptable Daily Intake (ADI) for both synthetic beta-carotene and beta-carotene derived from Blakeslea trispora has been set at up to 5 mg/kg bw (JECFA, 2002). However, safety assessment data for beta-carotene derived from Blakeslea trispora are limited, and therefore the present sub-chronic oral toxicity study was conducted in rats. When groups of 10 male and 10 female F344 animals were fed beta-carotene at dietary levels of 0, 0.2, 1.0 and 5.0 % for 13 weeks, there were no treatment-related adverse effects on body weight, food and water consumption, urinalysis, ophthalmology, hematology and serum biochemistry findings and organ weight data. On clinical observation, red feces were observed in both sexes of the 0.2%, 1.0% and 5.0% group animals and necropsy revealed all rats of the treated groups to have reddish discoloration of the contents of the gastro-intestinal tract, due to pigmentation and thus lacking toxicological significance. On histopathological examination, sporadic spontaneous lesions known occur in this strain of rats were the only findings, with no specific relation to the test compound. Thus, the No-Observed-Adverse-Effect-Level

(NOAEL) was judged to be a dietary level of 5.0% (3127 mg/kg body weight/day for males, 3362 mg/kg body weight/day for females) of beta-carotene derived from Blakeslea trispora under the present experimental conditions.

**1389 DEPLETION OF T CELLS BY MONOCLONAL ANTIBODIES AGAINST MTHY-1.2 ANTIGEN REDUCES FUMONISIN B<sub>1</sub> TOXICITY IN MICE.**

N. Sharma, Q. He and R. P. Sharma. *Physiology and Pharmacology, university of Georgia, athens, GA*.

Fumonisin B<sub>1</sub> is a mycotoxin produced by *Fusarium verticillioides* that is frequently associated with corn. It produces species-specific and organ-specific toxicity, including equine leukoencephalomalacia, porcine pulmonary edema, and hepatic or renal damage in most animal species. Fumonisin B<sub>1</sub> perturbs sphingolipid metabolism by inhibiting ceramide synthase. Our previous studies indicated that fumonisin B<sub>1</sub> caused localized activation of cytokines secreted by macrophages and other cell types, which modulate fumonisin B<sub>1</sub>-induced hepatic apoptosis in male mice. In the current study, male athymic nude (nu/nu) mice and their wild type counterparts (nu/+), with and without depletion of T cells, were treated subcutaneously with 2.25 mg/kg/day of fumonisin B<sub>1</sub> for 5 days and sampled 1 day after the last injection. Depletion of T cells was achieved by intravenous injection of 50 µg monoclonal antibody against Thy-1.2 surface antigen of mature peripheral T lymphocytes, 24 h before first fumonisin B<sub>1</sub> treatment. The fumonisin B<sub>1</sub>-induced elevation in activities of circulating liver enzymes were not different between nu/nu and nu/+ mice, while depletion of T cells in nu/+ mice significantly prevented fumonisin B<sub>1</sub>-mediated liver toxicity, confirmed by analyses of circulating liver enzymes and apoptotic hepatocytes. Since all the fumonisin B<sub>1</sub>-treated groups had similar extent of hepatic sphinganine accumulation; the reduced toxicity of fumonisin B<sub>1</sub> in T cell depleted mice was not due to its effect on sphinganine accumulation. Expression of fumonisin B<sub>1</sub>-induced tumor necrosis factor  $\alpha$  and interleukin-12 was observed in nu/nu and nu/+ mice but not in T cell depleted nu/+ mice. This study suggested that T cells and corresponding proinflammatory cytokines have an important role in mediating fumonisin B<sub>1</sub>-induced hepatic toxicity. (Supported in part by USPHS ES 09403)

**1390 SAFETY EVALUATION OF A NEW ANTI-STALING AMYLASE ENZYME FOR BAKERY APPLICATIONS.**

Q. Q. Bui<sup>1</sup>, H. V. Thygesen<sup>2</sup>, L. S. Bollen<sup>3</sup>, Z. El-Salanti<sup>3</sup> and C. N. Edwards<sup>3</sup>. <sup>1</sup>*Genencor International, Palo Alto, CA*, <sup>2</sup>*Danisco A/S, Copenhagen, Denmark* and <sup>3</sup>*Scantox A/S, Lille Skensved, Denmark*.

This anti-staling product is a maltotetraose-forming amylase enzyme produced with a recombinant strain of *B. subtilis*. The enzyme was protein-engineered to increase thermostability and exo-specificity needed for bakery applications. Toxicology studies designed to demonstrate the product is safe for its intended uses were performed following the guidelines recommended by Pariza and Johnson (2001). Acutely, anti-staling amylase is non toxic by ingestion. No genotoxicity was observed in a bacterial reverse mutation assay at dose levels up to 5240 µg total protein/plate and an *in vitro* human lymphocyte chromosomal aberration test up to moderately toxic concentrations, both with and without metabolic activation. In a 90-day oral toxicity study in Sprague-Dawley rats, daily gavage of anti-staling amylase up to and including a dose level of 314.1 mg total protein/kg/day (509.4 mg TOS/kg/day; 17.5 mg enzyme protein/kg/day) did not result in any biological or statistical differences in body weight, feed consumption, hematology, clinical chemistry, organ weights, and clinical observations. In the open field testing, decreases in ambulatory movements were noted in treated females but were still within the historical control ranges collected at the testing facility. There were no histopathologic changes noted in treated animals. The NOAEL was established at 17.5 mg enzyme protein/kg/day. The average consumption of flour from bakery products is 3.25 g/kg bw/day and the typical dosage of anti-staling amylase is 0.5 to 4.0 mg enzyme protein/kg flour. The estimated daily intake of anti-staling amylase is thus 0.0016 to 0.0130 mg/kg bw. The NOAEL of 17.5 mg enzyme protein/kg/day would offer more than a 1000 X margin of safety. Collectively, the historic safety profile of the production organism *B. subtilis* and the results of the toxicology studies attest to the safety of this anti-staling amylase for bakery applications.

**1391 TIME- AND DOSE-DEPENDENT CHANGES IN SPHINGOID BASE 1 PHOSPHATES IN TISSUES FROM RATS FED DIETS CONTAINING FUMONISINS.**

R. T. Riley, J. L. Showker and K. A. Voss. *Toxicology and Mycotoxin Research Unit, USDA-ARS, Athens, GA*.

Fumonisins (FB) are mycotoxins found in corn. They are inhibitors of ceramide synthase (CS), a key enzyme in de novo sphingolipid biosynthesis. Inhibition of CS results in a marked increase in free sphinganine (Sa), an intermediate in de novo

biosynthesis, in rat liver and kidney; the primary target organs in FB fed rats. There is a close correlation between elevation in Sa and the extent and severity of toxicity in rodent liver and kidney. Sa is toxic to cultured cells and is believed to contribute to the liver and kidney toxicity of FB, however, inhibition of CS also decreases ceramide formation and potentially, increases levels of Sa-1-phosphate (Sa-1-P) and sphingosine (So)-1-phosphate (So-1-P). The present study was conducted to quantify the time- and dose dependent changes in Sa, So, Sa-1-P and So-1-P in kidney and liver of male Sprague-Dawley rats fed diets containing 0, 5 ppm and 50 ppm FB1 for 10 days. These tissues were microscopically examined for increased apoptosis and other FB-induced toxicity. At 50 ppm FB1, renal toxicity was first evident on day 3 and was maximal on day five, whereas, Sa and Sa-1-P were first elevated at day 1 and maximally elevated at day 5 to similar levels. So-1-P was first elevated on day 3 and maximally elevated on day 5, however, the level of elevation was 50 fold less than Sa-1-P. Neither So-1-P nor Sa-1-P was detected in control kidney. At 5 ppm FB1, renal toxicity was first evident on day 5 and was more severe on day 10, whereas, Sa was first elevated on day 1 and increased throughout the 10 day study. Sa-1-P and So-1-P were first elevated at days 3 and 5, respectively, and were further increased on day 10. Compared to kidney, liver toxicity was much more subtle, with an obvious but moderate effect only being seen in the high dose group on days 5 and 10 and was preceded by increases in Sa on day 3. There was no So-1-P or Sa-1-P detected in liver from control or FB1-fed animals. The high level of Sa-1-P in kidney from FB-treated rats suggests its involvement in FB-induced renal toxicity.

### 1392 TOXICOLOGY STUDIES ON ALLANBLACKIA SEED OIL.

L. J. Lea and S. O'Hagan. *Safety and Environmental Assurance Centre, Unilever, Bedford, United Kingdom.* Sponsor: P. Hepburn.

Allanblackia seed oil is derived from the seed of the Allanblackia tree (*Allanblackia stuhlmanni*) which grows in the tropical rain forest of Africa. The oil has a unique fatty acid composition, as it is composed predominately of stearic acid and oleic acid. This fatty acid profile and the arrangement of the fatty acids on the triglyceride backbone make the oil highly suitable for use in foods such as margarine. The oil has not been consumed to any significant extent outside Africa and has very little food use in the countries where Allanblackia trees grow such as Ghana and Tanzania. A programme of toxicology studies was conducted to confirm that Allanblackia seed oil is safe for use in food. Allanblackia seed oil was tested in two *in vitro* mutagenicity assays, an Ames test and mouse lymphoma assay, and a 90-day repeat dose oral toxicity rat study. Allanblackia seed oil was non-genotoxic in both *in vitro* assays. In the 90-day study Allanblackia seed oil was administered to Wistar (Cr: (WI) WU BR) rats at a dose level of 20% in a synthetic diet (AIN-93G). A high fat control diet containing 20% shea oleine was also tested in the study alongside a standard control diet with 7% soya oil. Minor changes in haematology parameters, clinical chemistry parameters and organ weights were observed in the Allanblackia seed oil group compared with the standard control. None of the organ weight changes were accompanied by histopathological alterations. These changes also occurred to a similar or lesser extent in the shea oleine control group indicating that they were associated with a high fat diet rather an adverse effect of Allanblackia seed oil. These data demonstrate that Allanblackia seed oil is safe for use in food.

### 1393 SAFETY AND EFFICACY POTENTIAL OF A NOVEL ANTHOCYANIN-RICH MULTIPLE BERRY EXTRACT IN *IN VIVO* MODELS.

M. Bagchi<sup>1</sup>, D. Bagchi<sup>1, 2</sup> and C. Sen<sup>3</sup>. <sup>1</sup>*InterHealth Research Center, Benicia, CA, Creighton Medical Center, Omaha, NE and*<sup>3</sup>, *Ohio State Medical Center, Columbus, OH.*

Edible berry extracts rich in anthocyanins possess a broad spectrum of therapeutic and anti-carcinogenic properties. Anthocyanins repair and protect genomic DNA integrity. Six berry extracts (wild blueberry, bilberry, cranberry, elderberry, raspberry seeds, and strawberry) were studied for antioxidant efficacy, cytotoxic potential, cellular uptake, and anti-angiogenic properties. Recently we evaluated various combinations of edible berry extracts and developed a synergistic formula, OptiBerry, which exhibited high ORAC value, low cytotoxicity, and superior anti-angiogenic properties compared to the other combinations tested. This study was focused to determine the broad spectrum safety and antioxidant efficacy of OptiBerry. We investigated the acute oral, acute dermal, primary dermal irritation and primary eye irritation toxicity of OptiBerry. Acute oral LD<sub>50</sub> of OptiBerry was found to be greater than 5, 000 mg/kg in both male and female Sprague-Dawley rats. Acute dermal LD<sub>50</sub> of OptiBerry was found to be >2, 000 mg/kg. No changes in body weight or adverse effects were observed following necropsy. In New Zealand albino rabbits, primary skin and primary eye irritation tests were also conducted. OptiBerry was classified as slightly irritating to the skin and minimally irritating to the eye. We assessed the antioxidant potential of OptiBerry in rats and mice using EPR imaging for whole-body redox status and glutathione levels by

HPLC. This study employed a clinically relevant hyperbaric oxygen (HBO) exposure system to study the antioxidant properties of OptiBerry. OptiBerry feeding (8 weeks) significantly prevented HBO-induced GSH oxidation in the lung and liver of vitamin E deficient Sprague-Dawley rats. Furthermore, OptiBerry fed mice (2 weeks), when exposed to HBO, demonstrated significant protection against HBO-induced oxidation of mice compared to the unfed controls by EPR imaging. Taken together, these results indicate that OptiBerry is safe and possesses antioxidant properties in addition to being anti-angiogenic.

### 1394

#### A 90-DAY DIETARY TOXICITY STUDY OF HEATED DAG OIL AND HEATED TG OIL IN RATS.

C. P. Chengelis<sup>1</sup>, J. B. Kirkpatrick<sup>1</sup>, W. B. Lawrence<sup>1</sup>, O. Morita<sup>2</sup>, Y. Tamaki<sup>2</sup> and H. Suzuki<sup>2</sup>. <sup>1</sup>*WIL Research Laboratories, Inc., Ashland, OH and*<sup>2</sup>*Kao Corporation, Haga Tochigi, Japan.*

This study evaluated the possible toxic effects of heated DAG oil (diacylglycerol oil) and heated TG oil (Triacylglycerol oil) when given in the diet at levels up to 5.5% (55, 000 ppm) for 90 days to rats. DAG oil is a cooking oil which contains >80% diglycerides, <20% triglycerides and <5% monoglycerides. The heated oils were prepared by taking DAG oil and TG oil separately and batch frying potato slices in deep fryers at 180 degrees Celsius for 8 hours per day on three consecutive days. The treated oils were then stored frozen until use on study. A special diet was prepared so that all of the dietary fat could be provided by heated DAG oil or unheated DAG oil at varied concentrations. Dietary concentrations (% heated DAG oil/% unheated DAG oil) of 0%/5.5% (unheated DAG oil control), 1.0%/4.5%, 2.75%/2.75%, and 5.5%/0% were presented daily, seven days per week, for a minimum of 90 days. Two additional groups received the special diet with 5.5% of unheated TG oil or 5.5% of heated TG oil. The TG oil contained >85% triglycerides, <10% diglycerides and <5% monoglycerides. The fatty acid composition for DAG oil and TG oil was closely matched. All groups consisted of 10 male and 10 female Cr:CD(SD)IGS BR rats and were fed ad libitum. The clinical condition of the animals, body weights, body weight gains, food consumption, ophthalmic examinations, functional observational battery and motor activity, clinical pathology evaluations, organ weights, gross and histopathologic findings were unaffected by either heated DAG oil or heated TG oil compared to the unheated oils or when the results in the two 5.5% heated oil groups were compared. Feeding diets prepared with the heated DAG oil or heated TG oil resulted in no obvious toxic effects. Thus, the no-observed-effect levels (NOELs) for dietary exposure of heated DAG oil or heated TG oil were 5.5% (55, 000 ppm), the highest levels tested, under the conditions of this study.

### 1395

#### ACCUMULATION OF SPHINGOID BASES AND SPHINGOID BASE 1-PHOSPHATES: A POSSIBLE MECHANISM FOR FUSARIUM VERTICILLIOIDES CORN-SEEDLING DISEASE.

L. D. Williams<sup>1, 2</sup>, A. E. Glenn<sup>2</sup>, C. W. Bacon<sup>2</sup>, M. A. Smith<sup>1</sup> and R. T. Riley<sup>2</sup>. <sup>1</sup>*Environmental Health Sciences, UGA, Athens, GA and*<sup>2</sup>*TMRU, USDA, Athens, GA.*

Sphingolipids are important structural components of membranes involved in signaling pathways that regulate cell growth and death. Fumonisins (FB) are water soluble mycotoxins produced by *F. verticillioides*, which is parasitic to corn. FBs are inhibitors of ceramide synthase (CS), a key enzyme in sphingolipid biosynthesis. Inhibition of CS causes an increase in sphinganine and sphingosine (phytosphingosine in plants), as well as their respective 1-phosphates, which is used as a biomarker for FB activity. While FB is not known to cause plant disease in the field, it is found in the ear, roots, and stalks of corn. The objectives of this study were to determine the dose- and time-dependent effects of FB1 in soils on i) root development and ii) disruption of sphingolipid metabolism in roots. Sterilized corn seeds were germinated and planted in sterile potting soil (10/pot) and watered with solutions of FB1 (0, 1, 5, 10, and 20 µg/ml). The seedlings were dosed with FB1 on days 2, 4, and 6 after planting, followed by ddH<sub>2</sub>O as needed until harvest. The experiment was split into two time groups (3 reps per dose), the first group was harvested on day 8 and the second group was harvested on day 21. There was a dose dependent reduction in root mass in the 21 day time group at 5, 10, and 20 µg/ml FB1, while there was a slight increase in root growth at 1 µg/ml FB1. FB1 was detected in the soils as well as the roots, and the levels were closely correlated with the FB1 dosage. There was a dose dependent elevation in sphingoid bases and their 1-phosphates in the root tissues from both time groups. These results show that under laboratory conditions FB1 in soils can i) affect root growth and alter seedling performance, ii) FB1 in soil can be taken up by roots, iii) FB1 in soils can cause marked dose-dependent elevation in sphingoid bases and their 1-phosphates that precede reduced root growth.

DEVELOPMENTAL TOXICITY OF DIETS CONTAINING FUMONISIN B<sub>1</sub> TO LM/BC AND CD1 MICE: A COMPARATIVE STUDY.

K. A. Voss<sup>1</sup>, J. B. Gelineau-van Waes<sup>2</sup>, R. T. Riley<sup>1</sup>, T. D. Burns<sup>3</sup> and C. W. Bacon<sup>1,4</sup>. <sup>1</sup>Toxicology & Mycotoxin Research Unit, USDA-Agricultural Research Service, Athens, GA, <sup>2</sup>Genetics, Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE and <sup>3</sup>Interdisciplinary Program in Toxicology, University of Georgia, Athens, GA.

Fumonisin mycotoxins are found in corn and corn-based food. Their health effects in humans are unknown, however, it has been suggested that they might be a risk factor for neural tube defects (NTDs) in populations consuming contaminated corn as a dietary staple. Fumonisin B<sub>1</sub> (FB<sub>1</sub>) was not teratogenic when given orally to pregnant CD1 mice during gestation days (GD) 7-15 whereas intraperitoneal injection of  $\geq 5$  mg/kg BW FB<sub>1</sub> to pregnant LM/Bc mice on GD 7.5-8.5 caused NTDs. To compare NTD susceptibility in these strains, female LM/Bc (n=8/group) and CD1 mice (n=10/group) were fed diets containing 0 (control), 50 or 150 ppm FB<sub>1</sub> (provided by *F. verticillioides* culture material) beginning 5 weeks before mating. Pregnant females and their litters (mating produced  $\geq 5$  litters/strain-group) were examined for gross malformations, especially NTDs in the fetuses, by necropsy after GD16. The high-dose diet was maternally toxic to both strains as established by microscopic examination of the maternal livers. Within each strain, no unequivocal effects on mating, fertility, maternal weight, and litter size were noted. Neither fetotoxicity nor NTDs were found in control or low-dose litters of either strain. One of five (20%) LM/Bc high-dose litters was positive for NTDs (1 of 10 fetuses was affected). In contrast to the LM/Bc strain, no NTDs were found in the high-dose CD1 litters but fetotoxicity was found in two of the litters (n=9) from this group; the incidence of dead fetuses therein ranged from 40 to 64%. These results suggest that (a) the dietary NOEL for NTDs in LM/Bc mice is  $> 50$  ppm FB<sub>1</sub>; (b) NTDs develop at maternally toxic doses of FB<sub>1</sub>; (c) strain-dependent differences in sensitivity to fetotoxicity and NTDs exist; and (d) studies are needed to define the NTD dose-response and the physiological factors underlying NTD development in FB<sub>1</sub>-fed mice.

## A 90-DAY DIETARY STUDY ON CARRAGEENAN WITH EMPHASIS ON THE GASTROINTESTINAL TRACT.

D. C. Nuber<sup>1</sup>, M. L. Weiner<sup>1</sup>, W. Blakemore<sup>1</sup>, J. F. Harriman<sup>2</sup> and S. M. Cohen<sup>3</sup>. <sup>1</sup>Toxicology, FMC Corporation, Princeton, NJ, <sup>2</sup>Toxicology, WIL Research Laboratories, Ashland, OH and <sup>3</sup>University of Nebraska Medical Center, Omaha, NE.

Carrageenan is a food additive, approved globally for food use. Recent publications have alleged carrageenan as a carcinogen. In response, a GLP subchronic dietary toxicity study in rats was conducted on commercial kappa carrageenan, molecular weight distribution at 4.6% below 50k Daltons. The molecular weight was tested by triple detection (right angle/low angle light scattering, viscometer & refractometer). Groups of Fischer 344 rats (20/sex/group) received control or treated diets at levels of 0, 2.5, and 5.0% for 90 days. Homogeneity, stability and verification of dose level in test diets were determined weekly. Clinical examinations were done daily. Individual food consumption/body weight measurements were made weekly. Ophthalmic exam was conducted prior to and at the end of treatment. Hematology/serum chemistry and urinalysis evaluations were done at necropsy, as were organ weight determinations for adrenals, brain, heart, kidneys, liver, ovaries, spleen, testes, and thyroid with parathyroids. Full histopathological evaluation of organs was conducted on the control and 5.0% groups. Special microscopic examinations of hematoxylin-eosin stained cross sections of paraffin-embedded rolled colon were conducted in control and high-dose animals. Clinical signs were limited to soft feces in high dose animals and to a lesser extent in low dose animals. There were no treatment-related effects on body weights or hematology and urinalysis parameters. Lower serum albumin and cholesterol levels in high dose males were not considered to be biologically significant. There were no treatment-related effects on organ weights or ophthalmic, macroscopic, or microscopic findings. The gastro-intestinal tract appeared normal in detailed histopathology. The NOAEL is 5% in the diet (3394 and 3867 mg/kg/day in males and females, respectively).

## TANNIC ACID IS A PROOXIDANT AND INDUCES CYCLOOXYGENASE-2 IN HUMAN COLON CELLS.

J. P. Gray<sup>1,2</sup>, V. Mishin<sup>1</sup>, D. E. Heck<sup>1,2</sup> and J. D. Laskin<sup>2,3</sup>. <sup>1</sup>Pharmacology and Toxicology, Rutgers University, Piscataway, NJ, <sup>2</sup>Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ and <sup>3</sup>Environmental & Occupational Medicine, UMDNJ - Robert Wood Johnson Medical School, Piscataway, NJ.

Tannic acid (penta-*m*-digalloyl glucose) is a common dietary constituent present in a variety of foods, beverages and medicinal products. It is generally thought to be an antioxidant and in some studies has been shown to exhibit antimutagenic and anti-carcinogenic properties. At low levels in the diet, tannic acid reduces spontaneous

hepatomas in C3H mice and has been proposed as a chemopreventative agent for colon cancer. In the present studies we demonstrate that tannic acid also possess prooxidant activity which may be cytotoxic for colon cells. We found that, in the presence of transition metals, tannic acid (10-100  $\mu$ M) generates hydroxyl radicals as measured by the hydroxylation of terephthalate, an aromatic trapping agent. Hydroxyl radical production by tannic acid was pH dependent and optimal at pH 7.4. Using plasmid DNA unwinding assays, hydroxyl radical production by tannic acid was found to be sufficient to cause single and double strand DNA breaks. In human colon CX-1 cells, we found that tannic acid readily induced lipid peroxidation. This was associated with induction of cyclooxygenases-2 (COX-2) mRNA, an important gene product known to regulate inflammatory mediator production in the colon. Inhibition of tannic acid-induced production of reactive oxygen intermediates by DMSO (0.5%), a hydroxyl radical trap, was found to suppress plasmid DNA strand breaks and inhibit lipid peroxidation and expression of COX-2 in CX-1 cells. Taken together, our data suggest that dietary tannic acid has prooxidant activity that can damage DNA and cause production of cytotoxic inflammatory mediators via production of hydroxyl radicals. Production of reactive oxygen intermediates by tannic acid and subsequent cellular injury may contribute to the development of colon cancer. Supported by NIH grants ES05022, ES007148, CA093798 and CA100994.

## GENOTOXICITY STUDIES ON DIETARY DIACYLGLYCEROL (DAG) OIL.

T. Kasamatsu<sup>1</sup>, R. Ogura<sup>1</sup>, N. Ikeda<sup>1</sup>, O. Morita<sup>1</sup>, K. Saigo<sup>2</sup>, H. Watabe<sup>3</sup>, Y. Saito<sup>3</sup> and H. Suzuki<sup>1</sup>. <sup>1</sup>Safety and Environmental Research Section, Kao Corporation, Ichikai, Haga, TOCHIGI, Japan, <sup>2</sup>Shin Nippon Biochemical Laboratories, Ltd., Miyanoura, Yoshida, KAGOSHIMA, Japan and <sup>3</sup>Mitsubishi Chemical Safety Institute, Ltd., Hasaki, Kashima, IBARAKI, Japan. Sponsor: C. Chengelis.

Dietary Diacylglycerol (DAG) oil is an edible oil enriched in DAG (more than 80%). A recent investigation indicated that DAG oil or its components may have beneficial effects on the prevention and management of obesity. We evaluated the genotoxic potential of DAG oil using standard genotoxicity tests. Bacterial reverse mutation assay (Ames test), the chromosomal aberration assay in cultured Chinese hamster lung cells (CHL/IU), and a bone marrow micronucleus assay in ICR CD mice were employed in the present study. In addition we have tested the possibility that genotoxic substances may be formed during cooking, heated DAG oil was prepared by batch frying potato slices in the oil at 180°C for 8 hr/day for 3 consecutive days. Therefore, genotoxicity tests were also performed on heated DAG oil. Results obtained did not show any genotoxic effect on either unheated DAG oil or heated DAG oil. We conclude that there are no safety concerns on the genotoxicity of DAG oil under the conditions for normal use.

## ISOTHERMAL MODELS FOR THE PREDICTION OF NUTRIENT INTERACTIONS WITH MYCOTOXIN SORBENTS.

J. F. Taylor, E. Afriyie-Gyawu, H. J. Huebner and T. D. Phillips. Faculty of Toxicology, Texas A&M University, College Station, TX.

A variety of sorbent materials are frequently added to animal feeds to bind and reduce the bioavailability of mycotoxins in the gastrointestinal tract. However, the safety of many of these products has not been established. Importantly, sorbents that are nonselective may interact with nutrients, minerals, and other feedborne chemicals to pose significant hidden risks. The purpose of this study was to develop a rapid screening method to assess dietary sorbent interactions with selected nutrients. A variety of clay-based materials and activated carbon, were tested for their ability to sorb vitamin A and riboflavin from aqueous solution. Equilibrium adsorption isotherms were run for each sorbent using a modification of methods previously established. Vitamin A and riboflavin were analyzed with a UV-VIS spectrophotometer at 292 nm and at 445 nm, respectively. The maximum capacities ( $Q_{\max}$ ) and affinity constants ( $K_d$ ) at 25°C for the sorption of each vitamin were determined with a computer fitted Langmuir equation. An organophilic montmorillonite clay and an activated carbon strongly sorbed vitamin A with  $Q_{\max}$  values of 4.00 mol/kg and 0.552 mol/kg, respectively. Affinity constants ( $K_d$ ) for these sorbents were determined to be  $1.94 \times 10^4$  and  $4.15 \times 10^5$ , respectively. Sodium montmorillonite and carbon also exhibited significant binding of riboflavin ( $Q_{\max} = 0.193$  mol/kg;  $K_d = 1.95 \times 10^5$  and  $Q_{\max} = 0.267$  mol/kg;  $K_d = 1.48 \times 10^6$ , respectively). Other sorbents including NovaSil clay showed negligible interaction with either vitamin. In previous studies, NovaSil has been shown to bind aflatoxins with high affinity *in vivo*. These experiments confirm the selectivity of this clay and suggest that isothermal analysis can be utilized to predict interactions of dietary sorbents with important nutrients. Further studies will assess the ability of isothermal modeling to delineate interactions of sorbents with other important feed additives (NIEHS P42 ES04917, USAID LAG-G-00-96-90013-00).

EFFECTS OF A LOW-CARBOHYDRATE DIET ON MARKERS OF OXIDATIVE STRESS IN TISSUES FROM DIABETIC AND NON-DIABETIC RATS.

J. B. Watkins, Z. T. Kamuren, D. F. O'Neill and R. A. Sanders. *Medical Sciences, Indiana University School of Medicine, Bloomington, IN.*

Increased oxidative stress in diabetes is partly attributed to the generation of reactive molecules from elevated blood glucose levels, with consequent development of secondary complications. Because a low-carbohydrate (low-carb) diet improves glycemic parameters, this study examined whether a low-carb diet (carbohydrates 5.5%, fats 68% by calories) confers beneficial effects on the oxidative status of the heart, kidney and liver in diabetes. Male and female normal and streptozotocin-induced diabetic rats were fed standard chow (carbohydrates 63%, fats 11%, by calories) or low-carb diet for 30 days. Elevated glucose, HbA1c, and alanine and aspartate aminotransferases in diabetic animals were reduced or normalized by the low-carb diet. Diabetes increased cardiac activities of glutathione peroxidase and catalase relative to controls. The low-carb diet normalized cardiac glutathione peroxidase in diabetic animals, and reduced catalase in the female rats. In kidney, glutathione peroxidase activity was increased in diabetic animals relative to non-diabetic controls and was not corrected by the diet. Low-carb fed diabetic rats had increased and decreased activities of renal glutathione reductase and SOD relative to diabetic animals on the control diet. No significant differences were observed between normal controls and normal low-carb diet rats except for increased renal glutathione peroxidase activity in the male rats. In liver, diabetes was associated with a decrease in catalase activity and glutathione levels and an increase in glutathione peroxidase and  $\gamma$ -glutamyltranspeptidase activities. Decreased hepatic glutathione peroxidase activity and MDA content were noted in diet-treated diabetic rats. No diet-induced changes in superoxide dismutase were noted in any tissue. Overall, the low-carb diet helped stabilize hyperglycemia and did not produce overtly negative effects in tissues of normal or diabetic rats.

**1402**

CHRONIC TOXICOLOGICAL EVALUATION OF NOVASIL CLAY IN THE DIET OF SPRAGUE-DAWLEY RATS.

E. Afriyie-Gyawu<sup>1,2</sup>, J. Mackie<sup>3</sup>, B. Dash<sup>1,2</sup>, M. C. Wiles<sup>2</sup>, J. Taylor<sup>1,2</sup>, H. J. Huebner<sup>1,2</sup>, H. Guan<sup>1</sup>, T. Lili<sup>4</sup>, J. Wang<sup>4</sup> and T. D. Phillips<sup>1,2</sup>. <sup>1</sup>*Faculty of Toxicology, Texas A&M University, College Station, TX*, <sup>2</sup>*Veterinary Integrative Biosciences, Texas A&M University, College Station, TX*, <sup>3</sup>*Veterinary Pathobiology, Texas A&M University, College Station, TX* and <sup>4</sup>*Texas Tech University, Lubbock, TX*

NovaSil (NS) clay, a common anti-caking agent in animal feeds, has been reported to diminish bioavailability and adverse effects of aflatoxins in short-term studies. The potential toxicity of long-term dietary exposure to NS has not been determined. Five to six week old male and female Sprague-Dawley rats were fed rations containing 0, 0.25, 0.5, 1.0, or 2.0% (w/w) levels of NS for 28 weeks. NS showed negligible levels of dioxin and furan contaminants. Octachlorodibenzo-p-dioxin (2.34 ng/kg) was the only contaminant found above the limit of detection (LOD = 1.02 ng/kg). Total feed consumption, cumulative feed consumption, body weight, total body weight gain, feed conversion efficiency, and relative organ weights were unaffected in either sex at the doses tested. At necropsy, there were no abnormalities in tissues of interest (liver, kidneys, lungs, heart, brain, spleen, tibia, uteri and ovaries). Analysis of whole blood showed no significant differences in hematological parameters between NS-fed rats and controls with the exception of males consuming 0.25% NS (higher mean corpuscular hemoglobin). Red and white blood cells appeared normal and morphologically similar. Serum biochemical analysis was generally normal but indicated that Ca was slightly increased in 0.5% and 2.0% NS-treated females. Serum and hepatic vitamin A and vitamin E were unchanged in all groups except females consuming 1.0% NS and showing a slight increase in serum vitamin A. Serum Fe and Zn levels were unchanged except in males consuming 1.0% NS which showed increased Fe. However, the difference observed did not demonstrate dose-dependency. Results suggest that dietary inclusion of NS at levels as great as 2.0% (w/w) does not result in overt toxicity. These findings (as well as others) support the use of NS clay dietary interventions for human populations at high risk for aflatoxicosis (NIEHS P42 ES04917, USAID LAG-G-00-96-90013-00).

**1403**

ACRYLAMIDE, HEAVY METAL COMBINATION TOXICITY AND GLUTATHIONE DEPLETION.

C. Siegers<sup>1</sup>, M. M. Schulze<sup>1</sup> and J. B. Schulze<sup>2</sup>. <sup>1</sup>*Institute of Experimental and Clinical Pharmacology and Toxicology, Luebeck, Germany* and <sup>2</sup>*Office of the Dean, Medical Faculty, Frankfurt, Germany*.

Acrylamide (AA) has recently been detected as contamination in heated food products. In higher concentrations it is neurotoxic and clastogenic and has been classified as a possible human carcinogen. Although it has low toxicity in cell cultures of hepatic, renal and intestinal cells its toxicity is increased by addition of heavy met-

als like Hg or Cd, but not As. Since AA as well as its metabolite glycinamide are partly detoxified by glutathione coupling, combination toxicity may be related to additive glutathione depletion. In order to clarify the mechanism of AA toxicity singly and in combination we measured glutathione content and depletion of glutathione by L-buthionine sulfoximide (1 mM BSO) and determined cytotoxicity in parallel by neutral red uptake and LDH release. In renal LLC-MK2 and intestinal I-407 cells treatment of cells by BSO for 24 hours and additional AA treatment with 0, 1  $\mu$ g/ml for another 24 hours cytotoxicity was not detectable, in accordance with the lack of AA toxicity in control cells. In hepatic Hep G2 cells LDH release was increased and neutral red uptake decreased in parallel at the highest AA concentrations tested (>0.06  $\mu$ g/ml); control Hep G2 cells were not affected by AA up to 100  $\mu$ g/ml. Compared to control cells addition of AA did slightly decreased glutathione content by 25% in either of these cell lines. Glutathione depletion has been shown to increase cytotoxicity of all three heavy metals in cells and *in vivo*. Therefore, data will be presented on cellular glutathione changes by heavy metals, effect of glutathione depletion on heavy metal and AA cytotoxicity and the relationship of combination toxicity to alterations in glutathione changes.

**1404**

SAFETY ASSESSMENT OF LYSINE MAIZE.

B. Hammond, T. Reynolds, J. Kronenberg and K. Glenn. *Monsanto Company, St. Louis, MO.*

Maize grain used in animal diets is deficient in the essential amino acid lysine. A new maize variety has been developed for animal feed that has increased levels of lysine. Although this variety will be identity preserved for use in poultry and swine feed, it might inadvertently enter the human food chain. Therefore, the human food safety assessment of lysine maize (LM) grain was undertaken, including analysis of the introduced protein (*Corynebacterium* dihydrodipicolinate synthase - cDHDPS). cDHDPS has the same function as the DHDPS protein present in maize, but is not feedback inhibited by lysine. Bioinformatic analysis revealed that the protein is not structurally or functionally related to known protein toxins or allergens, and the function of this enzyme raise no safety concerns. cDHDPS is readily degraded *in vitro* in simulated gastric fluid. cDHDPS did not produce adverse effects in mice when given as a single dosage of 800 mg/kg BW, which provides a large safety margin compared to potential human dietary exposures. The high dose acute mouse test is appropriate for assessing protein safety since most known protein toxins act through acute mechanisms. Compositional analysis of the grain was also undertaken to assess the level of increased lysine content and to characterize any changes in lysine-related metabolites. The composition of LM was comparable to that of conventional maize varieties, with the exception of increased lysine and its catabolites, saccharopine and alpha-amino adipate. There is a history of safe consumption of these catabolites as they are present in common foods. Dietary exposure to lysine catabolites from ingestion of common foods exceeds exposures from inadvertent human food use of LM. In addition, grain from LM, along with the control and several conventional maize varieties, was also fed to rats for 90 days at levels up to 33% in the diet. There were no adverse effects in rats fed LM grain, and the rat dietary exposure considerably exceeded potential human exposure, should the grain inadvertently enter the human food chain. The weight of evidence supports the safety of LM for farm animal and human consumption.

**1405**

EVALUATION OF THE SUBCHRONIC TOXICITY OF 1507XNK603 TRANSGENIC MAIZE.

S. A. MacKenzie<sup>1</sup>, C. Pavely<sup>2</sup>, L. A. Malley<sup>1</sup>, N. E. Everds<sup>1</sup>, G. P. Sykes<sup>1</sup>, B. Delaney<sup>1</sup> and I. Lamb<sup>2</sup>. <sup>1</sup>*DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE* and <sup>2</sup>*Pioneer Hi-Bred International, Inc., Johnston, IL.*

Three groups of adult male and female rats (12/sex/group) were fed diets formulated with a transgenic maize line (1507xNK603) containing genes that express the Cry1F, CP4 EPSPS, and PAT proteins, for approximately 90 days. The grain received 2 in-field applications of glufosinate and/or glyphosate herbicides. Four additional groups were fed diets formulated with a near isoline, non-transgenic hybrid maize line, or one of three non-transgenic, commercial hybrid maize lines. The Cry1F protein provides insecticidal activity against lepidopteran pests. The CP4 EPSPS and PAT proteins provide tolerance to herbicides containing glyphosate and glufosinate-ammonium, respectively. All grains and diets were analyzed for nutrients, fiber/energy, amino acids, minerals, vitamins, and contaminants and found to be comparable. Grain and diets were also analyzed for transgenic genes and/or proteins (presence and activity). No diet-related differences were observed among groups fed the different diets, with respect to body weight and nutritional parameters, clinical signs, ophthalmology, neurobehavioral assessments, clinical pathology, organ weights, and gross or microscopic pathology. Under the conditions of this study, diets containing a transgenic strain of maize, irrespective of herbicide treatment, produced no adverse effects in rats, compared to diets containing a non-transgenic, near isoline strain of maize or a non-transgenic, commercial strain of maize.

INDUCTION OF COLON TUMORS IN C57BL/6J MICE FED MEIQX, IQ OR PHIP FOLLOWED BY DEXTRAN SULFATE SODIUM TREATMENT.

A. Nishikawa, T. Imazawa, Y. Kuroiwa, K. Kanki, Y. Ishii, Y. Kitamura, T. Umemura and M. Hirose. *Pathology, National Institute of Health Sciences, Tokyo, Japan.* Sponsor: M. Ema.

MeIQx, a heterocyclic amine, has been shown to induce tumors in several organs including the liver, but consistently failed to induce intestinal tumors in rodents whereas the other heterocyclic amines IQ and PhIP exert colon tumorigenicity in rats. Recently, however, we found that dietary MeIQx induces genotoxicity in the colon as well as the liver of 2 different types of reporter gene-transgenic mice at subcarcinogenic doses such as 300 ppm. In the present study, in order to clarify a possibility whether MeIQx can induce colon tumors, C57BL/6J mice that have been used for both transgenic models were fed MeIQx, IQ or PhIP at a dose of 300 ppm for 12 weeks, and thereafter twice received 1-week treatment with dextran sulfate sodium (DSS) apart 2 weeks. After twenty weeks, colon tumors including adenocarcinomas were found at incidences of 26%, 24% and 45% in the groups receiving MeIQx, IQ and PhIP, respectively, which were significantly ( $P<0.05$  or 0.01) different from the DSS alone value (0%). On the other hand, MeIQx did not significantly induce any tumors in C57BL/6J mice or gpt delta mice even when fed at 300 ppm for 78 weeks, suggesting that the treatment of MeIQx alone was not sufficient to promote colon tumors. Thus our results clearly indicate that in addition to IQ and PhIP, MeIQx can induce colon tumors in mice under a colon tumor-promotional condition.

**1407**

INHIBITION OF AFB<sub>1</sub> ACTIVATION AND AFB<sub>1</sub>-DNA ADDUCT FORMATION BY DIETARY BUTYLATED HYDROXYTOLUENE IN TURKEYS.

J. A. Guarisco, J. O. Hall and R. A. Coulombe. *Toxicology Graduate Program, Utah State University, Logan, UT*.

Aflatoxin B<sub>1</sub> (AFB<sub>1</sub>) is potent hepatotoxin and a common contaminant of foods and feeds. Poultry are extremely susceptible to this mycotoxin, a condition we have shown to be associated with a combination of efficient hepatic cytochrome P450 (CYP)-mediated activation and deficient glutathione S-transferase (GST)-mediated detoxification. Previously, we showed that dietary butylated hydroxytoluene (BHT) protects against nearly all clinical signs of aflatoxicosis in turkeys. To determine the mechanism of chemoprevention, we examined the effect of BHT on CYP-mediated activation and GST-mediated detoxification of AFB<sub>1</sub>. Our data indicates that BHT appears to act primarily by inhibition of AFB<sub>1</sub> activation, rather than by induction of protective GSTs. Liver microsomal activation of AFB1 to AFBO was inhibited by BHT by apparent classic Michaelis competitive kinetics ( $K_i = 5.38$  mM). Likewise, dietary BHT significantly inhibited hepatic microsomal AFB<sub>1</sub> activation in addition to related CYP indicator activities. Dietary BHT also significantly reduced AFB<sub>1</sub> bioavailability as well as hepatic AFB<sub>1</sub>-DNA adduct formation at several time points compared to control birds after oral administration of [<sup>3</sup>H]-AFB<sub>1</sub>. Despite induction of hepatic GST indicator activities, we found no measurable effect toward specific AFB<sub>1</sub> detoxification by GST. These data support our hypothesis that the observed *in vivo* chemoprevention by BHT is due to inhibition of hepatic CYP-mediated AFB<sub>1</sub> activation to reactive toxic intermediate(s). (Supported in part by USDA-National Research Initiative grants 97-3081 and 02-35204-12294)

SAFETY ASSESSMENT AND RISK/BENEFIT ANALYSIS OF THE USE OF AZODICARBONAMIDE IN BABY FOOD JAR CLOSURE TECHNOLOGY: PUTTING TRACE LEVELS OF SEMICARBAZIDE EXPOSURE INTO PERSPECTIVE.

V. M. Lee-Brotherton, B. S. Lynch, K. Musa-Veloso, G. H. Goodfellow, E. Cheng, L. A. Haughton and E. R. Nestmann. *CANTOX Health Science Intl., Mississauga, ON, Canada*.

Trace levels of semicarbazide (SEM) discovered in bottled foods (especially baby foods) led to action by the European Food Safety Authority (EFSA) to eliminate possible exposure to this hydrazine compound. This would be via a ban in 2005 in Europe of the jar sealing technology known as Press On-Twist Off ("PT") closures. Azodicarbonamide, which is used in PT closures for the formation of a hermetic seal, partially degrades with the heat of processing to form SEM. The potential risks of SEM have been evaluated in the context of the benefits of the PT technology. SEM shows limited genotoxicity *in vitro* that is largely prevented by S9. Negative results were found *in vivo* in DNA alkaline elution assays and in UDS assays. This is in contrast to the genotoxic hydrazines that also have been shown to cause tumors. Carcinogenicity studies of SEM are of limited quality and show a questionable weak effect in mice and no effect in the rat at high doses, which are not relevant

to human exposure at trace levels. IARC has assigned SEM as Group 3, "not classifiable as to its carcinogenicity to humans". Based on exaggerated estimates of exposure to infants consuming baby foods compared to a NOAEL in developmental toxicity studies, the margin of safety is more than 21,000. Since the risk of an adverse effect is negligible, it is clear that any theoretical risk is outweighed by the benefits of continuing use of the PT closure to ensure both the microbial integrity and availability of commercial baby foods as a valuable source of infant nutrition.

INHIBITORY EFFECTS OF PLATYCODON GRANDIFLORUM ON 4-(METHYLNITROSAMINO)-1-(3-PYRIDYL)-1-BUTANONE (NNK)-INDUCED LUNG TUMORIGENESIS IN A/J MICE.

S. Roh<sup>4</sup>, D. Shin<sup>1,2</sup>, K. Lee<sup>1</sup>, Y. Chung<sup>3</sup>, C. Choi<sup>3</sup>, Y. Cho<sup>4</sup> and H. Jeong<sup>1,2</sup>.

<sup>1</sup>*Pharmacy, Chosun University, Kwangju, Kwangju, South Korea*, <sup>2</sup>*Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea*, <sup>3</sup>*Division of Food Science, Chinju International University, Chinju, South Korea* and

<sup>4</sup>*Department of R&D, Jangsaeng Doraji Co., Ltd., Chinju, South Korea*.

The present study was undertaken to estimate the effect of aqueous extract from the roots of *Platycodon grandiflorum* A. DC, Changil (CK) on 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK)-induced lung tumorigenesis in A/J mice. Mice were given an intraperitoneal injection of NNK to induce pulmonary neoplasms. They also received CK as a drinking water as night for 23 weeks, starting 1 week after the NNK injection. Treatments with CK reduced the incidence of lung tumors. CK treatment lowered the multiplicity of lung neoplasms with statistical significance. Immunohistochemically, CK reduced proliferating cell nuclear antigen (PCNA)-positive index in the lung tumors without affecting PCNA index in hyperplastic alveolar cell lesions. These results suggest that CK inhibits the development of lung tumors in mice treated with NNK, due to the suppression of initiation stage.

**1410**

FOUR WEEKS EXPOSURE TO A NOVEL NUTRITIONAL MIXTURE CONTAINING A SERIES OF POLYPHENOLIC PHYTOCHEMICALS ANTAGONIZES ACETAMINOPHEN-INDUCED HEPATOTOXICITY *IN VIVO*.

S. Stohs<sup>1</sup>, A. Nagori<sup>2</sup>, A. Naqvi<sup>2</sup>, N. Shah<sup>2</sup> and S. D. Ray<sup>2</sup>. <sup>1</sup>*Res & Dev, AdvoCare International, Carrollton, TX* and <sup>2</sup>*Mol. Toxicology. Prog. Division of Pharmacology Scs., Long Island University, Brooklyn, NY*.

From a disease-prevention perspective, recent progress in phytochemical and nutraceutical research clearly suggests 'benefits outweigh the risk' pattern. Powerful antioxidant properties have been the most acclaimed mechanism of action for these entities. Surprisingly, however, no studies have attempted to evaluate the combined antitoxic potential of a phytochemical-nutraceutical mixture (PNM) in *in vivo* models. Therefore, this study was designed to investigate whether pre-exposure to a unique PNM has the ability to impede mechanistic events involved in acetaminophen (AP)-induced hepatotoxicity. Besides several vitamins and minerals, key phytochemical components of PNM were: citrus flavonoids, red wine polyphenols, Garcinia, Gymnema, Ginkgo, Ephedra sinica, Camelia sinensis, Silybum, Guarana, Eluthero, Allium sativum and Ocimum basilicum extracts. To assess PNM's anti-toxic properties, groups of animals (ICR mice, 3 months old) received either a control diet or PNM containing diet for 4 weeks. On day-28, half of each group received saline i.p., while the other half of each group of mice received AP 400 mg/kg i.p. All the animals were sacrificed 24 hours after AP exposure. Serum and liver samples were analyzed. AP caused massive liver injury (ALT U/L: Control- 26±2; AP: 12880±1320) and oxidative stress (%Lipid peroxidation, MDA: Con-100%; AP:268%) coupled with genomic DNA fragmentation (Control-100%; AP:288%). PNM-exposure significantly reduced animal mortality and all the AP-induced events (In PNM+AP: ALT- 1397±122 U/L; MDA-125%; DNA frag-122%) including apoptotic and necrotic cell deaths. Collectively, our investigation suggests that PNM-exposure can serve as a much more powerful blend in antagonizing toxicants rather than phytochemical or nutraceutical alone, and PNM may potentially shield vital target organs from toxicities caused by intentional or accidental exposures to structurally and functionally diverse drug and chemical entities.

*IN VITRO* EFFICACY OF PLANT-EXTRACTS USED FOR ALTERNATIVE TREATMENT OF SNAKEBITES IN NIGERIA.

I. U. Asuzu<sup>1</sup>, A. Harvey<sup>2</sup> and H. M. Lantum<sup>3</sup>. <sup>1</sup>*Department of Veterinary Physiol. & Pharmacology, University of Nigeria Nsukka, Enugu, Nigeria*, <sup>2</sup>*Department of Physiol. & Pharmacology, University of Strathclyde, Glasgow, United Kingdom* and <sup>3</sup>*African Society for Toxicological Sciences (ASTS), Rochester, NY*.

Snakebites are a significant cause of death in Nigeria. Many citizens come in contact with deadly snakes on a daily basis. Due to high cost of conventional antivenom many victims patronize native doctors who use decoctions from plant ex-

tracts. This study describes the *in vitro* protective effects of a variety of plant extracts used for treating snakebite victims. Active ingredients were extracted from plant aqueous homogenates with 50% methanol. The extracts were tested for protective activity against the venoms of *Echis ocellatus* (*EO*), *Bitis arietans* and *Naja naja nigricollis* (*NN*) that are either neurotoxic, haemotoxic or myotoxic. Protective effects of the extracts against corresponding toxic activities of the venoms were tested in the chick biventer cervicis (cbc) muscle preparation, the egg embryo anti-haemorrhagic assay and cytotoxicity assay in skeletal muscle cells ( $C_2C_{12}$ ). Extracts that showed protective effects against some or all of the toxic effects of the venoms were further fractionated by bioassay-guided chromatographic separation methods to obtain active fractions or pure compounds. Five plant extracts showed protective activities against the toxic effects of the snake venoms. *Parkia biglobosa* (*PB*) stem bark extract for instance, significantly ( $p \leq 0.001$ ) protected the cbc muscle preparation from *NN* venom-induced inhibition of neurally evoked twitches when added to the bath 3–5 min before or after the venom. It reduced the loss of agonist responses to acetylcholine, carbachol and KCl, which are normally inhibited by *NN* venom. The extract (75–300  $\mu$ g/ml) significantly ( $p \leq 0.05$ ) protected  $C_2C_{12}$  cells against the cytotoxicity of *NN* and *EO* venoms. Egg embryos exposed to lethal concentrations of *EO* venom for  $\geq 12$  h were protected by *PB* extracts. The extract (5–10  $\mu$ g/1.5 ml) completely blocked the haemorrhagic activity of the venom. Plant extracts thus offer an alternative to antivenom therapy.

#### IMMUNOMODULATING AND ANTIOXIDANT EFFECTS OF MEXICAN STRAINS OF LENTINUS LEPIDEUS, GANODERMA APPLANATUM AND ARMILLARIA TABESCENS.

X. S. Ramirez-Garcia<sup>1</sup>, L. Garza-Ocanas<sup>1</sup>, F. Garza-Ocanas<sup>2</sup>, Y. Alcaraz-Contreras<sup>1</sup> and M. Salinas-Carmona<sup>3</sup>. <sup>1</sup>*Farmacología Y Toxicología, Fac de Medicina, UANL, Monterrey, Nuevo Leon, Mexico*, <sup>2</sup>*Silvicultura, Fac de Ciencias Forestales, UANL, Monterrey, Nuevo Leon, Mexico* and <sup>3</sup>*Inmunología, Fac de Medicina, UANL, Monterrey, Nuevo Leon, Mexico*.

A number of bioactive molecules (polysaccharides), including antitumor substances, have been identified in many Basidiomycetes mushrooms species growing in Asia. Those substances produce their antitumor effects by activating different immune responses in the host. In spite of the great number of mushrooms species growing in Mexican forests most of them have scarcely been investigated. In this study we evaluated the antitumoral, immunomodulating and antioxidant activity of aqueous extracts prepared from *Lentinus lepideus*(L.l), *Ganoderma applanatum*(G.a) and *Armillaria tabescens*(A.t) collected in Nuevo Leon, Mexico and cultivated *in vitro*. Aqueous extracts were administered p.o. at 20 mg/Kg to Balb/c mice and immunomodulating activity was evaluated according to the technique of Cunningham. Chang liver cells and HepG2 cells were exposed to the extracts (0.24 to 500 mg/mL) for 72 h and selective cytotoxicity was evaluated by the MTT test. The antioxidant effect was evaluated by the dichlorofluorescein diacetate (DCFDA) fluorescent probe in Chang liver cells. No significant difference between the CT50 of neoplastic and benign cells was found with any of the extracts. L.l and A.t increased the immune response by 84% and 55% respectively. L.l, G.a and A.t produced an inhibition of 75%, 65% and 49% of the xantine oxidase activity. Considering the results obtained in this study fractioning of the extracts of L.l, G.a and A.t will be carried out in order to know which fraction has the active principles.

#### NUCLEAR TRANSLOCATION OF NF-KB/REL COMPONENT BY PCSC22 ISOLATED FROM PORIA COCOS SCLEROTIUM.

Y. J. Jeon. *Pharmacology, Chosun University, Kwangju, South Korea*. Sponsor: H. Kim.

The sclerotium of *Poria cocos* Wolf, which grows on the roots of pine trees, has long been used as a sedative and diuretic (Chang and But, 1987). The accumulating data revealed that certain ingredients of the sclerotium of *Poria cocos* showed anti-tumor activities (Kanayama, 1986). Although the mechanism of anti-tumor activity is not known, the polysaccharides may potentiate the host defense mechanism through the activation of immune system. In the present study we show that PCSC22, a polysaccharide isolated from the sclerotium of *Poria cocos* with one percent sodium carbonate, significantly induces nitric oxide (NO) production and inducible NO synthase (iNOS) transcription. To further investigate the mechanism responsible for the induction of iNOS gene expression, we investigated the effect of PCSC22 on the activation of NF-kB/Rel, whose binding site was located in the promoter of iNOS gene. Immunohistochemical staining of p65 and p50 showed that PCSC22 produced strong induction of NF-kB/Rel nuclear translocation. Electrophoretic mobility shift assay (EMSA) and reporter gene assay further confirmed the activation of NF-kB/Rel by PCSC22. In conclusion, we demonstrate that PCSC stimulates macrophages to express iNOS gene through the activation of NF-kB/Rel.

#### 1414

#### SAFETY AND TOXICOLOGICAL EVALUATION OF A NOVEL NIACIN-BOUND CHROMIUM.

M. Shara<sup>1</sup>, T. Yasmin<sup>1</sup>, M. Bagchi<sup>2</sup>, A. Chatterjee<sup>1</sup>, H. G. Preuss<sup>3</sup> and D. Bagchi<sup>2</sup>. <sup>1</sup>*Pharmacy Science, Creighton University, Omaha, NE*, <sup>2</sup>*Research Center, InterHealth USA, Benicia, CA* and <sup>3</sup>*Medical Center, Georgetown University, Washington, DC*.

Chromium is an essential trace element required for normal protein, fat and carbohydrate metabolism. Niacin-bound chromium (NBC) is a unique form of bioavailable chromium that promotes a healthy lipid profile. This study was carried out to determine the safety of NBC. Acute oral, acute dermal, primary dermal irritation and primary eye irritation toxicity of NBC was evaluated. Ames bacterial reverse mutation assay, mouse lymphoma test and a dose-dependent 90-day subchronic toxicity was also conducted. In safety studies, the acute oral LD<sub>50</sub> of NBC was greater than 5,000 mg/kg in male and female Sprague-Dawley rats. No changes in body weight or adverse effects were observed following necropsy. Acute dermal LD<sub>50</sub> of NBC was greater 2,000 mg/kg. NBC was classified as slightly irritating in primary skin irritation testing in New Zealand Albino rabbits. Primary eye irritation test was conducted with NBC on rabbits. NBC was non-irritating to the eye. NBC did not induce mutagenic effects in bacterial reverse mutation test in five *S. typhimurium* strains (TA1535, TA98, TA100, TA97a and TA102), either with or without metabolic activation. Similarly, NBC didn't induce mutagenic effects in the mammalian cell gene mutation test in L5178Y mouse lymphoma cells TK (+/-), either with or without metabolic activation. A subchronic oral toxicity study was conducted at doses of 5, 50 and 125 ppm NBC for 90 consecutive days. No significant changes in selected organ weights individually and as percentages of body and brain weights were observed at 90 days of treatment. NBC supplementation did not cause changes in hepatic lipid peroxidation and DNA fragmentation after 30, 60 or 90 days of treatment. Hematology, clinical chemistry and histopathological evaluations revealed no abnormal findings. Taken together, the above results demonstrate the safety of NBC.

#### 1415

#### INHIBITORY EFFECTS OF KAHWEOL AND CAFESTOL ON CARRAGEENAN-INDUCED INFLAMMATION IN MOUSE AIR POUCH MODEL.

H. Jeong<sup>1,2</sup>, J. Kim<sup>1,2</sup> and K. Jung<sup>1,2</sup>. <sup>1</sup>*Pharmacy, Chosun University, Kwangju, Kwangju, South Korea* and <sup>2</sup>*Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea*.

Recent studies have shown the chemoprotective effects of kahweol and cafestol, which are coffee-specific diterpenes. This study investigated the effects of kahweol and cafestol on the inflammatory response induced by carrageenan in the mice. Air pouches were induced subcutaneously on the backs of mice and injected with carrageenan. The mice were treated with vehicle, kahweol, or cafestol at a dose of 5–10  $\mu$ g/kg one hour before carrageenan challenge. After carrageenan challenge (48 h), the air pouches were removed and analyzed. The volume, protein amounts, and cell count in the exudation obtained from the kahweol, or cafestol-treated mice were significantly reduced compared to those from vehicle-treated animals. The contents of prostaglandin E2, TNF-alpha and the mRNA for cyclooxygenase-2 were also suppressed in these animals. The histological examination displayed the suppression of the inflammatory response in the pouch tissues from kahweol, or cafestol-treated mice. Histological examination showed suppression of the inflammatory response in the pouch tissue from kahweol, or cafestol-treated mice.

#### 1416

#### UP-REGULATION OF CYCLOOXYGENASE-2 EXPRESSION BY CHICKEN OVALBUMIN IN MURINE MACROPHAGES.

K. Jung<sup>1,2</sup>, J. Kim<sup>1,2</sup> and H. Jeong<sup>1,2</sup>. <sup>1</sup>*Pharmacy, Chosun University, Kwangju, Kwangju, South Korea* and <sup>2</sup>*Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea*.

Chicken ovalbumin is one of the major egg white allergens that cause IgE-mediated food hypersensitivity. In the present study, we investigated the effects of ovalbumin on the cyclooxygenase-2 (COX-2) gene expression in the mouse macrophage cell line RAW 264.7. Ovalbumin significantly increased the prostaglandin E2 production and the expression of COX-2 mRNA and COX-2 protein in a dose-dependent manner. To investigate the significant cis-acting regions which COX-2 promoter, transient transfection experiments were carried out using reporter vectors harboring deleted COX-2 promoters. The transcriptional factor binding sites for activator protein 1 (AP-1) and NF-kB between -574 and -51 could be important for the induction of COX-2 by ovalbumin. The results of these studies suggest that induction of transcriptional activation of COX-2 by ovalbumin might be mediated through the AP-1 and NF-kB activation.

ANTIOXIDATIVE EFFECTS OF *PAECILOMYCES TENUIPES* ON CARBON TETRACHLORIDE-INDUCED HEPATOTOXICITY IN PRIMARY CULTURES OF ADULT RAT HEPATOCYTES AND *IN VIVO*.

I. Jun<sup>1</sup>, S. Hyun<sup>1</sup>, J. Lee<sup>2</sup>, T. Jeon<sup>1</sup>, S. Lee<sup>1</sup>, C. Jin<sup>1</sup>, D. Lee<sup>1</sup>, G. Kim<sup>1</sup> and T. Jeong<sup>1</sup>. <sup>1</sup>College of Pharmacy, Yeungnam University, Kyungsan, South Korea and <sup>2</sup>College of Natural Resources, Yeungnam University, Kyungsan, South Korea.

*Paecilomyces tenuipes* (PT), which is one of the cordyceps species belonging to *Ascomycetes*, has been used for medicinal purposes due to its wide physiological activities. The protective effects of PT against carbon tetrachloride (CCl<sub>4</sub>)-induced toxicity in adult rat hepatocytes were investigated in the present studies. After the monolayer was obtained by culturing the hepatocytes for 4 hrs, the medium was changed with fresh medium. Then PT extracts at 1, 2 and 5 mg/ml and/or CCl<sub>4</sub> at 4 mM were treated directly to the culture medium for 24 hrs. PT extracts protected the levels of glutathione, oxidized glutathione, glutathione peroxidase and catalase from reduction by CCl<sub>4</sub>. For *in vivo* studies, Sprague-Dawley rats were administered with PT extracts at 0.25, 0.5 and 1.0 g/kg p.o. once daily for 7 consecutive days. Thirty minutes after the final administration with PT, the rats were treated i.p. with CCl<sub>4</sub> at 0.5 ml/kg. PT extracts also protected the levels of glutathione, oxidized glutathione, glutathione peroxidase and catalase from reduction by CCl<sub>4</sub>. These results indicated that PT extracts might have hepatoprotective activities against CCl<sub>4</sub> by the protection of hepatic sulphydryl depletion.

NATURAL PRODUCTS DISCOVERY THROUGH DEVELOPMENT THE CHALLENGES AND THE OPPORTUNITIES.

C. B. Spainhour and J. Fogelman. Calvert Laboratories, Olyphant, PA.

The WHO estimates that approximately 80% of the world population relies primarily on traditional medicines as sources for their primary health care. Over 100 chemicals that are considered to be important drugs that are either currently in use or have been widely used in one or more countries in the world have been derived from a little under 100 plants. Approximately 75% of these substances were discovered as a direct result of studies focused on the isolation of active substances from plants used in traditional medicine. Drug development historically has relied only on a small number of molecular prototypes to produce new medicines. Only approximately 250 discrete structural prototypes have been used up to 1995 and most of these chemical platforms have been derived from natural sources. While recombinant proteins and peptides are gaining market share, low molecular weight compounds still remain the predominant choice for therapeutic intervention. The overwhelming concern today in the pharmaceutical industry is to improve the ability to quickly find new drugs. This will only be successfully accomplished if the procedures for drug target elucidation and lead compound identification and optimization are themselves optimized. However, the ability to accelerate the identification of pertinent lead compounds will only be achieved with the implementation of new ideas to generate varieties of structurally diverse test samples. Natural products are the most potent sources of new drug leads. This is because the degree of chemical diversity found in natural products is broader than that from any other source. However, natural products present challenging problems in the management of their discovery programs as well as the management of their development programs. Of particular note are the issues of purification, synthesis, identification and formulation. Lessons learned from prior problems and failures in development are presented. The use of totally new strategies for discovery and solutions to the problems of development of natural products need to be considered and are presented.

PRO-APOPTOTIC EFFECTS OF THE TROPICAL GINGER COMPOUND, 1'-ACETOXYCHAVICOL ACETATE, ON HUMAN BREAST CANCER CELLS *IN VITRO*.

H. E. Kleiner<sup>1,2</sup> and C. T. Campbell<sup>1</sup>. <sup>1</sup>Pharmacology, Louisiana State University-Health Sciences Center, Shreveport, LA and <sup>2</sup>Feist-Weiller Cancer Center, Louisiana State University-Health Sciences Center, Shreveport, LA.

The tropical ginger compound, 1'-acetoxychavicol acetate (ACA) possesses cancer chemopreventive properties in several models (oral mucosa, skin, colon) but its effects on breast cancer have not been evaluated. To determine whether ACA may also be effective at blocking mammary carcinogenesis, preliminary studies were performed in human breast cancer derived MCF-7 and MDA-MB-231 cells. The effects of ACA on cell viability were assessed using 3-(4, 5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfonylphenyl)-2H-tetrazolium (MTS) and Trypan Blue exclusion analysis. ACA significantly decreased cell viability in a time-and dose-dependent manner using both assays, with effective concentrations  $\leq 10 \mu\text{M}$ . Morphological examination of cells through light microscopy, as well as, 4', 6-diamidino-2-phenylindole dihydrochloride (DAPI) staining, suggested ACA induced apoptosis. To further investigate its pro-apoptotic effects, Annexin V/Alexa Fluor 88 staining was visualized using Flow Cytometry. At 6 h and 24 h after treatment with ACA (10-50  $\mu\text{M}$ ), there was a significant dose-dependent increase in the percentage of cells undergoing late apoptosis in both cell lines. We hypothesized that

ACA may have inhibitory effects on ornithine decarboxylase (ODC), a putative oncogene upregulated in most tumors, that metabolizes polyamines that are essential for cell growth. ACA (10-50  $\mu\text{M}$ , 6 h) blocked ODC activity by 90-99% and 84-85% in MCF-7 and MDA-MB-231 cells, respectively. These results suggest ACA may have potential chemoprotective effects against the later stages of breast cancer. This research was sponsored by a Grant-in-Aid (Intramural Award).

NOTOGINSENG ATTENUATES LPS-INDUCED PRO-INFLAMMATORY MEDIATORS IN ANTIGEN PRESENTING CELLS.

A. Rhule<sup>1</sup>, S. Navarro<sup>2</sup>, J. Smith<sup>1</sup> and D. M. Shepherd<sup>1, 2</sup>. <sup>1</sup>Ctr for Environ Health Sciences, University of Montana, Missoula, MT and <sup>2</sup>Biomed Pharmacology Sciences, University of Montana, Missoula, MT.

The USFDA does not regulate herbal or dietary supplements as drugs although many may have associated therapeutic effects and/or toxicities. In this regard, the immunomodulatory effects of *Panax notoginseng* on cultured dendritic cells (DC2.4) and macrophages (RAW 264.7) were investigated. Notoginseng inhibited the production of LPS-induced TNF $\alpha$  by the phagocytic cells in a concentration-dependent manner as measured by ELISA. TNF $\alpha$  production by both the dendritic cells and macrophages was inhibited in samples treated with notoginseng 24 hours prior to and concurrent with LPS addition, but not in samples treated 8 hours after LPS stimulation. Also, COX-2 and IL-1 $\beta$  mRNA levels in RAW264.7 cells stimulated with LPS were inhibited by notoginseng. The effects of notoginseng on expression of the accessory molecules CD40, CD14, CD86 and TLR4 on phagocytic cells stimulated with LPS were analyzed by flow cytometry. CD86 expression was decreased while CD14 expression was unaffected following exposure to 50  $\mu\text{g}/\text{ml}$  notoginseng. There was also a trend towards a decrease in CD40 expression and an increase in TLR4 expression in both the macrophages and dendritic cells. The immunomodulatory effects of Rb1 and Rg1 ginsenosides, the purported bioactive components of our notoginseng extract, were investigated. Both Rb1 and Rg1 inhibited TNF $\alpha$  levels in the RAW264.7 cells following LPS stimulation, whereas only Rg1 inhibited TNF $\alpha$  production by DC2.4 cells. However, neither purified ginsenoside compound inhibited LPS-induced TNF $\alpha$  production to the same extent as the whole notoginseng extract suggesting that additional, as of yet unidentified, compounds probably contribute to the overall bioactivity of this herbal extract. Collectively, these results indicate that notoginseng inhibits the activation of RAW264.7 and DC2.4 cells and demonstrate that notoginseng possesses anti-inflammatory properties *in vitro*. This work was supported by a grant from NSF-EPSCoR (EPS0091995).  $\alpha\beta\mu$

EFFECTS OF MURINE CYP1A1 IN MOUSE HEPATOMA HEPA-1C1C7 CELLS BY CATECHIN AND 3', 4', 3, 5, 7-O-METHYLATED CATECHIN.

E. Han<sup>1, 2</sup>, J. Kim<sup>1, 2</sup>, H. Kim<sup>1, 2</sup>, Y. Hwang<sup>1, 2</sup>, T. Jeong<sup>3</sup>, E. Lee<sup>3</sup> and H. Jeong<sup>1, 2</sup>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea and <sup>3</sup>Pharmacy, Yeungnam University, Kyungsan, South Korea.

Green tea catechin is known to exert chemopreventive effects in many cancer models. In the present study, we investigated the effect of catechin and 3', 4', 3, 5, 7-O-methylated catechin on 2, 3, 7, 8-Tetrachlorodibenzo-p-dioxine (TCDD)-inducible P450 1A1 gene expression in mouse hepatoma Hepa-1c1c7 cells. 7-ethoxresorufin O-deethylase (EROD) activity in the Hepa-1c1c7 cells was significantly increased by 3', 4', 3, 5, 7-O-methylated catechin but not catechin. TCDD-induced cytochrome CYP1A1-specific EROD activity was markedly reduced in the concomitant treatment of TCDD and 3', 4', 3, 5, 7-O-methylated catechin but not catechin. TCDD-induced CYP1A1 mRNA level was also markedly suppressed in the concomitant treatment of TCDD and 3', 4', 3, 5, 7-O-methylated catechin but not catechin. A transient transfection assay using dioxin-response element (DRE)-linked luciferase and electrophoretic mobility shift assay revealed that 3', 4', 3, 5, 7-O-methylated catechin reduced transformation of the aryl hydrocarbons (Ah) receptor to a form capable of specifically binding to the DRE sequence in the promoter of the CYP1A1 gene. These results suggest the down regulation of the CYP1A1 gene expression by 3', 4', 3, 5, 7-O-methylated catechin in Hepa-1c1c7 cells might be antagonism of the DRE binding potential of nuclear Ah receptor.

SUPPRESSION OF MURINE CYP1A1 IN MOUSE HEPATOMA HEPA-1C1C7 CELLS BY FORMONONETIN.

E. Hann<sup>1, 2</sup>, J. Kim<sup>1, 2</sup> and H. Jeong<sup>1, 2</sup>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.

Isoflavone phytoestrogen, formononetin, is 4-O-methyl derivatives of daidzein. In the present study, we investigated the effect of formononetin on 2, 3, 7, 8-Tetrachlorodibenzo-p-dioxine (TCDD)-inducible P450 1A1 gene expression in mouse hepatoma Hepa-1c1c7 cells. TCDD-induced cytochrome CYP1A1-specific

7-ethoxyresorufin O-deethylase (EROD) activity was markedly reduced in the concomitant treatment of TCDD and formononetin in a dose dependent manner. TCDD-induced CYP1A1 mRNA level was also markedly suppressed in the concomitant treatment of TCDD and formononetin. A transient transfection assay using dioxin-response element (DRE)-linked luciferase and electrophoretic mobility shift assay revealed that formononetin reduced transformation of the aryl hydrocarbons (Ah) receptor to a form capable of specifically binding to the DRE sequence in the promoter of the CYP1A1 gene. These results suggest the down regulation of the CYP1A1 gene expression by formononetin in Hepa-1c1c7 cells might be antagonism of the DRE binding potential of nuclear Ah receptor.

#### 1423 CAFFEIC ACID PHENETHYL ESTER SUPPRESSED IN B16F10 MELANOMA CELL METASTASIS

D. Shin<sup>1,2</sup> and H. Jeong<sup>1,2</sup>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.

Metastasis of cancer cells to distant sites is one of the major deciding factors in cancer outcome. In fact, prognosis of cancer is mainly determined by the invasiveness of the tumor and its ability to metastasize. In this study, we assayed the preventive and therapeutic effects of Caffeic acid phenethyl ester (CAPE) derived from honey-bee propolis on the experimental lung metastasis induced by B16F10 melanoma cells in C56BL6 mice. CAPE clearly inhibited both B16F10 melanoma cell adhesions to the extracellular matrix proteins as well as invasion through Matrigel-coated filter. In addition, CAPE significantly inhibited the proliferation of B16F10 melanoma cells in a dose-dependent manner. In B16F10 melanoma lung metastasis experiment, CAPE showed remarkable inhibitory effects on the lung tumor colonization in a dose-dependent manner. These results demonstrate that anti-metastatic activity of CAPE resulted from blocking of proliferation and invasion of the melanoma cells. Taken together, the results of our study provide evidence that CAPE possess an anti-metastatic activity.

#### 1424 SUPPRESSIVE EFFECT OF GAMMA-TOCOPHEROL ON PROSTATE CANCER DEVELOPMENT IN PB/SV40 T ANTIGEN TRANSGENIC RATS.

S. Sugiura<sup>1</sup>, S. Takahashi<sup>1</sup>, T. Murasaki<sup>1</sup>, M. M. Said<sup>1</sup>, S. Suzuki<sup>1</sup>, K. Abe<sup>2</sup>, M. Asamoto<sup>1</sup> and T. Shirai<sup>1</sup>. <sup>1</sup>Department of Experimental Pathology and Tumor Biology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan and <sup>2</sup>Eisai Co., Ltd., Tokyo, Japan.

Vitamin E is the general name for a family of eight different compounds which is one of the most researched in medicine.  $\gamma$ -Tocopherol is the major form of vitamin E, but has drawn little attention compared with  $\alpha$ -tocopherol, the predominant form of vitamin E in tissues and the primary form in supplements. Epidemiological studies have indicated that plasma concentrations of  $\gamma$ -tocopherol are inversely associated with the risk of prostate cancer. In addition, recent studies have indicated that  $\gamma$ -tocopherol exerts inhibitory effects on growth of prostate cancer cell lines. However, *in vivo* studies of effects of  $\gamma$ -tocopherol on prostate carcinogenesis have not been reported. The aim of the present study was to evaluate the effects of  $\gamma$ -tocopherol on prostate cancer development using the probasin(PB)/simian virus 40(SV40) T antigen transgenic rat established in our laboratory. Five week old male PB/SV40 T antigen transgenic rats were given  $\alpha$ - (50mg/kg diet) or  $\gamma$ -tocopherol (50, 100mg/kg diet) in vitamin E free diet for 10 weeks. There were no treatment-related changes with reference to body or relative prostate weights, as well as food consumption. Furthermore, there were no significant differences in the incidences of prostate adenocarcinomas in any of the prostate lobes. However, quantitative analysis of proliferative lesions revealed a significant suppressive effect of  $\gamma$ -tocopherol in the ventral ( $P<0.05$ ) and dorsal lobes ( $P<0.01$ ), with dose-dependence. The results thus indicate that  $\gamma$ -tocopherol may suppress rat prostate carcinogenesis. Investigations of potential mechanisms of the observed anticancer effects are now on-going.

#### 1425 SUBCHRONIC GAVAGE TOXICITY STUDY OF GINKGO BILOBA EXTRACT IN FISCHER 344 RATS AND B6C3F<sub>1</sub> MICE.

L. M. Fomby<sup>1</sup>, M. Hejmancik<sup>1</sup>, M. J. Ryan<sup>1</sup>, C. Colleton<sup>1</sup>, D. Orzech<sup>2</sup> and P. Chan<sup>2</sup>. <sup>1</sup>Battelle, Columbus, OH and <sup>2</sup>NIEHS, Research Triangle Park, NC.

There is limited information pertaining to the toxicity of the widely used dietary supplement *Ginkgo biloba* extract (GBE). The purpose of this study was to evaluate the toxicity of GBE in 0.5 percent aqueous methylcellulose administered to male and female Fischer 344 (F344) rats and B6C3F<sub>1</sub> mice. Rats were administered 0, 62.5, 125, 250, 500, and 1000 mg/kg GBE (at 5 mL/kg) and mice were administered 0, 125, 250, 500, 1000 and 2000 mg/kg GBE (at 10 mL/kg) by the gavage route for up to 14 weeks. All treated rats were similar to controls in overt behavior and in general health and appearance. Weekly and terminal mean body weights of GBE treated rats were similar to control. Slight, but statistically significant increases in mean total protein and albumin concentrations were observed in male rats at all

dosages. Group mean liver and liver-to-body weights were statistically significantly increased in all dosage groups. Histopathological observations included centrilobular and midzonal hepatocellular hypertrophy in GBE treated rats of both sexes and midzonal hepatocellular vacuolization in treated males. Thyroid hyperplasia was observed in all GBE treated rats. Weekly and terminal mean body weights of GBE treated mice were similar to control. Ruffled fur was observed in 1000 and 2000 mg/kg male mice between weeks 7 and 8 and weeks 5 and 9, respectively. There were no alterations in measured hematologic parameters. Increased mean liver and liver-to-body weights were observed at all male and female mouse dosages. Decreased mean kidney and kidney-to-body weights were observed in 2000 mg/kg male mice. Organ weight changes were correlated with histopathological findings. Hepatocellular hypertrophy was noted in all male and female treatment groups and decreased renal cytoplasmic vacuolization was noted in male mice at  $\geq 500$  mg/kg. In conclusion GBE treatment to F344 rats resulted in hepatic and thyroid effects while hepatic and renal effects were observed in B6C3F<sub>1</sub> mice. This work was supported by NIEHS Contract No. N01-ES-35502

#### 1426 INHIBITORY EFFECT OF KAHWEOL AND CAFESTOL ON TGF-BETA-INDUCED FIBROSIS IN HEPATIC STELLATE CELLS.

K. Jung<sup>1,2</sup> and H. Jeong<sup>1,2</sup>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.

Activation of hepatic stellate cells and increasing of collagen content have been identified as a critical step in hepatic fibrogenesis and are regulated by several factors including cytokines and oxidative stress. In this study, we investigated the effects of kahweol and its dehydro derivative, cafestol, two diterpenes that are present in considerable quantities in coffee beans, on hepatic fibrosis in hepatic stellate cells. We report that kahweol and cafestol decreases TGF-beta-stimulated collagen I/III mRNA expression. The mRNA expressions of TGF-beta-induced collagen type I/III were measured by RT-PCR. As the results, kahweol and cafestol inhibited collagen I/III mRNA expression in a dose dependent manner. Furthermore, the effects of kahweol and cafestol on expression of alpha-smooth muscle actin (a-SMA) and collagen type I/III, were evaluated utilizing immunocytochemistry. Kahweol and cafestol reduced expression of a-SMA and collagen type I/III proteins compared with TGF-beta-induced hepatic stellate cells. Moreover, kahweol and cafestol decreased TGF-beta-induced proliferation of hepatic stellate cells. These results suggested that the effects of kahweol and cafestol on the hepatic fibrosis in stellate cells may, at least in part, be due to its ability to reduce proliferation and collagen synthesis.

#### 1427 ANTI-ANGIOGENETIC EFFECTS OF CAFESTOL AND KAHWEOL ON HT-1080 FIBROSARCOMA CELLS.

Y. Chung<sup>3</sup>, D. Shin<sup>1,2</sup>, K. Oh<sup>1,2</sup>, E. Woo<sup>1,2</sup>, C. Choi<sup>3</sup>, D. Kim<sup>4</sup> and H. Jeong<sup>1,2</sup>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea, <sup>3</sup>Division of Food Science, Chinju International University, Chinju, South Korea and <sup>4</sup>Pathology, College of Oriental Medicine, Daejeon University, Daejeon, South Korea.

Cafestol (CA) and its dehydro derivative, Kahweol (KA), are two diterpenes that are present in considerable quantities in coffee beans, as well as in the final, unfiltered beverage e.g. in Turkish or Scandinavian style coffees. They have been shown to possess both adverse and chemoprotective properties. In the present study, we identified the effect of CA and KA on angiogenesis. A cytotoxicity assay of CA and KA in HT-1080 fibrosarcoma cell showed the decrease effect in cell viability by a dose-dependent manner but no significant influence on the growth of human microvesSEL endothelial cell-1 (HMEC-1). CA and KA inhibited the vascular endothelial growth factor (VEGF)-induced tube formation of HMEC-1 in dose-dependent manner. VEGF production from HT-1080 cells was also inhibited by treatment with CA and KA. CA and KA inhibited both VEGF-induced vessel formations in the C57BL/6 mouse matrigel plug assay. Taken together, the results of our study provide evidence that CA and KA possess an anti-angiogenic potential that is a new insights and previously unrecognized biologic activity.

#### 1428 GREEN TEA INFUSION PREVENTS DUAL PROMOTING EFFECTS OF PENTACHLOROPHENOL, AN ENVIRONMENTAL POLLUTANT, ON HEPATO- AND CHOLANGIO-CARCINOGENESIS OF MICE INDUCED BY DIETHYLNITROSAMINE.

T. Umemura<sup>1</sup>, R. Hasegawa<sup>2</sup>, K. Keita<sup>1</sup>, Y. Kitamura<sup>1</sup>, A. Nishikawa<sup>1</sup> and M. Hirose<sup>1</sup>. <sup>1</sup>Division of Pathology, National Institute of Health Sciences, Tokyo, Japan and <sup>2</sup>Division of Medical Safety Science, National Institute of Health Sciences, Tokyo, Japan.

In order to explore a possibility of custom drinking of green tea infusion being efficacious to reduce the carcinogenic risk induced by environmental exposure to pentachlorophenol (PCP), we examined the effects of green tea infusion on the dual

promoting action to hepato- and cholangio- carcinogenesis in mice exposed to DEN. In the first experiment, groups of 15 male mice were initially treated with diethylnitrosamine (DEN) at a dose of 20 ppm in the drinking water for the first 8 weeks followed a 4 week recovery interval by PCP at concentrations of 0 (basal diet), 300 and 600 ppm in the diet for 23 weeks. Further groups of animals were treated with DEN and PCP in the same manner as above and 2 % green tea infusion (GT) instead of the drinking water was given 2 weeks before and during PCP exposure. PCP exposure at the high dose promoted DEN-induced hepatocarcinogenesis, and also progressed cystic hyperplasias of intrahepatic bile ducts to cholangiocellular tumors. Co-administration of GT was able to prevent the increases of incidences and multiplicities of DEN-induced hepatocellular tumors due to PCP exposure and also arrest the progression of cystic hyperplasias to cholangiocellular tumors by PCP treatment. In the second experiment, co-treatment with GT in the drinking water from 1 week before 300 or 600 ppm PCP treatment in the diet to the end of the experiment at week 3 in B6C3F1 male mice was able to inhibit increases of serum ALT activities, 8-oxodeoxyguanosine (8-oxodG) levels in liver DNA and labeling indices (LIs) of bromodeoxyuridine (BrdU) in hepatocytes and intrahepatic biliary epithelia induced by PCP. These findings suggest a possibility of usual intake of green tea reducing the carcinogenic risk caused by an environmental pollutant, PCP which might involve oxidative stress in its carcinogenesis.

#### 1429 TWO-GENERATION REPRODUCTION STUDY OF TEAVIGO™ (EPIGALLOCATECHIN GALLATE) IN RATS.

R. Isbrucker<sup>1</sup>, J. A. Edwards<sup>2</sup>, E. Woltz<sup>2</sup> and E. Marsden<sup>3</sup>. <sup>1</sup>Burdock Group, Washington, DC, <sup>2</sup>DSM Nutritional Products Ltd., Kaiseraugst, Switzerland and <sup>3</sup>MDS Pharmacology Services, L'Arbresle, France. Sponsor: J. Griffiths.

Epigallocatechin gallate (EGCG) is a principal polyphenolic compound of green tea and has received wide attention for its potential anti-cancer and cardioprotective effects. Although several *in vivo* toxicity studies have been reported, the effects of EGCG on reproduction and fertility are not clearly documented. Sprague-Dawley rats were administered 0, 1200, 3600 or 12000 ppm Teavigo™ (91% EGCG) in their diet for two consecutive generations, commencing 10 weeks prior to F<sub>0</sub> mating and continuing through to the maturation and reproductive evaluation of the F<sub>1</sub> generation. Although the highest dosed F<sub>0</sub> rats showed signs of reduced body weight and food consumption there was no influence on their mating, fertility or survival. However, a slight increase in the post-natal mortality of their offspring was observed. Also, a slight delay in sexual maturation of the F<sub>1</sub> animals receiving 12000 ppm was noted, which is likely due to the reduced growth rate of these rats. No obvious evidence of toxicity effects on reproduction, or reduced fertility was observed among adult animals dosed at 3600 ppm and histology showed no abnormal findings. A slight increase in pup mortality in the 3600 ppm group was attributed to the increased food consumption and increased EGCG intake by nursing dams. Also, weanling pups had EGCG plasma levels higher than in the adults. Teavigo™ was found to have a NOAEL of 3600 ppm for general toxicity, fecundity and fertility in adult rats. A NOAEL of 1200 ppm is posited for effects on growth and development of nursing offspring.

#### 1430 SUPPRESSION OF LIPOPOLYSACCHARIDE-ACTIVATED CYCLOOXYGENASE-2 EXPRESSION BY BIOCHANIN A IN MURINE MACROPHAGE RAW 264.7 CELLS.

J. Kim<sup>1,2</sup>, E. Han<sup>1,2</sup> and H. Jeong<sup>1,2</sup>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.

Biochanin A is an isoflavonoid phytoestrogen found in soybean and possesses anti-tumorigenic, anti-oxidant, anti-microbial properties. In the present study, we investigated the effects of biochanin A on the cyclooxygenase-2 (COX-2) gene expression, which plays a crucial role in many physiological and pathological processes in macrophages. Treatment with biochanin A significantly decreased the production of LPS-induced prostaglandin E2 and the expression of COX-2 mRNA in lipopolysaccharide (LPS)-activated RAW 264.7 macrophages in a dose-dependent manner. Transient transfection experiments also showed that LPS-induced increase in COX-2 promoter activities was suppressed by biochanin A. This study suggests that modulation of COX-2 expression by biochanin A may be important in the prevention of inflammation.

#### 1431 RUTAECARPINE IS AN AGONIST OF THE ARYL HYDROCARBON RECEPTOR.

T. Jeong<sup>3</sup>, E. Han<sup>1,2</sup>, J. Kim<sup>1,2</sup>, H. Kim<sup>1,2</sup>, Y. Hwang<sup>1,2</sup>, E. Lee<sup>3</sup> and H. Jeong<sup>1,2</sup>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea and <sup>3</sup>Pharmacy, Yeungnam University, Kyungsan, South Korea.

Rutaecarpine is a major quinazolinocarboline alkaloidal component of *Evodia rutaecarpa* Bentham (Rutaceae). Rutaecarpine has been characterized to the effects of cytochrome P450 s (CYPs) metabolism *in vivo* and reported as a potent inhibitor of

CYP1A2 in both mouse and human liver microsomes. In the present study, we investigated the effect of rutaecarpine on CYP1A1 gene expression in mouse hepatoma Hepa-1c1c7 cells. Cultured mouse hepatoma Hepa-1c1c7 cells were treated with rutaecarpine to assess the role of rutaecarpine on CYP1A1 expression. CYP1A1-specific 7-ethoxyresorufin O-deethylase (EROD) activity in the Hepa-1c1c7 cells was significantly increased by rutaecarpine. Furthermore, rutaecarpine caused an increase in the level of CYP1A1 mRNA, indicating that it may be an agonist of the aryl hydrocarbon receptor (AhR). A transient transfection assay using dioxin-response element-linked luciferase and electrophoretic mobility shift assay revealed that rutaecarpine increased transcription of a reporter vector containing the CYP1A1 promoter. These results suggest that rutaecarpine might be an agonist of the AhR in Hepa-1c1c7 cells.

#### 1432 EXPRESSION PROFILING OF ESTROGEN RESPONSIVE GENES FOR PHYTOESTROGENS BY DNA MICROARRAY ASSAY.

D. Han<sup>1</sup>, R. Ise<sup>1</sup>, Y. Takahashi<sup>2</sup>, S. Terasaka<sup>1</sup>, A. Inoue<sup>1</sup>, M. Tanji<sup>1</sup> and R. Kiyama<sup>1,3</sup>. <sup>1</sup>Department R & D, InfoGenes Co., Ltd., Ibaraki, Japan, <sup>2</sup>Industrial Research Institute of Tottori Prefecture, Tottori, Japan and <sup>3</sup>National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan. Sponsor: M. Denison.

Phytoestrogens have attracted significant attention because of their ability to modulate the action of estrogen, which can be used for anti-cancer agents, hormone therapeutic agents, dietary additives and supplements, and antimicrobial agents. However, the gene networks and molecular pathways by which phytoestrogens regulate these events are only partially understood. Understanding more about the gene function networks and signal transduction pathways initiated or mediated by these compounds, we here examined phytoestrogens such as isoflavones, flavones, flavonols, and coumestrol, naringenin and phloretins by using a DNA microarray assay. Of the 172 estrogen responsive genes, expression profiles of phytoestrogens were compared using correlation coefficients, or R values, after a correlation analysis by linear regression. While R values indicate the similarity of the response by the genes, we also examined the genes by cluster analysis and by their specificity to phytoestrogens (specific to isoflavones, flavonols, flavones and all except with ipriflavone) or gene functions. Several genes were selected from p53-related genes, Akt2-related genes, MAPK-related genes, Ras superfamily genes and AP-1 family and related genes. We further examined the extracts from two local crops of soy beans such as Kuro-daizu or Mochi-daizu by comparing the gene expression profiles with those of a natural estrogen or phytoestrogens as a first step in utilizing the expression profiles for various applications. The approach described here would be useful for analyzing plant extracts for various purposes including screening new estrogenic compounds, examining food processing methods, a quality control of food products and understanding the effects of phytoestrogens. Supported by the Preventing Public Pollution from the Ministry of the Environment of Japan.

#### 1433 MICROARRAY ANALYSIS OF T-2 TOXIN-INDUCED APOPTOTIC LESIONS OF THE LIVER, PLACENTA AND FETAL LIVER IN PREGNANT RATS.

S. Sehata<sup>1</sup>, N. Kiyosawa<sup>1</sup>, F. Atsumi<sup>1</sup>, K. Ito<sup>1</sup>, T. Yamoto<sup>1</sup>, M. Teranishi<sup>1</sup>, K. Uetsuka<sup>2</sup>, H. Nakayama<sup>2</sup> and K. Doi<sup>1</sup>. <sup>1</sup>Medicinal Safety Research Laboratories, Sankyo Co., Ltd., Shizukawa, Japan and <sup>2</sup>Department of Veterinary Pathology, Graduate School of Agricultural and Life Sciences, The University of Tokyo, Tokyo, Japan.

T-2 toxin is a trichothecene mycotoxin produced by *Fusarium* spp. It is known that T-2 toxin induces apoptotic lesions in many tissues. It is also reported that pregnant mice treated with T-2 toxin exhibited fetal death and fetotoxicity in addition to maternal toxicity, and apoptosis was also observed in these systems. However, the mechanism of T-2 toxin-induced toxicity in pregnant rats is unknown. The purpose of the present study is to examine the T-2 toxin-induced gene expression changes in pregnant rats. Pregnant rats on day 13 of gestation were treated orally with 2 mg/kg of T-2 toxin and sacrificed at 1, 3, 6, 9, 12 and 24 hours after the treatment. Histopathologically, the number of apoptotic cells was increased in the dams liver, placenta and fetal liver after the treatment. To examine the gene expression profiles, we performed GeneChip microarray analysis in these tissues at 3 selected time points based on the results of TUNEL-staining. As the results, the increased expressions of oxidative stress- and apoptosis-related genes were detected in the dams liver, placenta and fetal liver from pregnant rats treated with T-2 toxin. The decreased expressions of lipid metabolism- and drug-metabolizing enzyme-related genes were also detected in these tissues. As regarding apoptosis, the results suggested that MAPK pathway might be involved in the mechanisms of T-2 toxin-induced apoptosis. In addition, increased expression of *c-jun* gene was consistently observed in these tissues. Our results suggest that the mechanism of T-2 toxin-induced toxicity in pregnant rats is due to oxidative stress followed by the activation of MAPK pathway, and finally apoptosis may be induced. *c-jun* gene may play an important role in T-2 toxin-induced apoptosis.

1434

FUMONISIN B<sub>1</sub> ACTIVATES SERINE PALMITOYLTRANSFERASE AND SPHINGOSINE KINASE, ENZYMES IMPORTANT IN SPHINGOLIPID METABOLISM, IN MOUSE LIVER.

H. Suzuki, Q. He and R. P. Sharma. *The University of Georgia, Athens, GA.*

Fumonisins B<sub>1</sub> (FB<sub>1</sub>) is a mycotoxin produced by *Fusarium verticillioides*, a common fungus in corn and other crops. FB<sub>1</sub> causes equine leukoencephalomalacia, porcine pulmonary edema, cancer in liver of female mice and in kidney and liver of male rats. It is hepatotoxic and nephrotoxic in most animal species. The primary biochemical effect of FB<sub>1</sub> is inhibition of ceramide synthase leading to the accumulation of free sphingoid bases (sphinganine and sphingosine), sphingoid base metabolites, and depletion of more complex sphingolipids. The treatment of FB<sub>1</sub> increases the sphinganine and sphingosine levels in liver of female mice. The hepatopathy is closely correlated with the disruption of sphingolipid metabolism. In this study, we investigated the effects of FB<sub>1</sub> on serine palmitoyltransferase (SPT), the enzyme synthesizing 3-ketosphinganine in *de novo* biosynthetic pathway of sphingolipids, and sphingosine kinase (SPHK), the enzyme converting free sphingoid bases to their respective phosphates. Female BALB/c mice were subcutaneously injected with 2.25 mg FB<sub>1</sub>/kg daily for 5 days. One day after the last treatment, the expression of SPT1 and SPT2 was increased by 4.7- and 5.3-fold, respectively, in liver. The activity of SPT was increased in liver from FB<sub>1</sub>-treated mice. FB<sub>1</sub> dramatically increased the expression of hepatic SPHK to 25-fold. These increases were accompanied by induction of inducible nitric oxide synthase (iNOS) in liver, suggesting that the production of enzymes was mediated via NF<sub>κ</sub>B activation. It appears that the accumulation of free sphingoid bases and their metabolites will be influenced by activation of the above enzymes and may amplify the toxic response to FB<sub>1</sub>. (Supported in part by USPHS ES 09403)

IN VITRO STUDIES CONFIRM SYNERGISTIC EFFECTS OF FUMONISIN B1 AND OCHRATOXIN A IN VIVO.

E. E. CREPPY<sup>1</sup>, P. Chiarappa<sup>2,1</sup>, I. Baudrimont<sup>1</sup>, P. Borracci<sup>2</sup>, S. Moukha<sup>3,1</sup> and M. CARRATU<sup>2</sup>. <sup>1</sup>Toxicology, University Bordeaux 2, Bordeaux, France, <sup>2</sup>Pharmacology and Human Physiology, Medical School, University of Bari, Bari, Italy and <sup>3</sup>MycSA, INRA, Villeneuve d'Ornon, France.

Contamination of food and feeds by mycotoxins is a major problem of human and animals health concern which is also extremely detrimental to economy. Mycotoxins producing moulds may produce a diversity of toxins such as aflatoxins, ochratoxins, trichothecenes, zearalenone, fumonisins, tremorgenic toxins and ergot alkaloids. Indeed, more than one mycotoxin are found usually in the same contaminated commodities, rising the problem of multi-toxicosis in which the respective metabolites are also involved. The risk assessment for humans potentially exposed to multi-mycotoxins suffers very much from the lack of adequate food consumption data. Furthermore, for a given mycotoxin synergism and antagonism with other mycotoxins found in the same food commodities are not taken into account. The case of combination of ochratoxin A (OTA) and fumonisins B1 (FB1) has been addressed in the present paper with the purpose of predicting the *in vivo* toxicity using a simple *in vitro* test, i.e. neutral red uptake, in three different cell-lines, C6 glioma cells, Caco-2 cells and Vero cells. Using the following equation [1], *in vivo* toxicity (LD<sub>50</sub>) is in adequation with *in vitro* data, (IC<sub>50</sub> values) for both toxins as well as for the combination of 10 microM OTA and variable concentrations of FB1 (10 to 50 microM). Thus such a simple *in vitro* test may help predicting *in vivo* toxicity of combinations of mycotoxins naturally occurring in foodstuffs. Reference [1] Spielmann, H., Genschow, E., Liebsch, M., Halle, W., Determination of the starting dose for acute oral toxicity (LD<sub>50</sub>) testing in the up and down procedure (UDP) from cytotoxicity data. CYTOKINE GENE EXPRESSION IN RAT MICROGLIA EXPOSED TO THE MARINE TOXIN DOMOIC ACID.

A. M. Mayer, M. Guzman, R. Peksa, M. L. Hall and M. J. Fay. *Pharmacology, Midwestern University, Downers Grove, IL. Sponsor: W. Prozialeck.*

The molecular pathology of Amnesic Shellfish Poisoning, one of the shellfish poisoning syndromes in the United States caused by the marine glutamate analog domoic acid (DOM), is incompletely understood. Our working hypothesis is that DOM may activate rat neonatal microglia to cause generation of cytokines, and toxicity to the nervous system. We have reported that *in vitro* treatment of microglia with DOM leads to TNF- $\alpha$  protein release (Mayer et al. *BioMedCentral Pharmacology* 1:7-19, 2001). The purpose of our study was to investigate cytokine gene expression in 4-24 hour DOM [1mM]-treated microglia using a cytokine-specific cDNA array (SuperArray Inc., Bethesda, MD). Through side-by-side hybridization with cDNA probes prepared from mRNA from control or 4, 8, 16 and 24 hour DOM-treated microglia the expression of 18 cytokine genes was determined. Control microglia expressed 4 genes constitutively *in vitro*: interleukin (IL)-

1 $\beta$ , IL-2, IL-16 and TGF  $\beta$ 1. Over a 24-hour observation period, DOM increased expression of IL-2, IL-16 and TGF  $\beta$ 1 by 201, 333 and 220 % of control expression, respectively. Concomitantly, DOM decreased expression of IL-1 $\beta$ . Our current data demonstrates that DOM can affect microglia cytokine gene expression *in vitro* in a time-dependent manner. Furthermore these data provide additional experimental evidence to support our working hypothesis (Mayer A. et al. *The Toxicologist* 78 (S-1): 162, 2004). Supported by R15 ES12654-01 from NIEHS, NIH to AMSM.

COMPARISON OF WEEKLY EXPOSURES TO ANATOXIN-A AND NICOTINE ON THE MOTOR ACTIVITY OF RATS.

K. A. Jarema, J. D. Farmer and R. C. MacPhail. *NHEERL, USEPA, Research Triangle Park, NC.*

Anatoxin-a is a nicotinic cholinergic agonist that is produced by several genera of cyanobacteria, and has been implicated in several poisoning episodes of wildlife, livestock, domestic animals and people. Previous research on nicotine has obtained tolerance and sensitization to its effects on motor activity even when it was administered at weekly intervals. We therefore compared the effects of weekly anatoxin-a and nicotine on the motor activity of rats. Adult male Long Evans rats were tested daily (M-F) in a photocell device, that recorded both horizontal and vertical activity, during 30-min sessions. Anatoxin-a and nicotine were given s.c. once a week for four weeks, just prior to a test session. Anatoxin-a was given as the (+) isomer and as the racemate. Dose ranges for each compound were: (+)-anatoxin-a, 75-225  $\mu$ g/kg; (+/-)-anatoxin-a, 200-950  $\mu$ g/kg; and (-)-nicotine, 300-1800  $\mu$ g/kg. Each experiment also included a saline-vehicle control group. Nicotine initially decreased both horizontal and vertical activity. Tolerance developed to nicotine's effects with weekly administration. Both forms of anatoxin-a also initially decreased horizontal and vertical activity. In contrast to nicotine, however, the effects of either form of anatoxin-a did not change with weekly administration. Thus, anatoxin-a and nicotine can be distinguished by their effects on motor activity with weekly treatment. This is an abstract of a proposed presentation; the information does not necessarily reflect Agency policy.

1438

NICOTINE EFFECTS ON THE ACTIVITY OF MICE EXPOSED PRENATALLY TO THE NICOTINIC AGONIST ANATOXIN-A.

R. C. MacPhail, J. D. Farmer, K. A. Jarema and N. Chernoff. *NHEERL, USEPA, Research Triangle Park, NC.*

Several studies in the literature have shown that exposure of mice and rats to nicotine early in development alters its effects when the rodents are subsequently challenged with nicotine. Anatoxin-a is a nicotinic agonist produced by several genera of cyanobacteria, and has caused numerous deaths of wildlife, livestock and domestic animals world-wide. We therefore determined the effect of nicotine on the motor activity of adult mice that had been exposed prenatally to anatoxin-a. Pregnant CD-1 mice received either saline vehicle or one of two doses of (+/-)-anatoxin-a (125, 200  $\mu$ g/kg), i.p., on GD 13-17. As adults (8 months), control mice of both genders were used to determine the effect of nicotine (0, 0.1, 0.3, 1.0 or 3.0 mg/kg, s.c.) on motor activity measured for 30-min in a photocell device. Under these conditions, nicotine produced dose-related decreases in both horizontal and vertical activity, with an ED<sub>50</sub> estimated to be 0.65 mg/kg. Next, additional control mice and mice exposed prenatally to anatoxin-a received the nicotine ED<sub>50</sub> and saline vehicle, in a counterbalanced fashion, with one week separating treatments. Nicotine decreased both horizontal and vertical activity in all mice, regardless of prenatal anatoxin-a treatment. Thus, no enduring effects of prenatal anatoxin-a were obtained in adult mice following nicotine challenge. This is an abstract of a proposed presentation; the information does not necessarily reflect Agency policy.

HEAVY METAL EXPOSURE FROM HERBAL SUPPLEMENTS IN NIGERIA.

O. E. Orisakwe<sup>1</sup>, E. Obi<sup>1</sup>, D. N. Akunyili<sup>2</sup>, B. Ekpo<sup>3</sup> and H. M. Lantum<sup>4</sup>.

<sup>1</sup>Department of Pharmacology, College of Health Sciences, Nnamdi Azikiwe University, Nnewi, Nigeria, <sup>2</sup>National Agency for Food and Drug Administration and Control (NAFDAC), Lagos, Nigeria, <sup>3</sup>Department of Biochemistry, College of Medical Sciences, Abia State University, Lagos, Nigeria and <sup>4</sup>African Society for Toxicological Sciences (ASTS), Rochester, NY.

The uses of herbal products are not regulated in Nigeria and many low-income countries and are freely available to everyone. The safety of these herbal medicines is poorly understood. This study characterizes the content of cadmium, copper, iron, nickel, selenium, zinc, lead and mercury in a random sample of Nigerian traditional products. Ready-to-use herbal products were purchased from the open market and digested using HNO<sub>3</sub>. The heavy metal content of the digested filtrate

was determined by atomic absorption/flame emission spectrometry, Uni-Cam Model 929. Mercury content was determined by the flameless Atomic Absorption Spectrometry using the cold vapor phase. Reference blanks and spiked samples used for quality control were within  $\pm 5\%$ . The result showed that 100% of the samples contained elevated amounts of heavy metals. The estimated daily intake (range; threshold g/day) from consumption of these products was - cadmium (0.6-4.8; 0.06), copper (15.3-97.5; 12), iron (13.7-123.8; >1), nickel (2.5-78; >0.1), selenium (6.3-123.8; >0.2), zinc (0.8-27.5; >20), and lead (0-27; 0.5). Mercury was detected in one sample (0.06; >0.05). These data alert us to the possibility of heavy metal toxicity from herbal products in Nigerian. The public health hazards from ingestion of herbal medicines should be identified and disclosed by in-depth risk assessment studies.

#### ADDITIVE EFFECTS OF FUMONISIN B1 AND DEOXYNIVALENOL IN THE HUMAN INTESTINAL CELL LINE, CACO2.

E. E. CREPPY<sup>1</sup>, J. H. KOUADIO<sup>1,3</sup>, T. M. MOBIO<sup>1</sup>, I. BAUDRIMONT<sup>1</sup>, S. MOUKHA<sup>2</sup> and S. D. DANO<sup>3</sup>. <sup>1</sup>Toxicology, University Bordeaux 2, Bordeaux, France, <sup>2</sup>MycSA, INRA, Villeneuve d'Ornon, France and <sup>3</sup>Faculty of Pharmacy, Toxicology, University of Abidjan, Abidjan, Côte d'Ivoire, France.

Fumonisin B1 (FB1) and vomitoxin, Deoxynivalenol (DON) are mycotoxins produced by Fusarium species, namely *F. Verticilloides* (formerly *F. Moniliforme*) and *F. graminearum* and *F. Culmorum* respectively. These mycotoxins jointly occur in maize. Therefore combinations of these toxins have been tested in the human intestinal cell line, Caco2 for general cytotoxicity i.e. Neutral red and MTT tests and protein synthesis measured by 3H-Leucin incorporation. Data show that both decrease cell viability by 37% at 10 microM for FB1 and by 19 to 48% at 4 to 20 microM for DON respectively. Both inhibit protein synthesis by 45% and 61% for FB1 and DON at 10 microM respectively. Interestingly the combination of these two toxins leads to additive effects and not to synergistic effects as previously reported for the combination of FB1 and ochratoxin A (OTA). #### POLYNUCLEAR AROMATIC HYDROCARBONS (PAHS) FROM BUTADIENE SOOT ARE CONCENTRATED WITHIN LIPID RESERVOIRS IN HUMAN RESPIRATORY EPITHELIAL CELLS.

G. Murphy, W. Henk, S. Barker and A. Penn. CBS, LSU School of Vet. Med., Baton Rouge, LA.

Butadiene soot (BDS), a polynuclear aromatic hydrocarbon (PAH)-rich, metals-poor particulate mixture generated from the incomplete combustion of 1, 3-butadiene, a high volume petrochemical, is an environmental pollutant and a potential respiratory toxicant. The majority of freshly generated BDS is <2.5 microns in diameter (PM2.5). Actively growing, non-confluent BEAS-2B cells, a human broncho-epithelial cell line, exposed to BDS generated in our laboratory, displayed a PAH-associated, time-dependent, cytosolic, punctate blue fluorescence following excitation at 365 nm. Cell proliferation was suppressed during exposure to BDS (24-72 hr). Thorough washing of the culture dishes to remove BDS allowed proliferation to resume. The BDS (PAH)-associated cytosolic, punctate fluorescence exhibited low levels of co-localization with a lysosomal marker (Lyso-Tracker Red) and an autophagic vacuole marker (monodansylcadaverine). Exposure of BDS-treated cells to an endosomal compartment marker (dextran-tetramethylrhodamine) revealed no discernable co-localization. These results suggest that the cytosolic punctate fluorescence develops neither from a purely endocytic process nor through a predominantly lysosomal association. Cells stained with a fluorescent cholesterol ester analog (cholesterol BODIPY C11), however, exhibited pronounced co-localization of cytosolic lipid-staining and BDS-associated fluorescent vesicles, strongly suggesting that PAHs initially adsorbed onto BDS particles are concentrated within BEAS-2B cells in lipid vesicles. Combined with previous studies of the physico-chemical properties of BDS, this evidence supports the hypothesis that BDS damages respiratory epithelial cells through a process that includes retention of PAHs within cellular lipid storage units. (Supported by Louisiana Governors Biotechnology Initiative).

#### 1442

#### ACTIVATION OF INFLAMMATORY MEDIATORS AND POTENTIAL ROLE OF AIR POLLUTION PARTICULATES AND AH-RECEPTOR LIGANDS IN FOAM CELL FORMATION.

C. F. Vogel, E. M. Sciullo and F. Matsumura. ETOX, UC Davis, Davis, CA.

Epidemiological data and animal experiments have indicated that exposure to air pollution particulates (PM) as well as Ah-receptor (AhR) ligands such as 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) can lead to cardiovascular toxicity and atherosclerosis.

Monocytes/macrophages are known to play a key role in atherosclerosis by releasing proinflammatory cytokines and the formation of foam cells. Foam cells are lipid-laden macrophages residing in the vessel wall and furthering the local inflammatory response. Our hypothesis is that PM, especially their organic components, exert an inflammatory response leading to the formation of macrophage-derived foam cells. Here, we investigated the effect of TCDD, used as prototype of AhR ligands, and Urban Dust Particulate Matter (UDP; SRM#1649a) including the organic extracts of UDP (OE-UDP), and stripped UDP (sUDP) on formation of foam cells. Our findings show that, like oxidized low density lipoprotein (oxLDL), TCDD as well as UDP promote the formation of atherosgenic foam cells derived from U937 macrophages, verified by increased lipid/cholesterol accumulation and extensive formation of blebs on the cell surface, which are hallmarks of foam cells. Screening the expression pattern of the most important mediators of the inflammatory response involved in atherosclerosis and foam cell formation demonstrated a time- and dose-dependent increase of cyclooxygenase-2 (COX-2), interleukin-1 $\beta$  (IL-1 $\beta$ ), and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) in U937 macrophages treated with TCDD or UDP. Changes of these inflammatory mediators were followed by significantly elevated levels of matrix degrading metalloproteinases (MMP)-1, MMP-3, MMP-12 and MMP-13. Increased expression of MMPs was associated with enhanced cell migration of U937 macrophages indicating the biological activity of the MMPs. These findings clearly indicate that UDP and AhR ligands, like TCDD, stimulate differentiation of U937 macrophages into potentially plaque forming foam cells.

#### 1443

#### PULMONARY EXPOSURE TO RESIDUAL OIL FLY ASH (ROFA) IMPAIRS SYSTEMIC MICROVASCULAR ENDOTHELIUM-DEPENDENT DILATION.

T. R. Nurkiewicz<sup>2</sup>, M. A. Boegehold<sup>2</sup>, D. W. Porter<sup>1,2</sup>, M. Barger<sup>1</sup>, A. F. Hubbs<sup>1</sup>, L. Millecchia<sup>1</sup> and V. Castranova<sup>1,2</sup>. <sup>1</sup>PPRB, NIOSH, Morgantown, WV and <sup>2</sup>Physiology and Pharmacology, West Virginia University, Morgantown, WV.

Epidemiology studies link elevated ambient particulate matter (PM) with increased cardiovascular mortality and morbidity. However, the mechanisms involved are unclear. The present study investigated whether pulmonary exposure to PM could alter systemic microvascular function. Rats were exposed to ROFA (0.1, 0.25, 1, or 2 mg/rat), TiO<sub>2</sub> (0.25 mg/rat) or saline by intratracheal instillation. At 24 hr post-exposure, bronchoalveolar lavage (BAL) was performed to monitor markers of pulmonary damage and inflammation. Another set of rats was prepared for histopathological analysis. A third set of rats was used for *in vivo* microscopic analysis of the arterioles of the exteriorized right spinotrapezius muscle, leaving innervation and feed vessels intact. BAL markers of pulmonary damage and inflammation were elevated at 1 and 2 mg/rat ROFA, but not after 0.1 and 0.25 mg/rat ROFA or 0.25 mg/rat TiO<sub>2</sub>. Histopathology indicated the presence of slight focal inflammation at all PM exposures. *In vivo* microscopic analysis indicated that ROFA did not affect resting systemic microvascular diameter or tone. However, ROFA significantly inhibited vasodilation in response to luminaly injected Ca<sup>2+</sup> ionophore (A23187), with complete inhibition at  $\geq 0.25$  mg/rat ROFA and 65% inhibition at 0.1 mg/rat. The effect of 0.25 mg/rat TiO<sub>2</sub> on A23187-induced vasodilation was similar to 0.25 mg/rat ROFA. Pulmonary PM exposure did not affect the responsiveness of arterial smooth muscle to a nitric oxide generator indicating an effect on endothelial cells. In addition, ROFA (2 mg/rat) resulted in systemic inflammation as evidenced by: (1) adherence of PMN to the systemic arterioles, (2) increased FMLP-induced chemiluminescence from isolated blood PMN, and (3) increased dihydroethidium oxidation at the arteriolar wall. These results indicate that pulmonary exposure to ROFA causes systemic inflammation, which compromises the influence of nitric oxide on endothelium-dependent vasodilation.

#### 1444

#### DETECTION AND MOLECULAR ANALYSIS OF PARTICULATE AIR POLLUTION-INDUCED CARDIOPULMONARY OXIDATIVE STRESS USING A TRANSGENIC MOUSE MODEL AND EMERGING TECHNOLOGIES.

K. Dreher<sup>1</sup>, E. Roberts<sup>2</sup>, S. Malstrom<sup>3</sup> and A. Malekafzali<sup>4</sup>. <sup>1</sup>NHEERL, USEPA, Research Triangle Park, NC, <sup>2</sup>North Carolina State University, Raleigh, NC, <sup>3</sup>Xenogen Corp., Alameda, CA and <sup>4</sup>Arcturus Biosciences Inc., Mountain View, CA.

Identification of particle characteristics and biological mechanism(s) responsible for the adverse pulmonary and cardiovascular responses associated with particulate air pollution exposure remains a critical research activity. We have employed an oxidative stress sensitive and bioluminescent reporter transgenic mouse model, hemeoxygenase-1 (HO-1) luciferase, in order to identify *in situ* induction of oxidative stress within lung and heart tissues following pulmonary aspiration (50  $\mu$ g/50  $\mu$ l/mouse) of a suspension of residual oil fly ash (ROFA) particles. HO-1 induction in lung and heart tissue protein extracts was measured by chemiluminescence at various times following exposure. Pulmonary and cardiac chemiluminescence increased at

2h ( $p<0.001$ ) and 24h ( $p<0.05$ ) post-exposure, respectively. Increased chemiluminescence in lung tissue protein extracts correlated with elevated levels of luciferase protein. Bioluminescent staining of lung and heart frozen tissue sections demonstrated localized areas of oxidative stress. RNA was recovered from these regions of interest following laser capture microdissection. Gene expression profiling by microarray analysis of recovered RNA samples is currently ongoing. These results demonstrate the ability of air pollution particles derived from oil combustion to induce local and systemic oxidative stress which in turn may result in acute organ injury as well as potentially contribute to disease processes that have oxidative stress as a common pathological etiology. Funding: EPA/NCSU Training Agreement CT826512 to E. Roberts. (This abstract does not reflect EPA policy)

#### 1445 CONCENTRATED AMBIENT AIR POLLUTION CREATES OXIDATIVE STRESS IN CNS MICROGLIA

B. Veronesi<sup>1</sup>, O. Makwana<sup>2</sup>, M. Pooler<sup>2</sup>, J. Carter<sup>1</sup>, J. Royland<sup>1</sup> and L. Chen<sup>3</sup>. <sup>1</sup>NHEERL, USEPA, Research Triangle Park, NC, <sup>2</sup>Toxicology Program, NCSU, Raleigh, NC and <sup>3</sup>Department of Environmental Health, NYU, Tuxedo, NY.

Particulate matter (PM) is known to affect extrapulmonary targets. Nanometer size PM particles carry free radical activity on their surface and damage target tissues through oxidative stress (OS). Recently, we've reported a 29% reduction of CNS neurons (i.e., n. compacta of the substantia nigra) in a transgenically modified mouse strain (Apo E<sup>-/-</sup>) exposed for 5 mo to concentrated northeastern regional background ambient particles (CAPs) (Veronesi et al., Inhalation Toxicology in press). Since these neurons are highly sensitive to OS mediated damage, the response of microglia (the brain macrophage) to the same CAPs was examined. Immortalized, mouse microglia (BV2) were exposed to high and low potency CAPs (as determined by NF- $\kappa$ B activity) and endpoints, indicative of oxidative stress mediated inflammation, were collected. ATP levels, assayed with Luciferase-based chemiluminescence, were significantly reduced after 5 min exposure to  $>250$   $\mu$ g/ml mitochondrial depolarization after 30 min exposure. Significant increases in TNF  $\alpha$ , IL6 and IL1  $\beta$  were shown after 6 hr exposure. Glutathione and non-protein sulphydryl levels, markers of OS were also significantly increased at 25-100  $\mu$ g/ml concentrations. Cells, exposed for 4 hrs to 75  $\mu$ g/ml of the high or low potency CAPs, were analyzed for genomic expressions, using an Affymetrix microarray. Bioinformatics indicated highly significant changes in genes associated with cell cycling, apoptosis, adhesion molecules, NF- $\kappa$ B, Toll receptors, Superoxide dismutase, proinflammatory cytokines, oncogenes, TNF receptors and others. Taken together, these data indicate that CNS microglia respond to concentrated ambient PM with changes suggestive of OS mediated inflammation. (This abstract has been reviewed by the USEPA, NHEERL and does not necessarily reflect its policy).

#### 1446 EFFECTS OF PARTICULATE MATTER ON THE PULMONARY AND VASCULAR SYSTEM: TIME COURSE IN SPONTANEOUSLY HYPERTENSIVE RATS.

M. E. Gerlofs-Nijland<sup>1</sup>, A. F. Boere<sup>1</sup>, D. C. Leseman<sup>1</sup>, J. A. Dormans<sup>1</sup>, T. Sandstrom<sup>2</sup>, R. O. Salonen<sup>3</sup>, L. Van Bree<sup>1</sup> and F. R. Cassee<sup>1</sup>. <sup>1</sup>Centre for Environmental Health Res., Lab. for Toxicol., Pathol. & Genetics or Environmental Assessment Agency, RIVM, Bilthoven, Netherlands, <sup>2</sup>Respiratory Medicine and Allergy, University Hospital Umea, Umea, Sweden and <sup>3</sup>Department Environmental Health, National Public Health Institute, Kuopio, Finland.

Within the scope of two multi center projects, "Health effects of particles from motor engine exhaust and ambient pollution" (HEPMAP) and "Chemical and biological characterization of ambient air coarse, fine, and ultrafine particles for human health risk assessment in Europe" (PAMCHAR), the present study aimed to optimize the design for PM toxicity screening studies in terms of dose and time between a single intratracheal exposure and the determination of the biological responses in compromised rats. PM was sampled at a road tunnel (RTD) using a high volume cascade impactor. Spontaneously hypertensive rats were exposed to EHC-93 or different doses of RTD. Autopsy was performed at 4, 24 or 48 hrs post-exposure. The neutrophil numbers in bronchoalveolar lavage fluid increased tremendously after exposure to relatively high RTD concentrations (10-15 fold) or EHC-93 (25 fold). Furthermore, PM exposure affected blood coagulation since plasma fibrinogen levels were increased significantly (1.2 fold). Pulmonary inflammation, oxidative stress, and changes in blood coagulation factors as well as circulating blood cell populations were observed within the range of 3 to 10 mg PM/kg body weight without the presence of significant pulmonary injury. At a lower dose only some inflammatory effects can be detected, which will probably be too small to discriminate between PM samples, and potential confounding effects were observed with the highest dose. In addition to dose, 24 hrs post-exposure seemed to be the appropriate time to assess relative toxic potency of PM since the majority of the health effects were observed one day after PM exposure compared to the other times examined. Aforementioned considerations provide a good foundation for the design of PM toxicity screening studies.

#### 1447

#### ENDOTHELIAL INJURY IN PARTICULATE MATTER (PM)-INDUCED CARDIOVASCULAR INJURY: KINETIC ANALYSIS OF GENE EXPRESSION PROFILES.

S. S. Nadadur and D. L. Costa. Pulmonary Toxicology, USEPA, Research Triangle Park, NC.

Numerous epidemiological studies established positive associations between ambient fine PM and cardiovascular morbidity and mortality. The biological basis for these adverse health effects is yet to be elucidated. Cardiovascular toxicity of fine PM and its toxic constituents may be direct or indirect. Vascular endothelial cells have been implicated in both direct and indirect cardiovascular effects of PM. To understand the role of endothelial injury and dysfunction in PM cardiovascular toxicity, we have initiated *in vitro* studies using primary human vascular endothelial cells. Acute exposure (25min) to a very low concentration (1mg/ml) of a model emission source PM, residual oil fly ash (ROFA) indicated differential gene expression profile for genes representing various functional groups such as cytokines, growth factors, vascular tone regulators, adhesion molecules, transporter proteins and voltage gated signaling mediators. Molecular observations observed at this early time point predicted alterations in plasma membrane structural and functional properties. Cytological observations at 8h post exposure indicated a role for these genes in the endothelial injury. To further understand the role of continuous exposure of endothelial cells to the same concentration of ROFA, we carried out exposure time kinetic studies at 25 min, 1, 3, 8, 12 and 24h. Gene expression profiles analyzed for ~20, 000 genes using human Affymetrix gene chips (H133A) at these time points clearly show time-dependent differential gene expression profiles consistent with progressive endothelial injury and dysfunction. The results of this study may provide insight to understand the role of the endothelium and the molecular basis for PM cardiovascular toxicity. It also may provide a biological basis for the discrepancies observed on the onset of acute myocardial events in cardiac patients associated with that ambient PM exposures. (This abstract does not reflect USEPA policy).

#### 1448

#### AIRBORNE PARTICULATE MATTER UPREGULATES INFLAMMATORY MARKERS IN THE MOUSE BRAIN: IMPLICATIONS FOR NEURODEGENERATION.

A. Campbell, A. Becaria, L. Mendez, S. C. Bondy, M. Oldham and M. Kleinman. Comm. & Env. Medicine, University of CA, Irvine, Irvine, CA.

Neurodegenerative diseases are multifactorial. Senescence is a common predisposing factor. However, genetic mutations and environmental factors have also been linked to the onset and progression of these disorders. While the pathological hallmarks of different age-related neurodegenerative diseases such as Alzheimer's disease, Parkinson's disease, multiple sclerosis, and amyotrophic lateral sclerosis are unique, certain underlying processes appear to be generally enhanced. These include oxidative and inflammatory events. Concentrated particulate matter present in polluted air enhances proinflammatory markers in the brain. The activated levels of the immune related transcription factor NF- $\kappa$ B were increased. Furthermore, the concentration of the cytokines IL-1 $\alpha$  and TNF- $\alpha$  were elevated. These effects were not due to the presence of endotoxin in the particulate matter. It is possible that this environmental exposure can trigger an innate-immune response in the CNS and by doing so aggravate already existing age-related adverse events. Transgenic models of neurodegenerative disorders can be an essential tool in determining whether environmental exposures do indeed contribute to and exacerbate pathological lesions associated with age-related disorders.

#### 1449

#### SOLUBLE NICKEL ASSOCIATED WITH RESIDUAL OIL FLY ASH INCREASES SUSCEPTIBILITY TO PULMONARY INFECTION IN RATS.

J. R. Roberts<sup>1,2</sup>, S. Young<sup>1</sup>, J. M. Antonini<sup>1,2</sup> and V. Castranova<sup>1,2</sup>. <sup>1</sup>NIOSH, Morgantown, WV and <sup>2</sup>WVU, Morgantown, WV.

Soluble metals of residual oil fly ash (ROFA), an air pollutant from the combustion of fossil fuel, may be associated with lung infection and morbidity in susceptible populations. The present objective was to determine which soluble metal in ROFA was associated with decreased clearance of bacteria from the lungs of rats. At day 0, rats were intratracheally instilled (IT) with soluble NiCl<sub>2</sub> (55.7 $\mu$ g), FeSO<sub>4</sub> (37.2 $\mu$ g), AlSO<sub>4</sub> (46.6 $\mu$ g), ZnCl<sub>2</sub> (8.69 $\mu$ g), or a mixture of the metals in quantities present in a 2.0 mg dose of ROFA as determined by elemental analysis. On day 3, rats were infected with an IT dose of  $5 \times 10^4$  *Listeria monocytogenes* and euthanized on days 6, 8 and 10. The left lungs were homogenized to assess bacterial load, and bronchoalveolar lavage (BAL) was performed on the right lungs to measure lung injury and inflammation. Cells from lymph nodes were analyzed to determine phenotype. On day 6, rats exposed to Ni or the metal mixture had an increased bacterial lung burden as compared to all groups, and rats exposed to Zn had a higher bacterial load when compared to rats exposed to Al, Fe, or saline control. Lactate

dehydrogenase and albumin levels in BAL fluid were 3 times greater in the Ni and mixed metal groups on day 6 as compared to controls. Treatment with Ni and the metal mixture resulted in a 3 and 2 fold increase, respectively, in the number of cells in the BAL at all time points. The number of T cells in the BAL of the Ni and the mixed metal groups was decreased on day 6 and the number of natural killer cells was decreased in the Ni group at all time points as compared to controls. The ratio of CD4<sup>+</sup> to CD8<sup>+</sup> T cells in the BAL and in the lymph nodes was higher in the Ni and mixed metal groups on day 6. In summary, rats treated with soluble Ni, alone or in a mixture with soluble Fe, Zn, and Al, showed increased lung injury, decreased bacterial clearance, and altered lymphocyte profiles at early time points post-infection. Thus, soluble Ni may play an important role in the increase in susceptibility to infection after ROFA exposure.

MEMBRANE PERMEABILITY AS A DETERMINANT OF ZN<sup>2+</sup>-INDUCED SIGNALING IN HUMAN AIRWAY EPITHELIAL CELLS.

R. Silbajoris<sup>1</sup>, T. Tal<sup>2</sup>, D. Graff<sup>1</sup>, P. A. Bromberg<sup>3</sup> and J. M. Samet<sup>1</sup>. <sup>1</sup>*Human Studies Division, NHEERL, USEPA, Chapel Hill, NC*, <sup>2</sup>*Curriculum of Toxicology, UNC-CH, Chapel Hill, NC* and <sup>3</sup>*CEMALB, UNC-CH, Chapel Hill, NC*. Sponsor: M. Madden.

Zinc (Zn<sup>2+</sup>) is an essential micronutrient but also a common metallic constituent of ambient air particulate matter (PM) that may play a role in PM-induced adverse health effects. *In vivo* and *in vitro* studies have shown that Zn<sup>2+</sup> exposure induces inflammatory responses in the airways. We have previously shown that exposure to Zn<sup>2+</sup> results in activation of multiple intracellular signaling intermediates, including the epidermal growth factor receptor (EGFR), in a variety of cell types. Based on this variability, we hypothesized that cellular permeability is a factor limiting the magnitude of signal transduction activation induced by Zn<sup>2+</sup>. To test this hypothesis, we used the Zn<sup>2+</sup> ionophore pyrithione to permeabilize the human bronchial epithelial cell line BEAS and primary human airway epithelial cell cultures (HAEC) to Zn<sup>2+</sup> and measured levels of EGFR phosphorylation. Treatment of BEAS cells with sub- to low-micromolar concentrations of pyrithione in the presence of 250  $\mu$ M extracellular Zn<sup>2+</sup> resulted in dose-dependent increases in Zn<sup>2+</sup>-specific fluorescence as determined by fluorometry using FURA-2. Lysophosphatidylcholine, a physiologically relevant permeabilizing agent, also increased Zn<sup>2+</sup> permeability in BEAS cells. Co-administration of 4  $\mu$ M pyrithione markedly potentiated Zn<sup>2+</sup>-induced EGFR phosphorylation at the auto- and trans-phosphorylation sites Y1068 and Y845, respectively, in HAEC. These findings show that Zn<sup>2+</sup> acts through an intracellular target to effect EGFR phosphorylation. Further, cellular permeability is a critical determinant of cellular responsiveness to signal initiation by exposure to Zn<sup>2+</sup>. Pathophysiological alterations in cellular homeostasis that may result in increased permeability to Zn<sup>2+</sup> influx and sensitize HAEC to the effects of inhaled Zn compounds are presently under investigation. Additionally, the possibility that xenobiotics with pyrithione-like properties exist in PM is also being studied. THIS ABSTRACT OF A PROPOSED PRESENTATION DOES NOT NECESSARILY REFLECT EPA POLICY.

**1451**

ZINC CONTENT IN BALTIMORE PM<sub>2.5</sub> SEAS SAMPLES IS NOT SOLELY RESPONSIBLE FOR CHEMOKINE OR CYTOKINE RESPONSE IN A549 ATII CELLS OR RAW 264.7 MONOCYTES.

R. J. Mirkus<sup>3,1</sup>, J. L. Powell<sup>1</sup>, J. Pancras<sup>2</sup>, J. M. Ondov<sup>2</sup> and K. S. Squibb<sup>1</sup>. <sup>1</sup>*Epidemiology and Preventive Medicine, University of Maryland, Baltimore, MD*, <sup>2</sup>*Chemistry and Biochemistry, University of Maryland, College Park, MD* and <sup>3</sup>*Health Effects Division, Office of Pesticides Prevention, USEPA, Washington, DC*.

For approximately a decade, metals have been hypothesized to contribute to the relationship between human exposure to fine particulate matter (PM<sub>2.5</sub>) and cardiopulmonary disease. Recently, the metal zinc has been shown to play a pivotal role in inducing cardiac lesions and inflammation *in vivo* (Kodavant *et al.* 2003). In order to test the hypothesis that zinc plays a central role in the release of soluble inflammatory mediators in the lung, we exposed human alveolar type II cells (A549) and monocyte cells (RAW 264.7) to fine particulate matter (PM<sub>2.5</sub>; SEAS samples) collected at the Baltimore Supersite during summer and winter intensive sampling periods in 2002. Median TNF- $\alpha$  levels from RAW 264.7 monocytes were greater following treatment with the November PM<sub>2.5</sub> samples, while MCP-1 release from A549 alveolar epithelial cells was significantly inhibited by the November samples, compared to the July PM<sub>2.5</sub>. A comparison of eleven metal concentrations measured by GFAAS revealed that Al, Fe, and Zn were the most abundant in both the July (Fe>Al>Zn) and November (Fe>Zn>Al) samples. Multiple linear regression revealed that Zn in combination with endotoxin, Cd, Fe, and particle number explained 50% of TNF- $\alpha$  release in November samples, while particle number and Fe explained approximately 44% of the inhibition of MCP-1 release in this same sampling period. Neither zinc, nor any other metal alone, was responsible for the release of the immune mediators. These results challenge prevailing research paradigms that view one or more metals as being solely responsible for the adverse

effects of inhaled PM<sub>2.5</sub> and demonstrate the need for more complex statistical approaches to aid in determining the relative contributions of the various components of PM<sub>2.5</sub>, as well as particle number, to cardiopulmonary inflammation. *Supported by the Baltimore Supersite Program grant R82806301*

EFFECT OF PULMONARY EPITHELIAL LINING FLUID ON OXIDATIVE STRESS AND DNA DAMAGE: COMPARISON AMONG ULTRAFINE PARTICLES, FERROUS SULFATE AND DIESEL PARTICLE EXTRACT.

T. Cheng, Y. Cheng and Y. Lei. *College of Public Health National Taiwan University, Taipei, Taiwan*. Sponsor: T. Ueng.

Previous studies have reported that particulate matter can induce oxidative stress and DNA damage. To protect lung cells against the exogenous oxidative stress, pulmonary epithelial lining fluid (ELF) consists of various antioxidants. However it is not clear which components of PM are affected by ELF. The aim of this study is to determine the effect of ELF on oxidative stress and DNA damage induced by several PM components including ultrafine particles, ferrous sulfate and diesel particle extract. In cell free system, ultrafine carbon black of 15 nm (ufCB; 0, 50, 150 $\mu$ g/ml), FeSO<sub>4</sub> (0, 100, 500 $\mu$ gM), and diesel particle extract (0, 250, 500 $\mu$ g/ml) were suspend in ELF or medium. Subsequently, we used transwell *in vitro* culture system with ELF or medium on the top of A549 cells and medium below. Again, similar concentrations for each component were used. After 4 hr of treatment, ROS was then measured using DCFH assay and DNA single strand breakage was also determined by single-cell gel electrophoreses (Comet assay). The results showed that in cell free system and A549 cells with culture medium, ROS increased with exposure to ufCB and FeSO<sub>4</sub>, but not with diesel particle extract. We also observed DNA SSB increased with FeSO<sub>4</sub> and diesel particle extract exposure in culture medium, but not with ufCB. When ELF was used to replace medium, ROS decreased significantly for both ufCB and FeSO<sub>4</sub> exposure in cell free and A549 cells. There was no increase for DNA SSB for each component in ELF. We conclude that ELF may decrease ROS levels and subsequent DNA SSB formation induced by ufCB and FeSO<sub>4</sub>.

EFFECTS OF PM-ASSOCIATED METALS ON MACROPHAGE iNOS AND ERK: A ROLE IN ALTERED IRON HOMEOSTASIS?

C. Prophete<sup>1</sup>, P. Maciejczyk<sup>1</sup>, K. Salnikow<sup>2</sup>, T. Gould<sup>3</sup>, T. Larson<sup>3</sup>, P. Jaques<sup>4</sup>, J. Koenig<sup>3</sup>, C. Sioutas<sup>5</sup>, M. Lippmann<sup>1</sup> and M. Cohen<sup>1</sup>. <sup>1</sup>*Environmental Medicine, New York University School of Medicine, Tuxedo, NY*, <sup>2</sup>*NCI, Bethesda, MD*, <sup>3</sup>*University of Washington, Seattle, WA*, <sup>4</sup>*Clarkson University, Potsdam, NY* and <sup>5</sup>*USC, Los Angeles, CA*.

Analyses of fine airborne PM<sub>2.5</sub> samples collected in New York City (NYC), Los Angeles, and Seattle during Fall 2001 indicated that inorganic composition varied from city to city, both in terms of absolute amounts of individual elements and their mass relationships to one another. We hypothesized that relative molar/mass relationships between select PM metals and Fe governs the pulmonary immunotoxic potential of a given day's (or city's) PM by affecting alveolar macrophage (AM) iron status, thereby altering their antibacterial function. To test this, iron response protein (IRP) binding activity in NR8383 rat AM was assessed after exposure to Fe alone or in combination with V, Mn and/or Al. In all studies, relevant molar ratios of the metals, as found in a representative 500  $\mu$ g sample of NYC PM, were used. Results indicated that V and Al, and to a lesser extent Mn, significantly changed IRP activity though the effects were not consistently dose-dependent. This disruption in IRP binding activity was thought to possibly be a result of competition for binding to a transferrin carrier; however, potential effects on IRP activity from the presence of nitric oxide (NO) needed to be ruled out. The results of analyses of concurrent expression of iNOS and phospho-ERK1/2 suggested that while V treatments did not activate NO formation, Al did - most likely via increases in lipid peroxidation that resulted in AP-1 activation. These results confirm that certain metals associated with PM might alter pulmonary immune competence in exposed hosts by impacting upon the Fe status of one major class of deep lung defense cell. This work was supported by EPA/PM Center Grant R82735101.

MUTAGENICITY AND CYTOTOXICITY OF MANUAL METAL ARC STAINLESS STEEL WELDING FUMES (MMA-SS) BY ITS PARTICLE SIZE.

I. Yu<sup>1,2</sup>, S. Maeng<sup>1</sup>, S. Kim<sup>1</sup>, J. Sung<sup>1,3</sup>, K. Chung<sup>2</sup>, S. Oh<sup>2</sup>, Y. Lee<sup>1</sup> and K. Kim<sup>1</sup>. <sup>1</sup>*Center for Occupational Toxicology, Occupational Safety & Health Research Institute, KOSHA, Daejeon, South Korea*, <sup>2</sup>*College of Pharmacy, Sung Kyun Kwan University, Suwon, South Korea* and <sup>3</sup>*College of Veterinary Medicine, Seoul National University, Seoul, South Korea*.

The particle size and metal components of fine particulates have been hypothesized to be important factors in determining in their toxicities and potential adverse health effects. To study cytotoxicity and mutagenicity of MMA-SS by their particle

size fractions, the fume particles were sampled from an exposure chamber and fractioned their size using an 8-stage cascade impactor. The size ranges of fume particles were divided in to 4 groups: group 0, total particles; group 1, 11-2.1  $\mu\text{m}$ ; group 2, 2, 1-0.65  $\mu\text{m}$ ; group 3, below 0.65  $\mu\text{m}$ . The composition of heavy metals in each sample group was analyzed using an atomic absorption spectrophotometry. The bacterial mutation assay using *Salmonella* TA 98 and TA 100 was carried out to compare the mutagenicities of four groups of welding fume particle fraction. The cytotoxicity assay using CHO cells was also performed using a cell counting assay kit. The concentrations of Cr in total suspended particulates of welding fume become higher as the particle sizes become smaller, while those of Mn, Ni and Fe showed similar levels in all size fractions. The mutagenicity in TA 98 without metabolic activation was confirmed in all sample groups but the initial concentration that began to show mutagenicity was lowest in the group 3. The mutagenicity induced by the metabolic activation was only detected in the group 3. TA 98 was shown to be the most sensitive to the finest particles. As for TA100, the mutagenicities were also found in all sample groups with or without metabolic activation. Mutagenicities were clearer in case without metabolic activation in both TA 98 and TA 100. Cytotoxicities also showed increasing patterns as the particle sizes become finer with a statistical significance ( $p<0.05$ ). These results indicated that particle size and Cr components played important roles in inducing mutagenicity and cytotoxicity by MMA-SS fume exposure.

DNA DAMAGE IN ALVEOLAR EPITHELIAL INDUCED BY INORGANIC AND ORGANIC SOLUBLE FRACTIONS FROM MEXICO CITY URBAN AIRBORNE PARTICULATE.

M. E. Gutierrez<sup>1,2</sup>, A. De Vizcaya-Ruiz<sup>1</sup>, M. Sordo<sup>3</sup>, P. Ostrosky<sup>3</sup>, D. A. Roubicek<sup>3,4</sup> and M. E. Cebran<sup>1</sup>. <sup>1</sup>Toxicology, CINVESTAV-IPN, Mexico City, Mexico, <sup>2</sup>Environmental Monitoring, CIIEMAD-IPN, Mexico City, Mexico, <sup>3</sup>IIB-UNAM, Mexico City, Mexico and <sup>4</sup>Mutagenesis and Cytotoxicity, CETESB, São Paulo, Brazil.

Particulate matter are a complex mixture of inorganic and organic compounds, some with carcinogenic potential (i.e. metals and PAH). We evaluated induced DNA damage and repair using the comet assay in A459 human lung epithelial cells exposed to water and organic soluble fractions from PM10 and PM2.5 of four regions (Xalostoc, Merced, Tlalnepantla and Pedregal) from Mexico City. PM soluble fractions extracted were chemically characterized for metals (Zn, Fe, V, Ni, Cu, Cr, Mn, Pb), ions (sulfate and nitrate), soluble protein and PAH (2 to 6 ring compounds). Results showed low PM levels and high concentration of Zn, Fe, Cu, V and Ni in the water-soluble extracts from Pedregal in comparison with high PM levels and low concentration of water-soluble metals for Xalostoc. Genotoxicity was measured after 48 hr exposures using three non-cytotoxic doses of the inorganic and organic extracts: 0.8, 1.2 and 1.6  $\text{m}^3/\text{ml}$  for PM10 and 0.05, 0.07 and 0.1  $\text{m}^3/\text{ml}$  for PM2.5. Genotoxicity of the two soluble fractions showed a significant increase in DNA migration with respect to non-exposed cells. The water soluble fraction (metals and ions) of PM exhibited higher DNA damage than the organic fraction (PAH) at equivalent doses. Also PM2.5 fractions showed a higher genotoxic damage than PM10, and PM from Pedregal resulted to be the most genotoxic from all regions. The level of induced DNA damage returned to near background levels within 2.5 h in all the conditions previously described. Our data indicates that genotoxicity of PM is determined by the chemical composition and aerodynamic diameter, thus representing an environmental risk factor. HEALTH EFFECTS OF ENVIRONMENTAL SHORT-TIME SULFUR DIOXIDE (SO<sub>2</sub>) EXPOSURE EMITTED FROM A VOLCANO IN MIYAKEJIMA ISLAND, SOUTH OF TOKYO.

H. Uno, H. Horiguchi and F. Kayama. Division of Environmental Medicine, Center for Community Medicine, Jichi Medical School, Tochigi, Tochigi, Japan. Sponsor: T. Yoshida.

Approximately 10% of volcanoes in the world exist in Japan. Mt. Oyama volcano in Miyakejima Island started erupting since June 2000. All the inhabitants evacuated since then. While it calmed down since the last eruption in 2002, the volcanic gas emission (mainly SO<sub>2</sub>) will not end for a while. For several reasons among the inhabitants, the rehabilitation project started in April 2003. About 70% of the former inhabitants expressed their willingness to come back to their home island with some risks of sulfur dioxide exposure. It is very important to monitor the ambient air quality in the island and estimate the future health effects for the inhabitants. We can prepare for measures to minimize the exposure and health effects. We conducted questionnaires among the inhabitants who joined the three-day trial stay project in the island in October, November and December 2003. The question-

naires included symptoms of respiratory tract, nasopharyngeal mucosa, skin and conjunctiva. In addition, we monitored the concentrations of sulfur dioxide in six regions of the island, and divided the inhabitants into two groups by the exposure levels of sulfur dioxide; high exposure group (those exposed to SO<sub>2</sub> higher than 2 ppm in 5-minute period value for more than 1.2 hours per day.) and less exposure group (remaining others). In order to exclude confounding factors sufficiently, such as gender, age and the symptom-related predisposed diseases, we performed analysis evaluating the symptoms as independent variables. These results indicated that all the symptoms were not significantly dependent on concentration of sulfur dioxide levels. In conclusion, the short-term sulfur dioxide exposure to them did not show increase of their symptoms. Finally, we hope that results of this study will be helpful for the risk managers in Japan and other countries that have a volcano emitting sulfur dioxide.

MEASUREMENT OF LUNG RESISTANCE AND COMPLIANCE FOR RESPIRATORY SAFETY PHARMACOLOGY STUDIES.

S. Mason, K. Norton and H. Penton. *Safety Pharmacology, CTBR Bio-Research Inc., Senneville, QC, Canada.* Sponsor: C. Banks.

The ICH S7A Guideline for Safety Pharmacology Studies calls for assessment of respiratory parameters to be performed, but only requires that respiratory rate, tidal volume and derived respiratory minute volume (RMV) are measured. While these are sufficient for the majority of new drugs, measurement of ventilatory patterns alone does not assess possible effects on the gas exchange function of the respiratory system, particularly lung mechanics. A method for investigating these effects in conscious animals was therefore developed at this laboratory, based on Murphy (1998). In this, lung compliance is calculated by measuring the pressure required to inflate the lung to maximum volume and lung resistance is calculated as the pressure required for maximum airflow during inspiration or expiration. To demonstrate this technique, three male Sprague-Dawley rats, previously surgically instrumented with DSI TA11PA-C40 telemetry transmitters, were dosed via a tail vein infusion with 30 mg/kg/min methacholine over an approximate 15 minute period. Respiratory rate, tidal volume and intrapleural pressure were continuously monitored using a head-out plethysmograph to record airflow and a DSI OpenArt V2.3 system connected to a Buxco BioSystem XA V2.9 to record pressure. Integration of the pressure and flow signals by the Buxco software provided data on dynamic resistance and compliance. For animals in this study, pulmonary pressure was increased by up to 200% compared to predose and control animal values, this effect being observed within approximately 5 minutes of the start of infusion. Lung compliance also decreased to approximately 70% of predose values and resistance increased by up to 300%. There was no consistent effect on tidal volume, respiratory rate or RMV, indicating that assessment of only ventilatory parameters in this study may not have detected methacholine-related respiratory changes. Measurement of lung mechanics in a conscious animal model such as the one employed here should therefore be considered in testing strategies for new drugs.

RELATIVE ACCURACY OF BIDE AND GUYTON FORMULA FOR CALCULATING RESPIRATORY MINUTE VOLUME.

K. Norton, S. Mason and A. Vieu. *Inhalation, CTBR Bio-Research Inc., Senneville, QC, Canada.* Sponsor: C. Banks.

Theoretical respiratory minute volume (RMV) values have historically been used to calculate achieved dose levels in inhalation toxicology studies. The aim of this investigation was to compare quantitatively measured RMV data to theoretical RMV, within the same population of animals, and determine possible effects on calculated achieved dose levels. RMV was calculated from tidal volume and respiratory frequency data, recorded from animals in a "head-out" plethysmograph using the Buxco Biosystem XA. The test system comprised three groups of Sprague-Dawley rats, Group 1 males aged 6 to 8 weeks weighing ~200-300 g (n=200), Group 2 males aged 11 to 13 weeks weighing ~300 to 450 g, (n=200) and Group 3 females aged 7 to 9 weeks weighing ~150 to 250 g (n=100). The mean 15-minute RMV for each animal was compared to the corresponding theoretical RMV calculated by the Bide or Guyton formula. Bide - Minute Volume (L/min) = 0.499\*[body weight<sup>0.809</sup>] Guyton - Minute Volume (mL/min) = 2.1\*[body weight<sup>0.75</sup>] For Group 1 the mean and standard deviation of the measured RMV was 236  $\pm$  61 mL/min, compared to theoretical measurement of 154  $\pm$  15 or 126  $\pm$  11 mL/min - an underestimation of 35% and 47% for the Bide and Guyton formulae, respectively. Group 2 had a mean and standard deviation measured RMV of 284  $\pm$  70 mL/min compared to a theoretical measurement of 224  $\pm$  12 or 178  $\pm$  9 mL/min - an underestimation of 21% and 39% for the Bide and Guyton formulae, respectively. Group 3 had a mean and standard deviation measured RMV of 214  $\pm$  62 mL/min compared to a theoretical measurement of 132  $\pm$  17 or 109  $\pm$  13 mL/min - an underestimation of 38% and 49% for the Bide and Guyton formulae, respectively. This data shows that although the ranges of Bide or Guyton formula overlaps

with in-life RMV mean values are lower in younger animals. Further investigation of older animals should provide a greater assessment of differences in measured versus calculated RMV and the effects on calculated achieved dose levels.

#### COUGHING MODEL BY INHALATION OF CITRIC ACID IN COMMON MAMMOSET (CALLITHRIX JACCHUS).

K. Wako, T. Kawasuso, H. Hiratsuka, M. Takechi and M. Tsuchitani. *Mitsubishi Chemical Safety Institute Ltd., Kashima-gun, Ibaraki, Japan.*

Some animal species, such as guinea pigs, rats and cats, have been used as coughing models to evaluate effects of antitussive drugs. However, it is well known that cough reactions to inhaled chemicals are different depending on the species. We investigated the coughing reactions using common marmosets by the inhalation exposure. [Methods] An ultrasonic nebulizer generated a mist from the 2.5% and 7.5% citric acid PBS solution. The mist was exposed to un-anaesthetized common marmosets restrained in a double-chamber for the measurement of respiratory physiology (Buxco Electronics Inc., NC). The exposure duration was set at five minutes for each citric acid concentration. A pressure-transducer and microphone detected the cough reactions. Three female marmosets (67-68 week-old; BW, approx. 350 g) were used in this study. [Results and conclusion] The inhalation exposure to citric acid induced coughing and sneezing among the common marmosets. These reactions increased in proportion to the citric acid concentrations. The marmosets reacted to the citric acid exposure immediately after the commencement of the exposure, and the respiratory reactions continued throughout the exposure duration. The reactions disappeared practically by eight minutes after the termination of the exposure. A previously published paper reported that rats did not reveal coughing reaction by the inhalation challenge. We reported that marmosets have a similar anatomical nasal structure to humans and macaques. It is unquestionable that to use marmosets in the evaluation of antitussive drug by the inhalation route is more advantageous because of its anatomical similarity. Moreover, the metabolism mechanism of antitussive drugs among the marmosets may be similar to the human. Consequently, as the coughing model, the marmosets are considered more advantageous for evaluation of antitussive drugs than the guinea pigs, rats and cats. The results of the present study suggested that the marmosets are useful as a coughing model with the present method.

#### APPLICATION OF THE GUINEA PIG COUGH MODEL TO SCREEN FOR TUSSIGENIC AND ANTI-TUSSIVE PHARMACOLOGY.

C. Banks, K. Norton and S. Groom. *Toxicology, CTBR, Senneville, QC, Canada.*

Cough can be an acute or chronic indication. In its acute form, cough is most often caused by upper respiratory tract infection or by irritation. In its chronic form, cough can be useful indicator of diseases such as asthma and COPD. The guinea pig cough model can be used for both of the above indications; screening compounds for either tussigenic or anti-tussive properties. This poster presents data generated for a citric acid induced cough model. Cough was measured using a Buxco plethysmography system in which we defined cough as a sharp increase in the inspiratory flow signal, followed by a rapid expiration at least 1.5 times the height of normal protrusion from the baseline. A representative event trace that captures the cough response is presented. Aerosol exposure to citric acid concentrations of 100, 200 and 300 mg/mL induced a cough response which was not strictly dose-dependent, in part due to the confounding effects of bronchoconstriction at the highest exposure concentration. Pretreatment of the animals with lidocaine hydrochloride at concentrations of 30 and 100 mg/mL reduced citric acid (200 mg/mL)-induced cough by 53 and 42%, respectively. These data are compared and contrasted to data generated for capsaicin-induced cough and are discussed relative to the practical and physiological considerations associated with measuring cough responses in guinea pigs.

#### MULTIDRUG RESISTANCE RELATED PROTEINS IN AIR-LIQUID INTERFACE CULTURE OF HUMAN LUNG CELLS.

H. Forth, A. W. Torky, A. Raemisch and E. Stehfest. *Environmental Toxicology, University of Halle, Halle / Saale, Germany.*

Multidrug resistance related proteins (MRP-proteins) are known to mediate drug resistance and xenobiotic tolerance, but localization and regulation of MRP isoforms in the lung are widely unknown. Candidates for regulation of MRP function are glutathione, metals and mediators of inflammation. Some MRPs may be involved in GSH dependent transport processes for metals. Several recent studies have shown that prostaglandins participate in endogenous regulation of the P-glycopro-

tein (mdr1) gene and it is conceivable that this is also true for MRPs. We have used explant cultures from normal human lung tissue from bronchi (NHBEC) and peripheral lung (PLC) in order to prove the cellular distribution of different MRP-isoforms and to prove whether and how prostaglandins modify MRP expression and/or function in normal human lung cells. Cells were maintained either under standard culture condition or in air-liquid interface cultures (dry-wet conditions). At least MRP isoforms 1, 3 and 5 have different distribution in dry-wet cultured cells compared to normal submerge cultures. Normal human lung cells are polarized in dry-wet culture conditions with MRPs expressed at the lateral and basal side of the cells. This was shown in NHBECs and PLCs by indirect immunofluorescence and confocal LASER scanning microscopy. Transport activity of MRP1 was studied using single cell fluorometry. NHBEC and A549 cells, a permanent human lung cell line, showed no alteration in transport activity of MRP1 after PG F2a. On the other hand, an increased transport activity was found after PGE2 (0.01 mM, 1d and 4d treatment). PLCs were much less sensitive towards PGE2 than NHBECs. These effects coincide with the rate of MRP1-mRNA expression obtained by real-time RT-PCR in the same trial. The cyclooxygenase inhibitors Indomethacin and Celecoxib inhibited also the transport activity of MRP1 in NHBEC and A549 cells. These results indicate that a link exists between inflammation reaction and regulation of MRP function in human lung. Supported by Philip Morris External Research Foundation

#### AN ASSESSMENT OF THE ESTROUS CYCLES OF SPRAGUE-DAWLEY RATS RESTRAINED IN TUBES FOR NOSE-ONLY INHALATION EXPOSURE.

M. Stoute, K. Robinson, A. Viau, L. Pinsonneault, M. Adamo, L. Pouliot and C. Banks. *Toxicology, CTBR, Senneville, QC, Canada.*

For fertility and early embryonic development studies (ICH?1) an assessment of estrous cycles is required. Nose-only inhalation exposure is a possible treatment route for these fertility studies. Therefore, an investigation was undertaken to determine the effects of tube restraint for nose-only inhalation exposure on the estrous cycles of Sprague-Dawley Crl:CD® (SD)IGS BR rats and to examine cyclicity at 7 weeks and 9 weeks of age. Rats were housed individually and were provided with food and water ad libitum. The animal room environment and photoperiod (12 hours light and 12 hours dark) were controlled. Rats were randomly assigned to 3 groups, room control or nose-only exposure restraint tube, at either 7 weeks or 9 weeks of age at the start of cycle assessment. The estrous cycles were assessed for 14 days prior to acclimation to tube restraint to confirm that rats were cycling normally. The estrous cycles were then recorded for an additional 14 days for the room control group. Rats in the tube restraint groups were acclimated to the tubes for 3 days at increasing times, 30, 60 and 130 minutes, respectively. Following the acclimation period, the tube restraint groups were placed in tubes for an additional 11 days for 60 minutes. The estrous cycles were recorded by examination of the vaginal smears. Nose-only tube restraint for 60 minutes per day had no adverse effect on the estrous cycle parameters (cycle length, number of days in estrous and number of cycles) of female CD IGS rats at 9 to 11 and 11 to 13 weeks. Therefore it was concluded that tube restraint for nose-only inhalation exposure does not adversely effect estrous cycles of rats from 9 to 13 weeks of age.

#### IMPACT OF LOW FLOW OPERATION IN THREE NOSE-ONLY EXPOSURE SYSTEMS.

O. R. Moss, A. R. James, C. U. Parkinson and B. A. Wong. *Computational Biology, CIIT Centers for Health Research, Research Triangle Park, NC.*

Directed-flow, nose-only (DFNO) exposure systems are designed to deliver a stable concentration of gas or aerosol to the animal with minimum mixing between the inhaled atmosphere and the exhaled breath. Exposure air exits a delivery tube and crosses a cavity before it reaches the animal nose and then reverses direction into the exhaust. Exhaled breath from the animal passes through portions of the same cavity before entering the exhaust. It is expected that the two airstreams mix during each breath. The degree of mixing and thus the reduction in the concentration of test material in the inhaled air is a function of geometry, minute ventilation of the animal and the flow rate of exposure air in the delivery tube. For any DFNO exposure system there is a flow above which dilution of the exposure atmosphere by breath is less than 10%. The impact of low flow was measured in a Cannon (Lab. Products, Seaford, DE), Jaeger Vaccine, and Jaeger 12-Port (CH Technologies Inc., Westwood, NJ) DFNO exposure systems. A Harvard Rodent Ventilator (Harvard Apparatus, S. Natick, MA) was used to simulate a rat minute ventilation of 200 ml/min at 150 breaths per minute. Butadiene (Linde Gas, Maumee, OH) was monitored with a Miran 1A (Foxboro Analytical, S. Norwalk, CT). Exposure air flow rates at each active exposure port were set to 1.5 to 4 times the minute ventilation of the simulated animal. Less than 10% reduction in concentration of test material was achieved when airflows for the Cannon, Jaeger Vaccine, and Jaeger 12-Port DFNO systems were respectively greater than 2.5, 2.5, and 1.7 times the minute ventilation of the animal.

SUPPLEMENTAL DOSING IN PRECLINICAL  
INHALATION STUDIES INCREASES SYSTEMIC  
EXPOSURES.

W. Lee<sup>1</sup>, F. Crofts<sup>2</sup>, A. Vieu<sup>1</sup>, M. Pino<sup>2</sup>, C. Banks<sup>1</sup>, S. Holt<sup>2</sup> and T. Monticello<sup>2</sup>. <sup>1</sup>Inhalation, CTBR Bio-Research Inc., Senneville, QC, Canada and <sup>2</sup>Drug Safety Evaluation, Sanofi-Aventis, Bridgewater, NJ.

Limitations of the exposure generation apparatus and physicochemical properties of the test article can restrict the maximum dose generated by the inhaled route of exposure for preclinical studies. Resultant inhaled doses oftentimes do not achieve adequate systemic exposure to permit the identification of potential extra-pulmonary target organ(s) of toxicity. To optimize systemic exposure and thus help establish target organ toxicity, we have implemented adjunct dosing for preclinical inhalation studies. For two inhaled asthma programs, in which the top inhaled dose was limited due to exposure generation (VLA4 and IL-4 targets), rats and dogs were exposed in 13-week toxicity studies by dry powder inhalation and an adjunctive route (either subcutaneous or oral, based on solubility of test article and oral bioavailability). The studies consisted of an air-sham control and a vehicle control (i.e. received inhaled lactose powder and the adjunct dosing vehicle via subcutaneous or oral route), and a low-, mid- and high-dose inhalation group. An additional high-dose inhalation group received adjunct compound (by the oral route for the IL-4 program and the subcutaneous route for the VLA4 program), at the maximally feasible dose, 1-hour following the daily inhalation session. Results of these studies indicate supplementing compound by the oral or subcutaneous route to the high-dose inhaled group can increase systemic exposures by 2 to 13-fold (Day 90 AUC) over the high-dose dry powder only group. Moreover, dosing dogs and rats to the adjunct vehicle had no deleterious effects on the vehicle control group as compared to the air-sham control group (based on clinical signs, food intake, and body weight). In conclusion, supplemental dosing offers an advantageous method of augmenting systemic exposure when limitations have been imposed by the inhalation exposure system and/or physicochemical properties of the test compound. Achieving higher systemic exposures increases the probability of establishing target organ toxicity.

APPLICATION OF THE AERONEB® PROFESSIONAL  
NEBULISER TO INHALATION DOSING SYSTEMS FOR  
DOGS AND PRIMATES.

G. Ian, B. Canham, N. Shepherd and P. Newham. Covance Laboratories Ltd., Harrogate, United Kingdom. Sponsor: D. Everett.

The compact, single-pass nebuliser was mounted close to the breathing zone in face masks and oropharyngeal dosing apparatus for inhalation exposure. No animals were used in this study, which was a system characterisation using aqueous Salbutamol. Delivery to the animal airways via a facemask was modeled by sampling from within a manikin head into a filter with a respiratory pump to simulate the animal breathing. Deposition was also measured in the mask and the exhaust system. Deposition in the dog manikin airway was ca 37%, while into the primate manikin airway this was ca 30%. In a similar experiment modeling delivery to a dog via an oropharyngeal tube, 45% of the generated Salbutamol was drawn into filters by the respiratory pump. The delivered aerosols were highly respirable aerosol, with average Mass Median Aerodynamic Diameter 1.8 micron. Used in conjunction with dog and primate inhalation dosing apparatus, the Aeroneb® Pro delivered respirable aerosols with good efficiency, offering advantages for inhalation toxicology studies.

PERFORMANCE OF FLOW-PAST AND  
CONVENTIONAL NOSE-ONLY INHALATION  
EXPOSURE SYSTEMS WITH POWDER AND DROPLET  
AEROSOLS.

I. Gilkison, B. Canham, N. Shepherd and P. Newham. Covance Laboratories Ltd., Harrogate, United Kingdom. Sponsor: D. Everett.

For snout-only exposure of rodents, two types of inhalation chamber are commonly used: a simple 30-cm cylinder with breathing ports in the side (ADG-type) and a "flow-past" system that delivers fresh aerosol to each animal individually via a manifold. We have evaluated both types of chamber equipped for the exposure of 120 and 128 animals respectively. Nominal aerosol concentrations were between 0.3 and 12 mg/L with 80 L/min air flow rate. Kaolin aerosol from a Rotating Brush Generator was delivered via the flow-past and ADG chambers with ca 25% and 35% efficiency respectively. The delivered Particle Sizes were ca 2.0 and 2.5 $\mu$ m Mass Median Aerodynamic Diameter (MMAD). Consistency of delivered aerosol concentration across all animal ports was e.g. 13% and 7% respectively at the high concentration. Greater variability of Kaolin concentration was observed with the flow-past chamber, possibly due to re-dispersal of impacted powder. An aqueous aerosol of 1% Sunset Yellow in buffer was generated from 1 to 4 Parry LC+ nebu-

lisers. Efficiency of delivery via the flow-past and ADG chambers was ca 60% and 75% respectively at high concentration and a similar 90% efficiency at low concentration. The delivered Particle Size was similar at ca 1.1  $\mu$ m MMAD. Consistency of delivered aerosol concentration was typically ca 10% for both chambers. It was concluded that while either chamber design can give consistent results with liquid aerosols, the advantages of the Flow

ANALYSIS OF UNRESTRAINED WHOLE-BODY  
PLETHYSMOGRAPHY (WBP) DATA BY SIGNAL  
PROCESSING AND MECHANISTIC MODELING.

P. M. Schlosser<sup>1</sup>, M. Breen<sup>2</sup>, Z. Chen<sup>3</sup>, B. Ettinger<sup>4</sup>, A. M. Jarabek<sup>1,5</sup>, S. Nandi<sup>6</sup>, B. Tapia-Santos<sup>7</sup>, E. Tewksbury<sup>1</sup>, H. J. Trussell<sup>8</sup>, H. Wilson<sup>8</sup> and B. A. Wong<sup>1</sup>. <sup>1</sup>CIIT-CHR, Research Triangle Park, NC, <sup>2</sup>Case Western Reserve U, Cleveland, OH, <sup>3</sup>Florida State U, Tallahassee, FL, <sup>4</sup>U of Georgia, Athens, GA, <sup>5</sup>USEPA, Washington, DC, <sup>6</sup>U of Massachusetts, Amherst, MA, <sup>7</sup>Centro de Investigacion en Matematicas, Guanajuato, Mexico and <sup>8</sup>North Carolina State U, Raleigh, NC.

Unrestrained WBP provides a measure of respiratory response to irritant gases. We first used WBP and BioSystem XA software (Buxco Electronics, Inc., Wilmington, NC) to collect and analyze respiratory data from rats. The software menu provides the model of "Drorbaugh and Fenn" (Pediatrics, 16:81-87, 1955; D&F) as one option but that model was derived for a completely sealed chamber and the current WBP has continual flow-through of air or exposure atmosphere. Since the software is proprietary, details of the data analysis code are unavailable. Therefore we re-derived the D&F model to include flow and created a program in Matlab (Mathworks, Inc., Natick, MA) to implement the model. Due to high noise in the raw data we also performed a spectrographic analysis to identify the frequency range of primary interest as well as persistent interference from mechanical or electrical noise. Visual investigation of the spectrograms allows for quick identification of periods of high vs. low noise, the general trend of the primary breathing frequency, and constant background noise. A low-pass digital filter was used to remove high-frequency noise from the data before respiration analysis. Criteria for breath length, volume, and volume balance were then applied to identify acceptable breaths, which were analyzed for breathing parameters. BioSystems output and our values for peak inspiratory flow and tidal volume compared well (e.g., 5.7 vs. 5.1 ml/s and 0.90 vs. 0.96 ml, respectively), but our estimated frequencies (e.g., 82 vs. 100 bpm) were substantially lower. Our model derivation for the flow-through WBP uses the same basic assumptions as D&F, is implemented in Matlab, and allows modification of the assumptions and equations as needed for subsequent research.

DESIGN AND CHARACTERIZATION OF A NOVEL  
ROBOTIC WELDING FUME INHALATION AND  
EXPOSURE SYSTEM FOR LABORATORY ANIMALS.

J. M. Antonini, A. Afshari, S. Stone, T. B. Chen, D. Schwegler-Berry, G. Fletcher, T. Goldsmith, K. Vandestouwe, W. McKinney, V. Castranova and D. Frazer. NIOSH, Morgantown, WV.

Respiratory effects observed in welders have included lung function changes, metal fume fever, bronchitis, and a possible increase in the incidence of lung cancer. Many questions remain unanswered regarding the causality and possible underlying mechanisms associated with the potential toxic effects of welding fume inhalation. The objective was to construct a completely automated, computer-controlled welding fume generation and exposure system to simulate real workplace conditions. The system was comprised of a programmable six-axis robotic welding arm, a water-cooled arc welding torch, and a wire feeder that supplied the wire to the torch at a programmed rate up to 300 in/min. For the initial studies, gas metal arc welding was performed using a stainless steel electrode. A flexible trunk was attached to the robotic arm of the welder and was used to collect and transport fume from the vicinity of the arc to the animal exposure chamber. Undiluted fume concentrations consistently ranged from 90-150 mg/m<sup>3</sup> in the animal chamber during welding. Temperature and humidity remained constant in the chamber during the welding operation. The welding particles were comprised of (from highest to lowest concentration) Fe, Cr, Mn, and Ni as measured by inductively coupled plasma atomic emission spectroscopy. Size distribution analysis indicated the mass median aerodynamic diameter of the generated particles to be approximately 0.24  $\mu$ m with a geometric standard deviation of 1.39. As determined by scanning electron microscopy, the generated aerosols were mostly arranged as chain-like agglomerates of primary particles. These characterization studies of the generated welding aerosol have indicated that particle morphology, size, and chemical composition are comparable to stainless steel welding fume generated in the workplace. With the development of this novel system, it will be possible to establish an animal model using controlled welding exposures to investigate how welding fumes affect health.

CONCENTRATION-DEPENDENCE OF STABILITY OF AEROSOLS OF MONOMERIC DIPHENYL-METHANE-4, 4-DIISOCYANATE (MDI).

J. Pauluhn. *Toxicology, Bayer HealthCare, Wuppertal, Germany.*

Polymeric diphenyl-methane-4, 4-diisocyanate (pMDI) is a reactive chemical intermediate with low vapor pressure. It is a major industrial chemical, mainly used for the production of polyurethanes. pMDI commonly contains 30-50% monomeric MDI (mMDI), the balance are higher oligomers. At room temperature mMDI is a waxy solid, whilst pMDI is a viscous liquid. Its vapor saturation concentration at normal room temperatures is in the range of 0.05-0.1 mg/m<sup>3</sup>, i.e., higher concentrations, as required for inhalation toxicity studies, can only be attained by aerosolization. For MDI, this objective is met by using highly specialized methodologies. The focus of this research is to analyze methodologies for testing of high (approx. 2000 mg/m<sup>3</sup>; the 1-hour LC<sub>50</sub> of mMDI is greater than 2240 mg mMDI/m<sup>3</sup>) and lower concentrations (0.1 mg/m<sup>3</sup>) of mMDI. The results show that mMDI, when evaporated at elevated temperature (90 DegC) has a markedly lower tendency to evaporate than predicted by thermodynamic calculations. In contrast, supersaturated vapor atmospheres could be generated at higher temperatures using bubblers systems and condensation aerosols were formed upon cooling. Aerosols were only detectable at concentrations above the vapor saturation concentration, i.e. 0.1 mg/m<sup>3</sup>. This supports the conclusion that mMDI condensation aerosol is thermodynamically unstable at or, below the vapor saturation concentration. Stable condensation aerosols of mMDI occurred only at supersaturated vapor concentrations in closed systems. Accordingly, for Agencies which mandate a specific physical form for the manifestation of an intrinsic hazard in experimental animals the toxicological significance of findings for humans needs to be challenged. This data suggest, that the intrinsic hazard of mMDI aerosol appears to be dominated by concentration rather than unique features of this chemical. The intrinsic hazards demonstrated in inhalation studies need to be associated with the actual physical form forced by specified testing conditions, which may not reflect the actual physical form present in the workplace.

DEVELOPMENT OF A NOVEL TRIPLE MANIFOLD NOSE-ONLY RODENT INHALATION SYSTEM: ACUTE TOXICITY OF RICIN AEROSOLS IN BALB/C MICE.

C. J. Roy<sup>1</sup>, N. Stahl<sup>2</sup> and J. M. Hartings<sup>3</sup>. <sup>1</sup>*Center for Aerobiological Sciences, USAMRIID, Fort Detrick, MD*, <sup>2</sup>*Cambridge Systems, Chantilly, VA* and <sup>3</sup>*Goldbelt Raven, Frederick, MD.*

Rodent inhalation nose-only-type exposure systems generally employ a single or double manifold design wherein an airborne substance at a particular concentration is generated and drawn past the snout of the animal before being exhausted from the system. Because of this design limitation, multiple discrete 'runs' of a particular system or concurrent use of many systems using multiple concentration levels are required to accomplish inhalation studies with multiple dosage groups. We have designed a singular tower inhalation system using a triple manifold configuration, electronically actuated directional flow valves, and an automated management platform, allowing simultaneous duration-based exposure of multiple dosage groups from a common aerosol stream. As a demonstration of the new design, groups of BALB/c mice were exposed to ricin toxin aerosols (MMAD=1  $\mu$ m,  $\sigma$ g=1.4) at 5.7  $\pm$  0.3  $\mu$ g/l for either 1, 3, or 15 min for corresponding inhaled doses of 5.4  $\pm$  0.3, 16.2  $\pm$  0.9 or 81.3  $\pm$  4.7  $\mu$ g/kg, respectively. Group survival results indicated consistency with the established ricin inhalation LD<sub>50</sub>, and confirmed the definable dose-response curve. These results suggest that the described system can reduce both inter-experimental aerosol concentration variability and the time required to complete studies involving multiple dosage levels as compared to conventional inhalation systems. These capabilities would allow protocol development for high throughput *in vivo* toxicity testing where inhalation is the desired route of exposure.

ESTABLISHMENT OF A BIOLOGICAL BIOASSAY FOR DETECTION OF LUNG TOXICITY DUE TO FINE PARTICLES.

M. Yokohira, K. Saito, H. Takeuchi, Y. Matsuda, Y. Zeng and K. Imaida. *Pathology and Host-Defence, faculty of medicine, Kagawa university, Kita-gun, kagawa, Japan.* Sponsor: T. Shirai.

In order to establish an appropriate bioassay for detection of lung damage after fine particle inhalation, sequential histopathological changes were examined after intratracheal instillation of quartz, as a typical lung toxic agent, into F344 male rats. Experiment 1: A total of 50, 10-week-old male F344 rats, were separated into two groups. Twenty five were exposed to quartz powder (DQ-12, 4mg/rat) suspended in saline (0.2ml) using an aerolizer and subgroups were killed on Days 1, 3, 7, 14, and 28 thereafter. The remaining 25 rats received the saline vehicle (0.2ml) as a control group and were killed on the same days. Both groups underwent assessment

of lung histopathology and immunohistochemical demonstration of BrdU, iNOS and MMP-3 as end-point markers. Days 1 and 28 after intratracheal instillation of test fine particles were suggested to be most appropriate for detection of acute and subchronic inflammatory changes, respectively. Furthermore, BrdU on Day 1 and iNOS on Day 28 proved to be suitable end-point markers for this purpose. Experiment 2: A total of 108, 10-week-old male F344 rats, were randomly separated into 8 groups. Seventy rats (5 groups) were exposed by intratracheal instillation to quartz, hydrotalcite, potassium octatitanate, palladium oxide or carbon black, 4mg/rat, suspended in 0.2ml control vehicle. Twenty eight (2 groups) animals were exposed by intratracheal instillation to 0.2ml saline and 0.2ml 10% propylene glycol 1% carboxymethylcellulose (PG-CMC) as controls, and the remaining 10 rats were maintained as an untreated group. Subgroups of 7 treated, 7 control and 5 untreated rats, were then killed on Days 1 and 28 and all groups underwent assessment of lung parameters as in Experiment 1. Quartz proved to be the most toxic to lungs and other particles were considered as exerting low toxicity on histopathological and immunohistochemical assessment. This instillation model can be used for detection of acute or subchronic lung toxicity due to inhaled fine particles.

GLASS BEAD INHALATION AND INDUCTION OF SILICOSIS.

L. Beyer and B. D. Beck. *Gradient Corp., Cambridge, MA.*

Silicosis is an occupational lung disease caused by the inhalation of silica of respirable size, in crystalline forms. Some have claimed that glass beads, because they too are composed of silica, are associated with silicosis. We reviewed and summarized the primary toxicological literature relating to glass beads, which consisted of 12 *in vitro* studies and 5 *in vivo* studies. The *in vitro* studies used glass beads primarily as negative controls (7/12 studies) in bioassays with alveolar macrophages (7 studies) or respiratory tissue from lungs and/or trachea (6 studies - 1 study used both tissue and macrophages). In the alveolar macrophage studies, glass beads decreased the viability of the macrophages and phagocytosis starting at about 100-1,000  $\mu$ g/mL, probably due to a particle loading effect. Four of the five *in vitro* studies using lung or tracheal tissue, showed few or no differences from untreated controls, and produced no fibrogenic responses and no effects in induction of DNA repair enzymes or cell proliferation. One study showed significant increases in hyperplastic, metaplastic, or dysplastic lesions, but only at the highest dose tested - 10,000  $\mu$ g/mL. In the *in vivo* studies, which were conducted using intratracheal administration of particles in rats, glass beads were used as an inert particle control. These studies showed only minimal (if any) differences in fibrogenicity or lung function parameters. In one study with serial sacrifices, the lungs of rats instilled with glass beads had minimal to moderate inflammation on post-treatment day 3, and in each successive sacrifice the lesions became less severe and affected fewer rats. We also reviewed the relevant occupational guidance numbers (and their basis) set by ACGIH and those promulgated by OSHA. OSHA has classified glass beads as "nuisance dust," since they contain no hazardous materials. Consequently, OSHA and others view glass beads as a safe alternative to the silica used in abrasive blasting. Based on our review of the primary literature, as well as occupational limits and their basis, we conclude that glass beads do not cause silicosis or other respiratory disease.

DEVELOPMENT OF TOLUENE AEGLS USING PBPK MODELING IN RATS AND HUMANS.

J. E. Dennis<sup>1</sup>, C. M. Troxel<sup>2</sup> and S. S. Talmage<sup>3</sup>. <sup>1</sup>*CETT, Colo State U, Ft. Collins, CO*, <sup>2</sup>*CMTox, Inc., Lander, WY* and <sup>3</sup>*ORNL, Oak Ridge, TN.*

AEGLs have historically been established using empirical approaches for extrapolation across time and applying uncertainty factors (UFs). While PBPK models have been primarily used for cancer and other chronic endpoint risk assessment in the past, we used PBPK models to provide an explicit basis for rat to human extrapolation for the acute endpoint relevant to toluene AEGLs. This context raised a different spectrum of modeling issues, including low- to high-dose extrapolation and the need to consider workload during emergencies. The PBPK model was adapted from existing toluene rat/human PBPK models using previously published physiological and kinetic parameters but adding a second low affinity enzyme. The model was validated with available high dose and workload data and a good fit was obtained to previously published blood and exhaled breath data. As found for some other solvents, blood levels in humans were lower than in rats due to a lower blood:air partition coefficient. AEGL values were calculated by 1) determining the blood level in rats at the point of departure for the AEGL-1, -2 or -3; 2) calculating the equivalent human exposure that resulted in the same blood level during human exposure for 10 and 30 minutes and 1, 4 and 8 hours; 3) applying intraspecies UFs for human variability. Thus, the PBPK approach explicitly dealt with both rat-human and temporal extrapolation. Human equivalent values were generally higher, but assuming a workload of 50W tended to negate the differences. Using

PBPK models provided a basis for setting the toxicokinetic UF in rat-human extrapolation to 1. The PBPK model also showed a significant difference in time-dependant AEGL values from those calculated with the ten Berge equation, which underestimates the equivalent exposure during early time points. For chemicals where PBPK models are available, the approach reduces extrapolation uncertainty and allows workload to be taken into account. [This abstract presents interim AEGL values that are subject to change pending further review.]

#### 1474 INTERIM ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR XYLEMES.

C. M. Troxel<sup>1</sup>, J. E. Dennison<sup>2</sup> and R. Benson<sup>3</sup>. <sup>1</sup>CMTox, Inc., Lander, WY, <sup>2</sup>CETT, Colorado State University, Fort Collins, CO and <sup>3</sup>USEPA, Denver, CO.

AEGLs represent threshold exposure limits for the general public and are applicable to emergency exposure periods ranging from 10 minutes to 8 hours. AEGL-1, AEGL-2 and AEGL-3 are developed for each of five exposure periods (10 and 30 minutes, 1, 4, and 8 hours) and are distinguished by varying degrees of toxicity ranging from mild sensory irritation to irreversible effects to death. AEGLs were developed for mixed xylenes, comprising three isomers: meta-xylene, ortho-xylene, and para-xylene. The AEGL-1 of 130 ppm is based upon the no-effect level for notable discomfort: only slight eye irritation was noted by human volunteers during a 30-minute exposure to 400 ppm mixed xylenes. A total uncertainty factor (UF) of 3 is applied: 1 for interspecies and 3 for intraspecies. Because irritation is considered a threshold effect and should not vary over time, the AEGL-1 threshold value is applied to all times. AEGL-2 values (1100, 590, 400, 400, and 400 ppm, respectively) are based upon the NOEL for the inability to escape: poor coordination was observed in rats 2 hours into a 4-hour exposure to 1300 ppm mixed xylenes. AEGL-3 values (3300, 1700, 1100, 1100, and 1100 ppm, respectively) are based upon a NOEL for death and reversible prostration in rats exposed for 4 hours to 2800 ppm mixed xylenes. A total UF of 3 was applied to both the AEGL-2 and -3 values: 1 for interspecies extrapolation and 3 for intraspecies extrapolation. A validated PBPK model was used to perform the extrapolation of rat to human blood concentrations for setting the AEGL-2 and AEGL-3 values. Using the PBPK model reduced the uncertainty in extrapolation, and allowed direct consideration of the activity level during chemical emergencies. The AEGL-2 and -3 values were set assuming a workload of 50W for 10 minutes, 30 minutes, and 1 hour. The 4- and 8-hour AEGL-2 and -3 values were set equal to the 1-hour AEGL values based on the assumption that this activity level would not be maintained. [This abstract presents interim AEGL values that are subject to change pending further review.]

#### 1475 A REVIEW OF THE BASIS FOR HYDROGEN CHLORIDE OCCUPATIONAL EXPOSURE LIMITS.

A. Havics<sup>1</sup> and M. P. DeLorme<sup>2</sup>. <sup>1</sup>QEPI, Indianapolis, IN and <sup>2</sup>DuPont Haskell Laboratory, Newark, DE.

Hydrogen chloride is a corrosive, colorless, water soluble compound that is a widely used commodity chemical in numerous forms and applications. Occupational exposures to hydrogen chloride are predominantly to the gas phase. The main issue related to occupational health is that hydrogen chloride is strong irritant to the eyes, mucous membranes, skin, and respiratory tract. For many decades the acceptable Occupational Exposure Limits (OELs) have ranged from 5-10 ppm as a ceiling or as a time-weighted-average (TWA). The basis of traditional OELs has been the reporting of a 10 ppm lowest observable adverse effect level (LOAEL) in humans for irritation. However, a recent review of the 10 ppm LOAEL showed it to be anecdotal since appearing in the literature about 1931. A more thorough investigation of the LOAEL source report, which dates back to 1889, reveals that the actual LOAEL cited was 100 ppm. It seems that in the 1930s there was a decimal point transposition that propagated the 10 ppm value throughout the literature to present day. Because of the apparent anecdotal nature of the data, limit setting bodies have discounted it in the risk assessment process. This has shifted the basis of hydrogen chloride risk assessment to studies revolving around negative findings in asthmatic subjects, which has lowered one of the OELs. Performing a risk assessment on negative data such as this can result in an unduly low OEL. This report is designed to reintroduce and clarify the reporting of the original data. The use of this original data fills the gap in the concentration-response curve providing a more robust risk assessment for hydrogen chloride. Inclusion of the data suggests that an OEL in the range of 5-10 ppm is acceptable for hydrogen chloride.

#### 1476 DEVELOPMENT OF ACUTE EMERGENCY GUIDELINE LEVELS (AEGLS) USING BENCHMARK DOSE (BMD) METHODOLOGY TO CALCULATE POTENTIALLY LETHAL EXPOSURES.

G. V. Alexeff, W. Tong, R. Broadwin and A. G. Salmon. OEHHA, Cal/EPA, Oakland, CA.

The National Advisory Committee for AEGLs for Hazardous Substances (NAC/AEGLs) establishes AEGL-3 values to assist emergency planners in preventing accidental exposures that increase the likelihood of death. Three methods have

been identified to establish a starting point for AEGL-3 values. The preferred method is to use a benchmark dose exposure calculation (BMC) of the 5% and 1% response. We compared the BMC method with the experimentally observed lethality thresholds (AEGL-3 NOAELs), and AEGL-3s estimated by one-third of the LC<sub>50</sub> (LC<sub>50</sub>/3) for 100 data sets using 40 different chemicals. Using U.S.EPA BMD software (BMDS) version 1.3.2, we also compared results of the BMD software to that of the Toxicology-Risk software (TRS) version 3.5. Previously we reported BMC<sub>01</sub>s and BMC<sub>05</sub>s, using TRS, were generally consistent with the NOAELs for lethality. We found a similar conclusion with the BMDS; that is, on average we found NOAELs to be up to 20% greater than the BMC<sub>01</sub> and BMC<sub>05</sub>. While we would have expected the LC<sub>50</sub>/3 method to be conservative, we found that it overestimated the BMDL in 25% of the cases. The occurrence of a shallower slope, i.e., less than 6, appeared to be a major factor in these cases. Finally, we compared the results of the TRS to the BMDS and found a strong correlation between the values. However, in 3% of the comparisons the values were substantially different, probably due to poor determination of the model. In conclusion, the AEGL-3 NOAEL, BMC<sub>05</sub>, BMC<sub>01</sub> and LC<sub>50</sub>/3 generally provided consistent values. However, in cases of slopes less than 6, the default uncertainty factor of 3 is not sufficiently conservative to estimate a non-lethal value.

#### 1477 USING ANIMAL LC50 DATA TO ESTIMATE ACUTE EXPOSURE LETHALITY THRESHOLDS FOR WORKERS.

A. J. Weinrich<sup>1</sup>, A. Maier<sup>2</sup>, A. Havics<sup>3</sup>, B. Gadagbui<sup>2</sup> and M. Osier<sup>4</sup>. <sup>1</sup>Education and Information Division, US CDC-NIOSH, Cincinnati, OH, <sup>2</sup>Toxicology Excellence for Risk Assessment, Cincinnati, OH, <sup>3</sup>pH2 Environmental, Indianapolis, IN and <sup>4</sup>Syracuse Research Corporation, Syracuse, NY.

Animal toxicology data are used to estimate acute chemical exposures that are safe for humans by applying a widely-used quantitative method to determine concentration-time mortality response relationships as well as uncertainty factors that depend on type and quality of data. We previously identified the quantitative methods for extrapolating from animal LC50s to immediately dangerous to life and health (IDLH) values among key uncertainties in methods NIOSH used for deriving IDLH values. These uncertainties result in part from the paucity of systematic correlations of acute inhalation exposure-response data in animals and humans. Using available data, we studied the following: + Reliability of a calculation method widely used for determining concentration-time mortality response relationships + Quantitative relationships between acute inhalation LC50s and lowest lethal concentrations in animals + Quantitative relationships between acute inhalation lethal exposure data in animals and humans. Our analyses indicate that experimental research to overcome data limitations and inconsistencies between studies is needed. Lethal exposure data in humans always will be limited to what can be deduced for case reports. To eliminate uncontrolled variables in correlations of exposure-response relationships between humans and experimental animals, we encourage future animal studies that attempt to replicate documented exposure conditions that led to human deaths. To improve data for developing acute exposure guidelines, we encourage experimental studies to determine relationships between animal exposures under these conditions and conditions assumed by guideline-setting organizations. The conditions assumed by NIOSH for IDLH values are a single 30-minute inhalation exposure followed by an extended observation period.

#### 1478 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR NITROGEN DIOXIDE AND NITRIC OXIDE.

C. S. Wood<sup>1</sup> and L. D. Koller<sup>2</sup>. <sup>1</sup>Oak Ridge National Laboratory, Oak Ridge, TN and <sup>2</sup>Loren Koller & Associates LLC, Corvallis, OR.

AEGLs represent threshold exposure limits for the general public and are applicable to emergency exposure periods of 10 min, 30 min, 1 hr, 4 hr, and 8 hr. NO<sub>2</sub> is an irritant to the mucous membranes; death is caused by bronchospasm and pulmonary edema. After the acute phase, apparent recovery may be followed by late-onset injury that manifests as bronchiolitis fibrosa obliterans. Inhaled NO has is used therapeutically but the toxicity is associated with both methemoglobin formation and oxidation to NO<sub>2</sub>. Because NO converts to NO<sub>2</sub> in the atmosphere, and NO<sub>2</sub> is more toxic than NO, the AEGL values for NO<sub>2</sub> are recommended for NO. AEGL-1 (discomfort) values (0.50 ppm for all time-points) were based on exposure of asthmatic volunteers to 0.5 ppm NO<sub>2</sub> for 2 hrs. 7/13 individuals experienced slight burning of the eyes, headache, and chest tightness or labored breathing with exercise but no changes in pulmonary function. No uncertainty factor was applied. AEGL-2 (disability) values (20, 15, 12, 8.2, and 6.7 ppm) were based on exposure of three healthy male volunteers to 30 ppm NO<sub>2</sub> for 2 hrs. The individuals perceived an intense odor upon entering the chamber; after 70 minutes, they experienced a burning sensation and an increasingly severe cough with marked sputum secretion and dyspnea. Towards the end of the exposure, the subjects reported the conditions as bothersome and barely tolerable. AEGL-3 (death) values (34, 25, 20, 14, and 11 ppm, respectively) were based signs of marked irritation and severe lung histopathology in monkeys exposed to 50 ppm NO<sub>2</sub> for 2 hrs. For AEGL-2 and -3 values, extrapolations were made with the equation C<sup>n</sup> × t = k using n = 3.5. The

value of n was calculated using data in five species of laboratory animal. A total uncertainty factor of 3 was applied to the AEGL-2 and -3 values including 3 to account for sensitive individuals and 1 for interspecies extrapolation. [This abstract presents Proposed AEGL values that are subject to change pending further review.] ORNL, managed by UT-Battelle LLC, for the US Department of Energy under contract DEAC0500OR22725.

**1479**

ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR NITRIC ACID.

D. F. Glass<sup>1</sup>, C. S. Wood<sup>1</sup> and L. D. Koller<sup>2</sup>. <sup>1</sup>Oak Ridge National Laboratory, Oak Ridge, TN and <sup>2</sup>Loren Koller & Associates LLC, Corvallis, OR.

AEGLs represent threshold exposure limits for the general public and are applicable to emergency exposure periods of 10 min, 30 min, 1 hr, 4 hr, and 8 hr. Nitric acid is a highly corrosive, strongly oxidizing acid. The course of toxicity following inhalation exposure to nitric acid is consistent between humans and animals and includes immediate irritation of the respiratory tract, pain, and dyspnea which are followed by a period of recovery that may last several weeks. After this time, a relapse may occur with death caused by bronchopneumonia and/or pulmonary fibrosis. AEGL-1 (discomfort) values (0.53 ppm for all time-points) were based on exposure of five healthy volunteers to 1.6 ppm nitric acid for 10 min. No changes in pulmonary function were observed. An uncertainty factor of 3 was applied to account for sensitive individuals. AEGL-2 (disability) and AEGL-3 values (death) were based on a lethality study in rats. Groups of 5 rats/sex were exposed nose-only for 1 hr to 260-3100 ppm of nitric acid aerosol followed by a 14-day observation period. AEGL-2 values (43, 30, 24, 6.0, and 3.0 ppm, respectively) were based on transient body weight loss following exposure to 460 ppm. AEGL-3 values (170, 120, 92, 23, and 11 ppm) were based on an estimated LC<sub>01</sub> of 919 ppm calculated by a log-probit analysis. For AEGL-2 and -3 values, extrapolations were made with the equation C<sup>n</sup> × t = k using default values of n = 3 for extrapolating to shorter durations and n = 1 for extrapolating to longer durations. A total uncertainty factor of 10 was applied to AEGL-2 and -3 values which includes 3 to account for sensitive individuals and 3 for interspecies extrapolation. [This abstract presents Proposed AEGL values that are subject to change pending further review.] Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the US Department of Energy under contract DEAC0500OR22725.

**1480**

INTERIM ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR AMMONIA.

K. A. Davidson<sup>1</sup>, L. A. Gephart<sup>2</sup> and S. D. Ripple<sup>3</sup>. <sup>1</sup>Oak Ridge National Laboratory, Oak Ridge, TN, <sup>2</sup>ExxonMobil Chem. Europe, Machelen, Belgium and <sup>3</sup>Dow Chem. Co., Midland, MI.

AEGL values represent threshold exposure limits for the general public applicable to emergency exposure periods of 10, 30 min and 1, 4, and 8 hrs and three severity levels ranging from mild sensory irritation to irreversible/disabling effects to death. Ammonia also has a 5-min value. Ammonia is a corrosive, alkaline gas that has a very strong odor; odor detection ranges from 5-53 ppm. The corrosive and exothermic properties of ammonia cause irritation and burns to eyes, skin, oral cavity, and respiratory tract, the severity depending on the exposure concentration. Low concentrations cause mild upper respiratory tract irritation, high concentrations cause tracheobronchial damage, and extremely high concentrations cause pulmonary edema and death. The AEGL-1 value of 30 ppm for all time points was derived from a human study showing mild respiratory tract irritation after exposure to 30 ppm for 10 min. AEGL-2 values of 380, 170, 160, 110, 110, and 110 ppm, respectively, were derived from a study in human volunteers reporting offensive eyes and respiratory tract irritation after exposure to 110 ppm for 1 hr. The AEGL-2 value for 1 hr was retained for 4 and 8 hrs because of human adaptation to ammonia. AEGL-3 values of 3800, 2700, 1600, 1100, 550, and 390 ppm, respectively, were derived from an estimate of the lethality threshold (LC01 = 3317 and 3374 ppm) calculated from acute lethality data from mice exposed to ammonia for 1 hr. An intraspecies uncertainty factor (UF) of 1 was applied for AEGL-1 and -2 derivations, and intraspecies UF of 1 and an intraspecies UF of 3 were applied for AEGL-3 derivation. The equation, C<sup>n</sup> × t = k, where n = 2, was utilized for time scaling of AEGL-2 and AEGL-3 where applicable. [This abstract presents interim AEGL values that are subject to change pending further review.] Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the US Department of Energy under contract DEAC0500OR22725.

EXTRAPOLATION OF LC50S TO SAFE EXPOSURE LEVELS - INSIGHTS FOR EMERGENCY RESPONDERS.

M. Fay<sup>1</sup>, B. Luukinen<sup>2</sup> and J. Holler<sup>1</sup>. <sup>1</sup>Toxicology, ATSDR/CDC, Atlanta, GA and <sup>2</sup>Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC. Sponsor: B. Fowler.

Health guidance values provide response managers with useful information for directing evacuations and reentry associated with acute hazardous chemical release. Because health guidance values have not been derived for many hazardous sub-

stances, we investigated the usefulness of extrapolating from published toxicological properties, in order to support response managers. For our dataset, we selected all 74 substances that currently have an inhalation Minimal Risk Level (MRL) from the Agency for Toxic Substances and Disease Registry (ATSDR). LC50 (lethal concentration 50%) values were located for 55 of these; 19 were insufficiently toxic or had no LC50s. A total of 227 LC50s were located for the 55 substances. Concentrations were standardized for LC50s and their respective MRLs. As an initial approach, we plotted LC50s against MRLs. In a log-log plot, a general linear trend was evident, yet the 227 datapoints were widely scattered ( $R^2=0.62$ ). The data were subsetted to control for differences in LC50 species or duration. Substantial variability remained while, at the same time, the number of datapoints was considerably reduced. We also attempted to control for the variability introduced by LC50 exposure time using the ten-Berge et al. (J Hazard Mater 13:301, 1986) modification to Haber's rule, but only a handful of substances had sufficient LC50 data for a reliable concentration exponent. We dropped the log-log plot approach in favor of percentile statistics concerning LC50/MRL ratios. The median LC50/MRL ratio was 14, 000 or, if MRL uncertainty factors are dropped to approximate No Observed Adverse Effect Levels (NOAELs), the median LC50/NOAEL ratio was 800. The 95th percentiles were 880, 000 and 32, 000 for LC50/MRL and LC50/NOAEL ratios, respectively. These results (and additional statistics to be presented) may provide guidance to response managers when handling data-poor substances.

**1482**

ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR HYDROGEN SULFIDE.

C. Bast<sup>1</sup> and S. J. Barbee<sup>2</sup>. <sup>1</sup>Oak Ridge National Laboratory, Oak Ridge, TN and <sup>2</sup>Arch Chemicals, Inc., Norwalk, CT.

AEGL values represent one-time exposures for increasingly severe effects with AEGL-1 being least and AEGL-3 being most severe. Hydrogen sulfide is a colorless, flammable gas at ambient temperature and pressure. It has an odor similar to that of rotten eggs and is both an irritant and asphyxiant. It acts similarly to cyanide by interrupting the electron transport chain through inhibition of cytochrome oxidase. AEGL-1 values (0.75 ppm, 0.60 ppm, 0.51 ppm, 0.36 ppm, and 0.33 ppm, for 10-min, 30-min, 1-hr, 4-hr, and 8-hr, respectively) were based on headache in asthmatic humans exposed to 2 ppm H<sub>2</sub>S for 30 minutes. AEGL-1 values were adjusted by a modifying factor of 3. AEGL-2 values (41 ppm, 32 ppm, 27 ppm, 29 ppm, and 17 ppm, for 10-min, 30-min, 1-hr, 4-hr, and 8-hr, respectively) were based on perivascular edema in rats exposed to 200 ppm H<sub>2</sub>S for 4 hours. The AEGL-3 values (76 ppm, 59 ppm, 50 ppm, 37 ppm, and 31 ppm, for 10-min, 30-min, 1-hr, 4-hr, and 8-hr, respectively) were based on a 1-hour lethality threshold in rats of 504 ppm H<sub>2</sub>S. Interspecies and intraspecies uncertainty factors of 3 each were applied to AEGL-2 and AEGL-3 values. AEGL-2 and AEGL-3 values were scaled across time using the exposure-concentration duration relationship, C<sup>4.4</sup> × t = k, shown to be valid for lethality in rats for H<sub>2</sub>S exposures ranging from 10-minutes to 6-hours. Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the US Department of Energy under contract DEAC0500OR22725.

**1483**

MINIMAL RISK LEVELS FOR HYDROGEN SULFIDE - UPDATE.

S. J. Chou<sup>1</sup>, M. Fay<sup>1</sup>, S. Keith<sup>1</sup> and L. Ingberman<sup>2</sup>. <sup>1</sup>Division of Toxicology, Agency for Toxic Substances and Disease Registry, Atlanta, GA and <sup>2</sup>Syracuse Research Corporation, Syracuse, NY. Sponsor: B. Fowler.

The Agency for Toxic Substances and Disease Registry (ATSDR) derives minimal risk levels (MRLs) for hazardous substances based on available toxicological and epidemiologic information, as detailed in the Agency toxicological profiles. An MRL is an estimate of the daily human exposure to a hazardous substance that is likely to be without appreciable risk of adverse, non-cancer health effects. The toxicological profile for hydrogen sulfide was recently updated; revisions of the acute inhalation MRL and the intermediate inhalation MRL were proposed. The acute inhalation MRL of 0.2 ppm was based on a lowest-observed-adverse-effect level (LOAEL) of 2 ppm for respiratory effects. Two out of 10 persons with asthma exposed to hydrogen sulfide for 30 minutes had changes in excess of 30% in airway resistance or specific airway conductance, suggestive of bronchial constriction. These individuals showed no significant changes in lung function (Jappinen et al. Br J Ind Med. 1990, 47:824-8). To derive the MRL, an uncertainty factor (UF) of 9 was applied, 3 for use of a minimal LOAEL, and 3 for human variability. The intermediate inhalation MRL of 0.02 ppm was based on a no-observed-adverse-effect level (NOAEL) of 10 ppm for respiratory effects in rats exposed to hydrogen sulfide for 6 hours/day, 7 days/week for 10 weeks. Olfactory neuron loss and basal cell hyperplasia in the olfactory epithelium of the nose were seen in rats exposed to 30 ppm and 80 ppm (Brennenman et al. Toxicol Pathol 2000, 28:326-33). To derive the MRL, a human equivalent concentration NOAEL was calculated and an UF of 30 was applied, 3 for animal to human extrapolation, and 10 for human variability. As hydrogen sulfide is a gas, inhalation is the major route of exposure. No federal air

quality standard presently exists for hydrogen sulfide. Health-based guidance values, such as MRLs, are useful for states and local municipalities when addressing community concerns regarding hydrogen sulfide emissions, for example, those from concentrated agricultural feeding operations.

**1484**

ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR HYDRAZINE (HZ), MONOMETHYLHYDRAZINE (MMH), AND DIMETHYLHYDRAZINE (DMH).

R. Young<sup>1</sup> and R. Thomas<sup>2</sup>. <sup>1</sup>ORNL, Oak Ridge, TN and <sup>2</sup>INTERCET, Ltd., McLean, VA.

AEGL values represent one-time exposures for increasingly severe effects with AEGL-1 being least and AEGL-3 being most severe. Hydrazines are highly reactive chemicals used in missile and rocket propellants and in chemical power sources. Their reactivity results in irritation and tissue damage upon exposure. AEGL-1 values for HZ (0.1 ppm) were developed based upon irritation. HZ AEGL-2 values (23 ppm, 16 ppm, 13 ppm, 3.1 ppm, and 1.6 ppm for 10-min, 30-min, 1-hr, 4-hr, and 8-hr, respectively) were based on nasal lesions in rats while AEGL-3 values (64 ppm, 45 ppm, 35 ppm, 8.9 ppm, and 4.4 ppm for 10-min, 30-min, 1-hr, 4-hr, and 8-hr, respectively) were based upon an estimated lethality threshold for rats. Insufficient data precluded the development of AEGL-1 values for MMH or DMH. AEGL-3 values for MMH (16 ppm, 5.5 ppm, 2.7 ppm, 0.68 ppm, and 0.34 ppm) were based upon an estimated lethality threshold for monkeys while AEGL-2 value were derived by a 3-fold reduction of the AEGL-3 values. AEGL-2 values for DMH were 18 ppm, 6 ppm, 3 ppm, 0.75 ppm, and 0.38 ppm using behavioral changes and muscle fasciculations in dogs as the critical effect. DMH AEGL-3 values (65 ppm, 22 ppm, 11 ppm, 2.7 ppm, and 1.4 ppm) were based upon a lethality threshold for dogs. The time-specific AEGLs for MMH and DMH were calculated using the equation,  $c^n \times t = k$ , where  $n$  of approximately 1 was empirically determined for both chemicals. In the absence of an empirically derived chemical-specific scaling exponent, temporal scaling for HZ used default values of  $n=3$  when extrapolating to shorter time points and  $n=1$  when extrapolating to longer time points. All AEGL values were developed using data-justified uncertainty factors. <sup>1</sup>Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the US Department of Energy under contract DEAC0500OR22725.

ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR 1, 1, 2-TETRAFLUOROETHANE.

S. S. Talmage<sup>1</sup>, G. Rusch<sup>2</sup> and H. T. Borges<sup>1</sup>. <sup>1</sup>Oak Ridge National Laboratory, Oak Ridge, TN and <sup>2</sup>Honeywell, Morristown, NJ.

AEGL values represent multiple guidance levels for rare exposures of increasingly severe effects, with AEGL-1 being least and AEGL-3 being most severe. AEGL values were developed for 1, 1, 2-tetrafluoroethane (HFC-134a), a colorless hydrofluorocarbon gas developed as a refrigerant replacement for ozone-depleting chlorofluorocarbons such as CFC-12. Due to its low water solubility and high vapor pressure, uptake is low, but rapid. Elimination is also rapid. Data for development of AEGL values were available from a clinical study and from laboratory studies with multiple species. As a consequence of its proposed use as an aerosol propellant for medicinal inhalers, clinical trials in patients with asthma and chronic obstructive pulmonary disease (COPD) have been performed. The AEGL-1 was based on a 1-hour concentration of 8000 ppm that caused no untoward effects in eight healthy human subjects. An intraspecies uncertainty factor (UF) of 1 was considered sufficient because no adverse effects were reported in therapy tests with sensitive populations (asthmatics and COPD patients) tested with metered dose inhalers. No time scaling was utilized as the clinical study showed that blood levels approached equilibrium after 55 minutes of exposure, and effects are determined by blood concentrations. The AEGL-2 was based on the no-effect concentration of 40,000 ppm for cardiac sensitization in dogs. The dog treated with epinephrine is considered a highly sensitive model for the cardiac effects that could be seen in humans. The levels of administered epinephrine represent an approximate 10-fold excess over the blood concentration that would be achieved endogenously in dogs or humans in highly stressful situations. Therefore, inter- and intraspecies UFs of 1 and 3 were applied. No time scaling was applied: cardiac sensitization is concentration-dependent; duration of exposure does not influence the concentration at which this effect occurs. The AEGL-3 was based on the same study in which 80,000 ppm induced cardiac toxicity in dogs. UFs and time scaling were the same as for the AEGL-2.

THE THERAPEUTIC EFFECTS OF LYOPHILIZED BLACK RASPBERRIES ON NMBA-INDUCED CARCINOGENESIS.

R. M. Aziz, R. Nines and G. D. Stoner. *Cancer Chemoprevention and Support*, The Ohio State University, Columbus, OH.

The incidence of squamous cell carcinoma (SCC) of the human esophagus has been linked to diets deficient in fruit and vegetables. Recently, we took a food based approach to prevention of esophageal SCC and found that administration of freeze-

dried strawberries and black raspberries, at concentrations of 5 and 10% in the diet, reduced esophageal tumors induced by the carcinogen, N-nitrosomethylbenzylamine (NMBA), by 40-60% in rats. In the present study, we determined if berries might also exhibit therapeutic effects against esophageal cancer. Six week-old male F344 rats were placed on AIN-76A diet and injected with 0.5 mg/kg NMBA once per week for 15 weeks. Four weeks later, when they had an average of 5 to 6 papillomas per esophagus, the rats were started on diets containing either 0, 5, 10, or 20% freeze-dried black raspberries. For several weeks after initiation of berry treatment, the survival of rats in berry-fed groups was higher than in rats fed control diet. After seven weeks of berry treatment, all surviving rats were sacrificed and esophageal tumor incidence, multiplicity and size determined. In animals fed 10% and 20% black raspberries, there were no significant differences in tumor incidence, multiplicity or size when compared to carcinogen controls. In contrast, rats fed 5% black raspberries had a significant ( $p<0.05$ ) reduction in tumor multiplicity when compared to carcinogen controls. These results suggest that freeze-dried black raspberries may have therapeutic value for the treatment of esophageal cancer. Studies are underway to confirm the therapeutic effect of berries on esophageal tumorigenesis.

EFFECTS OF DIETARY SELENIUM ON THE HEPATIC TUMOR PROMOTING ACTIVITIES OF PCBs.

D. N. Stemm<sup>1</sup>, L. W. Robertson<sup>3</sup>, J. C. Tharappel<sup>2</sup>, B. T. Spear<sup>4</sup>, H. J. Lehmler<sup>3</sup> and H. P. Glauert<sup>2</sup>. <sup>1</sup>Graduate Center for Toxicology, University of Kentucky, Lexington, KY, <sup>2</sup>Graduate Center for Nutritional Sciences, University of Kentucky, Lexington, KY, <sup>3</sup>School of Public Health, University of Iowa, Iowa, IA and <sup>4</sup>Department of Microbiology and Immunology, University of Kentucky, Lexington, KY.

Polychlorinated biphenyls (PCBs) are persistent organic pollutants that are tumor promoters in the liver. PCBs induce oxidative stress, which may influence carcinogenesis. Due to the antioxidant activities of selenium-dependent glutathione peroxidase and thioredoxin reductase, we hypothesized that selenium could inhibit the promoting activity of PCBs. We examined the effect of dietary selenium on the tumor promoting activities of two PCB congeners, 3, 3', 4, 4'-tetrachlorobiphenyl (PCB 77) and 2, 2', 4, 4', 5, 5'-hexachlorobiphenyl (PCB 153) using a 2-stage carcinogenesis model. An AIN-93 based purified diet containing 0.02 (low), 0.2 (adequate), or 2.0 (high) mg selenium/kg diet was fed to female rats starting ten days after administering a single dose of diethylnitrosamine (150 mg/kg). After being fed the experimental diets for 3 weeks, rats were injected i.p. with either PCB 77 or PCB 153 (300  $\mu$ mol/kg) every other week for 4 injections. Three days before euthanasia, the animals were implanted with osmotic pumps containing bromodeoxyuridine. Our results showed a significant increase in the number of placental glutathione S-transferase-positive foci in liver of animals that received PCB 77. In addition, the focal volume in the PCB 77 treated groups was markedly higher in the adequate selenium group compared with the low selenium group. The number of foci resulting from PCB 153 treatment was neither increased nor decreased; however, the focal volume was significantly increased in rats receiving adequate selenium compared with the low selenium group. Selenium did not affect cell proliferation in hepatocytes of the PCB treated groups. These findings indicate that selenium is not chemopreventive in the promotion of hepatic tumors by PCBs. **1488**

EFFECTS OF SELECTED DIETARY ANTIOXIDANT PHYTOCHEMICALS ON THE HEPATIC TUMOR PROMOTING ACTIVITY OF PCB-77.

J. C. Tharappel<sup>1</sup>, D. N. Stemm<sup>2</sup>, R. P. Bunaciu<sup>1</sup>, L. W. Robertson<sup>3</sup>, H. J. Lehmler<sup>3</sup>, B. T. Spear<sup>4</sup> and H. P. Glauert<sup>1</sup>. <sup>1</sup>Graduate Center for Nutritional Sciences, University of Kentucky, Lexington, KY, <sup>2</sup>Graduate Center for Toxicology, University of Kentucky, Lexington, KY, <sup>3</sup>School Of Public Health, University of Iowa, Iowa, IA and <sup>4</sup>Department of Microbiology and Immunology, University of Kentucky, Lexington, KY.

Polychlorinated biphenyls (PCBs) have complete carcinogenic and promoting activities in the liver, which may be brought about in part by the induction of oxidative stress. We examined the effects of several antioxidant phytochemicals on the tumor promoting activity of 3, 3', 4, 4'-tetrachlorobiphenyl (PCB-77). Female rats were first injected i.p. with DEN (150 mg/kg) and one week later the rats were fed an AIN-93 based purified diet or the same diet containing ellagic acid (0.4%), beta-carotene (0.5%), curcumin (0.5%), N-acetyl cysteine (NAC) (1.0%), CoQ10 (2.0%), resveratrol (0.005%), lycopene (10% as LycoVit [BASF], which contains 10% lycopene), or epigallocatechin-3-gallate (EGCG; a 1% green tea extract containing 16.5% EGCG and 33.4% total catechins). Rats were fed the diets for the remainder of the study. After 3 weeks, 2/3 of the control and all of the antioxidant diet-fed rats were injected i.p. with PCB-77 (300  $\mu$ mol/kg) every other week for four injections. All rats were euthanized 10 days after the last PCB injection. The rats that received PCB-77 alone showed a large increase in placental glutathione S-transferase (PGST)-positive foci in the liver. Lycopene decreased the number of

foci, while curcumin decreased the size of the foci. Beta-carotene decreased both the number and size of the foci. In contrast Ellagic acid increased both the number and size of the foci. All the other phytochemicals showed only minor effects. Compared with the PCB-77 group, CoQ10 increased cell proliferation in PGST-negative hepatocytes, whereas the other antioxidants had no effect. These findings show that some antioxidant phytochemicals can influence the promoting activity of PCB-77. (Supported by ES07380)

CHANGES IN DRUG METABOLISM AS A POTENTIAL MECHANISM FOR THE SYNERGISTIC INDUCTION OF APOPTOSIS IN MDA-MB-231 CELLS BY EGCG AND 4-OH TAMOXIFEN.

E. C. Stuart, J. P. Wilson, B. J. Bray and R. J. Rosengren. *Pharmacology & Toxicology, University of Otago, Dunedin, New Zealand.*

We have previously demonstrated that epigallocatechin gallate (EGCG) and 4-OH tamoxifen (4-OHT) are synergistically cytotoxic toward MDA-MB-231 human breast cancer cells, an ER $\alpha$  negative cell line. The current study was designed to elucidate the mechanisms responsible for this synergistic effect. To determine the role of apoptosis, MDA-MB-231 cells were treated with EGCG (25  $\mu$ M), 4-OH tamoxifen (0.7  $\mu$ M) or a combination of the two for 12, 24, 36 or 48 hours. DMSO (0.001%) served as the vehicle control. Cells were visually analyzed for apoptosis using acridine orange / ethidium bromide staining and this was confirmed by measuring caspase-3 activity via the cleavage of the DEVD moiety from DEVD-pNA. The results demonstrated that at 24 hr the EGCG + 4-OHT group showed condensed chromatin, while this did not occur until 36 hr in the EGCG group and 48 hr in the 4-OHT group. Caspase-3 activity confirmed the early occurrence of apoptosis in the EGCG + 4-OHT group. A potential mechanism for this effect may involve changes in the glucuronidation and/or methylation rate of EGCG. Our evidence that glucuronidation is likely to be of significance is demonstrated by the fact that the cytotoxicity of EGCG toward human breast cancer cell lines (MCF-7, T47D, MDA-MB-231), as determined by the sulforhodamine B assay, is inversely proportional to the glucuronidation capacity of the cell line ( $r^2 = 0.98$ ). We also have evidence that EGCG may form an active methylated metabolite similar to 2-methoxyestradiol. Specifically, the cytotoxicity of EGCG (25  $\mu$ M) toward MDA-MB-231 cells was reduced 14  $\pm$  1% when the cells were also incubated with the catechol O-methyltransferase (COMT) inhibitor pyrogallol (1  $\mu$ M). This indicates that the cytotoxicity of EGCG is increased when COMT is active. In conclusion, our results demonstrate that EGCG and 4-OH tamoxifen synergistically induce apoptosis in MDA-MB-231 cells and the mechanism for this effect is likely to involve tamoxifen-mediated changes in the metabolism of EGCG.

PHYTOESTROGENS AND DIETARY FATTY ACIDS INFLUENCE SPONTANEOUS MAMMARY TUMOR DEVELOPMENT IN IN TG.NK (MMTV/C-NEU) MICE.

M. Luijten<sup>1</sup>, A. Verhoeef<sup>1</sup>, J. Dormans<sup>1</sup>, D. Beems<sup>1</sup>, H. Van Kranen<sup>2</sup>, N. Nagelkerke<sup>1</sup>, H. Adlercreutz<sup>2</sup> and A. Piersma.<sup>1</sup> *National Institute for Public Health and the Environment, Bilthoven, Netherlands and<sup>2</sup> Folkhalsan Research Center, Helsinki, Finland.* Sponsor: J. Vos.

Breast cancer is the most frequent tumor type in women worldwide. Epidemiological studies on soy consumption during adulthood and breast cancer risk show either no association or a decreasing risk with increasing soy intake. In addition, high soy consumption during childhood or adolescence has been associated with a reduced breast cancer risk. The timing of phytoestrogen exposure within the life cycle may be critical. Isoflavones have been postulated as breast cancer protective constituents in soy. To investigate this hypothesis, we studied the effect of isoflavones in a high-fat diet on mammary tumor development using female heterozygous MMTV/c-neu mice. On regular chow these mice spontaneously develop mammary tumors at the age of about 6 months. Three different exposure protocols were used, either from conception to weaning, or from weaning onwards, or lifelong. These exposures were conducted on background diets enriched in either n-6 fatty acids or n-3 fatty acids. Mice fed n-3 rich diets appeared to develop mammary tumors 15 weeks later than mice fed the n-6 rich diet. Apart from the fatty acid content of the diets this may be due to the lower food consumption in the former group. In the mice fed the diets enriched in n-3 fatty acids, no significant effect of the isoflavones on mammary tumor development was observed. In the mice fed the diets enriched in n-6 fatty acids, no significant difference in mammary tumor multiplicity or mass at necropsy was found between any of the exposure protocols. However, in this diet group, a significant decrease of tumor incidence and a delay in tumor onset was observed in mice exposed to isoflavones from weaning onwards. Therefore, the effects of phytoestrogen exposure on tumor formation appear to depend on the composition of the background diet.

INFLUENCE OF METHOXYCHLOR EXPOSURE ON BREAST CANCER INCIDENCE IN FEMALE SPRAGUE-DAWLEY RATS.

S. M. Bandiera, J. K. Tai, E. G. Hrycay and T. K. Chang. *Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada.*

Endocrine disrupting chemicals may contribute to human breast cancer by altering expression of enzymes involved in estrogen biosynthesis and metabolism. Our objective was to examine the effects of pubertal exposure, or combined *in utero* and neonatal exposure, to an endocrine disrupting chemical, methoxychlor, on spontaneous and 7, 12-dimethylbenz[a]anthracene (DMBA)-induced mammary tumor formation in Sprague-Dawley rats. To achieve *in utero* exposure, methoxychlor was given by gavage, once daily, to pregnant rats at dosages of 5 (n=24) or 50 (n=24) mg/kg, starting at 3 days before mating until 7 days after parturition. The female offspring were monitored for the development of spontaneous mammary tumors and were terminated at 160 days of age. The dams were also monitored and killed at 117 days after parturition. In a second study, methoxychlor (50 mg/kg, n=41) or corn oil (n=41) was given by gavage, once daily, to pubertal rats for 16 consecutive days. At 60 days of age, half of the treated rats received a single dose of 20 mg of DMBA and the rest were treated with vehicle. The corn oil-treated rats also received either DMBA or vehicle. Rats were sacrificed at 160 days of age. No spontaneous mammary tumors were found in rats that received only methoxychlor during puberty or were exposed both *in utero* and neonatally. No tumors were found in control rats. With combined methoxychlor and DMBA treatment, 70% of the rats treated during puberty developed mammary tumors with a mean value of 2.6 tumors/tumor-bearing rat and a mean mass of 3.3 g/tumor. The earliest tumor was palpable on the 5th week after DMBA administration. For rats treated with corn oil and DMBA, the tumor incidence was 68% with a mean value of 1.8 tumors/rat and a mean mass of 1.7 g/tumor. The first tumor was observed on the 7th week after DMBA treatment. Histology analysis indicated that methoxychlor exposure induced mammary gland differentiation and increased the size and number of lobuloalveoli. Studies to measure CYP enzyme expression in mammary tissue are in progress.

BREAST CANCER CHEMOPREVENTION WITH THE POLYPHENOL RESVERATROL.

T. G. Whittsett and C. A. Lamartiniere. *Toxicology, University of Alabama at Birmingham, Birmingham, AL.*

Even with the advent of new and aggressive therapeutics, breast cancer remains a destructive disease and a leading killer among cancers. In the US alone, there are more than 215, 000 new cases expected this year. There is, and should be, a concerted effort to prevent breast cancer. One polyphenol that has received much attention for health benefits is resveratrol, a polyphenolic phytoalexin found in red grapes (red wine). We have investigated the chemopreventive properties of resveratrol using the dimethylbenz(a)anthracene (DMBA) model for mammary carcinoma in the female Sprague-Dawley rat. Dietary administration of pure resveratrol (1g/kg AIN-76A diet) was provided, starting at parturition. Control animals were fed the phytoestrogen-free diet, AIN-76A. This dose of resveratrol resulted in a serum concentration of 2 +/- 0.64  $\mu$ M. With at least 30 animals per group, tumor multiplicity, and latency were observed. Rats exposed to resveratrol via the diet showed a decrease in tumor multiplicity and had a longer latency as compared to control animals. Resveratrol in the diet resulted in no significant effect on body and uterine weights in 21 and 50 day old rats. In the uteri of 50 day old rats treated with resveratrol, we saw a decrease in protein levels of the steroid receptor coactivators: SRC-1, GRIP-1, and AIB1. While these coactivators are reported to increase the transcriptional activity of steroid receptors including estrogen, progesterone, and androgen receptors, resveratrol may attenuate sex steroid action by down-regulating their concentrations. The elucidation of the mechanisms for the preventive effects that we observe following polyphenol treatment will hopefully pave the way for clinical trials and the prevention of breast cancer. (Supported by NIH NCI P20 CA93753-02 and DOD DAMD17-00-1-0119).

**1493**

RESVERATROL ACTION ON STEROID AND GROWTH FACTOR SIGNALING IN TRAMP MICE.

C. E. Harper, B. B. Patel, J. Wang and C. A. Lamartiniere. *Toxicology, University of Alabama at Birmingham, Birmingham, AL.*

Prostate cancer is the most frequently diagnosed cancer in American men and is the second leading cause of death among men in the United States. Resveratrol, a natural polyphenolic phytoalexin, is abundantly present in peanuts, root extracts, grapes, and subsequently red wine. It has previously been shown that resveratrol inhibits the carcinogenic process at the initiation, promotion, and progression stages in cancer cells. We hypothesized that resveratrol will exert a chemopreventive effect via regulation of sex steroid and growth factor pathways. In the current study, five

week old C57BL/6 TRAMP (Transgenic Adenocarcinoma Mouse Prostate) offspring were fed AIN-76A diet supplemented with 625 mg resveratrol/kg diet, starting at 5 weeks of age. Controls received the phytoestrogen free diet, AIN 76A. Resveratrol did not significantly alter body and prostate weights or serum testosterone and estrogen concentrations in 12 and 28 week old mice. Dorsolateral prostates were dissected from 12 week old mice, and Western blot analyses or ELISA were performed to evaluate sex steroid and growth factor signaling. In the dorsolateral prostate, resveratrol significantly decreased insulin-like growth factor-1 (IGF-1) and estrogen receptor beta (ER-beta) and significantly increased androgen receptor (AR) and insulin-like growth factor receptor 1 (IGF-R1). ER-alpha and IGF-binding protein-3 (IGF-BP3) were not altered in resveratrol treated mice. The decrease in the potent growth factor, IGF-1, and the increase in the prostate tumor suppressor, ER-beta, may provide a biochemical basis for resveratrol suppressing prostate cancer without significant toxicity. (Supported by DOD DAMD PC 17-03-1-0153)

**1494** SUPPRESSION OF MMP EXPRESSION AND INVASION OF HUMAN CERVICAL CANCER CELL LINES HEA AND DOTC2 4510 BY NUTRIENTS.

M. Roomi, V. Ivanov, A. Niedzwiecki and M. Rath. *Cancer Division, Matthias Rath Research, Santa Clara, CA.*

**Objective:** Cervical cancer is the seventh most common cancer worldwide and the second most common cancer in women. This prompted us to investigate the anti-tumor effect of a unique nutrient formulation (NM) containing lysine, proline, arginine, ascorbic acid, and epigallocatechin gallate on human cervical cancer cells Hela and DoTc2 4510 by measuring: cell proliferation, modulation of MMP-2 and MMP-9 expression, and cancer cell invasive potential. **Materials and Methods:** Human cervical cancer cells Hela and DoTc2 4510 (ATCC) were grown in DME supplemented with 10% FBS, penicillin (100 U/ml) and streptomycin (100 mg/ml) in 24-well tissue culture plates. At near confluence, the cells were treated with the nutrient mixture (NM) dissolved in media and tested at 0, 10, 100, 500, and 1000 mcg/ml in triplicate at each dose. Cells were also treated with phorbol myristate (PMA) 200 ng/ml. Cell proliferation was evaluated by MTT assay, MMP expression by gelatinase zymography, and invasion through Matrigel. **Results:** NM showed significant antiproliferative effect on both human cervical cell lines. Zymography demonstrated expression of MMP-2 by untreated cervical Hela cells and induced MMP-9 by PMA -treated cells. NM inhibited Hela expression of MMP-2 and MMP-9 in a dose-dependent fashion, with virtual total inhibition of MMP-2 at 1000 mcg/ml and MMP-9 at 500 mcg/ml. Untreated DoTc2 4510 cells demonstrated MMP-9 expression, enhanced with PMA treatment, and inhibited by in a dose-dependent fashion with virtual inhibition at 500 mcg/ml. NM significantly reduced Matrigel invasion of Hela cells in a dose-dependent fashion, with 76% inhibition at 100 mcg/ml and 100% at 500 mcg/ml NM ( $p<0.0001$ ). NM inhibited invasion of DoTc2 4510 cells by 97% at 500 mcg/ml and 100% at 1000 mcg/ml ( $p<0.0001$ ). **Conclusion:** Our results suggest NM has great potential for therapeutic use in the treatment of cervical cancer, by inhibiting critical steps in cancer development and spread, such as cell growth, MMP expression and invasion.

**1495** ALTERED TRANSCRIPTIONAL REGULATION OF GENES INVOLVED IN AFLATOXIN GENOTOXICITY BY SULFORAPHANE (SFN) AND DIINDOLYLMETHANE (DIM).

K. Gross-Steinemeyer<sup>1</sup>, P. L. Stapleton<sup>1</sup>, F. Liu<sup>1</sup>, J. H. Tracy<sup>1</sup>, T. K. Bammmer<sup>1</sup>, S. C. Strom<sup>2</sup> and D. L. Eaton<sup>1</sup>. <sup>1</sup>*Env. Occup. Health Sciences, University Washington, Seattle, WA* and <sup>2</sup>*Pathology, University Pittsburgh, Pittsburgh, PA.*

Previous work from our laboratory has demonstrated that SFN provides substantial protection against aflatoxin B1 (AFB) genotoxicity, whereas DIM significantly increased AFB-DNA adduct levels in human hepatocytes. We determined the effects of SFN and DIM on mRNA expression of genes involved in biotransformation of AFB in human hepatocyte cultures from nine donors following 48 h incubations with 10 or 50  $\mu$ M SFN or DIM. DIM caused a 625- and 90-fold up-regulation of cytochrome P450 (CYP) 1A1 and CYP1A2 mRNA, respectively, at 50  $\mu$ M DIM, and a significant down-regulation of glutathione S-transferase (GST)M1 mRNA. SFN showed a dramatic and dose-dependent down-regulation of CYP3A4 mRNA (31% and 87% decrease at 10 and 50  $\mu$ M SFN) and, to a lesser extent, of CYP1A2 mRNA. SFN also decreased both GSTT1 and GSTM1 mRNA, but had no effect on hGSTA1. To distinguish between treatment effects on transcription vs. direct effects on enzyme activity, we compared changes in AFB-DNA adduct formation in human hepatocytes under the following conditions: (1) 48h SFN or DIM, then 6h AFB, (2) 48h SFN or DIM, then 6h AFB + SFN or DIM and (3) 6h AFB + SFN or DIM. The results demonstrated that effects on gene expression, but not catalytic activity, are responsible for the observed effects on AFB-DNA adduct formation for

both SFN and DIM. Surprisingly, the data indicated that the transcriptional repression of genes involved in AFB bioactivation but not induction of detoxification pathways contributed to the protective effects of SFN. The increase in AFB-DNA damage following DIM treatment may be explained through its substantial induction of CYP1A2 and/or its down-regulation of GSTM1. The increase in DNA damage by DIM raises potential safety risks for dietary supplements of DIM and its precursor indole-3-carbinol; the apparent down-regulation of CYP3A4 by SFN may have important implications for drug interactions (Supported by NIH grants ES05780 and P30-ES07033).

**1496**

MICROARRAY ANALYSIS OF LPS AND NAC-INDUCED GENE EXPRESSION AND RESULTANT SYNERGISM, POTENTIATION, AND ANTAGONISM IN WEHI-231 B LYMPHOMA CELLS.

K. R. Martin. *Nutritional Sciences, Penn State University, University Park, PA.*

Accumulating evidence suggests that dietary antioxidants can exhibit divergent effects in carcinogenesis possibly through changes in gene expression. In pilot experiments, we selected N-acetyl-L-cysteine (NAC) as a well-recognized antioxidant to test the effect on mitogen-stimulated B lymphoma cells. WEHI-231 murine B cells were cultured with media alone or containing NAC (1 mg/mL), lipopolysaccharide (LPS; 0.1 mg/mL), or both for 72 h to determine independent or combinatorial effects on gene expression using microarray analysis. LPS independently induced the expression of 16 genes including oxyR, Cebpd, Gadd45, Jun, Trafl, etc. NAC inclusion antagonized expression of five genes including Defcr, Krtap6-1, Magea8, Etsrp71, and oxyR. NAC independently induced 8 genes including Hsd3b6, Pit1, Vdr, Tph, etc., and co-incubation with LPS antagonized expression of 4 genes (Entpd5, Akp2, Cbln1, and Sitpec). Twelve genes were not expressed after either LPS or NAC alone but upon co-incubation displayed increased expression of 5 to 20-fold. Conversely, we noted independent LPS and NAC-induced gene expression each of which was antagonized by co-incubation. We observed synergistic interactions of NAC on LPS-stimulated expression of 3 genes (Pkib, Trafl and Jun) and of LPS on NAC-induced expression of two genes (Tph and Vdr). Collectively, we observed independent mitogen and NAC-stimulated gene expression, as well as synergism, potentiation, and antagonism upon co-incubation in a B lymphoma cell line. This supports that a dietary antioxidant can exhibit independent and diverse, interactive effects on gene expression in cancer cells (Supported by an Innovative Biotechnology Research Fund Grant from the Huck Biotechnology Institute, PSU)

**1497**

MODULATION OF ADULT RAT BENZO(A)PYRENE (BAP) METABOLISM AND DNA ADDUCT CONCENTRATIONS BY NEONATAL RESVERATROL (RVT) EXPOSURE.

A. RAMESH. *Pharmacology, Meharry Medical College, Nashville, TN.*

This study seeks to elucidate the role of resveratrol (RVT), a phytoestrogen on BaP metabolism in rat. Offspring of F-344 rats were neonatally treated on days 2, 4, and 6 postpartum with subcutaneous injections of RVT (10  $\mu$ mol/kg). Ten weeks after birth, the adult male rats were challenged with <sup>3</sup>H BaP (10  $\mu$ mol/kg) orally, and sacrificed 2 hours after BaP exposure. Prostate, testis, lung, liver, urine and feces samples were collected and extracted using a mixture of water, methanol and chloroform. The extracts were analyzed by reverse phase HPLC. DNA was isolated from the tissues. The DNA samples were digested with spleen phosphodiesterase, micrococcal nuclease and subjected to <sup>32</sup>P-postlabeling. The labeled adducts were separated by TLC and quantified by scintillation counting. The concentrations of BaP organic metabolites in RVT rats were lower compared to controls (vehicle-treated rats). The concentrations of aqueous metabolites were significantly increased in RVT-treated rats. In the organic phase, 3-OH BaP, 9-OH BaP, 4,5-dihydrodiol, 7, 8-dihydrodiol, 9, 10-dihydrodiol and 3, 6-dione were the major metabolites. In the aqueous phase, OH-glucuronides, OH-sulfates, 7, 8-diol GSH, 9, 10-diol GSH, 7, 8-epoxide GSH and 9, 10-epoxide GSH were the major metabolites. The balance between toxication and detoxication processes represented, respectively, by the 7, 8-dihydrodiol 9, 10-epoxide (the reactive metabolite of BaP) and 3(OH) BaP (the detoxication product of BaP) metabolite ratio in organs and body fluids was decreased by 40% in all the samples of RVT-treated rats. The BaP-DNA adducts concentrations showed a trend that mirrored the concentrations of BaP 7, 8-dihydrodiols in the organs studied with low concentrations of DNA adducts in RVT-treated rats compared to controls. Collectively these results suggest that RVT is capable of modulating the metabolic pathway of BaP towards detoxication thereby preventing the manifestation of toxicity (supported by NIGMS-SCORE grant #2S06GM08037-32, NIEHS grant #1R15ES12168-01 and NCRR-RCMI grant #G12RR03032).

EFFECT OF DIETARY FAT ON FLUORANTHENE (FLA) METABOLISM AND DNA ADDUCT FORMATION IN F-344 RATS.

S. WALKER, M. MATHIS, A. ADDAI and A. RAMESH. *Pharmacology, Meharry Medical College, Nashville, TN.*

This study was aimed at measuring the effect of dietary fat on metabolism and DNA adducts formation of fluoranthene (FLA), a polycyclic aromatic hydrocarbon compound, subsequent to acute oral exposure. Ten week-old F-344 male rats were given 50 µg/kg FLA by oral gavage using test meals comprising peanut, corn, and coconut oils as representatives of monounsaturated, polyunsaturated and saturated dietary fats respectively. Control animals were either exposed to vehicle only or unexposed. After exposure for 2 hours, rats were sacrificed. Trunk blood, urine, feces, stomach, intestine, liver, lung, and testis samples were collected. Samples were subjected to liquid-liquid extraction using water, methanol and chloroform. The extracts were analyzed for FLA /metabolites by reverse-phase HPLC with fluorescence detection. DNA was isolated from the tissues of interest. The DNA samples were digested with spleen phosphodiesterase, micrococcal nuclease and subjected to <sup>32</sup>P-postlabeling. The labeled adducts were separated by TLC and quantified by scintillation counting. The FLA metabolite, and DNA adduct concentrations varied with the type of dietary fat intake. For example FLA dosed in test meal containing saturated fat produced the greatest quantity of metabolites and adducts followed by test meals containing polyunsaturated and monounsaturated fat. The FLA 2, 3-diol is the predominant metabolite followed by i) trans-2, 3-dihydroxy-1, 1Ob-epoxy-1, 2, 3, 10b tetrahydro FLA (2, 3 D FLA), ii) FLA-2, 3-dione, iii) 3-hydroxy FLA and iv) 8-hydroxy FLA. Our studies indicate dietary fat type influences the quantitative and qualitative distribution of FLA metabolites in plasma and target tissues. The FLA-DNA adduct concentrations in target tissues were also reflective of the persistence of reactive metabolites of FLA in these tissues. Collectively, our findings suggest that ingested lipid type modulate FLA metabolism and DNA damage in exposed tissues (supported by NIEHS grant #1R15ES12168-01, NIGMS-SCORE grant #2S06GM08037-32, RISE grant #2R25GM 59994, and NCRR-RCMI grant #G12RR03032).

TRANSPLACENTAL GENOTOXICITY OF DIBENZO[A, L]PYRENE (DBP) AND THE EFFECT OF INDOLE -3-CARBINOL (I3C) IN THE MATERNAL DIET.

Z. YU<sup>1, 2</sup>, B. Mahadevan<sup>1</sup>, L. K. Siddens<sup>1, 2</sup>, D. J. Albershardt<sup>1</sup>, S. K. Krueger<sup>1</sup>, M. Louderback<sup>1</sup>, W. M. Baird<sup>1</sup> and D. E. Williams<sup>1, 2, 3</sup>. <sup>1</sup>*Environmental and Molecular Toxicity, Oregon State University, Corvallis, OR*, <sup>2</sup>*Linus Pauling Institute, Oregon State University, Corvallis, OR* and <sup>3</sup>*Marine and Freshwater Biomedical Sciences Center, Oregon State University, Corvallis, OR*.

The fetus is a sensitive target for chemically induced toxicity including carcinogenesis. The polycyclic aromatic hydrocarbons (PAHs) are known mouse transplacental carcinogens and DBP has been shown to be the most potent of the PAHs in most models, but, as yet, is untested as a transplacental carcinogen. In our study, pregnant mice were administered DBP by gavage (15 mg/Kg) on gestation day 17. DBP-DNA adducts, in putative maternal and fetal target tissues, were analyzed by 33P postlabeling and HPLC from 6 hr to 6 days after DBP dosing. Some pregnant mice were administered 2000 ppm I3C in the diet, beginning at gestation day 9. In a separate study, a single gavage of 14C-I3C (1 mCi/Kg body weight), showed the distribution of I3C in most maternal and fetal tissues peaked at 8 hr. The genotoxicity experiment was designed to examine the effect of the aryl hydrocarbon receptor (AHR) on the maternal and fetal response. Total DNA adducts were highest at day 2 in both maternal and fetal lung. Although similar HPLC adduct profiles were obtained, the fetal AHR genotype affected total binding. I3C in the maternal diet induced the expression, in maternal and fetal liver, of genes (microarray) and proteins (western blot) associated with phase I and phase II metabolism of DBP and this may be a mechanism for the I3C-dependent decrease in DBP-DNA adduction. (Supported by NIH grants CA90890, ES00210 and CA28825)

STUDY OF THE INHIBITING EFFECT OF DIETARY HYDROQUINONE ON ACETYLAMINO-FLUORENE INDUCTION OF INITIATION OF RAT LIVER CARCINOGENESIS.

M. J. Iatropoulos, A. M. Jeffrey, J. Duan and G. M. Williams. *New York Medical College, Valhalla, NY.*

Monocyclic phenolics (MPs) have been shown to inhibit the initiation of rat liver carcinogenesis induced by the genotoxic hepatocarcinogen 2-acetylaminofluorene (AAF). Hydroquinone (HQ), the simplest of the MPs, was studied for its ability at low dietary concentrations to inhibit the initiating effects of AAF in the rat liver. Six groups of male F344 rats were used. HQ was given daily ad libitum either at 0.05% (?25 mg/kg bw/d) or 0.2% (? 100 mg/kg bw/d) for 13 weeks, starting one week be-

fore AAF administration, and to 2 groups not receiving AAF. AAF was given intragastrically 3 times a week for 12 weeks at 3 mg/kg bw/time in 0.5% carboxymethyl cellulose and to an untreated group and the two groups receiving HQ. Weekly body weight gain over time, terminal body weights and absolute (mg) and relative liver/body weights were measured. At 13 weeks, DNA adducts (32P-postlabeling), cell proliferation (PCNA immunohistochemistry) and preneoplastic hepatocellular altered foci (HAF) (GST-P immunohistochemistry) were measured. The 2 HQ groups showed body weight gains comparable to controls for the duration of the study, whereas the AAF and HQ/AAF groups had a tendency to reductions in body weight gain. The same pattern was evident in the terminal body weights. These body weight differences were not significant. The absolute and relative liver weight changes showed no significant changes. AAF produced liver DNA adducts, and HQ at both 25 and 100 mg/kg/day significantly reduced adduct levels, by more than 45%. AAF exposure yielded about a 50% increase in hepatocellular proliferation and both HQ exposures significantly reduced the AAF-induced increases in proliferation. Likewise, AAF-induced GST-P+ HAF and these were significantly decreased by both doses of HQ. HQ by itself did not produce adducts and did not affect other parameters. Thus, under the conditions of this experiment, HQ at both 25 and 100 mg/kg/day given in the diet for 13 weeks did not produce any toxicity, but diminished AAF-induced effects in liver.

β-SITOSTEROL IN PSYLLIUM SEED HUSK RESTORES GAP JUNCTIONAL INTERCELLULAR COMMUNICATION IN H4-RAS TRANSFECTED RAT LIVER EPITHELIAL CELLS.

Y. Nakamura<sup>1</sup>, I. Hiroki<sup>1</sup>, N. Yoshikawa<sup>1</sup>, K. Sato<sup>1</sup>, K. Ohtsuki<sup>1</sup>, C. Chang<sup>2</sup>, B. L. Upham<sup>2</sup> and J. E. Trosko<sup>2</sup>. <sup>1</sup>*Food Science, Kyoto Pref. University, Kyoto, Japan* and <sup>2</sup>*NFSTC, Michigan State University, Lansing, MI*.

Psyllium (*Plantago ovata* Forsk; desert Indian wheat) is a common source of soluble fiber derived from the husk of the plant *Plantago ovata*, which is used for colon care with its moderate laxative effect. We previously determined that psyllium seed husk powder restores gap junctional intercellular communication (GJIC) in a tumorigenic WB-F344 rat liver epithelial cell line transfected with the *v-Ha-ras* oncogene (WBras), but not on WB cell lines, transfected with the *src*, *neu* and *myc* oncogenes. We have purified the active compound from the husk with an ethanol extract; HP-20 hydrophobic chromatography; silica gel adsorption column chromatography and TLC. This purified fraction, restores GJIC in WBrs cells, as determined by the scrape loading dye transfer assay. The active compound was identified to be β-sitosterol on the basis of gas chromatographic retention time and EI-MS spectrum of authentic β-sitosterol. β-sitosterol restored GJIC in WBrs cells at the dose of 2.4 µM. In addition, stigmasterol also had some activity to restore GJIC, but the activity shown needed a concentration of 3.6 µM. As determined by Western blot analysis, β-sitosterol and stigmasterol increased the level of connexin43 protein and its active-, phosphorylated, form that correlates with the restoration of GJIC in GJIC-deficient, tumorigenic WBrs cells. The psyllium seed husk has been widely used as a supplement to affect colon care, due to its high fiber content water-insoluble and -soluble dietary fiber. The present study finds another health-promoting ingredient, such as phytosterols (β-sitosterol and stigmasterol), showing an ability to restore GJIC in mutated *Ha-ras* oncogene transformed liver epithelial cells.

THE EFFECTS OF CO-ADMINISTRATION OF ANTIOXIDANTS AND DIMETHYLARSINIC ACID (DMA) ON THE BLADDER EPITHELIUM OF FEMALE F344 RATS.

S. M. Cohen<sup>1</sup>, L. L. Arnold<sup>1</sup>, M. Cano<sup>1</sup> and M. Wei<sup>2</sup>. <sup>1</sup>*Path/Micro, University of Nebraska Medical Center, Omaha, NE* and <sup>2</sup>*Pathology, Osaka City University Medical School, Osaka, Japan*.

Oxidative stress has been increasingly recognized as a possible mechanism in the toxicity and carcinogenicity of various chemicals, including arsenic. Therefore, treatment with antioxidants may afford a protective effect against arsenic-induced cytotoxicity and carcinogenesis. DMA has been shown to be a bladder carcinogen in rats when administered at high doses (100 ppm) in the diet or in the drinking water. The objective of this study was to evaluate the effects of co-administration of antioxidants with DMA on the rat urinary bladder epithelium *in vivo*. In a 10-week study, we co-administered 100 ppm DMA in the diet with 1000 ppm melatonin or 10, 000 ppm sodium ascorbate (NaAsc, the sodium salt of vitamin C) also in the diet or with 0.4 mg/kg N-acetylcysteine (NAC) in the drinking water to female F344 rats. Effects on the bladder epithelium were determined by light microscopy and BrdU labeling index. Mild simple hyperplasia was found in all DMA-treated groups, in 1 of 10 rats treated with melatonin alone, and 3 of 10 rats treated with NAC alone. There was no significant difference in the incidence of simple hyperplasia among the groups. The BrdU labeling index was significantly increased in all DMA-treated groups compared to the control group. Co-administration of NaAsc

significantly decreased the BrdU labeling index compared to the group administered DMA alone. Melatonin and NAC had no effects on the BrdU labeling index when co-administered with DMA. These results suggest that oxidative stress may in part be involved in DMA-induced rat bladder toxicity and proliferation, and therefore, vitamin C may afford inhibitory effects in DMA-induced bladder carcinogenesis in rats.

RAPID INDUCTION OF COLORECTAL TUMORS IN RATS INITIATED WITH 1, 2-DIMETHYLHYDRAZINE FOLLOWED BY DEXTRAN SODIUM SULFATE TREATMENT - POSSIBLE APPLICATION FOR A NEW MEDIUM-TERM RAT COLON BIOASSAY.

T. Imai, J. Onose, M. Hasumura, Y. Cho and M. Hirose. *Division of Pathology, National Institute of Health Sciences, Tokyo, Japan.* Sponsor: M. Ema.

To establish a rapid bioassay system with neoplastic end-points for detection of colorectal carcinogenesis modifiers, we evaluated the effects of dextran sodium sulfate (DSS) treatment on the different stages of carcinogenesis in rats initiated with 1, 2-dimethylhydrazine (DMH). F344 male rats were given three subcutaneous injections of DMH (40 mg/kg body weight) in a week, and were administered drinking water containing 1.0% DSS ad libitum either during or after the initiation period for a week, or both during and after initiation periods for 2 weeks. At week 10, the incidences and multiplicities of dysplastic foci/adenomas (Ad)/adenocarcinomas (Ca) were highest in rats treated with DSS after DMH-initiation period. At week 26, the incidences of Ca and their multiplicities were also highest in this group. In the next study, we examined ability of this model to detect modifiers of colon carcinogenesis. Groups of ten or fifteen rats were given the regimen of DMH and DSS treatment followed by free access to basal diet alone, basal diet containing 0.04% nimesulide or 2% lactoferrin as known inhibitors, 0.3% deoxycholic acid (DCA) as a promoter or 1.5% 1-hydroxyanthraquinone (1-HA) as a carcinogen were supplied for 7 or 17 weeks. At week 10, the incidence and multiplicity of combined Ad and Ca were decreased ( $p<0.05$  or 0.01) by nimesulide and lactoferrin, and values for Ad were increased ( $p<0.01$ ) in the 1-HA group. There were no clear changes in these parameters in the DCA group. At week 20, multiplicity and volume of the tumors were decreased ( $p<0.01$  or 0.05) in the nimesulide group, but without effect in lactoferrin group. Multiplicity and volume of tumors were increased ( $p<0.01$ ) in 1-HA group and a similar tendency ( $p=0.08$ ) was apparent with DCA. It is concluded that this medium-term bioassay system possibly offers a useful tool for detection of colorectal carcinogenesis modifiers within 10-20 weeks.

LACK OF CARCINOGENIC EFFECTS IN F-344 RATS FED BIS(2-ETHYLHEXYL)-1, 4-BENZENEDICARBOXYLATE (DEHT).

L. E. Navarro<sup>1</sup>, K. M. Ruble<sup>1</sup>, J. A. Deyo<sup>1</sup> and R. M. David<sup>2</sup>. <sup>1</sup>*Eastman Chemical Company, Kingsport, TN* and <sup>2</sup>*Eastman Kodak Company, Rochester, NY*.

A carcinogenicity study was conducted in F-344 rats to validate the long-term safety of DEHT, a new plasticizer, with potential for human exposure. Groups of 100 animals (50 males/50 females) were exposed to 0, 1500, 6000, and 12000 ppm DEHT in the diet for 104 weeks. The overall average achieved dosages were 79, 324 and 666 mg/kg/day for males and 102, 418 and 901 mg/kg/day for females. Bodyweight gain was significantly low throughout the treatment period, when compared to the controls, for both sexes receiving 12000 ppm. There were no effects on food consumption. There were no statistically significant differences in percent survival among any of the groups. Hematology evaluations did not show any toxicologically significant differences. A few blood chemistry values were different than controls for high dose animals with no obvious toxicological significance. Relative liver and kidney weights of high-dose females were slightly higher than controls, but males were not affected. A number of other inter-group differences attained statistical significance, when compared to controls, but these were not considered to be toxicologically significant. For animals killed after 104 weeks of treatment, there was a high incidence of opaque eyes for high dose females, but not males. Non-neoplastic findings in high dose females compared with controls included trends such as a decreased incidence of chronic progressive nephropathy, an increased incidence of loss of the outer nuclear layer of the retina in the eyes, and an increase in prominent eosinophilic inclusions in the nasal turbinates; in high dose males a decreased incidence of periportal hepatocyte vacuolation was detected; and a decreased incidence of mineralization of the papillary/pelvic epithelium of the kidney was recorded in both sexes receiving 6000 or 12000 ppm. There was no evidence of liver tumors, pancreatic tumors, or any other tumor type associated with DEHT treatment which is in contrast to results observed in similar studies with some ortho-phthalate plasticizers.

DIMETHYLARSINIC ACID (DMA): RESULTS OF CHRONIC TOXICITY/ONCOGENICITY STUDIES IN FISCHER F344 RATS AND B6C3F1 MICE.

M. Eldan<sup>1</sup>, L. L. Arnold<sup>2</sup>, M. van Gemert<sup>3</sup> and S. M. Cohen<sup>1</sup>. <sup>1</sup>*Luxembourg Industries (Pamol) Ltd., Tel-Aviv, Israel*, <sup>2</sup>*Path/Micro, University of Nebraska Medical Center, Omaha, NE* and <sup>3</sup>*Exponent, Washington, DC*.

Male and female Fischer F344 rats and B6C3F1 mice were treated with dietary dimethylarsinic acid (DMA) in 2-year feeding studies. Rats were treated with 2, 10, 40, or 100 ppm DMA. Mice were treated with 8, 40, 200, or 500 ppm DMA. Early in the study there was a low incidence of treatment-related mortality in male rats in the two highest dose groups (100 ppm-5/60, 40 ppm-1/60). There was no treatment-related mortality in female rats or in mice. The primary targets for DMA-induced toxicity in the rat and mouse were the urinary bladder and kidney. In the rat, treatment with DMA resulted in a dose responsive increase in urothelial cell hyperplasia at 40 and 100 ppm DMA. Bladder tumors occurred in male and female rats at 100 ppm DMA. The female rat appeared to be more sensitive to the urothelial effects of DMA. In the rat kidneys, there was an increased incidence of medullary nephrocalcinosis, medullary tubular cystic dilation, and hyperplasia of the epithelial lining of the renal papilla in both sexes at doses of 40 and 100 ppm DMA. In mice, treatment with DMA resulted in a dose-dependent increase in vacuolar degeneration of the urinary bladder epithelium without toxicity or proliferation in the 2 highest dose male groups and the 3 highest dose female groups. No treatment-related tumors were found in any mice at any dose of DMA. The NOEL in rats was assessed as 2 ppm in males and 10 ppm in females and in mice as 40 ppm in males and 8 ppm in females. Based on these studies, high doses of DMA are carcinogenic to the rat urinary bladder; DMA is not carcinogenic in the mouse. Subsequent research has demonstrated that the mode of action for the rat bladder carcinogenesis involves cytotoxicity, regenerative proliferation, and ultimately tumors.

GINGIVAL CARCINOGENICITY IN FEMALE HARLAN SPRAGUE-DAWLEY RATS AFTER ORAL TREATMENT FOR TWO YEARS WITH 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN AND DIOXIN-LIKE COMPOUNDS.

K. Yoshizawa<sup>1</sup>, N. J. Walker<sup>2</sup>, M. P. Jokinen<sup>5</sup>, A. E. Brix<sup>6</sup>, D. M. Sells<sup>7</sup>, T. Marsh<sup>1</sup>, M. E. Wydy<sup>3</sup>, D. Orzech<sup>3</sup>, J. K. Haseman<sup>4</sup> and A. Nyska<sup>1</sup>. <sup>1</sup>*Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC*, <sup>2</sup>*Laboratory of Computational Biology and Risk Analysis, NIEHS, Research Triangle Park, NC*, <sup>3</sup>*Toxicology Operation Branch, NIEHS, Research Triangle Park, NC*, <sup>4</sup>*Biostatistics Branch, NIEHS, Research Triangle Park, NC*, <sup>5</sup>*Pathology Associates - A Charles River Company, Durham, NC*, <sup>6</sup>*Experimental Pathology Laboratories, Research Triangle Park, NC* and <sup>7</sup>*Battelle Columbus Laboratories, Columbus, OH*.

We evaluated gingival toxicities induced by chronic exposure of female Harlan Sprague-Dawley rats to dioxin and dioxin-like compounds (DLCs). This investigation represents part of an ongoing initiative of the National Toxicology Program to determine the relative potency of chronic toxicity and carcinogenicity of polychlorinated dioxins, furans, and biphenyls. For two years, animals were administered by gavage 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD); 3, 3', 4, 4', 5-pentachlorobiphenyl (PCB126); 2, 3, 4, 7, 8-pentachlorodibenzofuran (PeCDF); 2, 2', 4, 4', 5, 5'-hexachloro-biphenyl (PCB153); or a tertiary mixture of TCDD, PCB126, and PeCDF; a binary mixture of PCB126 and 153; or a binary mixture of PCB126 and 2, 3', 4, 4', 5-pentachlorobiphenyl (PCB118); control animals received corn oil-acetone vehicle (99:1) alone. A complete necropsy was performed on all animals and microscopic examination of a full complement of tissues was performed, including upper palates with teeth. In the groups of animals treated with TCDD and the mixtures of TCDD, PCB126, and PeCDF; PCB126 and 153; and PCB126 and 118, the incidences of gingival squamous hyperplasia increased significantly. Moreover, the higher doses of TCDD, PCB126, and the mixture of PCB126 and 153 induced squamous cell carcinoma (SCC) in oral cavities. This investigation constitutes the first report showing that chronic administration of dioxin-like PCBs can induce gingival SCC in rats. These results indicate that dioxin and DLCs target the gingiva of oral cavity, in particular the junctional epithelium of molars.

**1507**

CHRONIC TOXICITY AND ONCOGENICITY STUDY OF OCTAMETHYLCYCLOTETRAZOSILOXANE (D4) IN FISCHER 344 RATS.

K. P. Plotzke<sup>1</sup>, P. A. Jean<sup>1</sup>, J. W. Crissman<sup>1</sup>, K. M. Lee<sup>2</sup> and R. G. Meeks<sup>1</sup>. <sup>1</sup>*Dow Corning Corporation, Midland, MI* and <sup>2</sup>*Battelle, Richland, WA*.

Chronic toxicity and oncogenicity of D4 was evaluated in Fischer 344 rats exposed by vapor inhalation (6 h/d; 5 d/wk) to 10, 30, 150, and 700 ppm D4 for up to 24 months. Effects on survival and body weight were limited to 700 ppm males. Survival was decreased to 38% as compared to 58% for control. Body weight was

reduced ≈6% in the latter months of study. Histomorphologic changes in the nasal cavity at 12 and 24 months were consistent with chronic inhalation of a mild irritant. Lymphocytic leukocytosis was present in 700ppm males and females at 3, 6, and 12 months. Liver weights were increased at 6 (≥30ppm males; 700ppm females), 12 (≥150ppm males and females), and 24 months (700ppm males; ≥150ppm females). Centrilobular hepatocyte hypertrophy was present in 700ppm males at 12 and 24 months. Kidney weight and severity of chronic nephropathy was increased for 700ppm males at 24 months. Kidney weight and incidence/severity of chronic nephropathy was increased for 700ppm (12 and 24 months) and 150 ppm (24 months) females. Uterine weight, incidence of endometrial epithelial hyperplasia, and endometrial adenoma (4 of 35 animals) were increased at 700ppm at 24 months. Endometrial adenomas were not present in unscheduled death animals or animals in the control or intermediate dose groups. Trend analysis identified this incidence profile as statistically significant (Peto, p<0.05). Histomorphological review of endocrine responsive tissues (pituitary, mammary gland, ovary, uterus, and vagina) from treated and control animals indicated that they were cycling normally at 12 months without evidence of abnormal endocrine balance. There were no differences in these endocrine responsive tissues, beyond those already identified for the uterus, to differentiate treated from control at 24 months. The uterine effects associated with chronic D4 exposure have prompted research efforts focused on understanding the mode of action and relevance to humans. (This work was supported in part by the Silicones Environmental, Health and Safety Council of North America)

## 1508

### CHRONIC TOXICITY AND ONCOGENICITY STUDY OF HEXAMETHYLDILOXANE (HMDS) IN FISCHER-344 RATS.

**M. L. Jovanovic**<sup>1</sup>, **S. D. Crofoot**<sup>1</sup>, **J. W. Crissman**<sup>1</sup>, **P. A. Smith**<sup>2</sup>, **K. P. Plotzke**<sup>1</sup> and **R. G. Meeks**<sup>1</sup>. <sup>1</sup>*Dow Corning Corporation, Midland, MI* and <sup>2</sup>*RCC Ltd, Itingen, Switzerland*.

Chronic toxicity and oncogenicity were evaluated in F344 rats exposed to HMDS by vapor inhalation (6 h/d, 5 d/wk) for 12 or 24 months, or for 12 months with a 12 month recovery period. Males and females were exposed to 100, 400, 1600 or 5000 ppm HMDS. All animals were monitored for mortality, clinical signs, food consumption and body weights. Clinical laboratory studies included hematology, clinical chemistry and urinalysis. There were no test article related mortalities or clinical signs. Slight reductions in female body weights (-2 to -8%) at the mid-high and high dose after 12 and 24 months of exposure were likely associated with reduction in food consumption (-4 to -9%). In female rats, there were no histopathologic findings considered to be test article related. In males, increased liver weights after 12 months at 1600 and 5000 ppm suggested metabolic adaptive changes. Microscopic examination of tissues taken at necropsy identified the kidneys, testes, and nasal cavities as target organs in males. In the kidneys, an increased incidence of intraluminal mineralization was noted in all males exposed to 1600 and 5000 ppm HMDS. Several renal tubular adenomas and carcinomas occurred in males after 24 months of exposure to 1600 (3 of 65) and 5000 ppm (6 of 65). Additional work showed an alpha 2u-globulin mediated mechanism responsible for the observed nephropathy and kidney neoplasia in males. Increased testes weights after 12 and 24 months of exposure correlated with histopathological data. After 12 months, a dose-related increased incidence of Leydig cell tumors was noted in all HMDS-exposed groups (Peto, p<0.05). After 24 months almost all males had this finding since these testicular tumors are spontaneous and common in F344 rats. The data suggest that HMDS exposure accelerated progression of this common tumor. Increased incidence of eosinophilic inclusions in the olfactory epithelium in males at all sacrifice points was consistent with chronic inhalation of a mild irritant and is generally seen in inhalation studies.

## 1509

### CHRONIC TOXICITY AND ONCOGENICITY STUDY OF DECAMETHYLCYCLOPENTASILOXANE (D5) IN FISCHER-344 RATS.

**S. D. Crofoot**<sup>1</sup>, **M. L. Jovanovic**<sup>1</sup>, **J. W. Crissman**<sup>1</sup>, **P. A. Smith**<sup>2</sup>, **K. P. Plotzke**<sup>1</sup> and **R. G. Meeks**<sup>1</sup>. <sup>1</sup>*Dow Corning Corporation, Midland, MI* and <sup>2</sup>*RCC Ltd, Itingen, Switzerland*.

Chronic toxicity and oncogenicity were evaluated in Fischer-344 rats exposed to D5 by vapor inhalation (6 h/d, 5 d/wk) for up to 24 months. Male and female rats were exposed to 10, 40, and 160ppm D5 for 6, 12 or 24 months, or for 12 months with 12 month recovery period (recovery group). All animals were monitored for mortality, clinical signs, food consumption and body weights. Clinical laboratory investigations included hematology, clinical biochemistry and urinalysis. There were no test article related mortalities, clinical signs or palpable masses. The slight increases in female body weights (0.7 to 9.2%) at 40 and 160ppm after 24 months of exposure and in the recovery group, and in all males exposed to D5 for 24 months (1.4 to 4.3%) lacked a dose relationship. Increased liver weights in males

after 24 months at 160 ppm and females after 6 and 12 months at 10 and 160 ppm showed no clear dose-response and no correlation with any histopathological change. In both sexes, histomorphologic changes in the nasal cavity at high-dose were consistent with chronic inhalation of a mild irritant commonly seen in inhalation studies as non-specific finding. In females, the most significant finding was an increased incidence of endometrial epithelial neoplasia, mainly adenocarcinomas after 24 months of exposure (Peto Mortality Prevalence test, Fisher Exact pair-wise comparison, p<0.05). Endometrial adenocarcinomas were noted in 1 female exposed to 10 ppm (N= 60) and 5 females exposed to 160 ppm D5 (N=60). The uterine effects associated with chronic D5 exposure have prompted research efforts focused on understanding the mode of action and relevance to humans. (This work was supported in part by the Silicones Environmental, Health and Safety Council of North America)

## 1510

### CHRONIC TOXICITY AND ONCOGENICITY STUDY OF POLYDIMETHYLSILOXANE (PDMS) 10 CST FLUID IN FISCHER 344 RATS.

**R. G. Meeks**<sup>1</sup>, **P. A. Jean**<sup>1</sup>, **J. W. Mertens**<sup>2</sup>, **K. S. Regan**<sup>3</sup>, **J. W. Crissman**<sup>1</sup> and **K. P. Plotzke**<sup>1</sup>. <sup>1</sup>*Dow Corning Corporation, Midland, MI*, <sup>2</sup>*WIL Research Laboratories, Ashland, OH* and <sup>3</sup>*Regan Path/Toxicology Services, Ashland, OH*.

Chronic toxicity and oncogenicity of PDMS was evaluated in Fischer 344 rats. Polydimethylsiloxane 10 cst fluid was mixed into the feed to provide for dietary exposures of up to 24 months. The diets were prepared to achieve dose levels of 0, 100, 300, and 1000 mg/kg/day. There were no indications of systemic toxicity at any dose level. There were no treatment-related effects on survival, body weight, food consumption, and clinical pathology parameters. Evidence of local irritation was noted in the eye (clinically, macroscopically, and/or microscopically) in males and females from all treatment groups at 24 months and in the nasolacrimal duct (microscopically) of 1000 mg/kg/day oncogenicity group males. These effects were considered to be treatment-related and attributed to deposition/adherence of PDMS-feed on the eye surface. There were no treatment-related neoplastic findings at any dose level. A statistically significant increase in incidence of pancreatic islet cell adenomas was identified in the 1000 mg/kg/day oncogenicity group males. The absence of an increase in relevant preneoplastic changes, the lack of an effect in treated females, the high incidence of islet cell adenomas in the recovery group control animals, and the published incidence range for control animals suggests that the increased incidence of islet cell adenomas in the 1000 mg/kg/day group males was not treatment-related. Based on the results of this study, the no-observed effect level (NOEL) for systemic toxicity of PDMS administered for 12 months was 1000 mg/kg/day for males and females. The NOEL for oncogenicity of PDMS administered for 24 months was 1000 mg/kg/day for males and females. (This work was supported in part by the Silicones Environmental, Health and Safety Council of North America)

## 1511

### HISTOGENESIS OF SPONTANEOUS LESIONS IN THE V-HA-RAS (TG.AC) MOUSE.

**A. HARGREAVES**, **M. Jacobsen**, **C. Sadler**, **S. Barrett** and **J. Wright**. *CTL Pathology, Syngenta, Macclesfield, United Kingdom*. Sponsor: **I. Kimber**.

The Tg.AC transgenic mouse carries a v-Ha-ras oncogene linked to a zeta globin promoter. The model has been shown to develop a range of epithelial and mesenchymal tumours, including neoplasms of odontogenic origin and squamous papillomas. Two studies using a total of 120 Tg.AC hemizygous mice were housed for a period of six months as part of a strain assessment. In the first study 30 males and 30 females were housed in groups of 5. There were several incidences of fighting within male groups. In the second study the males were singly housed. Upon histopathological examination, 3 odontogenic tumours and 22 squamous papillomas were observed within the group-housed males with 9 odontogenic tumours and 12 squamous papillomas observed within singly housed males. 15 odontogenic neoplasms and 4 squamous papillomas were observed within both groups of females. In addition there was a 100% incidence of retinal dysplasia. The 27 odontogenic tumours were divided into 3 main types i) Mesenchymal cells in a dense fibrous-like matrix, ii) Loose stroma surrounded by anastomosing cords of epithelial cells that exhibited squamous differentiation, and iii) Odontomas forming mineralised tooth structures surrounded by well-differentiated odontoblasts and ameloblasts. There were similarities between the tumours recorded in this study and human odontogenic tumours. Representative sections of each lesion were selected for various stains, both conventional and immunohistochemical. These included trichrome, reticulin, elastin, cytokeratin, vimentin, desmin, ki 67 and a number of neural markers. The 3 main groups of mouse odontogenic tumour showed variations in their staining characteristics and antigenic expression suggesting progression from type 1 to 3. Evidence of cell proliferation was not apparent. It is suggested that the Tg.AC mouse may prove a suitable model for its human counterpart, in the study of odontogenic tumorigenesis.

**1512****A CARCINOGEN BIOASSAY FOR COMPLEX MIXTURES.**

K. LaDow<sup>1</sup>, D. Warshawsky<sup>1</sup>, R. Albert<sup>1</sup>, W. Xue<sup>1</sup>, S. Spalding<sup>1</sup>, G. P. Boivin<sup>2</sup>, D. Ginsburg<sup>1</sup> and P. Succop<sup>1</sup>. <sup>1</sup>*Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH* and <sup>2</sup>*Pathology and Laboratory Medicine, University of Cincinnati College of Medicine, Cincinnati, OH*.

Complex mixtures of combustion products contain many carcinogens such as polycyclic aromatic hydrocarbons. Assessing the carcinogenic potency of mixtures by a conventional mouse skin tumor carcinogenesis protocol (CC) is time-consuming and expensive. Initiation protocols are of uncertain accuracy in the prediction of cancer outcome. We evaluated a mouse skin model using a dominant-negative p53 mutant mouse (Vp53) in an initiation-progression protocol (IP), concurrently applying a mixture and a promoter, 12-O-tetra-decanoylphorbol-13-acetate (TPA), for 26 weeks. The mixtures were also tested with Vp53 wild type mice in a CC protocol. Three dose levels of Benzo[a]pyrene (BaP) were first tested to confirm the sensitivity of the models. Four mixtures were then evaluated: a National Institute of Standard and Technology SRM 1597 Coal Tar mix (CT), a 7H-dibenzo[c, g]carbazole (DBC) and BaP mix (M1), two dose levels of coal tar creosote (Cr), and a DBC, BaP and CT mix (M2). No tumors developed in control mice. The percentage of mice with tumors was more than 50% in all mixture treatment groups except M1 and M2 CC. The tumors in CT first appeared at 13 weeks in IP and 15 weeks in CC, with 19 and 23 week latent periods, respectively. The M1 IP tumors first appeared at 10 weeks, with a 17 week latent period; there were no tumors in CC. The first M2 tumors appeared at 15 weeks in IP and 17 weeks in CC, with latent periods of 19 and 17 weeks, respectively. 10mg Cr tumors first appeared at 11 weeks in IP and 17 weeks in CC, with 17 and 21 weeks latent periods, respectively. The 20mg Cr tumors first appeared at 8 weeks in IP and 12 weeks in CC; latent periods were 15 and 16 weeks, respectively. In comparison to conventional protocols the IP protocol results in shorter latent periods and time to first tumor for complex mixtures. [USEPA Star Grant]

**1513****EVALUATION OF K6ODC TRANSGENIC MICE AS A DERMAL CARCINOGENICITY MODEL FOR ONCOGENIC DNA.**

T. J. Miller<sup>1</sup>, P. Espandiari<sup>1</sup>, R. Honchel<sup>1</sup>, A. D. Knapton<sup>1</sup>, J. Zhang<sup>1</sup>, E. Sistare<sup>1</sup>, L. Sheng<sup>2</sup>, A. M. Lewis<sup>2</sup>, K. Peden<sup>2</sup> and J. P. Hanig<sup>1</sup>. <sup>1</sup>*CDER, USFDA, Silver Spring, MD* and <sup>2</sup>*CBER, USFDA, Rockville, MD*.

Transgenic mouse models can serve as sensitive, short-term alternatives to traditional rodent 2-year cancer bioassays. K6ODC transgenic mice develop epidermal tumors when exposed to carcinogens via the promotional stimulus of enhanced expression of ornithine decarboxylase in keratinocytes. K6ODC mice were used in a 36-week study to test their susceptibility to oncogenesis by a plasmid expressing the human T24-H-ras gene, which was developed to evaluate risks posed by residual DNA in vaccines produced in neoplastic cell substrates. Male K6ODC and C57BL/6 mice (15 per group) were treated with H-ras plasmid (2.5, 250, 25000 ng), vector DNA, or saline on scarified skin or by subcutaneous injection. One group of K6ODC mice received a single exposure of 7, 12-dimethylbenz[a]anthracene ([DMBA], 200 nM) dermally. Microscopy of skin, heart, lung, liver, and spleen were performed after unscheduled euthanization or at study completion. DMBA-treated K6ODC mice developed papillomas by 6 weeks that increased in incidence to 25 weeks (9+/0.69 tumors/mouse, < 3mm, 13/15 responded). No tumors were detected in other groups in either mouse strain. Microscopy of skin sections confirmed papillomas in DMBA treated animals with dermal/sebaceous gland hyperplasia and follicular dystrophy in all skin samples, characteristic of this strain. Tissue analysis of K6ODC mice revealed amyloid deposition and neutrophilic infiltration within liver, heart, and spleen, and splenic atrophy regardless of treatment. Pathology was not detected in C57BL/6 mice. After week 15, 94% (126/134) of the K6ODC mice developed unexpected dermal eczema (unrelated to either treatment regimen) requiring unscheduled euthanization. By week 32, six of the eight surviving K6ODC mice showed difficulty in mobility and loss of balance. In this study, the K6ODC failure to develop papillomas to oncogenic DNA, progressive adverse health, and decreased long-term survival suggest that K6ODC mice are an inadequate alternative model for oncogenic DNA and chemical carcinogenicity testing.

**1514****DETERMINATION OF THE SKIN CANCER POTENTIAL OF PETROLEUM-DERIVED MATERIALS USING K6/ODC MICE.**

M. A. Amoruso<sup>1</sup>, G. W. Trimmer<sup>1</sup>, R. C. Forgash<sup>1</sup>, S. Gilmour<sup>2</sup> and J. J. Freeman<sup>1</sup>. <sup>1</sup>*Toxicology & Environmental Sciences, ExxonMobil Biomedical Sciences, Inc., Annandale, NJ* and <sup>2</sup>*Lankenau Institute for Medical Research, Wynnewood, PA*.

ExxonMobil and others in the petroleum industry have historically utilized the mouse dermal carcinogenesis bioassay to assess the carcinogenicity of petroleum-derived materials. Scientists have been searching for a faster, less costly but effective

means to identify carcinogenic compounds. The K6/ODC transgenic mouse shows promise as a replacement for the conventional two-year rodent dermal bioassay. Previously, our laboratory demonstrated that a single low topical dose of benzo(a)pyrene(i.e., 25 µg) could produce skin tumors in 60% of treated mice within 20 weeks. In the current study, ten groups of K6/ODC mice (15/group) were treated once per week as follows: Groups 1, 2 and 3 received 375, 750, or 1875 µg Catalytically Cracked Clarified Oil (CCCO; a high-boiling carcinogenic petroleum material) in acetone and Groups 4-10 received 37.5 microliters (neat) of Blend 1 (refined basestock + 10.5% aromatic extract), Blend 2 (refined basestock + 17.5% aromatic extract), Isodewaxed Hydrocracked Stock, Jet fuel, Deasphalted residual oil, Dewaxed Hydrocracked Lube Basestock and a Lubricant baseoil, respectively. Development of skin tumors was monitored weekly. At study termination (i.e., 6 months post dosing), histological examination revealed that 9/15 animals in Group 1, 12/15 animals in Group 2, 14/15 animals in Group 3, 4/15 animals in Group 4, 8/15 animals in Group 5 and 5/15 animals in Group 6 had developed tumors. Tumors were not observed in any of the animals in Groups 7 through 10. These findings are 100% consistent with the results obtained from 2-year skin painting bioassays with these same test materials. These results, pending QAU verification, provide further evidence of the utility of the K6/ODC mouse as a skin cancer model.

**1515****COMPARATIVE 30-WEEK DERMAL TUMOR PROMOTION STUDY USING SENCAR MICE: EVALUATION OF CIGARETTE SMOKE CONDENSATE FROM A CONTROL CIGARETTE AND TEST CIGARETTES WITH TWO BANDED CIGARETTE PAPER TECHNOLOGIES.**

D. R. Meckley<sup>1</sup>, D. H. Pence<sup>1</sup>, K. R. Van Kampen<sup>2</sup>, P. H. Ayres<sup>1</sup> and J. E. Swauger<sup>1</sup>. <sup>1</sup>*R.J. Reynolds Tobacco Company, Winston-Salem, NC* and <sup>2</sup>*The Van Kampen Group, Hoover, AL*.

A 30-week dermal tumor promotion study was conducted to evaluate the relative tumor-promoting potential of cigarette smoke condensate (CSC) collected from three test cigarettes utilizing banded cigarette paper technologies to that of a control cigarette without banded paper. Mainstream CSC's were collected by cold trap from smoke generators using the Federal Trade Commission puffing regimen. Female SENCAR mice were initiated with a single 75-µg application of 7, 12-dimethylbenz[a]anthracene (DMBA) to the clipped dorsal skin. Beginning one week later, the CSC's were applied to the skin three times per week for 29 weeks. Each CSC was administered at 9, 18, or 36 mg tar/200 µl application to groups of 40 animals. In addition to the appropriate sentinel, vehicle and positive controls, non-initiated mice received high-dose treatments of CSC from the control and test cigarettes. End-points included body weights, clinical observations, organ weights, dermal tumor development data and histopathology. The numbers of dermal tumors and the numbers of tumor-bearing animals for both the control and test CSCs were statistically different from the DMBA-initiated control group and increased with increasing exposure. When corresponding doses of test CSC were compared to the control CSC, no increases were noted. In this assay, the banded cigarette paper technologies associated with the test cigarettes did not adversely affect the dermal tumor-promotion potential of the CSC compared to CSC from a control cigarette that had no banded cigarette paper technology.

**1516****COMPARATIVE 13-WEEK INHALATION STUDY OF MAINSTREAM CIGARETTE SMOKE FROM CIGARETTES CONTAINING CAST SHEET TOBACCO.**

R. Potts, D. R. Meckley, K. Shreve, P. H. Ayres, D. H. Pence, C. D. Garner, D. J. Doolittle and J. E. Swauger. *Scientific & Regulatory Affairs, R. J. Reynolds Tobacco Company, Winston-Salem, NC*.

A subchronic, nose-only inhalation study was conducted to compare the effects of mainstream smoke from a Reference cigarette containing conventional reconstituted tobacco sheet at 30% of the finished blend to mainstream smoke from cigarettes containing 10% or 15% Cast Sheet (a specific type of reconstituted tobacco sheet) substituted for part of the conventional reconstituted tobacco. Male and female Sprague-Dawley rats were exposed for 1 hour a day, 5 days per week, for 13 weeks to mainstream smoke at 0, 0.06, 0.20, or 0.80 mg wet total particulate matter per liter of air. Clinical signs, body and organ weights, clinical chemistry, hematology, carboxyhemoglobin (COHb), serum nicotine, plethysmography, gross pathology, and histopathology were determined. Exposure to cigarette smoke induced a number of changes in respiratory physiology, histopathology, and serum nicotine and COHb levels when compared to sham animals. When corresponding dose groups of Reference and Cast Sheet mainstream smokes were compared, no biological differences were noted. At the end of the exposure period, subsets of rats from each group were maintained without smoke exposures for an additional 13 weeks (recovery period). At the end of the recovery period, there were no statistically significant differences in histopathological findings observed between the

Reference and either Cast Sheet cigarette. Substitution of 10% or 15% Cast Sheet tobacco for conventional reconstituted tobacco sheet in a cigarette does not alter the inhalation toxicology of the mainstream smoke when compared to mainstream smoke from a Reference cigarette containing conventional reconstituted tobacco sheet.

**1517**

DIFFERENTIATING INITIATING FROM PROMOTING EFFECTS OF CIGARETTE MAINSTREAM SMOKE IN THE PRODUCTION OF LUNG TUMORS IN A MOUSE INHALATION BIOASSAY.

S. F. Yee, M. Misra, J. Hamm, R. Leverette, S. Vulimiri, D. Heck and N. Rajendran, *Lorillard Tobacco Company, Greensboro, NC*.

In the present study, we tested a rodent inhalation model to differentiate the effects of mainstream cigarette smoke on tumor initiation and promotion. This study utilized 2R4F cigarette smoke as an initiator or promotor of lung tumors in a rodent model. Balb/c mice were initiated or promoted by 3 h/day, 5 d/wk for eight weeks, to air control or 3 separate exposures (50, 150, and 300 mg of total particulate matter (TPM)/m<sup>3</sup>) of nose-only cigarette smoke inhalation. In group A, 8 weeks of smoke inhalation was followed by 4 weekly injections of BHT (200mg/kg bw), and lungs were harvested 16 weeks after initial exposure. No significant elevation in lung adenomas was observed in group A. In group B, one injection of 3-MC (10mg/kg bw) was followed by 8 weeks of smoke inhalation under exposure conditions noted above, and lungs were harvested 16 weeks after initial injection. Air exposure, 50, 150, and 300 mg TPM/m<sup>3</sup> yielded an average of 0.05, 0.12, 0.20, and 0.22 lung adenomas/animal, respectively. CONCLUSIONS: Eight weeks of cigarette smoke did not display tumor-initiating effects under chemical promotion with BHT. However, cigarette smoke showed a dose-response in lung tumor promotion in mice chemically initiated with 3-MC. These findings suggest that cigarette smoke exposure is associated with low to moderate lung tumor promoting potential but little or no initiating potential in the Balb/c mouse strain under short-term cigarette smoke exposure conditions.

**1518**

CIGARETTE MAINSTREAM SMOKE AND GAS PHASE-DEPLETED PARTICULATE PHASE ENHANCE LUNG TUMORIGENICITY IN A/J MOUSE.

W. Stinn<sup>1</sup>, H. Haussmann<sup>1</sup>, A. Buettner<sup>1</sup> and J. H. Arts<sup>2</sup>, <sup>1</sup>*Philip Morris Research Laboratories GmbH, Cologne, Germany* and <sup>2</sup>*TNO Nutrition and Food Research, Zeist, Netherlands*.

Despite the established causality between tobacco smoking and lung cancer (IARC 2004), it is difficult to establish reproducible and validated animal inhalation models for this disease. These models are needed for the evaluation of potential risk-reduced products and chemoprevention. In order to further investigate the A/J mouse model for lung tumorigenicity, male A/J mice were whole-body exposed to diluted cigarette mainstream smoke from the standard reference cigarette 2R4F for 6 hours per day, 5 days per week for 5 months followed by 4 months without exposure. The animals were exposed to fresh filtered air, to whole smoke at concentrations of 0.12 or 0.24 mg total particulate matter (TPM)/l, to gas phase depleted particle phase (PP) at 0.24 mg TPM/l, which was generated by an activated charcoal adsorber, or to the gas phase of cigarette mainstream smoke at a concentration equivalent to 0.24 mg TPM/l. Lung tumor incidence and multiplicity were determined at 5 months in the control group and the whole smoke high dose group and at 9 months in all groups. At 5 months, the tumor response was comparable in the two groups. A distinct inflammation was indicated in the whole smoke high dose group by a severe increase in neutrophils and macrophages in bronchoalveolar lavage fluid. At 9 months, both cell types returned nearly to background levels; however, lung tumor incidence and multiplicity in the whole smoke groups were dose dependently higher by a factor of up to 3-fold compared to control. The lung tumor response was similar for PP and the high concentration of whole smoke. GP at the concentration used, failed to enhance lung tumor multiplicity above control level. Step-serial lung section analysis confirmed the macroscopic results. The lung tumor spectrum was the same in all groups with bronchio-alveolar adenoma being the most prominent lung tumor type. Further research is needed to evaluate the relevance of this model with regard to the human disease.

**1519**

INTERSPECIES SITE CONCORDANCE FOR MAMMARY CARCINOGENESIS BY ENVIRONMENTAL TOBACCO SMOKE.

A. G. Salmon, M. D. Miller and M. A. Marty, *OEHHA, California EPA, Oakland, CA*.

A problem in extrapolating animal bioassay data to human cancer risk is the variability of site concordance, for a particular carcinogen, between different animal test species and humans. Carcinogens active at the site of first contact often show site concordance, for similar exposure routes, but for systemically distributed car-

cinogens this depends on both the carcinogen and the organ system. This question is important to the study of contributing causes of breast cancer. Various environmental contaminants were tentatively associated with increased breast cancer incidence in ecological studies, but the epidemiological data are often conflicting or equivocal, so correlation with animal carcinogenicity becomes important in their interpretation. An example was identified during our re-evaluation of the health effects of exposure to environmental tobacco smoke (ETS). The summary odds ratio for breast cancer in women exposed to ETS was 1.89 (95% CI 1.52 - 2.36) for six recent case-control studies that enumerated all major sources of lifetime ETS exposure. On the other hand, earlier case-control studies, and a recent prospective cohort study, found lower, often non-significant, risk elevations. This may reflect less complete ETS exposure determination in those studies. Also, earlier studies of active smoking and breast cancer are non-positive, although a recent study reports this association. In this context the correlation with animal carcinogenicity data for identified components of tobacco smoke is useful. Tobacco smoke contains many carcinogens, some of which are up to ten times more abundant in sidestream smoke, the major source of ETS. We found 20 compounds in tobacco smoke that are identified (IARC 1, 2A or 2B) mammary gland carcinogens, including several polycyclic aromatic hydrocarbons and nitrosamines. These data suggest site concordance for mammary carcinogenesis in man and rodents, and provide substantial support for the conclusion that ETS exposure may be associated with increased incidence of breast cancer.

**1520**

DEVELOPMENT OF QUANTITATIVE QSAR MODELS TO PREDICT CANCER POTENCY OF CHEMICALS.

R. Venkatapathy<sup>1</sup>, C. Moudgal<sup>2</sup> and R. Bruce<sup>2</sup>, <sup>1</sup>*ORISE/NCEA-USEPA, Cincinnati, OH* and <sup>2</sup>*NCEA, USEPA, Cincinnati, OH*.

Two important disadvantages of long-term animal bioassays are that testing involves substantial amounts of time and money, and that high doses are usually used in the testing process. These disadvantages can be circumvented using Quantitative Structure-Activity Relationships (QSARs). There are a limited number of QSAR models to predict the carcinogenicity of various chemicals, a majority of which relate the carcinogenic potency to measures of carcinogenicity such as mutagenicity, lethal dose (LD50) or the maximum tolerated dose (MTD). In one such QSAR, Krewski et al. demonstrated a good correlation ( $r = 0.952$ ,  $N = 191$ ) between tumor dose that causes cancer in 50% of an exposed population (TD50) and the MTD. The objective of this study was to predict the carcinogenic potency of a wide variety of chemicals. Initially, this study aimed to duplicate the results of Krewski et al. using 467 rat TD50s of either sex from the carcinogenic potency and genotoxicity databases maintained by Gold et al. The MTDs for the 467 chemicals were calculated using the rat Maximum Tolerated Dose model in TOPKAT, a commercial QSAR software for toxicity prediction. Since the results from the previous analysis indicated that MTD was a poor predictor for TD50, this study aimed to develop a pilot QSAR model to predict the cancer potencies for 70 chemicals from the Integrated Risk Information System (IRIS) database using their physicochemical properties as predictor variables or descriptors. Initially, the molecular structures of the 70 IRIS chemicals were optimized to their lowest energy geometries using the CONFLEX module in CAChe (Computer Aided Chemistry) software. Three descriptor generating programs are being used to generate the predictor variables for the QSAR model: Molconn-Z, CAChe and AMPAC/CODESSA. Results from the final QSAR for the pilot study involving 70 chemicals indicate that electrostatic variables such as nucleophilicity and electrophilicity from the three programs mentioned above are better descriptors of cancer potency than MTD.

**1521**

CANCER RISK ESTIMATION FOR EXPOSURE TO NAPHTHALENE.

S. Hoover, J. P. Brown, A. G. Salmon, M. S. Sandy, L. Zeise and M. A. Marty, *OEHHA, California EPA, Oakland, CA*.

Naphthalene is a common air and soil pollutant. It is an industrial intermediate, a component of some fuels and a combustion byproduct. Naphthalene is identified as a California Toxic Air Contaminant (TAC) and a US Hazardous Air Pollutant. Naphthalene is listed as a chemical known to the State of California to cause cancer, and was recently classified as Group 2B (possibly carcinogenic to humans) by the International Agency for Research on Cancer. Recent National Toxicology Program (NTP) studies in rats showed clear evidence of a carcinogenic effect and provided data that allow satisfactory cancer risk assessment. Accordingly, and in view of the importance of naphthalene as an air pollutant, we developed a cancer risk assessment for the Hot Spots, TAC and Proposition 65 programs. Human cancer potencies and unit risk estimates were derived based on data from the NTP (2000) rat studies and the earlier NTP mouse studies, using both the linearized multistage model and the benchmark dose procedure, which avoids reliance on a specific tumor causation model. Available data on metabolism and genotoxicity supported the use of either the linearized multistage model or linear extrapolation from a benchmark in order to predict risk at low doses. Pharmacokinetic effects were examined but found not to have a substantial effect on the risk estimate. Since naphthalene induced significant increases in two different tumor types in the NTP male

rat study, a Monte Carlo procedure was used to provide a combined potency estimate. The recommended unit risk value for naphthalene was  $3.4 \times 10^{-5}$  ( $\mu\text{g}/\text{m}^3$ )<sup>-1</sup> and slope factor was  $1.2 \times 10^{-1}$  ( $\text{mg}/(\text{kg}\cdot\text{day})$ )<sup>-1</sup>. These values are based on the incidences of nasal respiratory epithelial adenoma and nasal olfactory epithelial neoplasia in male rats.

**1522**

PROTECTIVE EFFECT OF NRF2 ON THE MUSCLE OF MICE WITH AMYOTROPHIC LATERAL SCLEROSIS.

J. C. Kern<sup>1,2</sup>, A. D. Kraft<sup>1</sup>, A. Vermeern<sup>1</sup> and J. A. Johnson<sup>1,2</sup>. <sup>1</sup>*Pharmaceutical Sciences, University of Wisconsin-Madison, Madison, WI* and <sup>2</sup>*Molecular and Environmental Toxicology Center, University of Wisconsin-Madison, Madison, WI*.

Muscle atrophy is a primary characteristic of end-stage amyotrophic lateral sclerosis (ALS). This wasting effect stems from unknown mechanisms of motor neuron death in the spinal cord. A majority of ALS research has been performed in mice containing G93A mutant superoxide dismutase (SODG93A), which serve as excellent models for demonstrating consistent pathology compared to human patients. The mouse pathology displays increased oxidative stress similar in timing to our previous findings of the activation of the antioxidant response element (ARE) in ARE-hPAP mice crossed with SODG93A mice. The ARE is a DNA sequence present in the promoter of many detoxification enzymes and is activated by the transcription factor nuclear factor E2-related factor (Nrf2). To investigate the role of Nrf2 in the prevention of ALS, ARE-hPAP mice were injected with adenovirus containing Nrf2 (Ad-Nrf2) in the muscle at 45 days of age. They displayed sustained hPAP activity at 52 and 120 days of age that was strongest in the muscle followed by the spinal cord and brainstem, respectively. Further, retrograde transport of the hPAP activation demonstrates a possible protective effect on the motor neurons by Ad-Nrf2. By injecting Ad-Nrf2 in SODG93A mice at 45 days of age (a presymptomatic stage), the addition of Nrf2 was able to significantly delay downstream paralysis. The molecular basis for these effects was further explored using microarray technology of the infected muscle and suggests that novel secretory proteins and transport pathways are augmented to confer motor neuron protection. While the motor neurons in ALS are primarily targeted for death, we show that the muscle offers a unique supporting environment for protecting motor neurons and delaying paralysis. Support contributed by NIEHS: ES08089 and ES10042, ALSA, and the Robert Packard Center for ALS Research at Johns Hopkins. JCK is supported by NIEHS: ES013691 and ES0715-25

SENSITIVITY TO MITOCHONDRIAL COMPLEX II INHIBITORS, MALONATE AND 3-NITROPROPIONIC ACID IN NRF2 KNOCKOUT MICE.

M. Calkins<sup>1,2</sup>, R. J. Jakel<sup>1,3,4</sup> and J. A. Johnson<sup>1,2,5</sup>. <sup>1</sup>*School of Pharmacy, University of Wisconsin, Madison, WI*, <sup>2</sup>*Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI*, <sup>3</sup>*Neuroscience Training Program, University of Wisconsin, Madison, WI*, <sup>4</sup>*Medical Scientist Training Program, University of Wisconsin, Madison, WI* and <sup>5</sup>*Waisman Center, University of Wisconsin, Madison, WI*.

Huntington's disease (HD) is caused by a CAG repeat expansion in the first exon of the huntingtin gene resulting in massive striatal degeneration. Although the mechanism of cell death is unclear, there is evidence that this cell loss is in part due to mitochondrial dysfunction. Complex II inhibitors 3-nitropropionic acid (3NP) and malonate cause striatal damage reminiscent of HD and have been used extensively as Huntington's models. Previous research has shown that complex II inhibition involves oxidative stress and secondary excitotoxicity. Because Nrf2-dependant transcriptional activation via the antioxidant response element (ARE) is known to coordinate the upregulation of genes involved in combating oxidative insults and cytotoxicity, we investigated the significance of Nrf2 in 3NP- and malonate-induced toxicity. We found that Nrf2-deficient cells and knockout mice are significantly more vulnerable to malonate and 3NP. Additionally, complex II inhibition resulted in increased ARE-regulated transcription mediated by astrocytes. Taken together, these observations implicate Nrf2 as an essential inducible factor in the protection against complex II inhibitor-mediated neurotoxicity.

**1524**

NEUROPROTECTIVE EFFECTS OF METALLOTHIONEIN-III IN MUTANT EXPANDED POLYGLUTAMINE EXPRESSED NEUROBLASTOMA CELLS.

K. Lee<sup>1</sup>, Y. Hwang<sup>1,2</sup>, K. Jung<sup>1,2</sup>, D. Shin<sup>1,2</sup>, K. Oh<sup>1,2</sup>, J. Choi<sup>1,2</sup> and H. Jeong<sup>1,2</sup>. <sup>1</sup>*Pharmacy, Chosun University, Kwangju, Kwangju, South Korea* and <sup>2</sup>*Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea*.

Neuronal loss and intraneuronal protein aggregates are characteristics of Huntington's disease (HD), which is one of neurodegenerative disorders caused by an expanded polyglutamine [poly(Q)] tract in the disease protein. N-terminal fragments of mutant huntingtin produce intracellular aggregates and cause toxicity. Metallothioneins (MT) is a low molecular weight proteins characterized by its abundant content of cystein. MT-III, a number of MT family, is expressed in brain in contrast to MT-I and MT-II, those are found in most tissue. In the present study,

we identified MT-III inhibits aggregation of poly(Q) and suppress the poly(Q)-mediated cell death, using a cellular model of HD. We tested the hypotheses that MT-III may reduce poly(Q)-mediated cell death by inhibiting the mitochondrial death pathway. In neuroblastoma cells expressing mutants poly(Q), MT-III treatments resulted in increase of cell viability. Moreover, we identified that MT-III decreased release of cytochrome c and p53 expression. We propose that a poly(Q) can induce mitochondrial death pathway that directly contribute to cell death and that MT-III is an antagonist of this process.

**1525**

METALLOTHIONEIN III ATTENUATES 6-HYDROXYDOPAMINE-INDUCED APOPTOTIC CELL DEATH IN SH-SY5Y CELLS.

Y. Hwang<sup>1,2</sup> and H. Jeong<sup>1,2</sup>. <sup>1</sup>*Pharmacy, Chosun University, Kwangju, Kwangju, South Korea* and <sup>2</sup>*Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea*.

Metallothioneins (MTs) are low molecular weight, metal-binding proteins with established antioxidant capabilities. MT-III, a number of MT family, is expressed in brain in contrast to MT-I and MT-II, those are found in most tissue. In the brain, MT-III exhibits a free radical scavenging activity. Enhanced oxidative stress is implicated in the pathogenesis of neurodegenerative diseases such as Parkinson's disease. The catecholaminergic neurotoxin 6-Hydroxydopamine (6-OHDA) induces the production of reactive oxygen species (ROS), leading to neuronal cell death. In the present study, we investigated the effects of MT-III on 6-OHDA-induced apoptotic cell death using the human dopaminergic neuroblastoma cell line, SH-SY5Y. The co-treatments of cells with MT-III significantly attenuated 6-OHDA-induced ROS generation and subsequent apoptotic cell death. We also demonstrated that pretreatment alone with MT-III for 24 h prior to the exposure confers resistance against 6-OHDA-induced cell toxicity. These finding suggested that the MT-III acts principally as a radical scavenger to suppress the level of ROS, whereas the other mechanisms might be involved in the protective effects.

**1526**

MITOCHONDRIAL-DEPENDENT INITIATION OF APOPTOSIS AND FEEDBACK REGULATION BY PKC $\delta$  IN PROTEOSOME INHIBITOR MG-132-INDUCED DOPAMINERGIC DEGENERATION.

F. Sun, A. Kanthasamy, Y. Yang, V. Anantharam and A. G. Kanthasamy. <sup>1</sup>*Biomedical Sciences, Iowa State University Ames, IA*.

Ubiquitin-proteosome dysfunction is implicated in the development of Parkinson disease (PD) due to the accumulation of ubiquitin and  $\alpha$ -synuclein in Lewy bodies, the defining pathological change of PD patients. To understand the underlying mechanisms by which dysfunction of this system contributes to the dopaminergic degeneration, we investigated the effects of the proteosome inhibitor MG-132 on apoptotic cell death in rat mesencephalic dopaminergic neuronal (N27) cells. Treatment with 2.5, 5.0, and 10  $\mu\text{M}$  MG-132 resulted in dose- and time-dependent cytotoxicity. Exposure to 5.0  $\mu\text{M}$  MG-132 rapidly and progressively inhibited the proteosomal activity, with almost 50% proteosomal inhibition within 5 min. This potent proteosomal inhibition by MG-132 was accompanied by rapid releases of the proapoptotic molecules cytochrome c and Smac from the mitochondria to the cytosol. Caspase-9 and -3 were activated dramatically in a time-dependent manner, whereas caspase-8 was increased moderately. The caspase-9 inhibitor LEHD-fmk completely inhibited MG-132-induced caspase-3 activity, indicating that caspase-9 is a major upstream caspase responsible for caspase-3 activation. MG-132-induced caspase-3 proteolytically activated a key proapoptotic kinase, protein kinase C delta (PKC $\delta$ ), in a time-dependent manner. Suppression of PKC $\delta$  by the caspase-3 cleavage-resistant mutant (PKC $\delta$ -CRM) or the kinase inhibitor rottlerin significantly attenuated MG-132-induced DNA fragmentation, suggesting that PKC $\delta$  is a key downstream mediator of proteosome inhibitor-induced apoptotic cell death. Furthermore, PKC $\delta$ -CRM and rottlerin significantly attenuated caspase-9 and -3, suggesting the existence of a possible feedback amplification loop. Collectively, these results demonstrate that dysfunction of the ubiquitin-proteosome system initiates apoptosis through an intrinsic apoptotic pathway involving PKC $\delta$ , which has a significant regulatory role in the dopaminergic cell death process [supported: ES10586 & NS45133].

PROTEOSOME INHIBITOR ACLARUBICIN INDUCES DOPAMINERGIC CELL DEATH AND PARKINSON'S-LIKE SYMPTOMS IN MICE: IMPLICATIONS FOR UBIQUITIN-PROTEOSOME DYSFUNCTION IN PARKINSON'S DISEASE.

C. Latchoumycandane, A. Vellareddy, A. Kanthasamy and A. Kanthasamy. <sup>1</sup>*Department of Biomedical Sciences, Iowa State University Ames, IA*.

The ubiquitin-proteosome pathway has recently been suggested to be critical in the pathogenesis of Parkinson's disease (PD). Impairment of proteosome function promotes aggregation of key proteins, including  $\alpha$ -synuclein and ubiquitin, which

subsequently leads to development of Lewy bodies, a pathological hallmark of PD. In order to understand the cellular and molecular mechanisms of proteosomal dysfunction in PD, we tested aclarubicin, an anthracycline anticancer drug obtained from *Streptomyces galilaeus* known to inhibit proteosome activity, in both cell culture and animal models. Aclarubicin (6 mg/kg i.p.) was administered to C57 black mice for 6 consecutive days. Neurobehavioral analysis revealed that both the horizontal and vertical motor activity of aclarubicin-treated animals started to decrease 3 days post-treatment and progressed over time. Aclarubicin treatment did not alter the body weight of the animals. Neurotransmitter analysis revealed a significant depletion of dopamine and DOPAC in the striatum of aclarubicin-treated animals. Proteosome activity was increased in the substantia nigra, suggesting that proteosome levels may be upregulated during the early phase of aclarubicin treatment. To better understand the mechanism of aclarubicin-induced dopaminergic neurotoxicity, we treated mesencephalic dopaminergic neuronal (N27) cells, *in vitro* model of PD, with aclarubicin. Treatment of N27 cells with aclarubicin (0.1, 1, and 3  $\mu$ M) for 1-12 hr induced dose- and time-dependent cytotoxicity. The cytotoxicity was accompanied by a time-dependent decrease in proteosome activity. The known proteosome inhibitor MG 132 (positive control) dramatically reduced the proteosome activity. Together, these results indicate that aclarubicin can produce PD-like motor deficits and neurochemical changes in the C57 black mouse model, which may be a useful animal model for investigation of ubiquitin-proteosome impairment associated with PD. [supported:ES10586 & NS45133].

THROMBIN PRECONDITIONING PREVENTS STRIATAL ATROPHY AND DOPAMINERGIC TERMINAL LOSS, BUT NOT DOPAMINE DEPLETION IN A 6-HYDROXYDOPAMINE PARKINSON'S DISEASE MODEL.

J. R. Cannon<sup>1,2</sup>, Y. Hua<sup>1</sup>, G. Xi<sup>1</sup> and R. F. Keep<sup>1,3</sup>. <sup>1</sup>Department of Neurosurgery, The University of Michigan, Ann Arbor, MI, <sup>2</sup>Department of Environmental Health Sciences, The University of Michigan, Ann Arbor, MI and <sup>3</sup>Department of Physiology, The University of Michigan, Ann Arbor, MI.

Administration of low dose thrombin several days before lesioning is neuroprotective in stroke models, an effect termed thrombin preconditioning (TPC). Recently, we found that TPC reduces behavioral deficits in the 6-hydroxydopamine (6-OHDA) Parkinson's disease (PD) model. Here, the ability of TPC to prevent striatal atrophy, dopaminergic terminal loss, and catecholamine depletion in the 6-OHDA model was evaluated. All animals received 10  $\mu$ g of 6-OHDA onto the right medial forebrain bundle. Three days prior to lesioning, animals received either 1 U thrombin (n=17) or saline (n=14) 1 mm dorsal to lesion. All animals were sacrificed 21 days after 6-OHDA for either histology or striatal catecholamine determination, using HPLC with electrochemical detection. Coronal (20  $\mu$ m) sections at 1.7, 1.2, 0.7, 0.2, and -0.3 to bregma underwent standard H & E staining, and using NIH Image, lateral ventricular volume was determined for both the lesioned and nonlesioned sides. Additional striatal sections were stained for tyrosine hydroxylase, here a marker for dopaminergic terminals. Optical density in the striatum was used to quantify terminals. TPC animals exhibited significantly smaller ventricular volumes on the lesioned side than those pretreated with saline (1.45 $\pm$ 0.22 vs. 0.94 $\pm$ 0.08 mm<sup>3</sup> $\pm$ SE; SPC vs. TPC; Student's *t*-test, p<0.05), indicating decreased striatal atrophy in TPC animals. Additionally, TPC prevented dopaminergic terminal loss as evidenced by optical density ratios (lesioned/nonlesioned; 0.80 $\pm$ 0.09 vs. 0.51 $\pm$ 0.06; TPC vs. SPC; p<0.05). However, neither TPC nor saline prevented massive striatal dopamine depletion (>95%), a striking finding, considering morphological and behavioral protection. The results indicate that TPC is able to prevent striatal atrophy and dopaminergic terminal loss in a 6-OHDA PD model and may explain the observed behavioral protection. Mechanistic studies may reveal novel therapeutic pathways.

ROLE FOR PROTEASE-ACTIVATED RECEPTOR 1 (PAR1) IN MPTP-INDUCED DOPAMINERGIC NEUROTOXICITY.

C. Hamill<sup>1</sup>, M. Caudle<sup>2</sup>, J. R. Richardson<sup>2</sup>, G. W. Miller<sup>2</sup> and S. F. Traynelis<sup>1</sup>.

<sup>1</sup>Department of Pharmacology, Emory University, Atlanta, GA and <sup>2</sup>Center for Neurodegenerative Disease, Emory University, Atlanta, GA.

Protease-activated receptor 1 (PAR1) is a G-protein coupled receptor best-known for its role in blood coagulation. PAR1 is expressed in the CNS, particularly in the Substantia Nigra pars Compacta (SNc) and in astrocytes throughout the brain (J Neurosci 1995 Apr;15(4): 2906-19. and Exp Neurol. 2004 May; in press). Activation of this receptor has been implicated in neuronal death during transient focal ischemia and hypoxia, as well as in microglial activation, and in astrocyte proliferation. Due to its expression in the SNc and its putative role in neurodegeneration, we hypothesized that PAR1 activation might contribute to dopaminergic cell death in response to neurotoxins. To test our hypothesis, we used PAR1-/- and wild-type animals injected with the dopaminergic neurotoxin, 1-methyl-4-phenyl-

1, 2, 3, 6-tetrahydropyridine (MPTP). Wild-type and PAR1-/- animals received two subcutaneous injections of either vehicle or 10mg/kg of MPTP separated by 12 hours. After 48 hours, animals were sacrificed and the striata were removed and prepared for Western blot and HPLC. We observed that PAR1-/- mice appeared to be partially protected from dopaminergic cell loss following MPTP administration, as wild-type mice showed significantly greater loss of tyrosine hydroxylase (TH) protein. MPTP treatment reduced TH protein levels by 42.1 $\pm$ 4.1% in wild-type mice, but by only 8.1 $\pm$ 6.7% in PAR1-/- mice (ANOVA p<0.01 n=7-8). Similar results were seen for dopamine transporter (DAT) protein levels. Dopamine levels were reduced by 54.0 $\pm$ 5.4% in wild-type animals while there was only a 35.0 $\pm$ 4.0% decrease in PAR1-/- animals (ANOVA p<0.05 n=7-8 mice), further suggesting a protective phenotype in PAR1-/- animals. These results implicate the PAR1 receptor in the degeneration of the nigrostriatal dopamine system following neurotoxin exposure and indicate that there may be a link between blood-derived serine proteases and dopaminergic degeneration.

NICOTINE STIMULATION INDUCES TH MESSENGER RNA EXPRESSION AND TRANSCRIPTION RATE IN MN9D CELLS.

P. M. Radcliffe<sup>1</sup> and A. Tank<sup>2</sup>. <sup>1</sup>Toxicology, University of Rochester, Rochester, NY and <sup>2</sup>Pharmacology/Physiology, University of Rochester, Rochester, NY.

Although the transcriptional regulation of tyrosine hydroxylase (TH) gene expression has been widely studied in adrenal medulla and locus coeruleus (LC) models that express epinephrine or norepinephrine, very little is known about how the gene is regulated in dopaminergic neurons. Alterations in the normal function of mid-brain dopaminergic neurons occur in drug addiction, as well as movement disorders such as Parkinson disease and Tourette syndrome. Since dopamine biosynthesis is largely controlled by the activity of TH, information about the regulation of this enzyme may potentially be important for understanding the etiology of these pathologies. The goal of this study is to determine whether TH is transcriptionally regulated in dopamine neurons of the midbrain. Using the MN9D cell line, which is derived from midbrain dopaminergic neurons, we demonstrate that treatment of these cells with 100 micromolar nicotine for 15 minutes results in a 2.5-fold increase in TH gene transcription rate, as measured by an increase in the levels of TH gene primary transcripts. TH mRNA levels also increase in response to nicotine at later time points. These data suggest that acute exposure of midbrain dopaminergic neurons to nicotine induces TH mRNA via transcriptional mechanisms.

<sup>4</sup>Pathology, College of Oriental Medicine, Daejeon University, Daejeon, South Korea.

Alzheimer's disease (AD) is characterized by senior plaques, containing aggregated beta-amyloid peptide (A-beta), and neurofibrillary tangles in the AD brains. Metallothioneins (MTs) are low molecular weight, metal-binding proteins with established antioxidant capabilities. MT-III, a number of MT family, is expressed in brain in contrast to MT-I and MT-II, those are found in most tissue. The central hypothesis guiding this study is that MT-III may play an important role in amyloid precursor protein (APP) secretion and protection against toxicity induced by A-beta. The present study shows that MT-III enhances the release of the non-amyloidogenic soluble form of the alpha-amyloid precursor protein (sAPPalpha) into the cultured media of mouse neuro 2A neuroblastoma cells. MT-III is not only able to protect, but it can rescue neuro 2A cells against the A-beta toxicity. These results suggested that MT-III has protective effects against A-beta-induced neurotoxicity and regulates secretory processing of non-amyloidogenic sAPPalpha.

CHARACTERIZATION OF CEREBRAL SP1, A $\beta$  AND APP IN RATS: AN IMMUNOHISTOCHEMICAL STUDY OF AGING AND NEURODEGENERATION.

B. Brock, K. DiPalma, M. Basha and N. H. Zawia. Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.

A hallmark of Alzheimer's disease (AD) is the presence of plaques containing aggregated beta-amyloid peptides (A $\beta$ ), derived from the amyloid precursor protein (APP). APP over-expression has been associated with premature accumulation of A and plaque formation and has been linked to learning deficits in transgenic mice. We have found that APP and A $\beta$  over-expression as well as elevated Sp1 DNA-binding activity occur in rats which have been developmentally exposed to lead

(Pb). Recently *in vitro* studies in transfected cells demonstrated that over-expression of Sp1 results in an elevation of APP and overproduction of A $\beta$  (Christenson et al., 2004), while findings from our lab showed that the depletion of Sp1 greatly diminished the responsiveness of the APP promoter. These molecular studies implicate Sp1 as a primary regulator of the APP gene and a mediator of Pb-induced changes in APP expression. To determine whether the relationship between Sp1, APP, and A $\beta$  in the brain is consistent with these findings, we analyzed brain sections of 20 month old rats for Sp1, APP and A $\beta$  immunoreactivity. We found that the overall distribution of Sp1 and APP in various brain regions is similar and appears to be neuronal in origin. In some regions of the brain such as the cerebellum we found differential expression of Sp1, APP, and A $\beta$  which was restricted to the Purkinje cell layer. Consistently, Purkinje cells which over-expressed Sp1 also contained an over-abundance of APP and A $\beta$ . These *in vivo* immunohistochemical findings confirm the existence of a relationship between APP expression and Sp1, and suggest that overproduction of A $\beta$  occurs in cells where Sp1 is strongly present. Therefore, environmental models of AD should consider Sp1 as a potential target that could influence the process of amyloidogenesis.

#### THE CHOROID PLEXUS EXPRESSES THE ENZYMES NECESSARY FOR BETA-AMYLOID PRODUCTION.

E. L. Smith, J. S. Crossgrove and W. Zheng. *School of Health Sciences, Purdue University, West Lafayette, IN.*

Aggregation of beta-amyloid peptides are central in the formation of insoluble plaques seen in brains of Alzheimer's disease patients. Amyloid precursor protein (APP) cleavage by alpha-secretase leads to the release of a soluble peptide fragment, whereas cleavage by beta-secretase promotes the formation of insoluble beta-amyloid peptides. Gamma-secretase cleaves the carboxyl-terminus resulting in variable lengths of the peptides. While a role for the choroid plexus, which separates the blood from cerebrospinal fluid (CSF), in transporting amyloid peptides has been suggested, the question as to whether the tissue itself produces amyloid proteins was unanswered. The objective of this study was to test the hypothesis that the choroid plexus possesses the capacity to produce beta-amyloid. Proteins and total RNAs were extracted from rat choroid plexus tissue and Z310 cells, an established rat choroid epithelium cell line. Quantitative real-time RT-PCR revealed the presence of APP mRNA as well as those of two processing enzymes, alpha- and beta-secretase in both choroid plexus tissue and Z310 cells. We also compared the plexus expression of APP and secretases with brain capillaries isolated from various brain regions. All values were normalized to the mRNA levels of glyceraldehyde-3-phosphate dehydrogenase (GAPDH). Results showed that the choroid plexus expressed the same levels of mRNAs encoding APP, alpha-secretase, and beta-secretase as capillaries of hippocampus, frontal cortex, and cerebellum. Capillaries from the striatum had significantly higher APP and beta-secretase mRNAs than did the choroid plexus. Western blot analysis to confirm the presence of alpha- and beta- secretase, as well as APP proteins is currently in progress. In conclusion, our data indicate that APP and enzymes involving in its metabolism, i.e., alpha- and beta-secretase, appear to be present in the choroid plexus and brain capillaries, suggesting that the blood-CSF barrier and blood-brain barrier may participate in the production and secretion of beta-amyloid in the central nervous system.

#### THE CHOROID PLEXUS ACCUMULATES BETA-AMYLOID FROM BRAIN CSF: IMPLICATIONS FOR ALZHEIMER'S DISEASE.

J. S. Crossgrove, G. Li and W. Zheng. *School of Health Sciences, Purdue University, West Lafayette, IN.*

Beta-amyloid (A $\beta$ ) peptide accumulates and precipitates as insoluble plaques in the brains of Alzheimer's disease (AD) patients. A $\beta$  circulates throughout and between the blood and cerebrospinal fluid (CSF) by crossing the choroid plexus (CP), which comprises the blood-CSF barrier. This study examined the role of the CP in A $\beta$  movement in normal brain. CP tissue isolated from the brains of male Sprague-Dawley rats was weighed and incubated in an artificial CSF (aCSF) containing radiolabeled A $\beta_{1-40}$  ( $^{125}\text{I}$ A $\beta$ ) and a marker for extracellular space and diffusion,  $^{14}\text{C}$ sucrose. Uptake was determined as the ratio of radioactivity in tissue to aCSF.  $^{125}\text{I}$ A $\beta$  uptake into isolated rat CP was linear to 5 minutes, after which uptake leveled. Uptake of total  $^{125}\text{I}$  labeled species was not saturable, while the uptake of the unchanged  $^{125}\text{I}$ A $\beta$  was saturated only at the highest A $\beta$  concentration tested (1000 ng/mL). Low temperature inhibited  $^{125}\text{I}$ A $\beta$  uptake, while A $\beta$  binding partners transthyretin and RAGE (receptor for advanced glycation endproducts) had no significant effect. Apolipoprotein E3 inhibited uptake of total  $^{125}\text{I}$  label, but not that of  $^{125}\text{I}$ A $\beta$ . A primary culture of rat CP epithelial cells seeded onto Transwell chamber devices and grown to confluence was used to study the transepithelial transport and accumulation of A $\beta$ .  $^{125}\text{I}$ A $\beta$  and  $^{14}\text{C}$ sucrose were added to the donor chamber, and aliquots of receiver chamber aCSF were collected for 48 hours.  $^{125}\text{I}$ A $\beta$  permeability across the CP cell monolayers, determined from the slope of receiver chamber concentration over time, appears to be higher in efflux than influx studies. A $\beta$  accumulation into CP cell cultures was higher from the CSF-facing side

than the blood-facing side, suggesting that the CP is more effective in exporting A $\beta$  from the brain. These data suggest that the CP sequesters A $\beta$  from CSF and may be a site of normal brain A $\beta$  clearance. Whether a dysfunction of CP may affect A $\beta$  homeostasis in the brains of AD patients deserves further investigation.

### 1535

#### DIFFERENTIAL EXPRESSION OF GRP78 AND HSP70 IN PRIMARY BRAINSTEM AND CORTICAL ASTROCYTES EXPOSED TO 1, 3-DINTROBENZENE.

S. A. Runkle, S. R. Steiner and M. A. Philbert. *Toxicology Program, University of Michigan, Ann Arbor, MI.*

Exposure to 1, 3-dinitrobenzene (1, 3-DNB) results in a gliovascular lesion within specific brainstem nuclei. Although these regions have high energy requirements, this alone does not describe the observed pathology due to the absence of lesion in areas of similar energy demand. We investigated the possibility that acute *in vitro* neurotoxicity of 1, 3-DNB may be mediated through a disruptive effect by the compound on two key molecular chaperones, glucose regulated protein 78 (GRP78) and heat shock protein 70 (HSP70). Real time RT-PCR analysis of primary brainstem and cortical astrocyte cultures revealed GRP78 mRNA expression increased approximately two-fold in the brainstem, 2 hours post 1mM 1, 3-DNB exposure. Cortical GRP78 mRNA expression increased approximately two-fold, 4 hours after exposure. Regional differences in sensitivity were also observed with the positive control. Thapsigargin (1 $\mu$ M) induced a five-fold increase in brainstem GRP78 expression, in contrast, cortical expression levels were not significantly affected. Immunoblot analysis of brainstem astrocytes showed down-regulation of GRP78 protein expression at 0.5 and 2 hours and up-regulation to basal levels at 4 hours. No significant changes in GRP78 protein expression were observed in the cortical astrocytes after 6 hours of exposure. Immunofluorescence was used to monitor changes in HSP70 expression after 1, 3-DNB exposure in primary brainstem and cortical astrocytes. HSP70 was up-regulated at 2 hours in the cortical astrocytes and at 4 hours in the brainstem astrocytes. This data indicates that primary brainstem and cortical astrocytes respond differentially to oxidative cues after 1, 3-DNB exposure: brainstem astrocytes are significantly more sensitive. Temporal regulation of regional molecular responses to oxidative stress may underlie the differential susceptibility of brainstem astrocytes to 1, 3-DNB. This work was supported by NIH T32 ES07062 (SAR) and RO1 ES08846 (SRS & MAP).

### 1536

#### MIXED INHIBITION OF THE PYRUVATE DEHYDROGENASE COMPLEX BY M-DINITROBENZENE.

J. A. Miller and M. A. Philbert. *Toxicology Program, University of Michigan, Ann Arbor, MI.*

Pyruvate dehydrogenase (PDH), an essential multi-component enzyme complex responsible for the production of acetyl-CoA from glycolytically derived pyruvate, links glycolysis to the TCA cycle. The normal brain relies almost exclusively on the complete oxidation of glucose as its sole fuel source making PDH function critical in maintaining energy metabolism. Disturbances in the function of this enzyme complex frequently result in ensuing pathological states. m-Dinitrobenzene (DNB) has been shown to selectively affect glia-vascular components in distinct brainstem regions resembling the early effects of other acute energy deprivation syndromes. Previously we have shown the rapid and dose dependent inhibition of bovine heart PDH by DNB in purified enzyme reactions. To determine the nature of the inhibition we employed a standard spectrophotometric assay in which the production of the reduced form of nicotinamide-adenine dinucleotide (NADH) by bovine heart PDH was monitored at different substrate concentrations. Through examination of the double reciprocal plots of control versus enzyme incubated with DNB concentrations that have been shown to inhibit in the range of 20 to 60%, it was determined that DNB does not compete for either pyruvate or CoA but results in a mixed type inhibition mechanism. Lipoamide dehydrogenase, the E3 component of the enzyme complex, has been shown to possess nitro-reductase activity. To determine whether or not DNB acts as a specific E3 component inhibitor, oxidation of NADH was measured in the presence of lipoamide. No effect of varying the concentration of DNB was observed on the activity of the E3 component of the complex. In conclusion, DNB exerts its inhibitory effects on PDH via a mixed mechanism. One potential mechanism is through active site modification of either the E1 or E2 components of the complex but not through E3 effects. Further investigation into the mechanism of this inhibition is required. This work was supported by the NIH grant R01-ES08846.

### 1537

#### NITRIC OXIDE MEDIATES MITOCHONDRIAL DYSFUNCTION IN NEUROENDOCRINE TOXICITY.

D. E. Heck<sup>1,2</sup>, J. Gray<sup>1</sup>, D. Osbourn<sup>2</sup> and P. J. Smith<sup>2</sup>. <sup>1</sup>*Rutgers University, Piscataway, NJ* and <sup>2</sup>*Marine Biological Laboratory, Woods Hole, MA*.

Nitric oxide (NO) produced by neuronal nitric oxide synthase, is critical for activity of the neuroendocrine axis, mediating the functioning of the hypothalamic-pituitary-gonadal axis and the hypothalamic-pituitary-adrenal axis. However, NO released from neuroendocrine cells has also been implicated in disorders of these

conduits. In addition, reactive oxygen species (ROS) generated by dysregulation of mitochondrial oxygen sensing may also play a role in pituitary injury. To evaluate the role of NO in the pituitary, we first determined the levels of nitric oxide, and its effective radius, following release from GH3 adenocarcinoma pituitary cells. In these cells nitric oxide release is mediated by activation of L-channel agonists, therefore nitric oxide release was stimulated by membrane depolarizing concentrations of K<sup>+</sup> (25 mM) and by the L-channel calcium agonist Bay kappa 8644 (Bay K, 3  $\mu$ M) and measured using a NO self-referencing sensor. NO was released from GH3 cells immediately following treatment with K<sup>+</sup> and Bay K and could be detected at distances of up to 1 mm from the cells. Mitochondrial function, as measured by cellular oxygen uptake, was not altered by nitric oxide release. Potentially, nitrosation of critical mitochondrial proteins mediated by peroxynitrite, an intermediate formed by interaction of nitric oxide with ROS, is critical to tissue injury. In this regard, we found that O<sub>2</sub> uptake was diminished by the presence of peroxynitrite (10-100  $\mu$ M). In addition, dysregulation of mitochondrial O<sub>2</sub> sensing using nitroarginine methyl ester (1 mM) enhanced oxygen uptake and ROS generation. Taken together these data demonstrate that peroxynitrite, but not agonist-stimulated NO release, alters mitochondrial function in GH3 cells. Our findings also indicate that inhibition of O<sub>2</sub> sensing, through limiting mitochondrial NO production, results in ROS formation. We speculate that peroxynitrite formed in the degenerating pituitary mediates, in part, neuroendocrine toxicity. Supported by NIH grants ES05022, ES007148 and CA093798.

**1538** NITRIC OXIDE ACTIVATES P53 AND INDUCES APOPTOSIS IN NEURONAL PC12 CELLS.

C. Brynczka<sup>1,2</sup> and A. Merrick<sup>1</sup>. <sup>1</sup>National Center For Toxicogenomics, NIEHS, Research Triangle Park, NC and <sup>2</sup>Environmental and Molecular Toxicology, NCSU, Raleigh, NC.

These experiments tested the hypothesis that the p53 tumor suppressor protein and its regulatory elements are involved in nitric oxide (NO)-mediated toxicity in PC12 cells. In order to closely model physiological dopaminergic neurons, PC12 cells were differentiated with nerve growth factor (NGF) and exposed to the nitric oxide donor sodium nitroprusside (SNP). It was shown that differentiated PC12 neurons (dPC12) undergo marked decreases in cell viability following SNP treatment as determined by the MTS dye reduction assay. Pretreatment with the selective p38/MAPK inhibitor, SB202190, partially protected cells from SNP-induced death, implicating p38/MAPK in NO-mediated neuronal toxicity. Despite p53 accumulation and phosphorylation resulting from NGF-induced cell cycle arrest and senescence, additional modest p53 protein accumulation, acetylation and phosphorylation occurs following SNP treatment. Demonstrated NO-induced cytosolic cytochrome c release and caspase activation in dPC12 cells confirms the loss of dPC12 viability occurs through an apoptotic mechanism. Cell death following SNP treatment can be partially attenuated by transcriptional and translational inhibition with actinomycin D and cyclohexamide, respectively. Caspase activity profiling shows marked increases in caspase-1 activity, while several other caspases are significantly inactivated. Apoptosis following SNP treatment does not involve caspase 3/7 activation in differentiated PC12 cells. While p53 is transcriptionally active during NGF-mediated senescence, further study is underway to describe the p53-mediated events leading from senescence to apoptosis. We conclude that differentiated PC12 cells undergo apoptosis in response to SNP treatment, and that p53 is involved in this NO-induced neuronal toxicity. Further study of transcription complexes by p53-specific chromatin immunoprecipitation screening will define its role in neuronal cell death.

**1539** EVALUATION OF THE INTERACTION BETWEEN CAVEOLIN AND GLIAL FIBRILLARY ACIDIC PROTEIN IN C6 GLIA.

G. Velazquez<sup>1</sup>, E. E. Aquino<sup>1</sup>, N. Mayol<sup>2</sup>, H. Maldonado<sup>2</sup> and W. I. Silva<sup>1</sup>. <sup>1</sup>Physiology, UPR Medical Sciences Campus, San Juan, Puerto Rico and <sup>2</sup>Pharmacology, Caribbean Central University, Bayamon, Puerto Rico. Sponsor: B. Jimenez Velez.

Plasma membrane organelles known as caveolae (CAV) are involved in signal transduction events and subcellular transport. These roles of caveolae make it relevant in pathogen, drug entrance to the cell, and as targets for toxicity. The principal components of caveolae are the caveolins (cav), which exist in three different isoforms: cav-1, cav-2, and cav-3. These have been identified in glial cells, particularly the C6 astroglial cell line. In the evaluation of the role of Cav/caveolins in glial cells, here we seek to study their putative interactions with intermediate filaments (IF) proteins. This evaluation is being done in differentiated C6 astrocytes where glial fibrillary acidic protein (GFAP) is the major IF protein. The interaction of caveolin-1 and GFAP was evaluated via laser scanning confocal microscopy, which revealed discrete patches of cav-1/GFAP co-localization in plasma membrane CAV. Subcellular fractionation of CAV-rich microdomains using sodium bicarbonate su-

crose gradients shows co-fractionation of caveolin-1 and GFAP. Preliminary immunoprecipitation results using anti-cav-1 antibodies coupled to agarose beads also support a potential interaction between cav-1 and GFAP. GFAP and IF sequence analysis lead us to propose a novel caveolin-binding motif in the rod 1A region of IF proteins. Studies to confirm these preliminary finding are being undertaken. IF proteins may interact directly or indirectly with glial cell CAV, playing a potential role in their physiological functions, such as signal transduction, transcytosis, potocytosis, and endocytosis. In addition, the interaction between CAV and GFAP can be related with pathological disorders, such as Alexander's disease.

**1540** REACTIVE GLIOSIS IN NEUROTOXIC AND MECHANICAL INJURY MODELS.

C. L. Damiani, D. B. Miller and J. P. O'Callaghan. CDC-NIOSH, Morgantown, WV.

Reactive gliosis is a hallmark of disease-, trauma-, and chemical-induced damage to the CNS. This response is characterized by activation of microglia and astrocytes at sites of damage. Signaling pathways associated with the induction of gliosis remain elusive, but recent evidence implicates the Janus kinase (JAK)-signal transducer and activator of transcription-3 (STAT3) pathway. This pathway is a down-stream effector of cytokines linked to injury-induced astrogliol activation and subsequent expression of GFAP, a cellular response that appears to require STAT3 phosphorylation. Here, we seek to further characterize gliosis by elucidating ligands involved in STAT3 phosphorylation and the induction of GFAP. Two injury models were employed. First we administered, *in vivo*, saline or the dopaminergic neurotoxin, 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP, 12.5 mg/kg, sc). 12 hours post-treatment, coronal slices of striatum were examined for STAT3 phosphorylation and cytokine production. pSTAT3 was present in MPTP treated animals while absent in controls. Messenger RNA for gp130 cytokines [leukemia inhibitory factor (LIF) and oncostatin M (OSM)] as well as a glial-derived chemokine (CCL-2/MCP-1) was induced in MPTP treated animals. Striatal slices were then incubated in oxygenated buffer. Within 45 minutes, control striata also expressed p-STAT3 indicating that STAT3 activation can result from slice injury. To confirm the induction of pSTAT3 *in vivo*, stab wounds were made in striata of mice. GFAP was induced 48 hours after stab and this effect was preceded by pSTAT3 expression. In addition, mRNA for LIF, OSM, and MCP-1 was induced by 24 hours. Since these three ligands were upregulated in both damage models, they were incubated 45 minutes with untreated slices and slices were then assayed for pSTAT3. LIF and OSM promoted glial activation as evidenced by increased pSTAT3 and GFAP protein whereas CCL-2 inhibited gliosis. Together, these data suggest that glial chemokines and gp130 cytokines mediate/modulate reactive gliosis and that pSTAT3 is an early event in glial activation in both neurotoxic and mechanical injury.

**1541** ERK1/2-RSK2 STIMULATION OF MEF2C TRANSCRIPTION PROMOTES CORTICAL NEURON SURVIVAL.

Y. Wang, L. Liu and Z. Xia. Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.

Extracellular signal-regulated protein kinase (ERK) 1/2 pathway has been implicated in neuronal protection against several forms of neuronal apoptosis. However, the downstream mechanisms are not completely understood. Here we report that brain-derived neurotrophic factor (BDNF) protects embryonic cortical neurons from apoptosis after serum withdrawal. Furthermore, BDNF neuroprotection was mediated in part by activation of ERK1/2 signaling pathway. Importantly, we discovered that ERK1/2 activates ribosomal S6 kinase 2 (RSK2), which phosphorylates and activates myocyte enhancer factor 2C (MEF2C). We also provide evidence that RSK2/MEF2C are responsible for the neuroprotection afforded by ERK1/2. Together, our data identify ERK1/2-RSK2-MEF2C as a novel mechanism of neuroprotection.

**1542** DEVELOPMENTAL LEAD EXPOSURE AFFECTS THE SURVIVAL OF GRANULE CELLS IN THE RAT HIPPOCAMPUS.

T. Verina, C. A. Rohde and T. R. Guilarte. Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.

Environmental factors can modify cognitive function and synaptic plasticity by altering neurogenesis in the dentate gyrus (DG) of the hippocampus. We have previously shown that developmental lead (Pb<sup>2+</sup>) exposure impairs neurogenesis in the DG at postnatal day (PN) 50 (Verina, et al., *Toxicol. Sciences.*, 78(Suppl.):109, 2004), a time point in which Pb<sup>2+</sup>-exposed rats exhibit deficits in spatial learning

and hippocampal LTP. In the present study, we examined whether developmental Pb<sup>2+</sup> exposure influences the survival of newborn cells in the DG. Newborn cells were detected using the proliferation marker bromodeoxyuridine (BrdU). Daily injections of BrdU (100mg/kg) were administered to each rat from PN45 to 49. Animals were sacrificed 4 weeks after the last BrdU injection. BrdU-labeled cells were detected by immunohistochemistry and survival of newborn cells was measured after four weeks in the granule cell layer of DG (GCL) in controls and Pb<sup>2+</sup>-exposed rats. BrdU-positive cells were counted bilaterally at the level of the dorsal hippocampus. Cell counts were obtained individually from suprapyramidal (SP) and infrapyramidal (IF) blades of GCL and analyzed using a Poisson regression model with count as the response variable, area as an offset, and treatment group as a factor. There was a highly significant 27.5% decrease of BrdU-positive cells in GCL of Pb<sup>2+</sup>-exposed rats, which was more pronounced in the IF blade (34.2%). To identify potential mediators of the Pb<sup>2+</sup> effect on granule cell survival we assess levels of neurotrophic factors. Preliminary results indicate that the marked decrease in the survival of granule cells in the DG of Pb<sup>2+</sup>-exposed rats might be attributable to altered levels of neurotrophic factors. In summary, our present and previous study indicates that developmental Pb<sup>2+</sup> exposure reduces granule cell proliferation and survival and that this effect may be mediated by altered levels of neurotrophic factors. [Supported by grant number ES06189]

#### 1543

#### PPAR ALPHA ACTIVATION ENHANCES CYANIDE-INDUCED NEUROTOXICITY BY UP-REGULATION OF UCP-2.

X. Zhang, L. Li, K. Prabhakaran, J. L. Borowitz and G. E. Isom. *Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN.*

The activation of peroxisome proliferator-activated receptor alpha (PPAR $\alpha$ ) enhances cerebellar granule cell death, but the mechanism underlying PPAR $\alpha$  involvement in neuronal cell death is not known. Previous studies have shown that the PPAR $\alpha$  activator WY14, 643 induces up-regulation of Uncoupling Protein-2 (UCP-2) in rodent hepatocytes. To further explore the role of PPAR $\alpha$  in neuronal cell death and its potential function in the nervous system, we examined the effects of WY14, 643 on potassium cyanide (KCN)-induced cell death in rat dopaminergic N27 cells and expression levels of UCP-2. When cells were treated with either WY14, 643 (100  $\mu$ M) or KCN (300  $\mu$ M) alone, no significant cell death was observed. However, when WY14, 643 and KCN treatments were combined, the cells exhibited a significant level of necrotic cell death as compared to controls. Cell death was preceded by a marked decrease of cellular ATP levels and mitochondrial membrane potential ( $\Delta\psi$  m). The results also showed that cell death was blocked by pretreatment with MK-886, a non-competitive inhibitor of PPAR $\alpha$ . To determine the involvement of UCP-2 in the response, western blot analysis showed that KCN had no influence on expression of UCP-2, whereas pretreatment with WY14, 643 significantly increased UCP-2 expression. Inhibition of UCP-2 translation by transfection with UCP-2 siRNA (RNA-interference) protected cells from death. These results suggest a possible role of PPAR $\alpha$  in enhancement of toxicant-induced neuronal cell death in which PPAR $\alpha$  activation leads to up-regulation of UCP-2 and thus sensitizing the cells to mitochondrial dysfunction. (This study was supported by NIH grant ES04140)

#### 1544

#### NEUROPROTECTION AGAINST METHAMPHETAMINE (METH) AFFORDED BY PRETREATMENT WITH INCREASING DOSES OF THE DRUG IS DEPENDENT ON THE DOSING SCHEDULE OF METH USED DURING THE DRUG CHALLENGE.

D. L. Graham<sup>1,2</sup>, P. H. Noailles<sup>1</sup>, B. Ladenheim<sup>1</sup>, T. H. Moran<sup>3</sup> and J. L. Cadet<sup>1</sup>. <sup>1</sup>*Molecular Neuropsychiatry Branch, DHHS/NIH/NIDA/IRP, Baltimore, MD*, <sup>2</sup>*Program in Toxicology, University of Maryland School of Medicine, Baltimore, MD* and <sup>3</sup>*Department of Psychiatry and Behavioral Sciences, The Johns Hopkins University School of Medicine, Baltimore, MD.*

Because repeated intake of methamphetamine (METH) leads to the development of tolerance to its behavioral effects, human addicts usually take higher doses of the drug to achieve consistent euphoric effects. Although evidence exists that METH taken in this manner can cause degeneration of monoaminergic terminals in humans, it is still not clear if this is the case in animal models because the most common ways of assessing METH toxicity involve a METH challenge in animals that have not been exposed previously to the drug. Thus, the purpose of the present study was to evaluate the effects of two types of METH challenges on METH-induced monoamine depletion in the rat brain after pre-treatment of the animals with increasing doses of the drug. Adult male Sprague-Dawley rats were injected with METH or saline according to an escalating dose (ED) schedule for two weeks, followed by a challenge with either saline or one of two METH doses (10 mg/kg every 2 hrs X 3 injections or 5 mg/kg every hr X 6 injections). Brain regions were extracted at 2 or 24 hrs following the final injection. HPLC analyses revealed that

METH causes significant depletion of dopamine (DA) and serotonin (5-HT) in the striatum of saline-treated rats using either of the two challenge approaches. In addition, while there was significant protection from the 3 x 10 mg/kg METH challenge, there was no such protection in the animals treated with the 6 X 5 mg/kg challenge schedule after the animals were pre-treated with escalating doses of the drug. These results are compatible with the documentation of monoamine depletion in the brains of METH abusers.

#### 1545

#### SUBCHRONIC EXPOSURE TO LOW LEVELS OF POLYCHLORINATED BIPHENYLS REDUCES DOPAMINE TRANSPORTER AND VESICULAR MONOAMINE TRANSPORTER 2 LEVELS.

M. Caudle, J. R. Richardson and G. W. Miller. *Center for Neurodegenerative Disease, Emory University, Atlanta, GA.*

Polychlorinated biphenyls (PCBs) are ubiquitous environmental contaminants which have been shown to target the dopaminergic system, causing reductions of dopamine levels both in cell culture and in animal models. However, the mechanisms behind the actions of PCBs on the dopaminergic system are unclear. Previously, we reported that high-level acute exposure to Aroclor 1016 or 1260 reduces striatal dopamine and levels of the dopamine transporter (DAT) and vesicular monoamine transporter 2 (VMAT2) (Richardson and Miller, 2004). In this study, we examined the effects of daily exposure of mice to a 1:1 mixture of Aroclor 1254 and 1260, which is similar in composition to PCBs found to contaminate fish in the Great Lakes. Oral exposure of mice to 7.5 or 15 mg/kg/day for 14 days resulted in a dose-related decrease in the levels of DAT as determine by immunoblotting (15 and 60%), [<sup>3</sup>H]DA uptake (15 and 50%) and [<sup>3</sup>H]WIN 35, 428 binding (15 and 40%). Exposure of mice for 30 days resulted in a dose related decrease in levels and function of DAT as determined by immunoblotting (18 and 40%), [<sup>3</sup>H]DA uptake (40 and 60%) and [<sup>3</sup>H]WIN 35, 428 binding (25 and 50%). Reduction of VMAT2 (15 and 20%) was also observed. No changes were observed in tyrosine hydroxylase (TH) levels, suggesting that the decreases in DAT and VMAT2 were not the result of loss of dopamine neurons. These data suggest that low-level exposure to PCBs alters DAT and VMAT2 levels. Since DAT and VMAT2 play significant roles in the regulation of dopamine levels, alterations of these transporters may contribute to the reduction of dopamine levels observed in animals chronically exposed to PCBs. #### ACRYLAMIDE DISRUPTS UPTAKE OF DOPAMINE INTO RAT STRIATAL SYNAPTIC VESICLES.

R. M. LoPachin<sup>1</sup> and D. S. Barber<sup>2</sup>. <sup>1</sup>*Anesthesiology, Albert Einstein College of Medicine, Bronx, NY* and <sup>2</sup>*Center for Environmental Health and Toxicology, University of Florida, Gainesville, FL.*

Acrylamide (ACR) exposure impairs calcium-dependent neurotransmitter release from rat brain synaptosomes (Neurotoxicology 25: 349-363, 2004). Although the corresponding site and mechanism of action are unknown, it is possible that ACR decreases the presynaptic pool of releasable neurotransmitter by inhibiting synaptic vesicle (SV) transport and storage. To investigate this possibility, SVs were prepared from rat striatum and were exposed to graded concentrations of ACR (0.4-2.0M). Results show that ACR caused concentration-dependent decreases in vesicular <sup>3</sup>H-dopamine (DA) uptake (IC<sub>50</sub> = 243 mM). *In vitro* exposure of SVs to the sulphydryl reagent, N-ethylmaleimide (NEM), produced similar inhibitory effects (IC<sub>50</sub> = 0.006 mM). Kinetic analysis revealed that *in vitro* exposure to either ACR or NEM increased Km and decreased V<sub>max</sub>. Analysis of SVs from ACR-intoxicated rats (50 mg/kg x 8d or 21 mg/kg x 21 d) demonstrated similar alterations in kinetic parameters. These *in vitro* and *in vivo* changes are consistent with ACR addition of SV proteins resulting in mixed noncompetitive inhibition. Additional *in vivo* studies showed that ACR did not affect protein content or synaptosomal GSH levels, whereas *in vitro* ACR exposure caused no changes in vesicular DA retention. These results suggest that ACR causes direct inhibition of SV neurotransmitter storage and thereby decreases the releasable presynaptic pool. We hypothesize that ACR forms cysteine adducts, which inhibit the function of SV proteins that mediate DA uptake (VMAT2, v-ATPase). Sponsored by ESO3830-18.

#### INHIBITION OF HUMAN $\alpha$ 7 NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS BY THE VOLATILE ORGANIC SOLVENT TRICHLOROETHYLENE.

C. A. Meacham, A. S. Bale, P. J. Bushnell and T. J. Shafer. *Neurotoxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Volatile organic solvents (VOCs) such as toluene and perchloroethylene block currents mediated by neuronal nicotinic acetylcholine receptors (nAChR), an effect hypothesized to be a mode of action for these compounds. Trichloroethylene

(TCE) is a neurotoxic VOC that has behavioral effects similar to toluene and perchloroethylene. The present study examined the hypothesis that TCE will inhibit nAChR function in a manner similar to other VOCs. TCE effects on acetylcholine-induced currents through human  $\alpha 7$  receptors expressed in Xenopus oocytes were measured using two-electrode voltage clamp techniques. Acetylcholine-induced currents had an average amplitude of  $-257 \pm 121$  (n=7) nA. TCE caused a concentration-dependent inhibition of nAChR current amplitude. At a nominal TCE concentration of 250  $\mu$ M, TCE inhibited currents through  $\alpha 7$  receptors by 88% (n=4), while at a nominal concentration of 2500  $\mu$ M, inhibition was 93% (n=4). Effects of TCE on  $\alpha 7$  nAChR were rapid and completely reversible. Actual TCE concentration in the test medium was determined by gas chromatography of samples (nominally 50 - 5000  $\mu$ M) taken directly from the recording chamber. Linear regression indicated that nominal TCE concentrations of 250 and 2500  $\mu$ M corresponded to actual TCE concentrations of 50 and 500  $\mu$ M, respectively. These results indicate that TCE inhibits nAChR receptor function at low concentrations and suggests that disruption of nAChR function may be a common mode of action for neurotoxic VOCs. (This abstract does not reflect EPA policy).

**1548 XYLENE BLOCKS VOLTAGE-GATED CALCIUM CURRENTS IN PHEOCHROMOCYTOMA CELLS.**

T. J. Shafer. *Neurotoxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Volatile organic compounds such as toluene, trichloroethylene and perchloroethylene are potent and reversible blockers of voltage-gated calcium current ( $I_{Ca}$ ) in nerve growth factor (NGF)-differentiated pheochromocytoma (PC12) cells. It is hypothesized that effects of VOCs on  $I_{Ca}$  contribute to the acute neurotoxicity of VOCs. The present experiments examined the ability of xylene, a VOC that is structurally similar to toluene, to block  $I_{Ca}$  in PC12 cells. Whole-cell patch clamp techniques were utilized to examine xylene effects on currents elicited by a 200 ms voltage-step from a holding potential of -70 to +10 mV. Following exposure to 3000  $\mu$ M xylene (as mixed xylene isomers), peak  $I_{Ca}$  was reduced to  $21 \pm 9$  % of control amplitude while current amplitude immediately prior to the end of the voltage step was reduced to  $12 \pm 6$  % of control (n = 3). Xylene, at nominal concentrations between 150 and 3000  $\mu$ M, reduced  $I_{Ca}$  in a concentration-dependent manner. In addition to decreasing amplitude, xylene also altered the inactivation kinetics of  $I_{Ca}$ . In the absence of xylene, currents decayed with a single exponential and had a tau value of  $133 \pm 39$  msec (n = 3). In the presence of 1500  $\mu$ M xylene, inactivation kinetics were best fit by two exponential components with tau values of  $17 \pm 9$  and  $57 \pm 10$  msec (n=3). These data indicate that voltage-gated calcium channels are sensitive to the effects of xylene, and that xylene produces the same characteristic alterations in calcium channel function that are observed following exposure to toluene, perchloroethylene and trichloroethylene. Thus, VOCs have a common ability to disrupt calcium channel function, and this action may contribute to the neurotoxic effects of VOCs. (This abstract does not reflect EPA policy).

**1549 NEUROTOXIC (1, 2, 4-) AND NON-NEUROTOXIC (1, 3, 5-) TRIETHYLBENZENES.**

V. S. Palmer, D. D. Tshala-Katumbay, R. J. Kayton, P. S. Spencer and M. I. Sabri. *Center for Research on Occupational and Environmental Toxicology, Oregon Health & Science University, Portland, OR.*

We have reported the protein-reactive, chromogenic and neurotoxic properties of the aromatic and aliphatic gamma-diketone solvent metabolites 1, 2-diacetylbenzene (1, 2-DAB) and 2, 5-hexanedione (2, 5-HD), respectively; by contrast their corresponding non-chromogenic isomers, 1, 3-DAB & 2, 4-HD, respectively, fail to induce murine neuropathy, the hallmark of which is proximal (1, 2-DAB) or distal (2, 5-HD) axonal swellings (with distal atrophy) filled with maloriented neurofilaments (NF). We asked whether 1, 2, 4-triethylbenzene (1, 2, 4-TEB), the probable precursor of 1, 2, 4-triacylbenzene (1, 2, 4-TAB) shows comparable structure-dependent chromogenic and neurotoxic properties. Twelve week-old male C57BL/6 mice were dosed orally with 300 mg/kg (n=3), 600 mg/kg (n=3) or 900 mg/kg (n=3) body weight of 1, 2, 4-TEB, equivalent doses of 1, 3, 5-TEB (which lacks the 1, 2-diacetyl moiety), or an equal volume of the TEB Vehicle (olive oil), for 3 evenly spaced days/week for up to 12 weeks. Mice treated with 1, 2, 4-TEB excreted greenish urine after 5 (900 mg/kg), 14 (600 mg/kg) and 49 (300 mg/kg) days and, thereafter, developed muscle spasm and hind-limb weakness. Blue-greenish tissue from the central nervous system (frontal cortex, hippocampus, basal ganglia, cerebellum, medulla oblongata, lumbar and cervical spinal cord) and the peripheral nervous system (lumbar spinal ventral roots, dorsal spinal roots and ganglia, sciatic nerves) were sampled for light and electron microscopy. Mice treated with 1, 2, 4-TEB showed a dose-dependent 1, 2-DAB-like pattern of intramedullary, intraspinal and spinal root NF-filled axonal swellings presumably arising from proximal blockade of NF anterograde transport. Mice treated with 1, 3, 5-TEB or Vehicle lacked urine and tissue discoloration, hindlimb weakness, and

neuropathology. These results show that 1, 2-spaced ethyl moieties on a benzene ring are required to induce a 1, 2-DAB-like pattern of murine CNS-PNS proximal axonopathy. [Supported by NIEHS grants ES10338 and ES 11384 and Oregon Workers' Benefit Fund]

**1550 RAPID-ONSET GAMMA-DIKETONE AXONOPATHY IN HIPPOCAMPAL NEURONS IN CULTURE.**

D. D. Tshala-Katumbay, B. Sampo, V. S. Palmer, G. A. Banker, M. I. Sabri and P. S. Spencer. *Center for Research on Occupational and Environmental Toxicology, and Department of Neurology, School of Medicine, Oregon Health & Science University, Portland, OR.*

Aromatic and aliphatic hydrocarbons with a 1, 2-diketo side chain react with neuronal proteins and cause proximal axon swellings filled with neurofilaments and distal retrograde degeneration, respectively, in the peripheral and central nervous system (CNS) of rodents. Critical protein targets of these gamma-diketones have yet to be identified. We used low-density primary cultures of rat hippocampal neurons to examine responses to neurotoxic 1, 2-diacetylbenzene (1, 2-DAB, gamma-diketone) vs. non-neurotoxic 1, 3-diacetylbenzene (1, 3-DAB, delta-diketone). These largely (85-90%) pyramidal nerve cells develop single elongate axons and dendritic arrays in which protein transport, delivery and fate can be characterized. Hippocampal neurons were incubated at 37 degrees C for up to 90 min. with concentrations of 1, 2-DAB (10, 250, 500, 1000, 2000 or 4000 micromolar), 1, 3-DAB (10, 250 micromolar) or DAB Vehicle (-1 micromolar acetone) in serum-free media. Cells were fixed at 30, 60 or 90 min. with 4% paraformaldehyde/4% sucrose in phosphate-buffered saline (pH 7.4) and examined by phase-contrast and/or Nomarski microscopy. 1, 2-DAB induced concentration- and time-dependent axonal beading reminiscent of wallerian-like degeneration. Distal, retrograde axonal beading was seen with 250 micromolar 1, 2-DAB but not with an equivalent concentration of 1, 3-DAB. High concentrations of 1, 2-DAB were acutely neurotoxic. No axonal beading was seen with 10 micromolar DAB or with Vehicle. These findings demonstrate a rapid alternative approach to study molecular mechanisms of gamma-diketone axonal degeneration. [Supported by NIEHS grants ES10338 and ES 11384 and Oregon Workers' Benefit Fund]

**1551 GAMMA-DIKETONE TOXICITY: A ROLE FOR STATHMIN IN NERVE AND TESTES DAMAGE?**

M. I. Sabri<sup>1</sup>, S. B. Hashemi<sup>1</sup>, S. Chohan<sup>1</sup>, S. Khalil<sup>1</sup>, A. B. Cranson<sup>1</sup>, D. D. Tshala-Katumbay<sup>1</sup>, V. S. Palmer<sup>1</sup>, J. G. Pounds<sup>2</sup> and P. S. Spencer<sup>1</sup>. *<sup>1</sup>Center for Research on Occupational and Environmental Toxicology; Department of Neurology, School of Medicine, Oregon Health & Science University, Portland, OR and <sup>2</sup>Molecular Biosciences, Pacific Northwest National Laboratory, Richland, WA.*

Stathmin is a ubiquitous, brain-enriched phosphoprotein that binds to tubulin and inhibits microtubule (MT) assembly. Preliminary studies show stathmin modulation in brains of mice treated with single doses of neurotoxic 1, 2-DAB (gamma-diketone) relative to non-neurotoxic 1, 3-DAB (delta-diketone). Stathmin is of special interest in relation to 1, 2-DAB-induced axonopathy because aged stathmin(-/-) mice also develop axonal degeneration. Another neurotoxic gamma-diketone, 2, 5-hexanedione, promotes MT assembly and acts as a Sertoli cell toxicant. To examine the effect of DAB isomers on stathmin, slices of rat testes were incubated with 1-10 mM 1, 2-DAB, 1, 3-DAB, or Vehicle, for 30 min at 37 degrees C. Tissues were homogenized in sample buffer and 6-12 microgram protein aliquots subjected to SDS-PAGE. Electrophoresed proteins were transferred to PVDF membranes and probed with anti-stathmin antibody. Stathmin was visualized (a) colorimetrically by applying secondary antibody conjugated with horse radish peroxidase (HRP) and streptavidin-HRP amplifying reagent or (b) fluorometrically by secondary antibody tagged with IR Dye-800. 1, 2-DAB reduced the intensity of the native stathmin band in a concentration-dependent manner: ~15%, ~20%, ~35% and ~50% at 1, 2, 5, and 10 mM respectively, with corresponding increases in high-molecular-weight protein adducts. By contrast, 1-10 mM 1, 3-DAB under similar conditions had no effect on stathmin, and adducts were not observed. Rat brain slices incubated with 1-10 mM 1, 2-DAB, but not equivalent concentrations of 1, 3-DAB, showed a similar pattern of stathmin loss. Stathmin, a MT-destabilizing cytosolic protein, is of potential mechanistic relevance to the tissue damage elicited by gamma-diketones. [Supported by NIEHS grants ES10338 and ES 11384 and Oregon Workers' Benefit Fund]

**1552 EFFECTS OF SUBACUTE AND CHRONIC ACRYLAMIDE DOSING ON FAST-TRANSPORTED PROTEINS INTO RAT NEUROMUSCULAR JUNCTIONS.**

D. W. Sickles and A. Testino. *Cellular Biology and Anatomy, Medical College of Georgia, Augusta, GA.*

Reductions in fast axonal transport and inhibition of the motor protein kinesin have been identified as molecular sites of action of the neurotoxicant acrylamide (Sickles, Neurotoxicology 23:223, 2002). We are determining whether these effects

reduce vital macromolecules in the distal axons sufficient to produce ataxia and paralysis. Previous work has identified specific reductions in ion channels to CNS and PNS nodes of Ranvier. Male, Sprague-Dawley rats (n=5/group;225g) were either given subacute exposure of acrylamide (50mg/kg/d ip for 10d) or were chronically exposed (2.8mM in drinking water; effective daily dose of 20-21mg/kg/d for 49d); saline-injected or regular drinking water served as controls. The extensor digitorum longus (EDL) and extensor carpi radialis (ECR), representing distal and more proximal NMJs, homogenates were used for semiquantitative dot blot analysis for synaptophysin, synaptotagmin and syntaxin content. Total muscle protein content was reduced 36 (EDL) - 39% (ECR) in chronic animals and 21 (EDL)-23% (ECR) by subacute treatment. These reductions did not parallel changes in NMJ proteins. Chronic treatment produced significant reductions in EDL synaptotagmin (-54%; relative units = 11.5±1.3 vs 5.25±2.4), and syntaxin (-30%; 23.3±4.2 vs. 16.3±2.6 but no significant change in synaptophysin. EDL NMJ proteins were always reduced more than ECR, the only significant change was a 32% reduction in synaptotagmin. Subacute ACR produced significant reductions in EDL synaptophysin (-62%), synaptotagmin (-57%) and syntaxin (-27%) while no significant changes were observed in the ECR muscle. These results clearly identify reductions in vital NMJ proteins following both subacute and chronic ACR exposure that are most pronounced in distal, in contrast to more proximal, NMJs. The spatial pattern is consistent with reduced fast transport as the cause of deficiencies. Reductions in these proteins are anticipated to compromise neurotransmission and produce symptoms, despite the absence of neurodegeneration. Supported by NIH # ES011223.

#### REDUCTIONS IN NEUROMUSCULAR JUNCTION CHOLINESTERASE ACTIVITY BY SUBACUTE AND CHRONIC ACRYLAMIDE EXPOSURE.

B. Newman, L. Oblak, D. Kumiski and D. Sickles. *Cellular Biology and Anatomy, Medical College of Georgia, Augusta, GA.*

Acrylamide has been demonstrated to inhibit fast anterograde motor protein kinesin and produce reductions in fast transport (Sickles, *Neurotoxicology* 23:223, 2002). To determine whether the reductions are sufficient to produce deficiencies in vital nerve terminal proteins, we have used semiquantitative analysis of a silver cholinesterase stain in distal neuromuscular junctions of the extensor digitorum longus (EDL) and the more proximal forearm extensor carpi radialis (ECR). Male, Sprague-Dawley rats (225g; n=5/group) were exposed to either: subacute ACR@ 50mg/kg/d for 12 days, chronic ACR @ 2.8mM in drinking water for average of 20-21mg/kg/d for 49d, saline ip control or regular drinking water control. Fifty NMJ per animal were photographed and analyzed using Zeiss Image manual outline by an investigator blind to experimental group. Chronic ACR treatment produced a significant 33% reduction in EDL NMJ cholinesterase (54.6±6.6 vs 36.5±2.9 relative units) with a non-significant 20% reduction in the ECR (41.2±5.6 vs 33.0±2.6). Acute treatment to ACR for 12 days was sufficient to initiate forelimb splay with severe splay in the hindlimb. Following this prolonged treatment, both the EDL and ECR NMJ cholinesterase were reduced by 49% and 38%, respectively. In all cases, EDL was reduced more than ECR. We conclude that ACR, at two different dosing rates that produce neurological symptoms, also produces reductions in NMJ cholinesterase. Significant reductions in cholinesterase were not observed in symptom-free muscles. The absence of neurodegeneration in acute animals indicate that protein deficiencies such as cholinesterase or other vital fast transported proteins may be sufficient to produce symptoms. The greater effect on EDL cholinesterase in comparison to ECR indicates that direct actions are not the cause of the reductions in cholinesterase. This spatial pattern is consistent with ACR-induced reductions in axonal transport. The reductions in cholinesterase are less than observed with other NMJ proteins (see accompanying abstract). Supported by NIH ES012233

#### HUMAN FLAVIN-CONTAINING MONOOXYGENASE: QUANTIFICATION IN HUMAN TISSUES.

J. R. Cashman and J. Zhang. *Human BioMolecular Research Institute, San Diego, CA.* Sponsor: D. Schlenk.

The flavin-containing monooxygenases (FMOs) comprise a family of FAD-, NADPH- and oxygen-dependent microsomal enzymes. The FMO constitute the second most important human monooxygenase system behind cytochrome P450 (CYP), attaining expression levels approaching 60% of CYP 3A in adult human liver. FMO catalyzes the oxygenation of many nitrogen-, sulfur-, phosphorous-, selenium-, and other nucleophilic heteroatom-containing chemicals and drugs. Five functional forms of FMO (i.e., FMOs 1-5) are present in humans, but it is FMO3 in adult human liver that has previously been identified as the major enzyme responsible for hepatic drug metabolism. Complete characterization of the FMO genes is needed to place this monooxygenase in context with other enzyme systems. The scope of this study was to quantify all the major FMO genes in the following

tissue: adult liver, kidney, lung, small intestine, and brain as well as fetal liver and fetal brain. The experimental procedure involved QPCR. The data gave a complete quantitative description of the copy number of each FMO gene in the tissues examined. The principal conclusions were surprising: FMO5 was prominent in adult and fetal liver and small intestine, FMO1 was prominent in adult kidney and FMO2 was prominent in adult lung. Evidence obtained showed that FMO1 was prominent in fetal brain while FMO2 was prominent in adult brain but the copy numbers were quite low and the result may be due to inadvertent sampling error. The data suggest that revision of our current ideas about the type and amount of FMO in the above-studied tissues is in order. For example, it is apparent that FMO5 is a major form of FMO present in important human tissue that does drug metabolism. However, our lack of understanding of FMO5 in so far as enzyme characterization and substrate specificity considerably confounds our understanding about the way FMO5 participates in human chemical or drug metabolism. Supported by NIH Grant DK59618.

### 1555

#### OXIDATION OF SELENOMETHIONINE BY FLAVIN-CONTAINING MONOOXYGENASES (FMOS).

D. Shi and D. Schlenk. *Department of Environmental Sciences, University of California, Riverside, CA.*

Selenium biotransformation into organoselenium forms by primary producers and subsequent accumulation by higher food chain organisms such as fish are critical for mechanistically understanding the adverse effects of selenium in aquatic organisms. Although previous laboratory and field studies have both demonstrated a good correlation between adverse effects and total selenium in fish tissue, direct confirmation of the most toxicologically important forms of organoselenium is lacking, with nearly all measurements being total selenium. To illustrate this, we hypothesize that following accumulation by fish organoselenides are oxidized to selenoxides by flavin-containing monooxygenase (FMO) upon the consumption of NADPH and oxygen. The generated selenoxide can be reduced to organoselenide by consuming the antioxidant glutathione. With the continuous redox cycling between organoselenide and selenoxide we hypothesize, glutathione will be depleted, eventually resulting in cellular toxicity. Therefore, in this study, an *in vitro* substrate dependent NADPH oxidation assay was performed to test the first step of the hypothesis, the oxidation of organoselenium by FMO. A series concentration of the organoselenium selenomethionine (0.05 — 2.0 mM) was incubated with 0.2 mM NADPH and 100 µg human microsomal FMO1 or FMO3 proteins in 50 mM KPO<sub>4</sub> buffer (pH 8.4) at 37 °C. The absorbance of NADPH (340 nm) of the reaction mixture was measured over 30 min at 5 min intervals, and a NADPH extinction coefficient of 6220 M<sup>-1</sup> cm<sup>-1</sup> was used in calculating catalytic constants. The results show that both FMO1 and FMO3 demonstrated catalytic activity for selenomethionine, with FMO3 having a lower Km than FMO1 (i.e., 172 µM and 617 µM, respectively), indicating that FMO3 is more reactive in catalyzing the oxygenation of selenomethionine to the oxide. Future study is required to directly detect the generation of selenomethionine oxide from selenomethionine oxidation by FMO.

#### COMPARISON OF MAJOR PHASE I AND PHASE II METABOLISM REACTIONS IN CRYOPRESERVED CYNO MONKEY AND HUMAN HEPATOCYTES.

B. R. Snodgrass<sup>1</sup>, P. V. Gagne<sup>1</sup>, P. L. Picano<sup>1</sup>, K. J. Lohnes<sup>1</sup>, S. P. Cain<sup>2</sup>, G. G. Zhang<sup>1</sup>, C. J. Patten<sup>1</sup> and C. L. Crespi<sup>1</sup>. <sup>1</sup>*Research & Development, BD Discovery Labware, Woburn, MA* and <sup>2</sup>*Operations, BD Discovery Labware, Woburn, MA*.

Cryopreserved hepatocytes are a powerful tool for *in vitro* metabolic profiling and toxicity assessment of New Chemical Entities (NCEs). *In vitro* studies of NCEs' metabolism and toxicity in hepatocytes are predictive of *in vivo* reactions and are recommended precursors to *in vivo* studies. Cryopreserved cynomolgus monkey and cryopreserved human hepatocytes were thawed and assessed for Phase I and Phase II metabolic activity, viability over a four-hour incubation period, and lactate dehydrogenase (LDH) leakage when exposed to known toxins. Phase I reactions measured included 6b-hydroxylation of testosterone, O-deethylation of phenacetin, 1'-hydroxylation of bufuralol, and 2-hydroxylation of p-nitrophenol. Glucuronidation and sulfation of 7-hydroxycoumarin were assessed as representative Phase II reactions. Thawed cryopreserved hepatocytes from both species maintained all Phase I and Phase II metabolic activity tested over a four-hour incubation period and demonstrated only a small decline in viability. Both species were comparable in 6b-hydroxylation of testosterone and glucuronidation of 7-hydroxycoumarin, while on average cynomolgus monkey hepatocytes were more active than human in O-deethylation of phenacetin (5-fold) and 1'-hydroxylation of bufuralol (9-fold). Both species hepatocytes demonstrated comparable LDH leakage when exposed to increasing Tamoxifen concentrations. These data demonstrate conservation of Phase I and Phase II metabolic activity in cryopreserved cyno monkey and human hepatocytes and that both species' cryopreserved hepatocytes are useful for *in vitro* metabolism and toxicity studies of NCEs.

## COMPARISON OF CELLULAR MODELS FOR ASSESSING LIVER TOXICITY.

R. Maitra, K. Moore, S. Frank and A. Higgins. *Ichora, Inc., Research Triangle Park, NC.* Sponsor: J. Hamilton.

Prediction of toxicity through *in vitro* modeling can reduce cost of drug development. *In vitro* models while used in exploratory toxicology, vary considerably in terms of their lineage, properties, and applicability. For example, most hepatocyte cell lines have limited expression of P450 enzymes, and as such, have limited capability to transform xenobiotics. By contrast, freshly isolated primary hepatocytes have abundant expression of most P450 enzymes but rapidly lose this function during culture. However, primary cells are diverse in their genetics and their metabolism is affected by underlying physiological conditions of donors. We investigated several hepatic *in vitro* models - human HepG2 and THLE-3 cells, rat H4IIE-C3 cells, as well as, freshly isolated primary rat (PRH) and human (PHH) hepatocytes for their comparative sensitivity to the model hepatotoxicant, acetaminophen (APAP). APAP remains the main cause of acute liver failure in the US due to over-dosage. Cellular toxicity, as determined by suppression of relative intracellular ATP level, was recognized in every model, implying specific toxicity to APAP. Resistance to APAP correlated negatively with reported expression of CYP2E1, the purported major form of P450 involved in APAP-metabolism with HepG2 cells demonstrating maximum resistance to the test agent. By contrast rat H4IIE-C3, PHH and PRH; cells expressing CYP2E1 were sensitive to toxicity with lower IC50 values. Interestingly in PHH, APAP toxicity positively correlated with degree of liver steatosis in donors. Our results indicate that cells can be used for predictive toxicology but are subject to the same sources of variability, such as genetics and underlying disease conditions, as intact subjects. These limitations should be taken into consideration when choosing an appropriate model system for predictive toxicology.

## PANCREATIC AND HEPATIC ETHANOL TOXICITY IN HEPATIC ALCOHOL DEHYDROGENASE DEFICIENT DEER MICE: MORPHOLOGICAL AND BIOCHEMICAL CHARACTERIZATION.

K. Bhopale<sup>1</sup>, H. Wu<sup>1</sup>, P. Boor<sup>1</sup>, G. A. Ansari<sup>1</sup> and B. S. Kaphalia<sup>1</sup>. <sup>1</sup>*Pathology, University of Texas Medical Branch, Galveston, TX*, <sup>2</sup>*Pathology, University of Texas Medical Branch, Galveston, TX*, <sup>3</sup>*Pathology, University of Texas Medical Branch, Galveston, TX*, <sup>4</sup>*Pathology, University of Texas Medical Branch, Galveston, TX* and <sup>5</sup>*Pathology, University of Texas Medical Branch, Galveston, TX*.

Chronic alcohol abuse is one of the major causes of pancreatic and hepatic diseases and many chronic alcoholics die before reaching the clinical stage of the diseases. The mechanism and etiologic agent(s) involved in alcoholic pancreatitis and hepatitis are not known. Oxidative metabolism of ethanol catalyzed by alcohol dehydrogenase (ADH) is generally impaired during chronic alcohol abuse and inhibition of hepatic ADH is shown to facilitate nonoxidative metabolism of ethanol to fatty acid ethyl esters (FAEEs). FAEEs are known to cause pancreatic and hepatic toxicity *in vitro* and pancreatitis-like injury in rat model. In order to understand the mechanism and etiology of alcoholic pancreatitis and hepatitis, hepatic ADH deficient (ADH-) deer mice and ADH normal (ADH+) deer mice were fed ethanol (4%, wt/v) via Lieber-DeCarli liquid diet. Control animals were pair-fed with isocaloric liquid diet. Following 60 days of ethanol treatment, 11 out of 18 ADH-deer mice died as compared to 1 out of 16 ADH+ deer mice. All surviving animals were sacrificed, whole blood was collected to obtain plasma and organs were excised for histopathology. Pancreatic damage was evident by vacuolization, edema, necrosis and loss of acinar cells in some areas. Extensive vacuolization, displacement or absence of nucleus was seen in some hepatocytes in ethanol-fed ADH- deer mice. No significant histopathological changes were found in other organs of both ethanol-fed deer mice strains. There was no death in control groups of both strains, and minimal change in histology. Correlation of the histopathological changes seen in the pancreas and liver will be established with biochemical changes in the plasma with an ultimate aim to develop biomarkers of alcoholic pancreatitis and hepatitis.

## VARIABILITY IN METABOLISM OF CHLORAL HYDRATE IN HUMAN HEPATOCYTES.

A. Bronley-DeLancey<sup>2</sup>, D. G. Hoel<sup>2</sup> and D. C. McMillan<sup>1</sup>. <sup>1</sup>*Department of Pharmacology, Medical University of South Carolina, Charleston, SC* and <sup>2</sup>*Department of Biostatistics, Bioinformatics and Epidemiology, Medical University of South Carolina, Charleston, SC*.

Chloral hydrate is a sedative drug that is also a CYP 450-derived metabolite of the suspect human carcinogen, trichloroethylene (TCE). Chloral hydrate is metabolized in the liver to the rodent hepatocarcinogen, trichloroacetate (TCA), by aldehyde dehydrogenase (ALDH), and to the non-carcinogenic metabolite, trichloroethanol (TCE-OH), by alcohol dehydrogenase (ADH). Both ALDH and

ADH are polymorphic in humans, which predicts that human disposition of chloral hydrate into the carcinogenic vs. non-carcinogenic pathways will show inter-individual variation. This raises the possibility that sub-populations of humans will produce greater amounts of TCA relative to TCE-OH and hence have a greater risk of developing liver tumors after exposure to TCE. To assess the variability of chloral hydrate metabolism in humans, chloral hydrate (0.5-2.0 mM) was added to human hepatocyte suspensions obtained from commercial sources. Incubations were carried out for 10 min at 37°C, and the reactions were stopped by the addition of an esterizer solution. The formation of TCA and TCE-OH was measured using head-space gas chromatography with electron-capture detection. Initial velocities of chloral hydrate metabolism (pmol metabolite/10<sup>6</sup> cells/min) were used to calculate the Km and Vmax values for each metabolite. We report significant variability in chloral hydrate metabolism in 10 human hepatocyte samples. TCE-OH was the major metabolite (Km of 7.64 mM ± 2.97 SEM) among donors; variability in TCA formation (Km of 7.72 mM ± 4.99) was also observed. These results indicate that humans may not be uniform in their capacity to metabolize chloral hydrate to TCA and TCE-OH. Supported by DOE cooperative agreement DE-FC09-02CH11109.

## TOXICOKINETIC ASPECTS OF HEPATOTOXIC INTERACTIONS BETWEEN BENZENE AND TCE.

A. Freidig<sup>1</sup>, H. Wortelboer<sup>1</sup>, W. Heijne<sup>1</sup>, R. Sterum<sup>1</sup>, M. Schut<sup>1</sup>, D. Jonker<sup>1</sup>, H. El-Masri<sup>2</sup>, D. Moffett<sup>2</sup> and J. Groten<sup>1</sup>. <sup>1</sup>*TNO Voeding, Zeist, Netherlands* and <sup>2</sup>*ATSDR, Atlanta, GA*.

In an ongoing 3-year project, mechanistic models are being established for both, toxicokinetic and toxicodynamic interactions within mixtures. One of the focus areas is the interaction of benzene and trichloroethylene (TCE) in the liver of rats treated repeatedly with both compounds. *In vivo* microarray data of mixture experiments have shown, that peroxisome proliferation caused by TCE alone was increased by concomitant benzene dosing. To establish the nature of the interaction, *in vitro* experiments were performed in rat hepatocyte sandwich cultures to study the impact of each of the two compounds on liver enzyme activities of CYP2E1 and GST, both of which are known to be relevant for the metabolism of benzene and trichloroethylene. A computational PBTK (physiologically based toxicokinetic) model was used to connect *in-vitro* data with *in vivo* experiments. It was found that repeated benzene dosing increased the activity of CYP2E1 in the hepatocyte cultures. Using a PBPK model for TCE, it could be shown that at higher oral doses of TCE such an increase of activity leads to marked increases of trichloroacetic acid levels. Using this combined approach, the nature of the experimentally observed interaction between TCE and benzene could be explained as a toxicokinetic interaction.

## IN VITRO AND IN VIVO KINETICS OF MIDAZOLAM IN COMMERCIALLY RAISED GAMEBIRDS.

K. Cortright and A. Craigmill. *Environmental Toxicology, UC Davis, Davis, CA*.

Species differences in drug metabolism can affect therapeutic efficacy and residues in food animals. To examine species differences with regard to cytochrome P450 3A capabilities, *in vitro* and *in vivo* studies were conducted with a marker substrate (midazolam) in commercially raised pheasant, turkey, chicken and bobwhite quail. Microsomal incubations with midazolam (1.25-20 uM) were analyzed using HPLC with UV detection. *In vitro* kinetic parameters for oxidation of midazolam to both the 1-hydroxymidazolam (1-OH) and 4-hydroxymidazolam (4-OH) metabolites were estimated. The apparent Vmax for the major metabolite, 1-OH, in pheasant, turkey, chicken and bobwhite quail was 419.8+21.7, 209.6+11.6, 167.2+11.3 and 120.4+7.0 pmoles product/mg x min, respectively. The apparent Michaelis constant, Km, was 10.5+1.5, 3.0+0.7, 1.8+0.6 and 1.8+0.6 uM in pheasant, turkey, chicken and bobwhite quail, respectively. The apparent Vmax values calculated for the 4-OH metabolite showed a similar pattern of activity between the species examined, but with more variability and much less affinity. Values were 187+63.4, 84.6+17.4, 26.1+7.0 and 26.2+0.7 pmole product/mg x minute, for pheasant, turkey, chicken and bobwhite quail, respectively. The calculated Km values were 75.2+37.9, 84.6+17.4, 17.8+11.4, and 26.6+1.6 uM. *In vitro* inhibition studies were also conducted with a prototypical inhibitor of CYP3A, ketoconazole, at 3.125-100 uM and at a substrate concentration of 25 uM. Pheasant were most sensitive to inhibition, quail were least sensitive and chicken and turkey were intermediate. *In vivo* pharmacokinetic studies were conducted in all species at a dose of 5 mg/kg. Results indicate that pheasant and turkey are similar in their kinetic profiles of midazolam even though turkeys appear to achieve much deeper levels of sedation. These studies suggest that extrapolating dose regimens from one species to another, even within the same family (ie. Galliformes), should be done conservatively at best.

## HEPATIC MICROSOMAL METABOLISM OF LITHOCHOLIC ACID.

A. K. Deo and S. M. Bandiera. *Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada.*

The purpose of the present study was to investigate the *in vitro* metabolism of lithocholic acid (3 $\alpha$ -hydroxy-5 $\beta$ -cholanoic acid, LCA). The metabolites formed were detected using liquid chromatography-electrospray mass spectrometry (LC-MS). LCA was incubated with a reaction mixture containing rat hepatic microsomes. A liquid-liquid double extraction method with d4-cholic acid as an internal standard was utilized. Metabolites were separated using a C18 (octadecyl) reversed-phase column and detected in single ion recording (SIR) mode. Assay conditions were validated and optimized for effective analysis. The limit of detection was 50 ng/ml. The recovery of the authentic metabolite standards averaged 80-100%. The identities of five metabolites of LCA were confirmed using authentic standards. The major metabolites were found to be murocholic acid (MUCA) and isolithocholic acid (ILCA). Minor metabolites were identified as  $\beta$ -muricholic acid ( $\beta$ -MCA), 6-keto lithocholic acid (6KLCA) and ursodeoxycholic acid (UDCA). In addition, six other unidentified metabolites were also detected. Metabolite (MUCA, ILCA, UDCA and 6KLCA) formation followed typical Michaelis-Menten kinetics and kinetic constants ( $K_m$  and  $V_{max}$ ) for these metabolites were calculated from triplicate measurements. The possibility that  $\beta$ -MCA could be metabolized to secondary metabolites is under investigation. The identities of specific CYP enzymes involved in the formation of LCA metabolites and the effect of treatment of cytochrome P450 enzyme (CYP) inducers such as dexamethasone, 3-methylcholanthrene, and phenobarbital on the metabolism of LCA in rats are currently underway.

## IN VITRO METABOLISM OF 4-VINYLPHENOL AND STYRENE IN MOUSE, RAT AND HUMAN MICROSOMES.

M. Bartels<sup>1</sup>, D. Rick<sup>1</sup>, F. Zhang<sup>1</sup>, E. Leibold<sup>2</sup>, H. Gelbke<sup>2</sup> and G. Cruzan<sup>3</sup>.  
<sup>1</sup>Toxicology, Dow Chemical, Midland, MI, <sup>2</sup>BASF, Aktiengesellschaft, Ludwigshafen/Rhein, Germany and <sup>3</sup>ToxWorks, Bridgeton, NJ.

4-Vinylphenol (4VP) has been identified as a minor urinary metabolite of styrene in rats and human volunteers. This compound has been shown to be both a hepatotoxin and pneumotoxin in mice. 4VP is thought to be a transient metabolite of styrene, since it is not seen in *in vitro* incubations of styrene with microsomes from lung or liver of the rat and mouse. This lack of measurable 4VP is attributed to the rapid metabolism of this compound to other, unidentified products. The current study was designed to characterize reactive metabolites of styrene, arising via the 4VP pathway, in the lung tissue of the mouse, rat and human donors. Incubations of radiolabeled 4VP with mouse lung tissue microsomes afforded two major metabolites. The mass spectrum for both products was consistent with incorporation of one oxygen atom. Coincubation with glutathione (GSH) was performed to trap reactive metabolites of 4VP. LC/MS/MS analysis afforded identification of these metabolites as GSH conjugates of ring-hydroxylated- and side-chain epoxide products of 4VP. MRM-LC/MS/MS analysis of incubates of styrene, GSH and lung tissue microsomes afforded identification of these two GSH-containing metabolites in tissue from mouse, rat or human. Relative formation rates for both 4VP-GSH conjugates were mouse > rat > human. These results should provide useful data in characterizing the relative toxicity of styrene in these three species. (This work was funded by the Styrenics Steering Committee of the European Chemical Industry Council- CEFIC).

## COVALENT MODIFICATION OF AMINO ACID NUCLEOPHILES BY STYRENE OXIDE.

W. Yuan, J. Chung and J. Zheng. *Pharmaceutical Sciences, Northeastern University, Boston, MA.*

Styrene is widely used as one of the most important industrial materials for production of synthetic rubbers, plastic, insulation, fiberglass, automobile parts. Its major metabolic route in rats, mice and human involved conversion of styrene to styrene oxide by cytochrome P450. This fairly reactive metabolite has been reported to form covalent bonding to cellular macromolecules, such as proteins. Among 21 amino acids, Cys, Lys, Arg, His are the amino acids possibly responsible for nucleophilic protein modification. The purpose of this study is to compare the susceptibility of these nucleophilic amino acid residues to electrophilic styrene oxide. Model peptides, including PFECG, PFFHCG, PFVCG, PFKCG, PFRCG, were incubated with styrene oxide and analyzed by liquid chromatography/electrospray tandem mass spectrometry. All Cys residues of the peptides were found to be modified by styrene oxide. Little modification was observed at Lys, Arg, His and Glu of the corresponding peptides. Kinetic studies showed that the neighboring amino acid residues have little effect on the reactivity of cysteine. Only Lys slightly increased the reactivity of cysteine towards styrene oxide. In conclusion, Cys is the

most reactive amino acid residue responsible for peptide modification by electrophilic agents. Neighboring amino acid residues have little influence on the reactivity of cysteine.

## NITROREDUCTION OF TATTOO PIGMENT YELLOW 74 BY XANTHINE OXIDASE: FORMATION OF A DNA ADDUCT AND MUTAGENICITY OF THE NITROSO REDUCTION PRODUCT.

P. C. Howard<sup>1</sup>, Y. Cui<sup>1</sup>, L. H. Couch<sup>1</sup>, M. I. Churchwell<sup>1</sup>, D. R. Doerge<sup>1</sup>, P. P. Fu<sup>1</sup>, J. Wang<sup>2</sup>, T. Chen<sup>2</sup>, N. Mei<sup>2</sup> and M. M. Moore<sup>2</sup>. <sup>1</sup>Division Biochemical Toxicology, NCTR, USFDA, Jefferson, AR and <sup>2</sup>Division Genetic and Reproductive Toxicology, NCTR, USFDA, Jefferson, AR.

Pigment Yellow 74 (PY74), a monoazo pigment used in paints, dyes and printing inks, is also found in some tattoo inks. We have previously shown that PY74 photodecomposes in simulated sunlight to various products. We have also shown that PY74 is metabolized primarily by cytochromes P450 (CYP) 1A1 and 1A2 to a 4'-phenol metabolite, which is further metabolized by CYP 1A1 or 1A2 through *O*-demethylation to a bis-phenol. PY74 is synthesized through reaction of the diazonium salt of 2-amino-5-nitroanisole with *o*-acetoacetaniside, and as such, has a nitro group that should be available for nitroreductive metabolism. The incubation of PY74 with a nitroreductase, xanthine oxidase, under hypoxic conditions leads to the reduction of the nitro group to an amine (NH<sub>2</sub>-PY74). Since the formation of NH<sub>2</sub>-PY74 would proceed through initial reduction of the nitro to a nitroso group, we synthesized the nitroso derivative (NO-PY74) to investigate its reactivity. The reduction of NO-PY74 with ascorbate in the presence of DNA resulted in the formation of a DNA adduct that was detected using <sup>32</sup>P-postlabeling. NO-PY74 mutagenicity was determined using the L5178Y *Tk*<sup>+/+</sup> mouse lymphoma assay; a clear dose response in cytotoxicity and mutagenicity was detected with up to 14  $\mu$ M NO-PY74. <sup>32</sup>P-Postlabeling analysis of the DNA isolated from L5178Y *Tk*<sup>+/+</sup> cells treated with 14  $\mu$ M NO-PY74 confirmed the presence of the same DNA adduct. These results indicate that nitroreduction of the tattoo pigment PY74 may be a bioactivation pathway. Further studies are focused on identification of the DNA adduct and determining if nitroreduction occurs *in vivo*.

## REACTIONS OF NITRIC OXIDE-DERIVED OXIDANTS WITH 4-ACETAMIDOPHENOL: FORMATION OF ELECTROPHILIC INTERMEDIATES.

R. M. Uppu<sup>1</sup> and R. J. Martin<sup>2</sup>. <sup>1</sup>Environmental Toxicology, Southern University, Baton Rouge, LA and <sup>2</sup>School of Human Ecology, Louisiana State University, Baton Rouge, LA.

Nitric oxide ( $\cdot$ NO) is an important bio-molecule eliciting hormonal and toxic properties. The toxic effects of  $\cdot$ NO manifest as a result of the formation of peroxynitrite (PN; ONOOH  $\leftrightarrow$  ONOO $^-$  + H $^+$ ; pKa $\approx$ 6.2) and its free radical products  $\cdot$ NO $_2$ , CO $_3$  $^{2-}$  and  $\cdot$ OH, the latter being formed in yields up to 40 mol% via H $^+$ -assisted or CO $_2$ -catalyzed isomerization to NO $_3$  $^-$ . The information on the involvement of  $\cdot$ NO-derived oxidants (NOx) in xenobiotic metabolism resulting in electrophilic intermediates is limiting. It was reasoned that NOx can cause metabolic activation, especially in xenobiotics that have nitrogen or sulfur in a low oxidation state. In an effort to establish this concept, we conducted studies of oxidative transformation of 4-acetamidophenol (4-AP) by PN and PN/CO $_2$  adducts at pH 7.2. The 4-AP, a popular over-the-counter drug (which causes hepatic failure in accidental overdosing) was chosen for its toxicity. Based on the initial concentration of PN in the reaction, the yields of oxidation of 4-AP were 34 $\pm$ 1.0 mol%. One of the major products of 4-AP oxidation was 3-nitro-4-acetamidophenol, identified by co-chromatography with standard and by fragmentation pattern in GC/MS and FAB/MS analysis. It accounted for 30 $\pm$ 1.8 mol% of the oxidation of 4-AP. Another product identified was N-acetyl-1, 4-benzoquinoneimine (NBQI). This decays in phosphate buffer at pH 7.2, with a half-life of 2 min, and can be trapped as stable adducts of N-acetyl-L-cysteine and glutathione. In these reactions, the NBQI formed can arylate the thiol/thiolate functionality and inhibit glyceraldehyde-3-phosphate dehydrogenase, a key enzyme of glycolysis. These findings suggest that xenobiotic activation by nonenzymatic, putative oxidants from  $\cdot$ NO metabolism may contribute to long-term toxicity due to alkylation of proteins and, possibly, nucleic acids. (Funding from NIEHS ES10018 and Louisiana Biomedical Research Network is acknowledged).

## THE ROLES OF LIVER AND TARGET-TISSUE P450-MEDIATED DMBA METABOLISM IN DMBA-INDUCED DNA ADDUCT FORMATION IN THE MAMMARY GLAND.

H. Cui, J. Gu, L. Zhang, Q. Zhang and X. Ding. *Wadsworth Center, Albany, NY.*  
 7, 12-Dimethylbenz[a]anthracene (DMBA) is a potent mammary gland carcinogen in rodents. The aim of this study was to determine the roles of liver and target-tissue cytochrome P450-mediated DMBA metabolism in DMBA-induced DNA

adduct formation in the mammary gland. The role of microsomal P450 in DMBA-induced DNA adduct formation was confirmed using a mouse model (designated the Cpr-low mouse) that has a globally suppressed expression of the NADPH-cytochrome P450 reductase (Cpr) gene (Wu et al., *J. Pharmacology Expt. Ther.* In press, 2005). The role of hepatic P450-mediated metabolism in mammary gland DMBA-induced DNA adduct formation was determined using a mouse model (designated the liver-Cpr-null mouse) that has liver-specific deletion of the Cpr gene (Gu et al., *J. Biol. Chem.*, 278, 25895-25901, 2003). Mice were treated orally with DMBA (50 mg/kg/day for 3 days). The level of DNA adducts in the mammary gland, determined by  $^{32}\text{P}$ -postlabeling, and DMBA blood concentrations following DMBA treatment were monitored. We found that the level of total DNA adducts in the mammary gland was about 72% and 80% lower in the liver-Cpr-null mice and the Cpr-low mice, respectively, than in wild-type mice. In the liver-Cpr-null mice, DMBA was eliminated more slowly than in the wild-type mice, with a three-fold difference in area under the curve (AUC) between the two strains. Thus, in spite of a greater bioavailability of DMBA, the level of DNA adducts was significantly reduced in the mammary gland of the mutant mice than in the wild-type mice. These results suggest that, following systemic exposure to DMBA, hepatic P450-mediated generation of either intermediate metabolites or the ultimate carcinogenic metabolite plays a critical role in the formation of DNA adducts in the breast tissue. Additional studies designed to directly examine the role of local metabolic activation in the formation of DNA adducts in the mammary gland are underway. (Supported in part by grant DAMD17-02-1-0404 from USAMRAA)

## 1568

### VINCLOZOLIN *IN VITRO* METABOLISM BY RAT LIVER MICROSONES.

A. Sierra-Santoyo<sup>1</sup>, R. Harrison<sup>2</sup>, B. Edwards<sup>2</sup>, H. A. Barton<sup>2</sup> and M. F. Hughes<sup>2</sup>. <sup>1</sup>Toxicology Section, CINVESTAV-IPN, Mexico City, D.F., Mexico and <sup>2</sup>NHEERL/ORD/ETD/PKB, USEPA, Research Triangle Park, NC.

Vinclozolin (V) is a fungicide used in agricultural settings. V administered to rats is hydrolyzed to 2-[(3, 5-dichlorophenyl)-carbamoyl]oxy]-2-methyl-3-butenoic acid (M1) and 3', 5'-dichloro-2-hydroxy-2-methylbut-3-enanilide (M2). V, M1 and M2 have antiandrogenic properties by interacting with the androgen receptor. Data on V, M1 and M2 biotransformation is limited. Our objective was to study the *in vitro* metabolism of V by rat liver microsomes. V (12.5-200  $\mu\text{M}$ ) was incubated in 0.1 M phosphate buffer pH 7.4, 5 mM MgCl<sub>2</sub>, non-treated adult male Long-Evans rat liver microsomes (1-2 mg) and 1 mM NADPH for 30 min at 37°C. V metabolites from incubation media were extracted in acetonitrile and analyzed by HPLC/DAD/MS. Three metabolites were detected from rat liver metabolism. On the basis of their  $t_{\text{ret}}$ , UV/Vis spectrum and negative ESI mass spectra, two metabolites were identified as 3', 5'-dichloro-2, 3, 4-trihydroxy-2-methylbutylanilide (M4) ( $[\text{M}-\text{H}]^-$  at  $m/z$  293) and *N*-(2, 3, 4-trihydroxy-2-methyl-1-oxo)-3, 5-dichlorophenyl-1-carbamic acid (M5) ( $[\text{M}-\text{R}]^-$  at  $m/z$  246). Based on UV/Vis spectrum alone, a third unidentified metabolite (M6) co-eluted with M4. The  $K_m$  for co-eluted M4/M6 was 53.6  $\mu\text{M}$  and the  $V_{\text{max}}$  was 0.810 nmoles/min/mg protein. The  $K_m$  for M5 was 142.3  $\mu\text{M}$  and the  $V_{\text{max}}$  was 0.700 nmoles/min/mg protein. Extracting at a lower pH altered the  $K_m$  and  $V_{\text{max}}$  values for the 3 metabolites indicating the recovery of V metabolites is pH dependent. These results indicate that V is efficiently metabolized by rats liver microsomes. Determination of the metabolites of V will provide further insight into the relationship between toxicity and tissue dose of V and its metabolites. (Funded in part by NRC CR 828790. This abstract does not represent USEPA policy).

## 1569

### HYDROLYtic METABOLISM OF PYRETHROIDS BY HUMAN CARBOXYLESTERASES AND RODENT AND HUMAN LIVER MICROSONES.

M. K. Ross<sup>1</sup>, P. M. Potter<sup>2</sup> and A. Borazjani<sup>1</sup>. <sup>1</sup>Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS and <sup>2</sup>Mol. Pharmacology, St. Jude's Children's Research Hospital, Memphis, TN.

The mammalian carboxylesterases (CESs) are a multigene family of enzymes that have an important role in detoxifying pesticides, such as pyrethroids. The identities of the CES isozymes responsible for detoxification are poorly characterized. The objective of this study was two-fold: first, to determine the substrate specificity and kinetic properties of the major human liver CES enzymes (hCES1 and hCES2) using *cis*- and *trans*-permethrin, and second, to compare rat, mouse, and human liver microsomes for their ability to cleave several pyrethroid compounds, including permethrin. Recombinant CES enzymes and rodent and human liver microsomes were utilized so that rates of pyrethroid hydrolysis could be compared, as determined by HPLC analysis of metabolites. The results demonstrated that *trans*-permethrin was hydrolyzed markedly faster by hCES1 than hCES2 ( $k_{\text{cat}} = 13.9 \text{ min}^{-1}$  and  $1.2 \text{ min}^{-1}$ , respectively). However, the  $K_m$  for hCES2 was 56-fold lower than

for hCES1 ( $K_m = 103.5 \mu\text{M}$  and  $1.8 \mu\text{M}$  for hCES1 and hCES2, respectively), thus the apparently high affinity of *trans*-permethrin for hCES2 suggests that this isozyme may contribute to the detoxification of permethrin at low substrate concentrations ( $<10 \mu\text{M}$ ). In contrast, *cis*-permethrin was hydrolyzed much slower than *trans*, both by hCES1 and hCES2. The hydrolytic activity of liver microsomes toward *trans*-permethrin followed the species order mouse>rat>human. The  $V_{\text{max}}$  values of six individual human liver microsomes ranged from 0.36-1.50 nmol/min/mg protein, indicating interindividual differences in *trans*-permethrin hydrolysis proficiency. There were no marked differences in  $K_m$  values (14.7-21.0  $\mu\text{M}$ ) between rodent and human liver microsomes. Taken together, the kinetic parameters for the human CESs are consistent with *trans*-permethrin being more efficiently hydrolyzed than *cis*-permethrin, and both liver enzymes likely have a role during *in vivo* permethrin metabolism. (Supported by NIH P20RR017661).

### METABOLISM OF ARSENICALS MAY INFLUENCE THEIR PROLIFERATIVE EFFECTS ON HUMAN CACO-2 CELLS.

G. S. Bayse<sup>1</sup>, W. G. Kirlin<sup>2</sup>, A. M. Rollins-Hirston<sup>2</sup> and K. Jackson<sup>1</sup>.

<sup>1</sup>Chemistry, Spelman College, Atlanta, GA and <sup>2</sup>Pharmacology/Toxicology, Morehouse School of Medicine, Atlanta, GA.

Roxarsone (4-hydroxy-3-nitrobenzenearsonate) is used as a poultry feed additive for its antimicrobial and growth promoting effects. More than 90% of the additive is excreted unchanged. Recently, both USGS and USEPA have expressed concern due to the more than 2 million pounds/year, excreted into waterways. The reduction product, 3-amino-4-hydroxy-benzenearsonate (AHBA) has been identified as a metabolite from animal, microbial, and geologic reactions found in groundwater and sediments and its proposed oxidation product, an azobenzene has been described. The potential toxic effects of these organoarsenicals as water contaminants should be evaluated for impact on humans. The human intestinal line, Caco-2, was exposed to Roxarsone, AHBA, and its acetylated product 3-N-acetylamo-4-hydroxybenzenearsonate (Acetarsone). At micromolar levels, proliferation, determined by [<sup>3</sup>H]- thymidine incorporation into DNA, was increased significantly with AHBA and Acetarsone, as compared to controls. Arsenate (iAs V) and arsenite (iAs III) were tested, but gave variable results. These observations on the organoarsenicals are supported by flow cytometric data, whereby cell cycle studies revealed an accumulation of cells in the S phase from both AHBA and Acetarsone. *In vitro* studies show that the N-acetylation of AHBA to Acetarsone is catalyzed by human N-Acetyltransferase (NAT) and that human CYP3A4 catalyzes an apparent oxidation of AHBA. The mRNAs for these key enzymes, NAT and CYP3A4, are expressed in Caco-2 cells, as shown by real-time PCR analysis. The aromatic amine AHBA then, has the potential both for acetylation and oxidation. The dynamics of the acetylation vs P450 pathways are established as important in considering potential toxicity of such compounds. The variable Caco-2 cell proliferation in response to different metabolites therefore may be dependent upon metabolic activation by competing acetylation and oxidation reactions. ### A NOVEL HALOENOL LACTONE DERIVATIVE POTENTIATES CYTOTOXICITY INDUCED BY CISPLATIN RETARDING THE GLUTATHIONE-MEDIATED DETOXIFICATION OF CISPLATIN IN HUMAN RENAL TUMOR CELL LINES.

J. Zheng and W. Wang. *Pharmaceutical Sciences, Northeastern University, Boston, MA.*

Drug resistance remains one of the primary causes of suboptimal outcomes in cancer chemotherapy. Over-expression of glutathione S-transferases (especially GST-Pi) has been found to play a significant role in multiple drug resistance in cancer chemotherapy. Our laboratory has designed and synthesized a haloenol lactone (HEL) derivative as a mechanism-based inactivator of GST-Pi. We found that pretreatment of 10 uM HEL potentiate the cytotoxicity induced by cisplatin in both human renal tumor cell line (UOK-130) and acquired cisplatin-resistant UOK130 cell line. The mechanism studies of HEL demonstrate that cytotoxic potentiation by HEL results from retarding the GSH-mediated detoxification of cisplatin. This compound depletes intracellular GSH as well as inactivates cytosolic GST thus reduces GSH-cisplatin conjugation. This compound is also shown to be an inhibitor of multidrug resistance-associated protein 1 (MRP-1) mediated drug resistance which is observed increased in acquired cisplatin-resistant UOK130 cell line. As a result, the metabolic inactivation of cisplatin was reduced and more DNA-DNA crosslinking was found in nucleus of UOK130 cells. In summary, a novel haloenol lactone was identified as a lead compound, capable of potentiating cytotoxicity by cisplatin at low concentration, through a mechanism retarding the total GSH-mediated detoxification of cisplatin.

BIOACTIVATION OF 1-CHLORO-2-HYDROXY-3-BUTENE TO 1-CHLORO-3-BUTEN-2-ONE, A NOVEL CROSS-LINKING AGENT.

A. A. Elfara, R. J. Krause, X. Zhang and C. A. Klumb. *Department of Comparative Biosciences, University of Wisconsin, Madison, WI.*

1, 3-Butadiene (BD) has been classified as "known to be a human carcinogen" primarily because epidemiological studies showed increased incidences of lymphohematopoietic cancers among workers occupationally exposed to BD. Previously we identified 1-chloro-2-hydroxy-3-butene (CHB) as a primary metabolite of BD by human myeloperoxidase, an enzyme located mostly in the bone marrow. In this study, we examined the *in vitro* metabolism of CHB to 1-chloro-3-buten-2-one (CBO) by purified liver alcohol dehydrogenase (ADH) and by rat bone marrow post-mitochondrial fractions (S9) and liver cytosol. Because CBO is expected to be highly reactive, we included glutathione (GSH) in the incubations as a trapping agent. In incubations with ADH and NAD, we detected three product peaks by HPLC that were both time- and NAD-dependent. These peaks co-eluted with peaks that were formed in the chemical reaction of CBO and GSH. The major peak was identified by mass spectrometry (MS) as the di-GSH conjugate of CBO. These results and the instability of the other two peaks suggest the minor peaks were the mono-GSH conjugates. In incubations with rat bone marrow S9 fractions or liver cytosol, the di-GSH conjugate peak was detected and its formation was substrate- and protein-dependent. Since CBO readily formed the di-GSH conjugate, we examined its ability to form hemoglobin crosslinks in freshly isolated mouse erythrocytes. Red blood cells were incubated with 5 or 10 mM CBO for 1 h, the globin isolated, and run on SDS-PAGE. Globin dimers and trimers were detected using silver staining with both CBO concentrations. The presence of crosslinks was also confirmed by MS. These results show that CHB is a substrate for ADH. CBO formed in bone marrow or liver could readily react with GSH or form crosslinks with macromolecules. The high reactivity of CBO suggests a role for this compound in the toxicity and carcinogenicity of BD. (Supported by ES06841)

4'-FLUORO SUBSTITUTION OF DESMETHYLATED ARZOXIFENE COULD DECREASE TOXICITY WHILE MAINTAINING ANTIESTROGENIC ACTIVITY.

H. Liu, G. R. Thatcher and J. L. Bolton. *Medicinal Chemistry and Pharmacognosy, University of Illinois at Chicago, Chicago, IL.*

The SERM, aroxifene is currently in clinical trials for the treatment of breast cancer. The active form of aroxifene *in vivo*, desmethylated aroxifene (DMA), can be metabolized to electrophilic/redox-active quinoids by rat and human liver microsomes which might contribute to the cytotoxicity and/or genotoxicity of DMA through depletion of GSH, alkylation of proteins, and induction of DNA single strand breaks. In the current study, a new fluorinated derivative unable to form a di-quinone methide, 4'-F-DMA, was synthesized. 4'-F-DMA showed similar ER binding affinity as compared to DMA. The antiestrogenic activity as measured by inhibition of estradiol-mediated induction of alkaline phosphatase activity in Ishikawa cells showed 10-fold lower activity for 4'-F-DMA compared to DMA; however, the antiestrogenic activity was comparable to raloxifene. Using MCF-7 cells transfected with the ERE-luciferase reporter system, antiestrogenic activity for 4'-F-DMA, DMA and raloxifene parallels that observed with alkaline phosphatase assay in Ishikawa cells. In microsomal incubations of 4'-F-DMA in the presence of GSH, no GSH adducts were detected. 4'-F-DMA and DMA were incubated with cryopreserved rat hepatocytes, only one glucuronide adduct was detected using LC-MS-MS for 4'-FDMA. In contrast, two glucuronide adducts and two GSH adducts were detected using LC-MS-MS for DMA. 4'-F-DMA showed less cytotoxicity compared with DMA, and induced less DNA single strand breaks than DMA in cryopreserved rat hepatocytes. Finally, the effect of 4'-F-DMA and DMA on GSH content in rat hepatocytes was examined. DMA significantly decreased the GSH levels within half an hour. In contrast, 4'-F-DMA did not cause any change in GSH levels in rat hepatocytes. These data suggest that 4'-F-DMA might be a promising SERM with similar activity to DMA and raloxifene and less toxicity. Supported by NIH grant # CA 798700

REDUCTION OF 1-FURAN-2-YL-3-PYRIDIN-2-YL PROPENONE, AN ANTI-INFLAMMATORY AGENT, BY CARBONYL REDUCTASE IN RAT LIVER MICROSONES.

S. Lee<sup>1</sup>, T. Jeon<sup>1</sup>, C. Jin<sup>1</sup>, S. Hyun<sup>1</sup>, G. Kim<sup>1</sup>, I. Jun<sup>1</sup>, D. Lee<sup>1</sup>, E. Lee<sup>1</sup>, Y. Jahng<sup>1</sup>, D. Kim<sup>2</sup> and T. Jeong<sup>1,2</sup>. *Yeungnam University, Kyungsan, South Korea and Bioanalysis and Biotransformation Research Center, Seoul, South Korea.*

Although oxidative biotransformation of xenobiotics by cytochrome P450s is the primary metabolic process for a number of xenobiotics, the reduction is also a significant step in the phase 1 biotransformation for a variety of aromatic, alicyclic and

aliphatic compounds bearing a carbonyl group. 1-Furan-2-yl-3-pyridin-2-ylpropenone (FPP-3) has recently been synthesized by our group. From serial studies, FPP-3 has been characterized to have an anti-inflammatory activity through the inhibition of the production of nitric oxidation and tumor necrosis factor- $\alpha$ . In the present studies, the metabolic fate and a possible involvement of carbonyl reductase in the metabolism of FPP-3 were partially investigated in rat liver microsomes. When FPP-3 was incubated with rat liver microsomes in the presence of NADPH, 2 major peaks were detected on an LC/MS/MS. Two peaks (i.e., M1 and M2) were believed to be the reduction on the propenone: M1 (1-furan-2-yl-3-pyridin-2-ylpropen-1-one) was a initial metabolite and M2 (1-furan-2-yl-3-pyridin-2-ylpropan-1-ol) was a secondary alcohol believed to be formed from M1 by carbonyl reductase. This biotransformation was a NADPH-dependent but a cytochrome P450-independent reaction, not only because the production of metabolites was not decreased by SKF-525A, a well-known cytochrome P450 inhibitor, but also because this reaction was inhibited by the *D, L*-glyceraldehyde, a substrate of carbonyl reductase. (Supported by a grant for the Institute for Drug Research, Yeungnam University, from the Korea Research Foundation).

PHASE 1 AND PHASE 2 METABOLISMS OF RUTAECARPINE IN MICE AND RATS.

G. Kim, D. Lee, S. Lee, T. Jeon, S. Hyun, C. Jin, I. Jun, E. Lee, Y. Jahng and T. Jeong. *College of Pharmacy, Yeungnam University, Kyungsan, Kyungbuk, South Korea.*

Recently, we have reported the *in vitro* metabolism of rutaecarpine, a new cytochrome P450-2 inhibitor, in rat liver microsomes. In the present studies, phase 1 and phase 2 metabolisms of rutaecarpine were compared in mice and rats using liquid chromatography-electrospray ionization tandem mass spectrometry. When urine, feces, sera and bile were analyzed following rutaecarpine administration to rats, 4 glucuronide and 4 sulfate conjugates were identified. In mice, the same 8 conjugates of rutaecarpine were detected. Sulfate conjugated 4 metabolites were either on the aromatic ring of the indole moiety (S1, S2 and S3) or on the aromatic ring of the quinazolinone moiety (S4). Other three metabolites (U1, U2 and U3) were believed to be glucuronidated on the aromatic ring of the indole moiety and last one (U4) was on the phenyl group of the quinazolinone moiety. The *in vitro* incubation of rutaecarpine in murine hepatocytes showed similar results. Our present results indicated that the metabolism of rutaecarpine in mice and rats is very similar. (Supported by a grant from Korea Research Foundation for the Institute for Drug Research, Yeungnam University)

METABOLIC SHIFT FOLLOWING MULTIPLE DOSES OF [14C]-1, 3-DINITROBENZENE TO RATS.

J. J. Tobias and T. Miller. *Toxicology, University of Kentucky, Lexington, KY.*

While ample data is available regarding the CNS toxicity of 1, 3-dinitrobenzene (1, 3-DNB) following multiple-dosing regimens, studies regarding the time-course of brain uptake into, as well as metabolism and disposition within the CNS have not been forthcoming. We previously proposed that metabolism is an essential determinant of the CNS toxicity observed following 1, 3-DNB administration and that neuronal nitric oxide synthase produces peroxynitrite when exposed to DNB isomers. In the present study, rats received either a single dose (10 mg/kg; ip in corn oil containing 20 microCi radiolabel) or were dosed dose q 12h X 3 doses. Forebrain, brainstem and cerebellum were collected at various times post-dose and analyzed for metabolites by HPLC. 1, 3-DNB reached peak brain levels one hour after ip injection and elimination data revealed apparent half-lives in brain of 3h in pons/medulla and cerebellum and 4h in brainstem. Brainstem and cerebellum contained double radiolabel of forebrain (2 vs 0.5 pmol/mg). 1, 3-DNB and 3-NA were the major compounds present in forebrain, cerebellum and brainstem following either single or multiple dosing regimens. Compounds present in brainstem 90 min after dosing were (expressed as % of the radiolabel present in the brain region): 1-nitroso-3-nitrobenzene-NNB (10%), 3-nitroacetanilide (13%), 3-nitroaniline-3-NA (21%) and 1, 3-DNB (58%). Following 3 doses, NNB (4%), 3-NA (58%), 1, 3-DNB (35%) and an unidentified fourth peak were detected in brainstem, however by 90 min 3-NA was no longer detectable. Cerebellum contained 2 major and 2 minor peaks at the 45 min time-point while only 3-NA (31%) and 1, 3-DNB (69%) were detected at 90 min. These data confirm that 1, 3-DNB is reductively metabolized *in vivo* and enters the CNS. Following either 1 or 3 doses the major metabolites were 1, 3-DNB and 3-NA. Additionally, brainstem and cerebellum are exposed to twice the 1, 3-DNB levels compared to forebrain. Furthermore, NNB was present cerebellum and brainstem in both single and multiple dose groups. Furthermore, an apparent shift in metabolism occurs following multiple doses of 1, 3-DNB.

METABOLISM OF METHACRYLONITRILE TO CYANIDE: INHIBITION BY CAFFEINE AND POTENTIATION BY ALCOHOL.

M. Y. Farooqui. *Biology, University of Texas Pan American, Edinburg, TX.*

We have reported earlier that caffeine inhibited and alcohol enhanced the toxicity of methacrylonitrile (MeAN) in male Sprague-Dawley rats. We have now studied the relationship between the toxicity of MeAN and its metabolism to cyanide using normal rats and those pre-treated with caffeine or alcohol or both. One group of experimental rats received an oral dose of 6 % MeAN solution in corn oil (equivalent to 0.5 LD50). Other three groups of rats were pre-treated with alcohol (2 ml of 50 % solution in water), caffeine (1 ml of 2 % solution in water) or both alcohol and caffeine twelve hours before receiving MeAN dose. The rats were closely observed for known signs of toxicity of nitriles. Three, six and twenty four hours after the treatments the rats were sacrificed under ether anesthesia for collection of blood, liver, kidney and brain. The concentration of cyanide was determined in blood, liver, kidney and brain. In the rats pre-treated with alcohol and alcohol + caffeine the cyanide concentration increased in the blood and other organs two to three fold whereas in rats pre-treated with caffeine alone the concentration of cyanide was not significantly different from controls. These results suggest that caffeine inhibited and alcohol enhanced metabolism of MeAN resulting in a significant increase in cyanide concentration in blood and organs. When rats were pre-treated with both caffeine and alcohol, caffeine could not provide this protection. The opposite effects of caffeine and alcohol may be through opposite modulation of microsomal activity. (Supported by NIH South Texas Doctoral Bridge Program Grant # 2 R25GM50080).

METABOLISM OF GERANYL NITRILE AND CITRONELLYL NITRILE BY PRIMARY HEPATOCYTES FROM MICE, RATS AND HUMANS.

R. A. Kemper<sup>1</sup>, D. L. Nabb<sup>1</sup>, S. A. Gannon<sup>1</sup>, T. A. Snow<sup>1</sup> and A. Apic<sup>2</sup>. <sup>1</sup>*DuPont Haskell Laboratory, Newark, DE* and <sup>2</sup>*Research Institute for Fragrance Materials (RIFM), Woodcliff, NJ.*

Geranyl nitrile (GN) and citronellyl nitrile (CN) are fragrance components used in consumer and personal care products. The metabolic clearance and biotransformation of GN and CN were compared in primary hepatocytes from mice, rats and humans. For determination of intrinsic clearance, GN and CN (25  $\mu$ M) were incubated with hepatocytes in sealed vials, and the headspace above the reaction was sampled periodically by solid phase microextraction and analyzed by GC/MS. For metabolite identification, GN and CN (250  $\mu$ M) were incubated with hepatocytes from each species for 60 min. Reaction mixtures were extracted and analyzed by GC/MS and LC/MS. Both GN and CN were rapidly metabolized in hepatocytes from all species. Within a species, intrinsic clearance was similar for both compounds, and increased in the order human < rat << mouse. For all species, estimated *in vivo* intrinsic clearance is well in excess of hepatic blood flow, so clearance in whole animals is expected to be flow-limited. Major common pathways for biotransformation of GN and CN involved 1) epoxidation of the 6-alkenyl moiety followed by conjugation with GSH, 2) hydroxylation of the terminal methyl group followed by direct conjugation with glucuronic acid in rodents or by further oxidation to the corresponding acid and formation of an acid glucuronide in humans. It is unclear if epoxidation of the 2-alkenyl group of GN occurs. The data from these experiments demonstrate significant species differences in hepatocyte clearance rates and suggest that metabolism of GN and CN is qualitatively similar across species. These data will be valuable in planning and interpretation of whole animal ADME studies and extrapolation of the results of rodent ADME studies to humans. This work was supported by RIFM.

KINETICS AND SCALING OF METABOLIC BIOTRANSFORMATION IN FISH: A COMPILATION OF RATE AND AFFINITY VALUES MEASURED UNDER PHYSIOLOGICAL CONDITIONS.

P. N. Fitzsimmons and J. W. Nichols. *USEPA/ORD/NHEERL/MED, Duluth, MN.*

Literature from the past twenty-five years was searched to obtain *in vitro* and *in vivo* metabolism information for fish collected under physiological conditions. Scaling factors were then used in conjunction with a venous equilibrium liver model and log Kow-dependent fat:blood partitioning relationship to convert *in vitro* hepatic metabolism data into whole-body clearance rates. In general, whole-body clearance values predicted by *in vitro* data under-predict reported levels of *in vivo* activity. This discrepancy is particularly apparent for high log Kow compounds due to the predicted effects of chemical hydrophobicity on plasma binding and steady-state volume of distribution. The data compiled in this study provide a basis for comparing metabolic activity within and among fish species, between fish and mammals, and between *in vitro* and *in vivo* test systems. This information can be used to im-

prove ecological risk assessments for metabolized compounds, parameterize chemical kinetic models, and optimize the design of field sampling efforts. (This abstract does not necessarily reflect EPA policy)

KINETICS AND SCALING OF METABOLIC BIOTRANSFORMATION IN FISH: EFFECTS ON BIOACCUMULATION PREDICTED BY INCORPORATING *IN VITRO* DATA INTO TWO KINETIC MODELS.

J. W. Nichols and P. N. Fitzsimmons. *USEPA/ORD/NHEERL/MED, Duluth, MN.*

Whole-body clearance rates based on *in vitro* hepatic metabolism data for fish were incorporated into a one-compartment bioaccumulation model. Using this model, metabolism was predicted to have little effect on chemical bioaccumulation due to: 1) high rates of branchial uptake for low log Kow compounds; and 2) low rates of metabolic clearance for high log Kow compounds. In a second model-based effort, *in vitro* metabolism data were used as inputs to a physiologically based toxicokinetic (PBTK) model for fish. This model provides for first-pass hepatic clearance of dietary contaminants and, at a fixed rate of metabolic activity, results in lower steady-state bioaccumulation of high log Kow compounds than levels predicted by a one-compartment model. In either case, however, model-predicted effects of metabolism on chemical bioaccumulation in fish underestimate impacts suggested by measured concentrations of well-metabolized compounds in field-collected animals. This discrepancy may be due to several factors including: 1) underestimation of true *in vivo* hepatic metabolism by *in vitro* assays; 2) failure of the scale-up procedure to account for non-hepatic metabolism; and 3) overestimation of chemical binding in blood. *In vivo* metabolism rates obtained by modeling to field data may be overestimated if models do not account for presystemic clearance (branchial or following dietary exposure) and metabolism at all relevant trophic levels. (This abstract does not necessarily reflect EPA policy)

MECHANISMS OF INTERACTIVE DEVELOPMENTAL TOXICITY OF POLYCYCLIC AROMATIC HYDROCARBONS IN ZEBRAFISH.

S. Billiard, D. Wassenberg, E. Linney and R. Di Giulio. *Duke University, Durham, NC.*

Polyyclic aromatic hydrocarbons (PAHs) are ubiquitous environmental contaminants and their prevalence in aquatic ecosystems warrants effective methods for assessing their risk. Some PAHs can mimic the embryotoxic effects of planar halogenated hydrocarbons (pHAHs) that are agonists for the aryl-hydrocarbon receptor (AHR), notably cranial deformities and cardiovascular defects. Studies have shown that pHAH toxicity is AHR-mediated and evidence suggests that some of this toxicity may be due to cytochrome P4501A (CYP1A) activity. Studies in our laboratory with killifish embryos have shown that co-exposure to the PAH-type AHR agonist  $\beta$ -naphthoflavone (BNF), and the partial AHR agonist and CYP1A inhibitor  $\alpha$ -naphthoflavone (ANF), significantly increased toxicity greater than that predicted from an additive PAH toxicity model. This enhanced toxicity contrasts to protective effects reported for CYP1A inhibition on the developmental toxicity of pHAH. Thus, the role of the AHR pathway and CYP1A activity in PAH toxicity is less clear. We repeated these experiments in zebrafish embryos to determine if PAH interactions observed in killifish were species-specific and, more importantly, to explore the mechanism by which inhibition of CYP1A activity leads to increased embryotoxicity in light of the molecular and genetic tools available for this model species. Zebrafish embryos were exposed to BNF alone and in combination with ANF at doses that by themselves were non-embryotoxic. As observed in killifish co-exposures, ANF decreased BNF-induced CYP1A activity and also caused greater pericardial edema and cranial deformities over those observed in BNF-alone, ANF-alone, or control groups. These data clearly show that enhanced toxicity observed between PAH-type AHR agonists and CYP1A inhibitors is not species-specific. However, the mechanism by which these interactions are greater-than-additive with respect to embryotoxicity remains unknown. We are currently using an antisense morpholino approach in zebrafish to elucidate the role of the AHR and CYP1A activity in the developmental toxicity of PAHs.

ALTERED GENE EXPRESSION AND DEVELOPMENT OF POTENTIAL BIOMARKERS IN MEDAKA (*ORYZIAS LATIPES*) BRAIN, LIVER, AND TESTIS FOLLOWING EXPOSURE TO FIBRATE PHARMACEUTICALS.

D. C. Bencic<sup>1,2</sup>, D. C. Volz<sup>1</sup>, P. Chen<sup>1</sup>, A. D. Biales<sup>2</sup>, J. M. Lazorchak<sup>2</sup>, D. E. Hinton<sup>1</sup> and S. W. Kullman<sup>1</sup>. <sup>1</sup>*Integrated Toxicology Program and Nicholas School of the Environment and Earth Sciences, Duke University, Durham, NC* and <sup>2</sup>*Molecular Ecology Research Branch, EERD, NERL, ORD, USEPA, Cincinnati, OH.*

To help address the consequences of increasing levels of environmental contaminants and to identify potentially novel markers of toxicity, we examined gene expression profiles from medaka (*Oryzias latipes*) exposed to a prototypical fibrate

pharmaceutical. Changes in gene expression in male medaka brain, liver and testis following 48 h exposure to 15  $\mu$ g (injected) of the antihyperlipidemic agent ciprofibrate (CF) were analyzed using suppressive subtractive hybridization. From a total of 1152 clones, 288 were sequenced and 100 were identified as differentially expressed. Furthermore, only 1 gene was shared among all three organs and less than 5% between any two organs, suggesting organ specific responses at the level of gene expression. The results of this CF and other xenobiotic induced gene expression studies were used to develop macroarrays specific for brain, liver, or testis containing 200-300 non-redundant cDNAs. Following 7 day water exposures to 10, 100, and 1000  $\mu$ g/l of CF or clofibrate, compound, dose, and organ specific altered gene expression was determined. Highly responsive genes were further validated using real-time QPCR. In order to associate changes in gene expression with altered phenotype, compound- and dose-dependent histopathology samples were also examined. A combination of macroarray, real-time QPCR, and histopathological techniques will aid in linking molecular events and biochemical alterations following exposure and provide a mechanism to evaluate exposure and effects at the individual and population levels. Research supported in part by grants from Duke University Integrated Toxicology Program (T32 ES07031), NCBC (ARG0030), and WERF (01HHE21T). Although this work was reviewed by the USEPA and approved for publication, it may not necessarily reflect official Agency policy.

### 1583 A CROSS-SPECIES APPROACH TO USING GENOMICS TOOLS IN AQUATIC TOXICOLOGY.

A. Miracle<sup>1</sup>, I. Knoebel<sup>1</sup>, D. Bencic<sup>1</sup>, D. Lattier<sup>1</sup>, R. Wang<sup>1</sup>, D. Villeneuve<sup>2</sup> and G. Ankley<sup>2</sup>. <sup>1</sup>EERD, USEPA, Cincinnati, OH and <sup>2</sup>MED, USEPA, Duluth, MN. Sponsor: T. Reddy.

Microarray technology has proven to be a useful tool for analyzing the transcriptome of various organisms representing conditions such as disease states, developmental stages, and responses to chemical exposure. Most commercially available arrays are limited to organisms that have complete, or near complete, genome information; few of which are relevant for non-mammalian toxicology. However, with the imminent completion of the zebrafish genome project, and the availability of high density microarrays, the zebrafish (*Danio rerio*) represents a useful species for focused toxicological research. An approach involving the transcriptional mining of the zebrafish for potential biomarkers to be validated for use in another cyprinid, the fathead minnow (*Pimephales promelas*), will be described as a useful cross-species comparison for using genomics in an organism without a defined genome. The high degree of evolutionary conservation in vertebrates of many biochemical and developmental pathways strongly supports the extrapolation of molecular data from one fish species to another. Linkage of other molecular measures and phenotypic effects are also required to interpret transcriptional comparisons between the species. Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy

### 1584 MICROARRAY ANALYSIS OF HEPATIC GENE EXPRESSION IN COHO SALMON (*ONCORHYNCHUS KISUTCH*).

H. LaVire<sup>1</sup>, P. Stapleton<sup>1</sup>, R. Beyer<sup>1</sup>, N. Scholz<sup>2</sup> and G. Evan<sup>1</sup>. <sup>1</sup>University of Washington, Seattle, WA and <sup>2</sup>NOAA, Seattle, WA.

Pacific salmon populations have declined markedly in the western United States, and exposure to agricultural and urban chemicals has been identified as a key determinant of salmon injury. Salmon undergo complex physiological transformations during the transition from juveniles to migratory adult stages that may affect susceptibility to chemical injury. In the current study, transcriptome profiling using a 16K salmonid microarray was conducted on liver mRNA samples from smolt-stage juveniles, adult males, and adult female Coho salmon (*Oncorhynchus kisutch*). The microarrays included ESTs and related sequences of genes pertaining to toxicological pathways of interest including oxidative stress, immune system regulation, cellular structure and function, and biotransformation. These genes also included several glutathione S-transferases (GST) with some structural similarity to -omega, -zeta, -pi, and -theta class GST. However, although over 90% of the cDNAs on the chip were homologous to known *Oncorhynchus* genes, less than 1% of the genes originated from *O. kisutch*. Accordingly, a subset of transcript expressions was validated using real-time quantitative PCR (QPCR). This subset included a GST pi homologue, which was cloned and sequenced from coho liver. Coho liver GST pi expression did not differ among the life stages and was well correlated with the gene array information. Preliminary screening of the baseline life-stage transcriptomes revealed several potential genes with ontology related to chemical injury and immune system regulation that were differentially expressed among the life stages. Following further validation of key genes by QPCR, the utility of this array platform will be evaluated in support of studies addressing mechanism-based markers of exposure, susceptibility, and biological effects in Coho salmon. Supported by P42-ES07375, P30ES07033, and Genome Canada.

### 1585

### THE USE OF RNA MICROARRAY TECHNOLOGY AS A BIOMARKER FOR EXPOSURE OF FATHEAD MINNOW (*PIMEPHALES PROMELAS*) TO 2, 4-DINITROTOLUENE.

J. L. Yoo<sup>1</sup>, J. A. Stevens<sup>1</sup>, A. B. Gibson<sup>1</sup>, C. D. Vulpe<sup>2</sup> and H. M. Wintz<sup>2</sup>. <sup>1</sup>Environmental Laboratory, USACE ERDC, Vicksburg, MS and <sup>2</sup>Nutritional Sciences and Toxicology, University of California, Berkeley, CA.

Production and use of 2, 4-dinitrotoluene (2, 4-DNT) and 2, 6-dinitrotoluene (2, 6-DNT) for military and civilian purposes has resulted in their release to the aquatic environment through various surface water pathways. The aquatic toxicology of the DNT homologues is poorly understood and this lack of knowledge contributes to uncertainty when assessing potential risks involved in exposure of aquatic species to these compounds. The purpose of this study is to characterize the effects of 2, 4-DNT and the associated mechanisms of toxicity in the fathead minnow (*Pimephales promelas*), through the use of RNA microarray technology. Larval ( $2.8 \pm 1.4$  mg) and adult ( $2.9 \pm 0.9$  g) minnows were exposed to 2, 4-DNT and the herbicide diquat dibromide for 10 days in independent static renewal exposures. Diquat dibromide exposures were conducted as a positive control for oxidative stress, the hypothesized mechanism of action of DNT. At the completion of the experiments survival and growth were assessed and tissues were collected for gene expression and chemical analyses. Significant mortality resulted in the  $51 \pm 7$  and  $80 \pm 4$   $\mu$ mole/L 2, 4-DNT treatments for the larval and adult experiments, respectively, with the larval life stage demonstrating the most sensitivity to 2, 4-DNT. No-observed-effect-concentrations (NOEC) were determined to be  $23 \pm 2$  and  $37 \pm 3$   $\mu$  mole/L 2, 4-DNT in the larval and adult experiments, respectively. The larval experiment produced a median lethal toxicant concentration (LC50) of  $32$  (28-37 95% Confidence Interval (CI))  $\mu$  mole/L 2, 4-DNT and a median lethal tissue residue (MLR) of  $155$  (142-169 95% CI)  $\mu$  mole/kg. Tissue residues increased in a concentration dependent manner in both the larval and adult experiments. Assessment of exposure and associated mechanisms of toxic action will be further investigated using microarray technology to explore gene expression profiles in collected tissues of exposed fish.

### GENE EXPRESSION PROFILING IN RAINBOW TROUT (*ONORHYNCUS MYKISS*), EXPOSED TO A VARIETY OF MODEL TOXICANTS.

I. Schultz, S. Hook and A. D. Skillman. Battelle PNNL, Sequim, WA.

The increased availability and use of DNA microarrays has allowed the characterization of gene expression patterns associated with different toxicants. An important question is whether toxicant induced changes in gene expression in fish are sufficiently diverse to allow for identification of specific modes of action or specific contaminants. In theory, each class of toxicant may generate a gene expression profile unique to its mode of toxic action. The latter will be influenced by dose, route of administration and developmental state among other potential modifying factors. We exposed isogenic (cloned) rainbow trout *Onorhyncus mykiss*, to sublethal levels of a series of model toxicants with varying modes of action, including ethynodiol (xeno-estrogen), trenbolone (anabolic steroid; model androgen), tetrabromodiphenyl ether (BDE-47, thyroid active), diquat (oxidant stressor), chromium VI, and benzo-a-pyrene (BaP) for a period of 1-3 weeks. Following exposure, fish were euthanized, livers harvested and RNA extracted. Fluorescently labeled cDNA were generated and hybridized against a commercially available Atlantic Salmon / Trout array (GRASP project, University of Victoria) spotted with 16, 000 cDNAs. The slides were scanned to measure abundance of a given transcript in each sample relative to controls. Data were analyzed via Genespring (Silicon Genetics) to identify a list of up and down regulated genes, as well as to determine gene clustering patterns that can be used as expression signatures. Initial analysis indicates each toxicant generated specific gene expression profiles. Most genes exhibiting altered expression responded to only one of the toxicants. Relatively few genes are co-expressed in multiple treatments. For example, BaP and Diquat, both of which exert toxicity via oxidative stress, up-regulated 28 of the same genes. Other genes associated with steroidogenesis, p450 and estrogen responsive genes appear to be useful for selectively identifying toxicant mode of in fish (Supported by the U. S. Department of Energy under contract DE-AC06-76RLO 1830 with Battelle PNNL).

### 1587

### NONYLPHENOL POLYETHOXYLATE INHIBITS TRANSPORT OF ESTROGENS INTO BILE IN THE CHANNEL CATFISH, *ICTALARUS PUNCTATUS*.

G. C. Hummelke and K. M. Kleinow. Comparative Biomedical Sciences, Louisiana State University, Baton Rouge, LA. Sponsor: M. James.

P-glycoprotein (Pgp) has been implicated in multixenobiotic resistance in aquatic species, including the channel catfish *Ictalurus punctatus*. This ABC transporter effluxes amphiphatic compounds, including environmental pollutants such as

nonylphenol polyethoxylate (NPE), from cells in tissues such as the liver. Recent studies suggest that Pgp also may play a role in regulating levels of steroid hormones. The interactions of NPE, the Pgp substrate rhodamine 123 (Rh123) and estradiol (E2) were assessed as they relate to Pgp transport, using an *in situ* -prepared isolated perfused catfish liver model. Our results demonstrate that catfish livers perfused with 1  $\mu$ M of Rh123 and 20  $\mu$ M NPE transport less Rh123 to bile than do untreated controls (con=11.43+3.44 nmol/kg body weight [bw]; NPE=3.43+1.66 nmol/kg bw,  $p<0.007$ ). Livers perfused with increasing doses of E2 (0.5-20  $\mu$ M) and either 1 or 5  $\mu$ M Rh123 showed a similar dose-dependent reduction in Rh123 transport. Dixon plot analysis (Ki=6.48) suggests a complex E2/Rh123 interaction that includes both competitive and uncompetitive components. Biliary transport of [<sup>3</sup>H]-E2 (1 nM; specific activity=41.3Ci/mmol) was examined alone, or with NPE (20  $\mu$ M), the Pgp-inhibitor verapamil (VRP; 20  $\mu$ M), lucifer yellow (LY; 5  $\mu$ M; a MRP substrate in fish), or VRP/LY (20  $\mu$ M/5  $\mu$ M). NPE, VRP, and VRP/LY reduced transport of [<sup>3</sup>H]-E2 molar equivalents (ME) by 51.7%, 45.7%, and 64.7%, respectively. LY alone did not reduce E2 ME movement. HPLC analysis of biliary [<sup>3</sup>H]-E2 ME indicates that E2-glucuronides were the major species transported. Treatment groups exhibiting decreased E2 ME transport (NPE, VRP, VRP/LY) showed an altered biliary metabolite profile compared to the control and LY groups. VRP inhibition of E2 ME transported into bile, E2/Rh123 interactions, and a lack of a LY effect suggest that Pgp is involved in E2 disposition. The changing character of E2 ME entering the bile and dixon analysis results may be indicative of additional mechanisms involved in transport. (NIEHS ES-07375)

**1588** ESTROGEN EQUIVALENTS AND CORRESPONDING CHEMICAL ANALYSES OF MARINE WATER SAMPLES COLLECTED ALONG A CORAL REEF.

A. M. Chaudhary<sup>1</sup>, L. R. Harrison<sup>2</sup>, S. I. Khan<sup>2</sup>, S. Singh<sup>3</sup>, A. Azua<sup>3</sup>, P. Gardinali<sup>3</sup> and K. L. Willett<sup>1</sup>. <sup>1</sup>*Pharmacology and Environmental Toxicology Research Program, The University of Mississippi, University, MS*, <sup>2</sup>*National Center for Natural Product Research, The University of Mississippi, University, MS* and <sup>3</sup>*Department of Chemistry, Florida International University, Miami, FL*.

The goal of this research is to assess the potential toxicological impacts of degraded water quality due to human derived activities in marine coastal areas along the Florida Keys. Sensitive marine species such as coral, sea grasses, and fish and invertebrates in their early stages of life may be at risk due to the introduction of pollutants, in particular those compounds with potential to disrupt the endocrine system. In this study, forty water samples were collected at Looe Key before, during and after the annual Underwater Music Festival. Samples were chemically analyzed for 8 pharmaceuticals and 14 steroids and screened for estrogen equivalents using the yeast estrogen screen. Estrogen equivalents ranged from nondetectable (nd) to 1300 ng/L. Even though recreational activities peaked during the day of the festival, higher average estrogen equivalents ( $730 \pm 125$  ng/L) were found in samples collected the day prior to the festival. This trend was supported by the analytical data where the sum of contaminant concentrations of these samples was statistically higher compared to data from the other collection times. Estrone (0.74 – 0.82 ng/L), equilin (nd – 0.88 ng/L), cholesterol (180 – 1250 ng/L), caffeine (nd – 31 ng/L) and DEET (nd – 17 ng/L) were detected in the majority of samples. However, no nonylphenol, bisphenol A, or ethynodiol was detected. Although the results do not indicate high potential risk to the ecosystem from acute recreational exposure, the presence of human-derived contaminants should not be downplayed. The estrogen equivalents detected at Looe Key were significantly lower than what we have found at waste water impacted marine sites (up to 6.6  $\mu$ g/L). (Supported by NOAA/NIUST).

**1589** MERCURY DISTRIBUTION IN SEDIMENTS AND UPTAKE BY PLANTS ALONG SNOW AND CHOCOLLOCCO CREEKS IN NORTHEAST ALABAMA.

A. C. Nichols<sup>1</sup>, D. A. Steffy<sup>1</sup> and S. Al-Hamdan<sup>2</sup>. <sup>1</sup>*Physical and Earth Sciences, Jacksonville State University, Jacksonville, AL* and <sup>2</sup>*Biology, Jacksonville State University, Jacksonville, AL*.

The lower part of the Snow Creek Watershed drains an urbanized area within the city of Oxford, AL. Approximately one mile before Snow Creek empties into Choccolocco Creek, it flows through a city park and a nearby shopping mall parking lot. The city park is in the floodplain of Snow Creek and contains baseball fields, playground areas, and tennis courts. Fill deposits used as landscape material in the construction of both the park and the shopping mall may have been contaminated with mercury (Hg) from industrial sources. This land now serves as a non-point source of Hg contaminated soil. Gradual erosion has redistributed contaminated sediment from this site downstream into Choccolocco Creek and its associated floodplain. Sediment samples were collected downstream from the confluence of Choccolocco and Snow Creeks for a distance of 25 miles. Mercury

contamination was detected a distance of fourteen miles downstream from Snow Creek. Sediments taken from Snow Creek upstream of the park and shopping mall had Hg levels of 0.06 ug/g, which appear to be the background level. Channel deposits from Snow Creek and Choccolocco Creek below the contaminated site had Hg levels that ranged from 0.08 to 2.46 ug/g. Soil samples taken from the city park had values as high as 6.58 ug/g. Three different plant species were collected from the contaminated area of Snow Creek and analyzed for total Hg. The metal was not detected in either Indian mock strawberry (*Duchesnea indica*) or Johnson grass (*Sorghum halepense*). However, Hg was detected in wild hops (*Humulus lupulus*), which grows abundantly in sun exposed areas along the creek. Hop samples had average Hg concentrations of 0.09 ug/g in leaves and 0.21 ug/g in stems. Soil concentration at the collection site was 0.55 ug/g. The periodic harvesting of this fast growing plant could provide a relatively inexpensive means of removing Hg from the contaminated soil.

**1590** IDENTIFICATION OF SELENOPROTEINS IN SELENIUM-SENSITIVE TISSUES IN JAPANESE MEDAKA (*ORYZIAS LATIPES*) USING TANDEMLY COUPLED HPLC-ICPMS.

K. A. Thrippleton<sup>1</sup>, A. Mason<sup>3</sup> and D. Schlenk<sup>2</sup>. <sup>1</sup>*Department of Environmental Toxicology, University of California, Riverside, Riverside, CA*, <sup>2</sup>*Department of Environmental Sciences, University of California, Riverside, Riverside, CA* and <sup>3</sup>*Department of Biological Sciences, California State University, Long Beach, Long Beach, CA*.

Selenium (Se) is an essential micronutrient for many organisms, but for oviparous vertebrates, Se at slightly elevated levels becomes highly toxic. Sulfur (S), a fundamental constituent of many proteins, is found in the disulfide bond linkages (S-S linkages) between amino acid strands. The similarities in chemical and physical properties of Se and S has been used to support the hypothesis that Se exerts its toxicity by interfering with disulfide bonds. This can result in distorted, dysfunctional proteins and enzymes, which ultimately could impair normal cellular biochemistry. Studies are currently underway to determine proteins in *O. latipes* that may be affected by Se toxicity after dietary exposure to the metal. Brine shrimp (*Artemia*) used for the dietary exposures to *O. latipes* were exposed to 100 ppm selenomethionine (SeMet) for 1 hour. Se levels in exposed *Artemia* averaged 5.82 nmol Se/mg dry weight. Assimilation of Se into proteins from *O. latipes* liver, gonad, and egg samples following dietary exposure were evaluated by tandemly coupled size-exclusion HPLC (SE-HPLC) ICPMS (Perkin Elmer 6100 DRC). Chemical resolution of Se from the polyatomic Ar<sub>2</sub><sup>+</sup> dimer at m/z 80 was accomplished using methane as a reactant gas. The identification of these Se-affected proteins could aid in better understanding of Se toxicity within oviparous organisms.

**1591** ACUTE TOXICITY AND BIOACCUMULATION OF TRIBUTYLTIN IN THE REEF BUILDING CORAL SPECIES ACROPORA SP. (STAGHORN CORAL).

J. Dwivedi<sup>2</sup>, K. Howell<sup>2</sup>, P. Nguyen<sup>3</sup> and L. D. Trombetta<sup>1</sup>. <sup>1</sup>*Pharmaceutical Sciences, St. John's University, Jamaica, NY*, <sup>2</sup>*Biological Sciences, St. John's University, Jamaica, NY* and <sup>3</sup>*Biological Sciences, Borough of Manhattan Community College, CUNY, New York, NY*.

Tributyltin oxide (TBTO) is used as a biocide by manufacturers of antifouling marine paint. Previous studies of marine species including gastropods, fish, algae and marine mammals, have shown the detrimental effects of TBTO exposure to non target organisms in the environment. Ship groundings result in the deposition of TBTO in the form of paint chips and contaminated debris. Two such groundings have occurred on the Great Barrier Reef, Australia. To better understand the impacts of acute TBTO exposure to reef building corals, coral fragments of *Acropora* sp. (staghorn coral) were housed in glass aquaria static tank systems with appropriate aeration. Metal halide/power compaq lighting systems provided dawn/dusk and daytime lighting during a 12 hour photo period. Individual 15 cm fragments were exposed to 100ng/l, 500ng/l or 1000ng/l of TBTO via water column. Non treated fragments were housed as controls. After 12hr exposure, fragments were fixed in 3% gluteraldehyde, and processed for scanning electron microscopy. Samples for light and transmission electron microscopy were decalcified after gluteraldehyde fixation and appropriately processed for sectioning. Graphite furnace atomic absorption spectrophotometry (GFAAS) was used to determine tin concentration. Chlorophyll extraction/colorimetric analysis were used to quantify loss of zooxanthellae (bleaching). Electron microscopy results demonstrate a dose dependant swelling and exfoliation of epithelium. GFAAS results show significant increase in tin concentrations of treated coral compared to controls. Colorimetric analysis of chlorophyll concentration exhibits a dose dependant release of zooxanthellae among treatment groups.

HYPERSensitivity OF THE ELASMOBRANCH  
UROLOPHUS JAMAICENSIS (YELLOW STINGRAY) TO  
TRIBUTYLTIN EXPOSURE.

J. Dwivedi<sup>2</sup> and L. D. Trombetta<sup>1</sup>. <sup>1</sup>Pharmaceutical Sciences, St. Johns University, Jamaica, NY and <sup>2</sup>Biological Sciences, St. John's University, Jamaica, NY.

Tributyltin oxide (TBTO) is the main constituent of tin based antifouling marine paint. It is used on the hulls of ships to prevent the growth of fouling organisms. Upon leaching from a variety of sources, TBTO binds strongly to suspended material. Elasmobranchs play an important role in the health and stability of the marine ecosystem. *Urolophus jamaicensis* represents the ideal study organism for the toxic effects of TBTO to these marine vertebrates. Previous work has shown that the elasmobranch gill is more sensitive to TBTO exposure than many species of teleost fish. This work is a continuation of a study to demonstrate the toxicity and accumulation of tin in gill tissue of the stingray *U. jamaicensis* after a single exposure of TBTO. This work demonstrates the alterations in the morphological architecture of the gill using LM, TEM, and SEM, the induction of stress proteins, and peroxidative damage in response to TBT exposure in doses much lower than previously reported. Animals were exposed to one of five experimental doses of TBTO (4ug/L, 2ug/L, 1ug/L, .5ug/L or .05ug/L). A sixth group served as a control population. Three hours following treatment animals were sacrificed, gill tissue removed, processed and stored for analysis. Results indicate that *U. jamaicensis* is hypersensitive to TBT exposure. The elasmobranch gill showed a distorted, swollen epithelium with exfoliation following acute exposure to as little as .05ug/l TBTO for 3 hours. TEM revealed swollen mitochondria with membrane disruption. Differential staining confirms no mucous production, and no inflammatory response. GFAAS results indicate that tissues of treated animals contained a significantly increased tin concentration as compared to controls. Western Blot analysis demonstrates the induction of the stress proteins Hsp 70 and HO1. 4HNE adduct formation determined by Western blot analysis provides further evidence that observed membrane degradation is a result of lipid peroxidation.

IN SITU BIOMONITORING TO ASSESS THE  
GENOTOXICITY OF PAH-CONTAMINATED  
SEDIMENTS TO JUVENILE COHO SALMON  
(ONCORHYNCHUS KISUTCH).

G. C. Barbee<sup>1</sup>, J. Barich<sup>5</sup>, B. Duncan<sup>5</sup>, J. W. Bickham<sup>2</sup>, C. W. Matson<sup>2</sup>, C. J. Hintze<sup>3</sup>, R. L. Autenrieth<sup>4</sup>, G. Zhou<sup>6</sup>, T. J. McDonald<sup>6</sup> and K. C. Donnelly<sup>6,1</sup>. <sup>1</sup>Veterinary Integrative Biomedical Sciences, Texas A&M University, College Station, TX, <sup>2</sup>Wildlife and Fisheries Sciences, Texas A&M University, College Station, TX, <sup>3</sup>Statistics, Texas A&M University, College Station, TX, <sup>4</sup>Civil Engineering, Texas A&M University, College Station, TX, <sup>5</sup>USEPA, Seattle, WA and <sup>6</sup>Environmental and Occupational Health, Texas A&M University System Health Science Center, College Station, TX.

Polycyclic aromatic hydrocarbons (PAH) are ubiquitous marine and freshwater sediment contaminants. However, limited information is available regarding the bioavailability and genotoxicity of sediment PAHs to aquatic organisms. We investigated an integrated biomonitoring approach using chemical analyses and biomarkers to characterize the bioavailability and genotoxicity of a complex PAH mixture in freshwater lake sediments associated with a former manufactured gas plant (MGP). Sediment PAH genotoxicity was assessed by flow cytometry, DNA adduct 32P-postlabeling, and erythrocyte micronuclei in juvenile coho salmon (*Oncorhynchus kisutch*) caged in the water column. Significant PAH-induced genotoxicity was observed with flow cytometry and DNA adduct 32P-postlabeling, but not with erythrocyte micronuclei. Chromosome damage measured by flow cytometry and hepatic DNA adducts correlated with sediment PAH concentrations. Total hepatic DNA adducts in salmon caged nearest the former MGP facility was 28.1 (SD = 4.7) RALx10E9, while salmon caged in a reference lake had 21.2 (SD = 2.4) RALx10E9 DNA adducts. These data indicate aged sediment PAHs can migrate into the water column and be genotoxic to caged salmon. The data are insufficient to determine if such genotoxicity will reduce salmon viability or reproductive capability, but show *in situ* biomonitoring using biomarkers and caged fish can be effective in sediment ecotoxicology studies.

EXPOSURE OF FATHEAD MINNOW TO FULLERENE  
AND SINGLE-WALLED CARBON NANOTUBES.

E. Oberdoerster<sup>2,1</sup>, A. Ortiz-Acevedo<sup>3</sup>, H. Xie<sup>3</sup>, P. Pantano<sup>3</sup>, R. H. Baughman<sup>3</sup>, I. H. Musselman<sup>3</sup>, R. K. Draper<sup>3</sup> and G. R. Dieckmann<sup>3</sup>. <sup>1</sup>Biology, Southern Methodist University, Dallas, TX, <sup>2</sup>Duke University Marine Laboratory, Beaufort, NC and <sup>3</sup>Department of Chemistry and Nanotech Institute, University of Texas, Dallas, TX.

A water-soluble fullerene derivative (nC60) has been shown to induce lipid peroxidation in the brains of juvenile largemouth bass (*Micropterus salmoides*). In addition, proteins related to an inflammatory response were up-regulated by nC60, as

were enzymes related to metabolism of organic molecules, most notably CYP2K1. This current study was done as a follow-up, and to expand the exposure regime to polypeptide-coated and uncoated single-walled carbon nanotubes (SWNTs). For this study, the nC60 was dissolved by stirring for two weeks in milliQ water. SWNT were water-solubilized using the synthetic helical peptide Nano-1. Adult male fathead minnows (*Pimephales promelas*) were dosed individually via the water column with either a) 0.5 ppm nC60 (positive control); b) 0.2 ppm Nano-1 wrapped SWNT; or c) 0.2 ppm SWNT (added to water, but did not disperse) in Reconstituted Hard Water (RHW) in 1L aquaria for 48 hours, with a 50% water volume change at 24 hours. Control fish were exposed to only RHW, and n=10 for each group except nC60, where n=5. At 48 hours, there was no mortality. Fish were euthanized using MS-222, rinsed and dried, weighed, and ten tissues were harvested from each fish. For both the Nano-1 SWNT and un-coated SWNT exposed fish, SWNTs were detected in the fecal material collected from the digestive tract, as was verified by Raman spectroscopy. For the Nano-1 SWNT exposures, clumps of SWNTs were visible on the gill, but similar clumps were not visible for the un-coated SWNTs. Tissues will be further analyzed for the presence of either SWNTs or the fullerene, and for possible oxidative damage. Livers are being processed by RT/RT-PCR for the induction of CYP2K1 mRNA to identify whether nano-1 wrapped SWNTs, unwrapped SWNTs, or nC60 can induce this enzyme in fathead minnows. This is only the first trial with this exposure regime, and will be repeated.

TEMPORAL PATTERNS OF MICROCYSTIN-LR  
CONTAMINATION IN LAKES OF WEST TEXAS.

M. Billam<sup>1,2</sup>, Q. Cai<sup>1,2</sup>, L. Tang<sup>1,2</sup>, P. Wang<sup>1,2</sup>, S. Mukhi<sup>1,2</sup>, Z. Wang<sup>1,2</sup>, H. Luo<sup>1,2</sup>, H. Guan<sup>1,2</sup> and J. Wang<sup>1,2</sup>. <sup>1</sup>Environmental Toxicology, Texas Tech University, Lubbock, TX and <sup>2</sup>The Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX.

Microcystin-LR (MCLR) is a predominant cyanotoxin which contaminates fresh water sources all over the world. MCLR is a hepatotoxic and a potent tumor promoter in animal models. In addition to linking to elevated incidence of gastrointestinal cancers in humans, ecotoxic effects of MCLR contamination are predominant in recent years, as demonstrated by growing reports on bloom outbreaks and large scale fish killed in many water bodies of USA, including lakes from west Texas. In this study, temporal patterns of MCLR contamination in Buffalo Springs Lake and Lake Ransom Canyon of west Texas were monitored over a year. Relationship between production of MCLR and various physicochemical parameters of water was investigated. MCLR in water samples were determined by ELISA and protein phosphatase inhibition assay and confirmed by HPLC. Results showed that in Buffalo Springs Lake, seasonal averaged concentration of MCLR was found to be  $1.78 \pm 1.43$  ppb ranged at 0.18 - 4.91 ppb in spring samples,  $0.41 \pm 0.09$  ppb ranged at 0.19 - 0.5 ppb in summer samples,  $0.46 \pm 0.41$  ppb ranged at 0.21 - 1.6 ppb in fall samples, and  $1.04 \pm 0.71$  ppb ranged at 0.09 - 2.43 ppb in winter samples, respectively. In Lake Ransom Canyon, the averaged concentration of MCLR was found to be  $1.08 \pm 1.29$  ppb ranged at 0.44 - 3.7 ppb in spring samples,  $0.83 \pm 0.46$  ppb ranged at 0.34 - 1.45 ppb in summer samples,  $0.44 \pm 0.03$  ppb ranged at 0.41 - 0.48 ppb in fall samples, and  $0.78 \pm 0.52$  ppb ranged at 0.30 - 1.76 ppb in winter samples, respectively. Seasonal fluctuation of MCLR concentrations were found to be correlated with values of water pH, temperature and dissolved oxygen. (Supported by the NIH grant CA94683)

GLUCURONIDATION OF DESMETHYL-  
METHOXYCHLOR IN THE CHANNEL CATFISH  
INTESTINE AND LIVER.

L. D. Stuchal<sup>1</sup>, K. M. Kleinow<sup>2</sup> and M. James<sup>1</sup>. <sup>1</sup>University of Florida, Gainesville, FL and <sup>2</sup>Louisiana State University, Baton Rouge, LA.

The chlorinated pesticide methoxychlor (MXC) is a Superfund toxic chemical whose mono- and bis-desmethylated metabolites (OH-MXC and HPTE respectively) interact with estrogen receptors and may be endocrine disruptors. Slow phase II metabolism of OH-MXC or HPTE may delay their excretion and contribute to MXC toxicity. The glucuronidation of OH-MXC was examined in detergent-treated microsomes from liver and intestine of control catfish, fish exposed to MXC, 2 mg/kg i.p. for 6 days before sacrifice and fish exposed to 3-methylcholanthrene (3-MC), 10 mg/kg i.p. 4 days before sacrifice. The assay used 14C-UDPGA and ion-pair extraction of product, and was optimized for concentration of detergent, microsomal protein and incubation time. Varying concentrations of OH-MXC or UDPGA were used to examine reaction kinetics. Hepatic microsomes from control and 3-MC-treated catfish had similar Km values of 250  $\mu$ M, however Vmax was significantly ( $p < 0.05$ ) higher in 3-MC-treated fish than controls (426 vs 277 pmol/min/mg protein). Microsomes from MXC-treated fish had a lower apparent Km value of 143  $\mu$ M but similar Vmax to controls, 291 pmol/min/mg protein. Product was formed in microsomes from MXC-treated fish without added substrate, suggesting the lower apparent Km was an artifact due to

residues of OH-MXC or HPTE. Analysis of these microsomes revealed residues of OH-MXC and HPTE, but not parent MXC. Intestinal microsomes from control and 3-MC-treated fish glucuronidated OH-MXC more rapidly ( $p<0.05$ ) than liver. Intestinal Vmax values were 536 and 1026 pmol/min/mg protein in control and 3-MC-induced fish respectively. Our results show that although OH-MXC was readily glucuronidated in catfish liver and intestine, the Km values for glucuronidation were 50-fold higher than for CYP-dependent formation of the OH-MXC and HPTE. This suggests that glucuronidation may be inefficient at environmental exposure concentrations. Supported in part by ES-07375.

DECABROMODIPHENYL OXIDE/ETHER (BDE-209): INVESTIGATION OF PHOTOLYTIC DEGRADATION IN A CONSUMER PRODUCT.

P. F. Ranken<sup>2</sup>, M. Hardy<sup>1</sup> and S. D. Landry<sup>2</sup>, <sup>1</sup>Health, Safety & Environment, Albemarle Corporation, Baton Rouge, LA and <sup>2</sup>Research & Development, Albemarle Corporation, Baton Rouge, LA.

Decabromodiphenyl oxide/ether (DBDPO) is a highly effective flame retardant used typically in styrenic resins requiring significant ignition resistance, e.g. US V-0 rating. Consumer products that may be flame retarded with DBDPO include electrical and electronic equipment such as television cabinet backs and wire and cable insulation, and upholstery textiles used in commercial applications. DBDPO represents over 80% of the global production of the flame retardant class known as polybrominated diphenyl ethers (PBDEs). PBDEs have received worldwide attention due to their detection in the environment. Those isomers most frequently detected contain four (mainly BDE-47), five (mainly BDE-99, 100) and six (mainly BDE 153, 154) bromine atoms, and appear to originate from the use of the pentabromodiphenyl ether (Penta) product. DBDPO's reductive debromination *in situ* within consumer products, with subsequent migration of breakdown product(s) out of the appliance and into the environment, has been suggested as a possible source of these environmental PBDEs. Using an accelerated aging process, we investigated DBDPO's potential to photodegrade in its most common US application, e.g. a TV cabinet back. The aging process exposed a sample cut from the back of retail TV to a Xenon Arc lamp for up to 900 hours, and was approximately equivalent to 16 years of indoor exposure to sunlight. Our results showed no generation of BDE-47 within the plastic, and potential generation of a maximum of  $8.6 \times 10^{-5}$  % of the BDE-99 contained in one year's global production of the Penta product. We also demonstrated photolytic degradation of BDE-47 and BDE-153, dissolved in organic solvent, via reductive debromination as well as by a competing process; that is, solvent trapping of the BDE radical. Based on these results, degradation of DBDPO in consumer products is an insignificant source of environmental PBDEs: 47, 99, 100, 153, and 154.

**1598**

HIGH-THROUGHPUT CHEMICAL SCREENING USING PROTEIN PROFILING OF FISH PLASMA.

R. T. Hudson, M. J. Hemmer, K. A. Salinas, S. S. Wilkinson, J. Watts, J. T. Winstead, P. S. Harris, A. Kirkpatrick and C. C. Walker. US-EPA, ORD, NHEERL, Gulf Breeze, FL. Sponsor: M. Barron.

Compounds that affect the hormone system, referred to as "endocrine-disrupting chemicals" (EDCs) cause human and animal health problems. It is necessary to test new chemicals for EDC effects, though current testing is time/animal intensive and costly. To screen the EPA inventory of ~ 87,000 chemicals, other methods must be developed. Protein profiling can be used for high-throughput ID of protein patterns indicative of a change in physiological status. This "fingerprint" can be used diagnostically to screen for chemical exposure. Using Surface Enhanced Laser Desorption/Ionization Time-of-Flight Mass Spectrometry (SELDI-TOF MS), we profiled plasma obtained from Sheepshead minnows (*Cyprinodon variegatus*) for endocrine-related changes in protein patterns. The fish were placed into flow-through aquaria consisting of duplicate tanks for treatment with each of the following: vehicle control (triethylene glycol, TEG), estrogen (17  $\mu$ -estradiol), EDC positive controls (methoxychlor and bisphenol) and EDC negative controls (endosulfan and chlorpyrophos). Test concentrations were maintained by intermittent seawater flow and by injection of the chemical and control treatments. After treatment, fish were sampled for their plasma. The plasma was applied to ProteinChip® arrays and analyzed. No significant difference was found between protein profiles of seawater control and TEG-treated fish. Proteins in the <20 kDa range had altered expression in response to estrogen exposure, with respect to controls. An estrogen-specific spectral fingerprint was found using the pattern recognition software, Biomarker Patterns. Using this pattern diagnostically to determine estrogenicity, the two EDC positive controls were classified by the software as estrogenic. The two EDC negative controls were classified as non-estrogenic. SELDI represents a viable and rapid means for assaying chemicals for estrogenic effects. Also, this protocol should be readily transferable to other species and other mechanisms of interest.

LOSS OF GLUTAMATE-CYSTEINE LIGASE MODIFIER SUBUNIT SENSITIZES CELLS TO CADMIUM TOXICITY.

S. N. Schneider, H. Lei, Y. Chen, D. W. Nebert and T. P. Dalton. University of Cincinnati Medical Center, Cincinnati, OH.

Glutamate-cysteine ligase modifier subunit (GCLM) has the overall effect of increasing the efficiency of glutathione (GSH) synthesis, an important antioxidant. *Gclm*(-/-) knockout cells have an approximately 80% lower level of GSH, and thus a compromised oxidant stress response. Numerous studies have demonstrated cadmium (Cd) as being a toxic metal which causes oxidative stress. To examine the role of *Gclm* in Cd toxicity, we exposed mouse fetal fibroblasts (MFFs) derived from wild-type [*Gclm*(+/+)] or *Gclm* null [*Gclm*(-/-)] mice to ranging doses (0-30  $\mu$ M) of cadmium chloride for 24 hours. *Gclm*(-/-) MFFs were nearly 15-fold more sensitive to Cd, EC50 of 1.2  $\mu$ M, compared with 17.5  $\mu$ M for *Gclm*(+/+) MFFs. Differential toxicity did not reflect a difference in  $^{109}$ Cd uptake between *Gclm*(+/+) and *Gclm*(-/-) cells. GSH binds Cd with high affinity ( $K_d = 10^{-10}$  M) and protection likely reflects Cd sequestration from sensitive cellular targets which may be decreased with GSH loss. Such cellular targets may include those that control transcriptional response of the Cd-binding and protective *Mt* gene products. Interestingly, accumulation of MT mRNA by Cd in *Gclm*(-/-) cells closely paralleled that of *Gclm*(+/+) cells. Thus, although *Gclm*(-/-) cells are sensitized to Cd toxicity, their protective response is similar to wild-type. In fact, at Cd concentrations in which *Gclm*(-/-) cells experience dramatic toxicity, induction of the *Mt* protective response is marginal. These data suggest that *Gclm*, and by extension GSH, is essential for protection against Cd toxicity and that "buffering" of Cd by GSH may be necessary for cells to mount a protective response. Supported in part by NIH grants R01 ES012463 and R01 ES010416-05.

CADMUM AND TERT-BUTYL HYDROPEROXIDE-INDUCED DIFFERENT PATTERNS OF CHANGES IN ENERGY AND REDOX STATES IN HEPG2 CELLS - THEIR CORRELATION WITH THE MODE OF CELL DEATH.

L. C. Yu<sup>1</sup>, K. F. Tse<sup>1</sup>, S. W. Pat<sup>1</sup>, N. K. Mak<sup>1</sup>, R. C. Gupta<sup>2</sup> and M. S. Yang<sup>1</sup>. <sup>1</sup>Biology, Hong Kong Baptist University, Hong Kong, China and <sup>2</sup>Toxicology, Murray State University Breathitt Veterinary Center, Hopkinsville, KY.

Cadmium (Cd) and tert-butyl hydroperoxide (t-BHP) are both toxic chemicals. These toxicants were used as models for studying cellular response to chemical stresses. The parameters examined included lipid peroxidation, energy state, redox state, mitochondrial membrane potential change and morphological appearance of apoptotic bodies in the cell nucleus. t-BHP caused lipid peroxidation in HepG2 cells in a dose-dependent manner. Compared to t-BHP, Cd caused a much lower dose-dependent increase in lipid peroxidation. At a higher concentration, Cd caused a dose-dependent decrease in GSH/GSSG while t-BHP caused only a small change in redox state. The two toxicants exerted different patterns of change in energy state. While both Cd and t-BHP caused a gradual decrease in the levels of total adenosine nucleotides (TAN=ATP+ADP+AMP), the relative amount of ATP/TAN increased and ADP/TAN and AMP/TAN decreased. The change resulted in a continuous increase in energy charge potential (ECP=[ATP+0.5ADP]/TAN). On the other hand, increasing concentrations of t-BHP initially caused a significant increase in ECP. As the dose increased, there was a decrease in ATP/TAN and increase in ADP/TAN and AMP/TAN. These changes resulted in a decrease in ECP. Under the specified culture conditions, increasing concentrations of t-BHP but not Cd caused a change in mitochondrial membrane potential, but apoptotic bodies appeared only in cells treated with Cd and not with t-BHP. The present study demonstrated that toxicants of different classes could cause different patterns of metabolic changes. These changes may reflect the modes of cell death.

IDENTIFICATION OF DOSE- AND TIME-DEPENDENT CHANGES IN CELLULAR METABOLIC EVENTS IN HEPG2 CELLS UPON EXPOSURE TO CADMIUM.

M. S. Yang<sup>1</sup>, L. C. Yu<sup>1</sup>, S. W. Pat<sup>1</sup>, K. M. Li<sup>1</sup>, N. K. Mak<sup>1</sup> and R. C. Gupta<sup>2</sup>. <sup>1</sup>Biology, Hong Kong Baptist University, Hong Kong, China and <sup>2</sup>Toxicology, Murray State University Breathitt Veterinary Center, Hopkinsville, KY.

Cadmium (Cd) is a toxic metal. The mechanisms of its action have been attributed to its ability to alter cellular energy metabolism, damage DNA, generate free radicals and oxidize proteins. Along the process leading to cell death, a number of events occur, including protective gene induction and attempt to repair. Failure of these processes ultimately resulted in cell death via apoptosis. Cd induces cellular apoptosis through either the caspase-dependent or -independent pathway. Apoptosis could also be a result of free radical generation or changes in energy metabolism. The present study aims to investigate the action of Cd on cellular metabolism of the HepG2 hepatoma cell line by examining the time-and dose-dependent changes in cellular energy state and redox state. The results demonstrated the 3-hr

LC50 for Cd was approximately 0.7 mM. There was a dose-dependent decrease in total adenosine nucleotides, which was correlated to a dose-dependent increase in percentage of cells with apoptotic nucleus. Upon analyzing the different adenosine nucleotides content, relative amount of ATP increased as the concentrations of Cd increased. On the other hand, there was a dose-dependent decrease in GSH/GSSG suggesting the occurrence of oxidative stress. Over a 3 hr exposure to 0.7 mM Cd, there was an initial fluctuation in GSH/GSSG ratio at 0.5 to 1.5 hr, which corresponded to a time-dependent change in intracellular free radical generation as detected by fluorescent staining with 2', 7'-DCF. Cellular energy state varied at different times. In addition to a gradual increase in relative ATP and energy charge potential over the 3 hr study period, there was a significant increase in relative ADP level after 1.5 hr, which was reverted to normal at 4 hr. It was suggested that this change may be related to cellular repair. The present study demonstrated the use of appropriate markers to identify the sequence of events occurred in cells following Cd exposure.

### CADMIUM DISRUPTS N-CADHERIN-DEPENDENT CELL-CELL JUNCTIONS AND ACTIVATES $\beta$ -CATENIN MEDIATED NUCLEAR SIGNALING IN ROS 17/2.8 CELLS.

W. C. Prozialeck<sup>1</sup>, N. Chandar<sup>2</sup>, K. Kolman<sup>2</sup>, P. C. Lamar<sup>1</sup> and M. J. Fay<sup>1</sup>.

<sup>1</sup>Pharmacology, Midwestern University, Downers Grove, IL and <sup>2</sup>Biochemistry, Midwestern University, Downers Grove, IL.

The N-cadherin/ $\beta$ -catenin complex serves as an important structural component of adherens junctions in various types of epithelial cells. In addition,  $\beta$ -catenin can function as a nuclear signaling molecule and regulate the expression of genes that are involved in cell-cycle control and apoptosis. The recent finding that the environment pollutant Cd can disrupt cadherin-dependent junctions in various types of epithelial cells has led us to examine the effects of Cd on N-cadherin-dependent cell-cell junctions and  $\beta$ -catenin regulated gene expression in ROS 17/2.8 cells. Results of immunofluorescent labeling studies showed that exposure to 5-10  $\mu$ M Cd for 0.5-3 hours caused the cells to separate from each other without detaching from the growing surface. This effect coincided with the loss of N-cadherin and  $\beta$ -catenin from the cell-cell contacts and the translocation of  $\beta$ -catenin to the cell nucleus. Additional studies utilizing the TOPFLASH  $\beta$ -catenin reporter gene construct showed that Cd caused a 2-3 fold increase in the expression of the  $\beta$ -catenin regulated luciferase reporter gene. These results provide additional evidence that the N-cadherin/ $\beta$ -catenin complex may be an important early target of Cd toxicity and they suggest that Cd can activate endogenous  $\beta$ -catenin nuclear signaling via TCF/LEF1 transcription factors. Supported by NIH Grant # R01 ES006478.

## 1603

### UPREGULATION OF $\gamma$ -GLUTAMYL CYSTEINE SYNTHETASE EXPRESSION IN CADMIUM-TREATED RAT FETAL LUNG FIBROBLASTS.

X. Luo<sup>1</sup>, D. Chou<sup>2,1</sup>, L. Chen<sup>2</sup>, Y. Zhao<sup>2</sup>, W. Li<sup>2</sup> and I. Chou<sup>1</sup>. <sup>1</sup>Microbiology, Boston University School of Medicine, Boston, MA and <sup>2</sup>Biochemistry, Boston University School of Medicine, Boston, MA.

Cadmium (Cd), a toxic metal of environmental and occupational health concerns, damages the microtubule cytoskeleton initiated by binding to critical tubulin sulphydryls and causes a biphasic response in total cellular glutathione (GSH). Since GSH is critical in protecting protein sulphydryls and providing cellular defense against Cd insult, we have explored mechanisms of Cd-mediated GSH elevation in rat fetal lung fibroblasts (RFL6) focusing on  $\gamma$ -glutamylcysteine synthetase ( $\gamma$ -GCS), the rate limiting enzyme in GSH biosynthesis. As measured by the Tietze assay, 4  $\mu$ M CdCl<sub>2</sub> treatment for 16 h increased total cellular GSH to 241% of the control (100% = 611 $\pm$ 73 ng GSH/mg total cell protein). These cells also showed a typical biphasic GSH response as evidenced by a decrease to 57% at 2 h followed by a steady recovery and overshooting reaching 134% and 249% (100% = 484 $\pm$ 56 ng GSH/mg total cell protein) at 4 h and 16 h, respectively, post incubation with Cd. Western blots showed enhanced  $\gamma$ -GCS protein expression (156% of control) in RFL6 cells treated with 4  $\mu$ M CdCl<sub>2</sub> for 16 h. Furthermore, as measured by the reverse transcription-polymerase chain reaction (RT-PCR) assays, the steady-state  $\gamma$ -GCS mRNA level was elevated to 280% of the control level under the same conditions. Notably, previous work has suggested that the Cd-elevated cellular GSH probably resulted from an increased synthesis based on studies using buthionine sulfoximine (BSO), which inhibits GSH biosynthesis. Since the rate-limiting  $\gamma$ -GCS is under feedback inhibition by GSH itself, the initial GSH reduction due to Cd binding would lessen its inhibition on  $\gamma$ -GCS thus enabling an upregulation of  $\gamma$ -GCS mRNA and protein expression resulting in enhancement of new GSH biosynthesis to replenish the initially reduced cellular GSH pools. These studies provide direct evidence for Cd stimulation of new GSH biosynthesis in RFL6 cells. ## 1604

### MECHANISMS OF CADMIUM TRANSPORT IN MDCK CELLS.

R. K. Zalups and S. Ahmad. Basic Sciences, School of Medicine, Mercer University, Macon, GA.

In humans exposed to cadmium (Cd) via oral and/or pulmonary routes, the kidney is by far the primary organ affected adversely by Cd. Although there are data indicating that proximal and distal portions of the nephron handle Cd, the mechanisms involved in this transport are poorly understood. Thus, the principal aim of the present study was to investigate mechanisms of Cd transport in cultured epithelial cells derived from proximal (NRK-52E cells) and distal (Madin-Darby Canine Kidney; MDCK) portions of the nephron. The rates of luminal uptake of Cd in NRK-52E cells (28.4 $\pm$ 4.2 pmol x mg protein<sup>-1</sup> x min<sup>-1</sup>) were significantly greater (2.7 fold) than those the MDCK cells (10.4 $\pm$ 0.12 pmol x mg protein<sup>-1</sup> x min<sup>-1</sup>). The calcium (Ca<sup>2+</sup>) channel blockers, verapamil or diltiazem, significantly inhibited the uptake of Cd only in the MDCK cells, but not in NRK-52E cells. This indicates that Cd transport in the distal nephron is mediated in part through the actions of Ca<sup>2+</sup> channels. Another important difference noted between these two cell lines is that under normal extracellular Ca<sup>2+</sup> concentrations, in the presence of ferrous iron (Fe<sup>2+</sup>), the uptake of Cd was significantly inhibited only in MDCK cells. These findings indicate that the Fe<sup>2+</sup> transporter, Divalent Metal Transporter 1 (DMT1), also transports Cd. Moreover, additive effects were documented in the MDCK cells when both Ca<sup>2+</sup> channel antagonists and Fe<sup>2+</sup> were present in the extracellular compartment. Overall our results indicate that at least two different transporters (Ca<sup>2+</sup> channels and DMT1) participate in the luminal uptake of Cd in distal portions of the nephron.

## 1605

### CADMIUM NEPHROTOXICITY IS ASSOCIATED WITH A LOSS OF N-CADHERIN MEDIATED ADHESION AND ALTERATIONS IN EPITHELIAL POLARITY IN THE PROXIMAL TUBULE.

W. C. Prozialeck and P. C. Lamar. Pharmacology, Midwestern University, Downers Grove, IL.

Recent studies from our laboratory have shown that the nephrotoxic metal Cd can selectively disrupt N-cadherin dependent cell-cell junctions in the proximal tubule of rat kidney. The objective of the present study was to determine whether or not the Cd-induced loss of N-cadherin-mediated adhesion resulted in any changes in the polarity of the epithelial cells of the proximal tubule. Male Sprague-Dawley rats received subcutaneous injections of Cd (0.6 mg/kg in isotonic saline, 5 days per week for up to 6 weeks). One day each week, 24-h urine samples were collected and analyzed for protein and creatinine. After 5-6 weeks, the Cd-treated animals developed significant proteinuria, with no change in creatinine excretion. Epithelial polarity was evaluated by examining the histochemical localization of the apical, brush border marker enzyme, alkaline phosphatase, and the basolateral marker protein, Na<sup>+</sup>, K<sup>+</sup>-ATPase. Results of immunofluorescent labeling studies revealed that the kidneys from the Cd treated animals exhibited a marked reduction in N-cadherin labeling in proximal tubule, along with pronounced changes in the localization of alkaline phosphatase and Na<sup>+</sup>, K<sup>+</sup>-ATPase. In the samples from control animals, the alkaline phosphatase labeling was localized at the apical cell surface, and the Na<sup>+</sup>, K<sup>+</sup>-ATPase labeling was concentrated at the basolateral cell surface. In the samples from the Cd<sup>2+</sup> treated animals, both molecules appeared to be diffusely distributed over the entire surface of the proximal tubule epithelial cells. These findings indicate that the Cd-induced loss of N-cadherin mediated adhesion results in alterations in renal epithelial polarity and the redistribution of cell surface proteins in the proximal tubule. Supported by NIH Grant R01 ES006478.

## 1606

### NECROSIS AND NOT APOPTOSIS IS THE PREDOMINANT MODE OF CELL DEATH IN MORTAL HUMAN PROXIMAL TUBULE CELLS EXPOSED TO CADMIUM CHLORIDE.

S. Somji<sup>1</sup>, S. H. Garrett<sup>1</sup>, M. Sens<sup>1</sup> and D. A. Sens<sup>2</sup>. <sup>1</sup>Pathology, University of North Dakota, Grand Forks, ND and <sup>2</sup>Surgery, University of North Dakota, Grand Forks, ND.

The third isoform of metallothionein, MT-3 was discovered recently and was thought to be expressed only in the brain. However, we have previously shown that MT-3 is expressed in the human kidney in situ, including the cells of the proximal tubule. A subsequent analysis of MT-3 expression demonstrated that cell cultures of mortal human proximal tubule cells also expressed MT-3. However, an immortalized human proximal tubule cell line, HK-2 did not express the MT-3 gene. Transfection of the MT-3 gene into the HK-2 cells resulted in an increase sensitivity of these cells to the cytotoxic effects of cadmium and this was correlated to an alteration in the mechanism of cell death, being changed from apoptosis in the HK-2 cells to necrosis in the MT-3 transfected cells. The goal of this study was to determine if the human proximal tubule cell (HPT) cultures that normally express the MT-3 gene had a mode of cell death similar to the HK-2 MT-3 transfected cells in response to cadmium. For this purpose, the HPT cells, HK-2 cell line and the

MT-3 transfected HK-2 cells were exposed to lethal and sub-lethal concentrations of cadmium chloride for various time periods. Apoptosis was measured by the release of cytochrome c from the mitochondria to the cytosol, activation of caspase 3 and 9, and DNA laddering. The release of lactate dehydrogenase from the treated cells was also measured. There was no activation of caspase 3 and 9 in the HPT and HK-2 MT-3 transfected cells in response to cadmium unlike the HK-2 cells which showed activation of caspases and DNA laddering in response to cadmium treatment. Furthermore, the release of LDH was highly elevated for the HPT and MT-3 transfected cells compared to the HK-2 cells. These results indicate that human proximal tubule cells do not undergo apoptosis in response to cadmium, rather necrosis seems to be the predominant mode of cell death.

**1607 CADMIUM-INDUCED CELL CYCLE ARREST IN RAT KIDNEY EPITHELIAL CELLS IS MEDIATED THROUGH P53 ACTIVATION.**

J. Xie and Z. A. Shaikh. *Department of Biomedical and Pharmaceutical Science, University of Rhode Island, Kingston, RI.*

Cadmium (Cd) induces apoptosis in different cell types, including the kidney cells. This study was designed to investigate the Cd-induced p53-mediated cell cycle arrest, which may lead to apoptotic cell death. Subconfluent cultures of a normal rat kidney proximal tubular epithelial cell line, NRK-52E, were treated for up to 24 h with 5-20  $\mu$ M CdCl<sub>2</sub> in DMEM containing 5% calf serum. By electrophoresis mobility shift assay, wild-type p53 was found to be up-regulated upon Cd exposure. Flowcytometric analysis of the cells revealed a significant time- and concentration-dependent increase in cells in G2/M phase of the cell cycle. Exposure to 20  $\mu$ M Cd for 24 h doubled the number of cells in the G2/M phase. The cell cycle arrest was closely related to the repression of cyclins A and B that control the progression of cells in different phases of the cell cycle. Additionally, Cd treatment led to down-modulation of cyclin-dependent kinases, cdk2 and Cdc2. Cells treated with Cd also showed elevated expression of cyclin-specific inhibitor p21 (WAF1/Cip1), a p53-controlled downstream gene product. These observations suggest that Cd-mediated cell cycle dysregulation is mediated via modulation of cyclin inhibitor, cyclin and cdk machinery, and that this process is p53-dependent. (Supported in part by NIH grant P20 RR016457)

**1608 CADMIUM-INDUCED CARCINOGENIC TRANSFORMATION OF HUMAN PANCREATIC DUCTAL CELLS.**

W. Qu<sup>1</sup>, B. Diwan<sup>2</sup>, D. Broderick<sup>1</sup>, M. Tsao<sup>3</sup> and M. Waalkes<sup>1</sup>. <sup>1</sup>*Laboratory of Comparative Carcinogenesis, NCI at NIEHS, Research Triangle Park, NC*, <sup>2</sup>*BRP, SAIC-Frederick, NCI at Frederick, Frederick, MD* and <sup>3</sup>*Ontario Cancer Institute, Toronto, ON, Canada.*

Human pancreatic cancer is a deadly disease with a poorly defined etiology. Cadmium is thought to be a plausible human pancreatic carcinogen. Thus, this study was designed to determine whether a nontumorigenic human pancreatic ductal epithelial cell line (H6c7) could be transformed *in vitro* by chronic low-level cadmium exposure. H6c7 cells were cultured in 0.5 or 1.0  $\mu$ M cadmium (as CdCl<sub>2</sub>) and compared to passage-matched control cells. At 11 weeks of continuous cadmium exposure the cells underwent a distinct morphological change from a round, epithelial-like form with consistent size to a fibroblastoid shape with heterogeneous sizes. After 21 week, these chronic cadmium exposed human pancreatic ductal epithelial (CCE-HPDE) cells showed atypical foci of cell mounding, indicative of a loss of contact inhibition, and had a marked increase in matrix metalloproteinase-9 secretion, which is common in cancer cells. CCE-HPDE cells were hyperproliferative with a growth rate about 2.5-fold higher than passage-matched control cells. Moreover, CCE-HPDE cells were able to grow much better in media containing suboptimal growth supplement (pituitary extract plus EGF) than control cells, indicating less dependence on exogenous growth factors for continued proliferation, a characteristic common in tumors. Marked over-expression of the oncogenes c-myc and c-jun and the positive cell-cycle regulatory gene cyclin D1 occurred in CCE-HPDE cells, as evidenced by up to 5-fold increases in both transcript and protein levels compared to control. Genomic DNA methylation, determined by methyl acceptance assay, was significantly reduced in CCE-HPDE cells. Taken together, these results indicate cadmium may well be able to induce carcinogenic transformation in human pancreatic ductal epithelial cells. CCE-HPDE cells are now being tested for tumor-forming ability after inoculation into nude mice.

**1609 CADMIUM MAY AFFECT THE LIGAND INDUCED MIGRATORY ABILITY OF IMMORTALIZED EXTRAVILLOUS TROPHOBLAST CELLS.**

M. M. Alvarez and C. Chakraborty. *Pathology, University of Western Ontario, London, ON, Canada.* Sponsor: M. Cherian.

A group of proliferative and migratory/invasive cytotrophoblast cells known as "extravillous trophoblast" (EVT) is the most important cell type in human placenta for maintaining attachment with the uterus and establishing easy uteroplacental blood

flow. Exposure of these cells to exogenous, toxic elements may disturb the function of the placenta, resulting in deleterious effects to the fetus. One element filling this description is cadmium (Cd<sup>2+</sup>), the concentration of which can be high in placenta of mothers who are exposed to tobacco smoke and those who work in welding and battery manufacturing. A large proportion of absorbed Cd<sup>2+</sup> cannot cross the placental barrier and as a result accumulates in the placenta. This metal may cause toxic effects to the cells or alter their normal function, possibly altering the migratory/invasive capabilities of these cells. Calcium (Ca<sup>2+</sup>) is an important element in cell motility. Impaired mobility/invasion may be the result of interference in Ca<sup>2+</sup> kinetics in these cells. As a first step in identifying the actions of Cd<sup>2+</sup> on EVT cell function we used immortalized, pure, first-trimester human EVT cells to study the effects of Cd<sup>2+</sup> on migration induced by insulin-like growth factor II (IGF-II), endothelin-1 (ET-1), prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), urokinase plasminogen activator amino terminal fragment (uPA ATF), and epidermal growth factor (EGF). Using transwell migration assays it was found that 0.5 to 1.0  $\mu$ mol/L of CdCl<sub>2</sub> abrogates EVT cell migration induced by IGF-II, PGE<sub>2</sub> and uPA ATF. Fluorometric studies show that intracellular calcium induction by different ligands may be impaired by small amounts of Cd<sup>2+</sup>.

**1610 CHRONIC EXPOSURE TO CADMIUM INDUCES ANEMIA WITH HIGH IRON STORAGE THROUGH DEFECTIVE IRON UTILIZATION AND ENHANCED IRON ABSORPTION IN RATS.**

H. Horiguchi, E. Oguma, H. Uno and F. Kayama. *Jichi Medical School, Tochigi, Japan.* Sponsor: T. Yoshida.

Chronic exposure to cadmium (Cd), one of the toxic heavy metals, can induce anemia, which has been considered to be derived from the setting of iron deficiency, hemolysis, and insufficient production of erythropoietin (EPO) from the kidney. In order to know detailed mechanism of the Cd-induced anemia, we investigated the relationship between anemia and iron metabolism in the rats exposed to Cd with or without iron deficiency. We injected rats with saline or Cd at 2.0 mg/kg s.c. twice a week for 3 months, with normal diet or low-iron diet (the iron contents are 60 ppm and 10-20 ppm, respectively), resulting in four groups of rats: saline with normal diet, saline with low-iron diet, Cd with normal diet, and Cd with low-iron diet. The group of saline with low-iron diet developed typical iron deficiency anemia, evidenced by the increased TIBC and EPO levels as well as the low levels of plasma iron and ferritin. On the other hand, the group of Cd with normal diet showed a different kind of anemia: a decreased plasma iron level along with highly elevated TIBC and ferritin (3 and 6 times higher than the group saline with normal diet, respectively) and a suppressed level in EPO. This result indicates that Cd would induce anemia by interfering with iron utilization for erythropoiesis while it enhances iron absorption, leading to a large amount of iron accumulation in a body. Furthermore, the group of Cd with low-iron diet showed the same degrees of anemia and EPO as those of the group of Cd with normal diet, although the magnitudes of elevation in TIBC and ferritin were lower than the group of Cd with normal diet. This result indicates that defective iron utilization, not iron deficiency, would contribute to the development of Cd-induced anemia significantly. In conclusion, chronic exposure to Cd induces anemia with high iron storage, which would be derived from defective iron utilization as well as enhanced iron absorption, not from iron deficiency.

**1611 BEHAVIORAL ALTERATIONS OF C57BL AND METALLOTHIONEIN KNOCK-OUT MICE PERINATALLY EXPOSED TO LOW LEVEL OF CADMIUM.**

C. Watanabe<sup>1</sup>, A. Watanabe<sup>1</sup>, M. Satoh<sup>2</sup>, K. Yoshida<sup>3</sup>, K. Mori<sup>3</sup>, H. Ishitobi<sup>1</sup> and A. Honda<sup>2</sup>. <sup>1</sup>*Human Ecology, University of Tokyo, Tokyo, Japan*, <sup>2</sup>*Hygienics, Gifu Pharmaceutical University, Gifu, Japan* and <sup>3</sup>*Endocrinology, Tohoku University School of Medicine, Sendai, Japan.*

While the renal toxicity is the cardinal feature of chronic cadmium (Cd) toxicity, little information is available regarding the developmental toxicity of Cd, especially at low exposure level. Since prenatal exposure to low level of Cd has been shown to accelerate sexual maturation presumably through endocrine mechanism, such exposure to Cd might result in developmental abnormality. To test this possibility, we have exposed wild-type C57BL and its metallothionein-I, II-null (MT-null) mice to 10 microg/mL Cd through drinking water from the beginning of gestation to 10 days after parturition. Behaviors of the offspring born to these mice were examined at the age of 8 to 9 weeks. Regardless the mice strain, the Cd-exposed females, compared to the non-exposed females, (i) were significantly less active in the open-field test [to examine the emotionality/activity] and (ii) exhibited shorter step-through latency (time to enter the dark compartment) in the 'pre-learning' session of the passive avoidance test [to assess the learning ability]. Neither of these effects was observed in males. In a separate experiment, Cd-exposed MT-null females showed

poorer performance than the non-exposed counterpart in Morris water maze, a test for spatial learning capacity, under the circumstance in which the difficulty of the task was increased. At postnatal day 10, right after the end of exposure, although the brain levels of Cd was as low as 0.1 ng/g, plasma thyroxine level was significantly decreased in Cd-exposed offspring, an effect being more distinct in the MT-null groups. These results suggested that perinatal, low-level exposure to Cd could lead to subtle alterations in the behaviors of matured mice. The mechanism for these effects, including the reason for the susceptibility of females and the possible contribution of the altered thyroid hormone level is warranted to be examined.

## 1612

### MODULATION OF ACUTE HEPATOTOXICITY OF CADMIUM BY SIMULTANEOUS ADMINISTRATION OF COBALT IN MICE.

S. Himeno. *Fac. of Pharmaceutical Sciences, Tokushima Bunri University, Tokushima, Japan.* Sponsor: M. Sato.

Acute toxicity of cadmium is characterized by hepatic lesion and testicular hemorrhage. Although the effects of metallothionein on cadmium toxicity have been well investigated, other mechanisms modifying cadmium toxicity have not been fully elucidated. To explore metallothionein-irrelevant modification of cadmium toxicity, we examined the effects of simultaneous administration of cobalt, which can hardly induce metallothionein, on acute toxicity of cadmium. Male ICR mice were injected with cadmium chloride and cobalt chloride simultaneously, and blood and liver samples were collected at 0, 0.5, 1, 3, 6, 12, 18, 24, 36 and 48 hrs after the treatment. The increase in GPT activity 24 hr after cadmium treatment was lowered by cobalt treatment dose-dependently. At the same time, cadmium-induced increase in concentrations of serum amyloid A (SAA), an acute phase protein, was decreased by cobalt dose-dependently. Cobalt did not induce metallothionein nor reduced tissue cadmium concentrations. Since SAA is regulated by interleukin-6 (IL-6), plasma concentrations of inflammatory cytokines were examined by ELISA. Cadmium treatment caused increases in plasma IL-6, the peak being both at 3 and 24 hr, accompanying a gradual increase in SAA. Although simultaneous cobalt treatment almost completely blocked the cadmium-induced increase in SAA, administration of cobalt alone or in combination with cadmium increased plasma IL-6 concentrations at 3 hr. Quantitative RT-PCR showed increases in mRNA levels of IL-6 in the liver of mice treated with cadmium and/or cobalt. Thus, cobalt is an inducer of IL-6, but reducer of cadmium-induced SAA. These results suggest that cytokines and acute phase proteins may be involved in the modulation of cadmium toxicity by cobalt.

## 1613

### LIVER INJURY IN METALLOTHIONEIN-NULL MICE AFTER TREATMENT WITH THIOACETAMIDE.

S. Jiang and G. M. CHERIAN. *Pathology, University of Western Ont, London, ON, Canada.*

This study was undertaken to understand the role of metallothionein (MT) on liver injury after chemical injury. Thioacetamide (TAA) which causes liver damage by oxidative stress was used in Wild-type (WTM) and MT-null (MT-N) mice. Both types of mice were injected with i.p. with 3 doses (150, 200 & 300 mg/kg) of TAA, and the serum enzymes alkaline phosphatase (ALP) and glutamate/pyruvate transaminase (GPT) were measured. The enzyme levels were highest at 24 hrs in MT-N, and were similar in both types of mice at 48 hrs. Histopathology examination showed necrotic hepatocytes around the central vein with infiltration of macrophages at 150 mg/kg of TAA in MT-N mice, and 200 mg/kg in WTM. Alaysis of glutathione (GSH) levels showed decrease in hepatic levels for both groups of mice 12 to 24 hrs after injection of 150 mg/kg. The hepatic MT levels were increased in WTM after injection of TAA and was highest at 12 hrs. The highest number of apoptotic bodies (TUNEL) was found in MT-null mice at 24 hrs after TAA (150 mg/kg) injection. The apoptosis was much less in wild type mice as compared to MT-null mice. These results confirm that MT-null mice with no MT was more susceptible to hepatotoxic effects of TAA than wild type mice. (supported by grants from CIHR).

## 1614

### THE NORMAL HUMAN PROSTATE EPITHELIAL CELL LINE, RWPE-1, AS AN *IN VITRO* MODEL SYSTEM OF METALLOTHIONEIN REGULATION IN THE PROSTATE.

R. K. Singh<sup>1</sup>, S. Somji<sup>1</sup>, M. Sens<sup>1</sup>, D. A. Sens<sup>2</sup> and S. H. Garrett<sup>1</sup>. <sup>1</sup>*Pathology, University of North Dakota, Grand Forks, ND* and <sup>2</sup>*Surgery, University of North Dakota, Grand Forks, ND.*

The prostate gland contains the highest content of zinc of any tissue in the body and this organ is sensitive to the development of tumors by the heavy metal cadmium. The intracellular handling of both these metals is controlled mainly by the

metal sequestering protein, metallothionein. In the human, this protein is produced by at least 10 closely related genes. The normal human prostate epithelial cell line, RWPE-1, has recently been utilized as an excellent model to study cadmium carcinogenesis *in vitro*. The purpose of this study was to characterize the expression of metallothionein in response to zinc and cadmium exposure. RWPE-1 cells were exposed to cadmium (3, 6 and 12  $\mu$ M) and zinc (75 and 100  $\mu$ M) for periods from 1 to 13 days. Cells were harvested for RNA and metallothionein mRNA levels were assessed with real time PCR. Cultured cells were also harvested for protein and metallothionein-1 and -2 protein levels assessed by immunodot blot with the E9 antibody. Levels of metallothionein protein attained tremendously high levels, up to 10 to 30 percent of the total soluble protein by day 4 in cadmium exposed cells, and up to 10 to 30 percent by day 1 in zinc exposed cells. Metallothionein protein expression was supported by the induction of MT-2A, -1E-, 1X, and -1A mRNA. The extreme levels of metallothionein attained during these metal exposures may relate to the zinc accumulating ability of the prostate gland.

## 1615

### METALLOTHIONEIN SUSTAINS METALLOPROTEINASE2 GENE EXPRESSION IN IMMORTALIZED FIBROBLAST CELLS.

M. Takiguchi<sup>1,2</sup>, M. Higashimoto<sup>2</sup>, S. Suzuki<sup>2</sup>, S. Yoshihara<sup>1</sup> and M. Sato<sup>2</sup>.

<sup>1</sup>*Faculty of Pharmaceutical Sciences, Hiroshima International University, Kure, Hiroshima, Japan* and <sup>2</sup>*Faculty of Pharmaceutical Sciences, Tokushima Bunri University, Tokushima, Tokushima, Japan.*

The metallothionein (MT), a cysteine rich and metal binding protein, is induced by various stress conditions. Recent study shows that MT, a cytosolic protein in resting cells, can be translocated transiently to the cell nucleus during cell proliferation and differentiation. These results indicate that MT may be associated with nuclear functions. However little is known the role of MT in cell nucleus. In the present study, we examined the gene expression profiles in two embryonic fibroblast cells isolated from wild-type and MT null mice using oligonucleotide micro-arrays (Intelligene mouse CHIP Set I Version 1.0, TAKARA Co.), containing 564 functionally characterized mouse genes and 301 Expressed Sequence Tags (EST). Both of cells were immortalized by SV40 large T-antigen. Three genes including matrix metalloproteinase2 (MMP2) gene were lower expressed, but other 3 genes including cryac crystalline  $\alpha$ C gene were rather higher expressed in MT null cells than wild-type cells. Lower expression of MMP2 gene in MT null cells was further confirmed by RT-PCR (Reverse Transcription- Polynucleotide Chain Reaction). The wild-type cells secreted more a 68 kDa type IV collagenase encoded by MMP2 gene than the MT null cells. These results represent that a stimulation of MMP2 gene expression by MT results in a significant secretion of a 68 kDa type IV collagenase in the wild-type cells, namely MT might regulate MMP2 gene expression. (Supported by a Grant-in-aid for General Research from the Ministry of Education, Sciences, Sports and Culture of Japan.)

### POST-TRANSLATIONAL STABILIZATION OF METALLOTHIONEIN ISOFORM 3 IN THE NORMAL BLADDER CELL LINE, UROTS.

D. A. Sens<sup>1</sup>, S. Somji<sup>2</sup>, R. Singh<sup>2</sup>, M. Sens<sup>2</sup> and S. H. Garrett<sup>2</sup>. <sup>1</sup>*Surgery, University of North Dakota, Grand Forks, ND* and <sup>2</sup>*Pathology, University of North Dakota, Grand Forks, ND.*

Metallothionein isoform 3 (MT-3) is overexpressed in most human bladder cancers but is not expressed in normal bladder epithelium. Previous work has shown that most tumor cell lines can support the expression of MT-3, unlike nontumorigenic lines which cannot support its expression. The normal bladder cell line, UROtsa, stably transfected with MT-3 under control of the cytomegalovirus promoter makes ample mRNA for MT-3, but very little MT-3 protein. To test the hypothesis that the lack of MT-3 protein expression is due to MT-3 mediated cell toxicity during the antibiotic selection of transfected clones, the MT-3 gene was expressed under the regulatable vector system, LacSwitch. Inducing expression of the cloned MT-3 gene with isopropyl- $\beta$ -D-thiogalactoside (IPTG) gave only a modest induction of MT-3 protein and clones did not exhibit slower growth rates in the presence of this inducer; however, a basal expression of MT-3 mRNA was detected without the inducer indicating that the inhibition of clone formation by MT-3 early in the transfection can not be ruled out. To test the hypothesis that inhibitors of protein degradation could stabilize the MT-3 protein leading to accumulation similar to that found in cancer cells, MT-3 stably transfected UROtsa cells were exposed to inhibitors of the proteosome (MG-132 and lactacystin), lysosomal acidification (chloroquine), calpain family of proteases (PD150606, MDL28170, and calpeptin), cysteine proteases (leupeptin) and serine proteases [phenylmethylsulfonyl fluoride (PMSF)]. These agents were added to cultures for 8 and 24 hr, and the cells were harvested for protein. MT-3 protein levels were measured using immunodot blot utilizing an MT-3 specific antibody. MG-132 increased MT-3 at 24

hr and lactacystin did so only at 8hr. PD150606 and MDL28170 were able to induce only at very high concentrations. These data suggest that control of MT-3 levels either directly or indirectly involve the proteosome and possibly calpain proteases

ACTIVITY OF METAL-RESPONSIVE TRANSCRIPTION FACTOR 1 IS MODULATED BY METALLOTHIONEIN.

T. Kimura<sup>1</sup>, N. Itoh<sup>2</sup>, T. Sone<sup>1</sup>, M. Isobe<sup>1</sup> and K. Tanaka<sup>2</sup>. <sup>1</sup>Department of Toxicology, Faculty of Pharmaceutical Sciences, Setsunan University, Hirakata, Japan and <sup>2</sup>Department of Toxicology, Graduate school of Pharmaceutical Sciences, Osaka University, Suita, Japan.

Zinc is an essential micronutrient involved in structural and regulatory cellular functions. Cytosolic zinc-binding protein, metallothionein (MT) is normally saturated with zinc. Zn-MT has the potential to act as an intracellular zinc pool. Destruction of Zn-MT might have implications for the bioavailability of zinc and signal transduction. Metal-responsive transcription factor 1 (MTF-1) plays an important role in the zinc-mediated transcriptional induction. In this study, we examined whether destruction of MT activates MTF-1. Activity of MTF-1 was determined by electrophoretic mobility shift assay. It is known that inhibition of protein synthesis by cycloheximide induces activation of MTF-1 and the inhibition increases degradation of protein. Using interleukin-6-treated cells and MT-overexpressing cells, we found that MTF-1 activation by cycloheximide depended on MT protein level. Also, oxidative stresses such as H<sub>2</sub>O<sub>2</sub> and *tert*-butyl hydroperoxide were used for degradation of Zn-MT. MTF-1, synthesized *in vitro* using reticulocyte lysate system, was not activated in the presence of H<sub>2</sub>O<sub>2</sub> alone. Activation of MTF-1 by H<sub>2</sub>O<sub>2</sub> required the presence of Zn-MT. In primary hepatocytes, oxidative stress activated MTF-1-DNA binding activity. This activation was not observed in MT-null hepatocytes. These findings suggest that destruction of Zn-MT activates MTF-1, and that MT plays an important role in zinc-mediated signal transduction.

THE EFFECT OF METALLOTHIONEIN ISOFORM-3 MUTANTS ON THE DIFFERENTIATION OF BREAST CANCER MCF-7 CELLS.

M. Sens<sup>1</sup>, S. H. Garrett<sup>1</sup>, S. Somji<sup>1</sup> and D. A. Sens<sup>2</sup>. <sup>1</sup>Pathology, University of North Dakota, Grand Forks, ND and <sup>2</sup>Surgery, University of North Dakota, Grand Forks, ND.

The third isoform of metallothionein, MT-3, was isolated as a down-regulated metal binding protein in Alzheimer's disease brain. The MT-3 protein was shown to possess a neuronal growth inhibitory activity that was not shared by any other member of the MT family. Studies from this laboratory have expanded the role of MT-3 as a growth regulating protein to cells outside the neural system. This was accomplished by showing that stable transfection of MT-3 into the PC-3 prostate cancer cell line or the MCF-7 and Hs578T breast cancer cell lines resulted in a marked inhibition of cell growth. Furthermore, studies from this laboratory also suggested that MT-3 might have a role in cell differentiation. This was suggested by studies which demonstrated that the stable expression of MT-3 restored active vectorial ion transport to a proximal tubule cell line that had lost this differentiated function. Active vectorial ion transport was monitored by the formation of out-of-focus areas of the cell monolayer known as domes, a hallmark of cultured renal epithelial cells that retain the *in situ* property of vectorial active transport. In the present study, site directed mutants of MT-3 were generated in an attempt to determine which epitope of the MT-3 protein was responsible for the growth inhibition noted when MCF-7 cells were stably transfected with the MT-3 gene. The first set of MT-3 mutants assessed possessed alteration in the  $\beta$ -domain of the protein, specifically, proline 7 and 9 were mutated to threonines and a mutant with the  $\beta$ -domain totally deleted from the protein. However, instead of these mutants having an effect on MCF-7 cell growth, transfection of either  $\beta$ -domain mutation into MCF-7 cell resulted in dome formation by the cells, indicating a gain-of-function for the differentiated property of vectorial active ion transport. These results suggest that the  $\beta$ -domain of MT-3 might suppress the ability of the  $\alpha$ - domain to generate a signal for cellular differentiation

PRODUCTION OF METALLOTHIONEIN POLYCLONAL ANTIBODIES USING CHICKENS AS MODEL.

E. Brambila<sup>1</sup>, A. Ortiz/Bueno<sup>1</sup>, B. Leon-Chavez<sup>1</sup>, W. Achanzar<sup>2</sup> and M. P. Waalkes<sup>2</sup>. <sup>1</sup>Clinical Chemistry, Benemerita Universidad Autonoma de Puebla, Puebla, Puebla, Mexico and <sup>2</sup>NIH, Research Triangle Park, NC.

Frequently the production of polyclonal antibodies (pAbs) against metallothioneins (MT) has been done in mouse, rabbits and lambs. In this work we describe the production of liver rat MT-pAbs in chickens. Liver MT-1 and 2 isoforms isolated from

Wistar rats (200g) treated by 3 days with cadmium chloride were used as immunogens. MT-1 and 2 were purified by exclusion (Sephadex G-75) and ionic exchange (DEAE Sephadex A-25) chromatography. Leghorn White chickens (28 weeks) were immunized with 3 doses of each isoform (100  $\mu$ g) emulsified with complete Freund adjuvant by two weeks. MT-pAbs were isolated from yolk eggs and purified by ammonium sulphate and IgY affinity chromatography. MT-pAbs were characterized by PAGE-SDS electrophoresis, western-blot and ELISA assays. MT-Abs were detected 20 days after the first immunization. Western-blot analysis showed a cross-reaction between MT-1 and 2 isoforms, however the Abs obtained did not react with other non-MT proteins in hepatic homogenates. Sensitivity assays showed that MT-pAbs detected MT-1 and 2 at nanogram levels. Data obtained suggest that chickens can be a useful model to raise MT-pAbs and is a good alternative to obtain Abs against mammal high homology proteins such as MT.

INTERACTION OF PB AND DEET, ALONE AND IN COMBINATION WITH P-GLYCOPROTEIN EXPRESSED IN E. COLI LEAKY MUTANT.

E. M. El-Masry and M. B. Abou-Donia. *Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

P-glycoprotein (P-gp), the most extensively studied ATP-binding cassette transporter, functions as a biological barrier by extruding toxic substances and xenobiotics out of cells. This study was carried out to determine the effect of DEET and PB alone and in combination on P-gp expression using *E. coli* leaky mutant transfected with *Mdr1* gene (*pT5-7/mdr1*), which codes for P-gp or lactose permease (*pT5-7/lacY*) as negative control. An *in vitro* cell resistant assay was used as an initial method for monitoring the potential of test drugs to interact P-gp. Cells were exposed to DEET, PB, daunomycin (a known P-gp substrate; was used as positive control) and reserpine (a known P-gp inhibitor; was used as negative control), it is readily apparent that P-gp confers significant resistance against PB and daunomycin while, reserpine and DEET significantly inhibited P-gp. Cells were grown in the presence of non-cytotoxic concentrations of daunomycin, PB, reserpine or DEET and membrane fractions were examined by Western immunoblotting for expression of P-gp. Daunomycin induced expression of P-gp more than PB, while reserpine and DEET significantly inhibited P-gp expression in cells harboring *mdr1*. Competitive photoaffinity labeling experiment performed with P-gp ligand [<sup>125</sup>I]-iodoarylazidoprazosin demonstrated that drugs that induced or inhibited P-gp transport activity actually bound P-gp. DEET was also found to be a potent inhibitor of P-gp-mediated ATPase activity, whereas, pyridostigmine bromide slightly increased P-gp ATPase activity. Cells expressing P-gp or *lac* permease as negative control were exposed to PB and DEET, alone and in combination. It is interesting that non-cytotoxic concentration of DEET significantly inhibited P-gp-mediated resistance against PB. This resulted in a reduction of the number of effective drug interactions with biological targets.

HORMESIS EFFECT OF TRACE METALS ON CULTURED NORMAL AND IMMORTAL HUMAN MAMMARY CELLS.

C. N. Cheng, A. Marino, C. M. Schmidt, R. Konsoula and F. A. Barile. *Pharmaceutical Sciences, St. John's University College of Pharmacy, Jamaica, NY.*

An *in vitro* study was conducted to determine the effects of variable concentrations of trace metals on human cultured mammary cells. Monolayers of human mortal (MCF-12A) and immortal (MDA-MB231) mammary epithelial cells were incubated in the absence or presence of increasing concentrations of arsenic (As), mercury (Hg) and copper (Cu) for 24-h, 72-h, 4-d, and 7-d. The MTT assay was used to assess viability for all time periods and cell proliferation was monitored for 4-d and 7-d studies. Monolayers were also labeled with 3 fluorescent dyes, in 24-h studies, as indicators for intracellular esterase activity, nucleic acid staining, and metabolic reduction. In addition, test medium was removed from select groups of cultures on day 4, replaced with fresh medium in the absence of chemical, and assays were performed on day 7 as above (recovery studies). The data suggest that there is a consistent protective and/or stimulating effect of metals at the lowest concentrations in MCF-12A cells that is not observed in immortal MDA-MB231 cells. In fact, cell viability of MCF-12A cells is stimulated by otherwise equivalent inhibitory concentrations of As, Cu, and Hg on MDA-MB231 cells at 24-h. Whereas As and Hg suppress proliferation and viability in both cell lines after 4-d and 7-d of exposure, Cu enhances these indicators in MCF-12A cells. MDA-MB231, however, recover better after 4-days of toxic insult. In addition, switching of media between the cell lines, or pretreatment with penicillamine, did not alter the hormesis effect displayed by MCF-12A, although proliferation of these cells was not maintained in the alternative medium. The study demonstrates that a hormesis effect from trace metals is detectable in cultured mammary cells using cell proliferation or MTT; fluorescent indicators, however, were not as sensitive. In addition, sensitivity

of mammary cells to lower concentrations of Cu, a biologically important trace metal, may play an important role in controlling cellular processes and proliferation. (Supported by NIH/NIEHS/AREA R15 ES012170-01).

#### INTERACTIVE TOXICITY OF MERCURY AND POLYCHLORINATED BIPHENYL IN THE NEUROELECTROPHYSIOLOGY OF RAT EMBRYO.

G. Balagopal<sup>1</sup> and H. Chan<sup>2</sup>. <sup>1</sup>*Human Toxicology Section - Standards Development Branch, Ontario Ministry of Environment, Toronto, ON, Canada* and <sup>2</sup>*Center for Indigenous People's Nutrition and Environment, Macdonald Campus, McGill University, Montreal, QC, Canada.*

Interactive neurotoxic effects of methylmercury (MeHg) and polychlorinated biphenyls (PCB) have been difficult to monitor due to multifarious neurobiochemical responses and mechanistic differences in mode of action. This study monitored neuroexcitotoxicity of MeHg and PCB 128 during ontogenesis in rat embryo. Non-specific neuroexcitotoxicity as electrochemical (EC) potential was monitored in cultured whole rat embryo exposed to MeHg and PCB. EC potentials were generated using the micro-needle platinum electrode inserted in the diencephalon region of embryonic brain at gestation day (GD) of 19.5. The shift in amplitude of the EC potential due to exposure to MeHg and PCB at different binary combinations in saline base was observed. Total voltages developed during the binary mixture exposure concentrations were (1) MeHg (10nM) + PCB (90nM) = 60.5 (SD 6.2), (2) MeHg (50nM) + PCB (50nM) = 108.7 (SD 8.7), and (3) MeHg (90nM) + PCB (10nM) = 111.5 (SD 12.4) on GD 19.5 day. These mixtures generated higher voltage potentials than the corresponding concentrations exposed to individual chemicals at similar exposure conditions. The increase in the EC potential due to binary combinations of PCB and MeHg are predominant synergistic responses of neuronal network stress and also attributed to specific uptake and ionization of these compounds. This methodology can be used as a quantitative risk assessment tool for studies on neurotoxic chemical mixtures and the quantification of the ion regulation expressed in mV also provides an insight for the mechanisms of neuro-response to the mixture of PCB and MeHg.

1623

#### COMPARATIVE EVALUATION OF SURFACTANTS ON IN VITRO RABBIT AND HUMAN CORNEAS.

H. F. Edelhauser<sup>1</sup>, B. Boykin<sup>1</sup>, G. Holley<sup>1</sup> and M. E. Blazka<sup>2</sup>. <sup>1</sup>*Emory Eye Center, Emory University, Atlanta, GA* and <sup>2</sup>*Colgate-Palmolive Co., Piscataway, NJ.*

**Purpose:** To develop an *in vitro* technique for comparison of corneal toxicity of surfactants in isolated rabbit and human corneas. **Methods:** Rabbit eyes were obtained from Pel-Freeze and human corneas, stored in Optisol GST<sup>TM</sup>, were obtained from the Georgia Eye Bank. Corneas were isolated and mounted for endothelial perfusion in an *in vitro* specular microscope. Surfactants (cetyl alcohol, CA; sodium lauryl sulfate, SLS; benzalkonium chloride, BAC; sodium sulfolaurate mixture, SSL) were applied to corneas with and without an intact epithelium. These 4 surfactants represent a range of Draize ocular irritation. The corneal endothelium was continuously perfused with a balanced salt solution. The effects of 3% SLS, 39% SSL and 1% BAC on the rabbit corneal tissue were evaluated after 3-, 9- and 20-min exposures and on the human corneal tissue after 3-min. At the end of the exposures, SLS, SSL and BAC were removed and the corneas perfused for 3 hr before being fixed for histological evaluation by light and electron microscopy. The effect of CA was similarly evaluated immediately after a 4-hr exposure in both species. **Results:** In the rabbit cornea, SSL, SLS and BAC showed time dependent corneal swelling and structural changes with associated damage to the endothelial layer. With both SSL and SLS, the 3-min exposure to the intact cornea caused epithelial damage and minimal stromal and endothelial changes. By comparison, when the epithelium was removed, SSL and SLS caused marked stromal and endothelial changes. After 9- and 20-min exposures (with and without epithelium), SSL and SLS caused marked changes in all layers of the cornea. At all time points, BAC caused extensive epithelial, stromal and endothelial damage. In both species, CA showed minimal corneal swelling and marked epithelial changes with no change to the endothelium. Human corneas exposed to the other 3 surfactants for 3-min showed the same corneal alterations as observed in the rabbit corneas. **Conclusion:** In both species, the rank order of corneal damage paralleled the Draize ranking: CA(SLS=SSL)(BAC).

1624

#### ESTABLISHMENT OF AN IN VITRO BRAIN BARRIER EPITHELIAL TRANSPORT SYSTEM FOR TOXICOLOGICAL STUDIES.

L. Shi and W. Zheng. *School of Health Sciences, Purdue University, West Lafayette, IN.*

The blood-cerebrospinal fluid barrier (BCB), which possesses tight junctions (TJ) between adjacent epithelia, is located in the choroid plexus in brain ventricles. An immortalized Z310 murine choroidal epithelial cell line was created in this labora-

tory (Zheng & Zhao, *Brain Res.*, 2002). The purposes of this study were (1) to identify representative TJ proteins in Z310 cells and (2) by using this cell line to develop an *in vitro* BCB transport model. Both RT-PCR and Western blot confirmed the presence of occludin, claudin-1 and ZO1, but not claudin-2 in Z310 cells. When Z310 cells were cultured on a two-chamber Transwell device, the permeability of [<sup>14</sup>C]sucrose across the cell monolayer, which allows for quantification of paracellular diffusion, was  $(5.98 \pm 0.27) \times 10^{-4}$  cm/min and TEER (transepithelial electrical resistance), which is an instantaneous measurement of ionic conductivity, was  $61.3 \pm 4.5$  ohm-cm<sup>2</sup>. Four approaches were used to improve the tightness of Z310 barrier: (1) Culturing the cells in astrocyte-conditioned medium increased TEER by  $33.0 \pm 2.7\%$  of controls (Z310 cells without treatment); (2) introduction of dexamethasone (1  $\mu$ M), which increases recruitment of TJ proteins, to the culture medium increased TEER by  $50.4 \pm 7.6\%$ ; (3) the presence of eicosapentaenoic acids (EPA) (10  $\mu$ M), an inducer of TJ proteins, increased TEER by  $38.4 \pm 2.3\%$ ; and (4) addition of EGF (100 ng/ml) to improve the cell differentiation increased TEER by  $40.3 \pm 8.9\%$ . Among tested chemicals, only dexamethasone significantly reduced [<sup>14</sup>C]sucrose paracellular permeability about 200-300% of controls. These data suggest that culture of Z310 cells on Transwell device in the presence of dexamethasone significantly increases tightness of Z310 cell monolayer (TEER and space marker permeability), which is highly comparable to primary culture of choroid plexus epithelial cells. This *in vitro* model appears to be suitable for transepithelial transport study of drugs and toxicants. Validation by using model drugs is in progress. (Support by Johnson & Johnson Focused Giving Program)

1625

#### A GERM-LINE STEM CELL LINE AS A MODEL FOR EVALUATING THE CYTOTOXICITY OF NANOPARTICLES *IN VITRO*.

L. Braydich-Stolle<sup>1</sup>, S. Hussain<sup>2</sup>, J. Schlager<sup>3</sup> and M. Hofmann<sup>1</sup>. <sup>1</sup>*Department of Biology, University of Dayton, Dayton, OH*, <sup>2</sup>*ManTech Environmental Technology, Inc., Dayton, OH* and <sup>3</sup>*Air Force Research Laboratory, Wright-Patterson AFB, Dayton, OH.*

The purpose of this study was to assess the suitability of a spermatogonial stem cell line as a sensitive model for toxicity studies in the male germ line, in particular for the cytotoxicity of nanoparticles. Gametogenesis is a complex biological process that is particularly sensitive to environmental and exogenous chemical insults. Because germ line stem cells self-renew and require specific conditions for their growth, many chemicals have a negative impact on their normal function. Ultimately, these effects can inhibit fertility, may have negative consequences on the development of the offspring, or can generate carcinoma. Recently, new nanomaterials such as diverse nanoparticles, fabric with nanotubes, nanowire for efficient energy transfer, lubricants with fullerene derivatives, and targeted quantum dots have received enormous attention to create new types of engineering tools including those for direct use in life systems. Nanomaterials, which are by definition of 1-100 nanometer in length, are being actively pursued to create materials with even more novel physical/chemical properties. However, there is a serious lack of information concerning their impact on human health and the environment. In the present study, the effects of different types (CdO, Ag, Mb and Al) and different concentrations of nanoparticles on spermatogonial stem cells were evaluated using light microscopy, cell proliferation and standard cytotoxicity assays. Our results demonstrate a concentration-dependent toxicity for all types of particles tested. As expected, CdO nanoparticles were highly toxic (EC50=0.5  $\mu$ g/ml), and were used as a positive control for system validation. Of the novel nanoparticles studied, Ag particles were the most toxic (EC50=7.5  $\mu$ g/ml) while Mb nanoparticles were the least toxic (EC50=75  $\mu$ g/ml). Further, our data suggests that spermatogonial stem cells provide a much more sensitive model than somatic cells to assess the cytotoxicity of nanoparticles *in vitro*.

1626

#### VALIDATION OF AN IN VITRO CELL LINE FOR SCREENING MYELOTOXICITY.

T. Huggett<sup>1</sup>, A. Saad<sup>2</sup>, T. Kelly<sup>1</sup>, F. Pognan<sup>3</sup>, M. Otieno<sup>1</sup> and D. Brott<sup>1</sup>. <sup>1</sup>*AstraZeneca Pharmaceuticals, Wilmington, DE*, <sup>2</sup>*AstraZeneca Pharmaceuticals, Södertälje, Sweden* and <sup>3</sup>*AstraZeneca Pharmaceuticals, Alderley Park, United Kingdom.*

Screening for potential bone marrow toxicants early in drug discovery may be useful in reducing compound attrition. Currently, *in vitro* colony-forming unit (CFU) assays, which are low throughput, are used to evaluate hematotoxicity prior to *in vivo* toxicology studies. The purpose of the present work was to develop a 96-well assay using murine M1 and FDCP1 myeloid cell lines as potential surrogates for the mouse CFU-GM assay; such an assay would significantly improve throughput. Relative cell number was determined by a luminescent-based assay that measures intracellular ATP. The assay was linear at seeding densities of 400 to 40,000 cells/well with a density of 4,000 cells/well chosen to ensure linearity of the signal after 4 population doublings or 96h. To validate the cell line assay, known myelotoxicants were used as positive controls and hepatotoxicants were used as negative

controls. Cells were treated with compound (0.3 $\mu$ M to 300 $\mu$ M) for 72h and ATP measured. Some of the compounds were also analyzed for hematotoxicity with the CFU-GM assay and comparisons were made with data reported in the literature where possible. The myelotoxicant carboplatin was potent in CFU-GM (IC50; 5.54 $\mu$ M), M1 (IC50; 4.5 $\mu$ M), and FDCP-1 (IC50; 30 $\mu$ M) assays, but less potent in erythroid cells (IC50; 113 $\mu$ M). M1 cells were generally found to be more sensitive than FDCP-1 cells and were used for subsequent experiments. Chloramphenicol, an erythrotoxicant, was not toxic in the M1 assay (IC50; >300 $\mu$ M), but was toxic to erythroid cells (IC50; 8 $\mu$ M), further indicating selectivity of the M1 assay. The hepatotoxins were not toxic to M1 cells. There was a good correlation ( $r^2=0.91$ ) between M1 and CFU-GM assays for 6 tested compounds. 13 other compounds screened through the M1 assay were compared with literature mouse CFU-GM data and there was a similar rank order of toxicity for the 2 assays, again showing a good correlation. In conclusion, the M1 cell line assay is a potential surrogate for the CFU-GM assay in predicting myelotoxicity.

## 1627 CORRELATION OF *IN VITRO* CYTOTOXICITY WITH PARACELLULAR PERMEABILITY IN CACO-2 CELLS.

R. Konsoula and F. A. Barile. *Pharmaceutical Sciences, St. John's University College of Pharmacy, Jamaica, NY.*

This *in vitro* study aims to develop a cell culture model that compares paracellular permeability (PP) with acute cytotoxicity (AT). Caco-2 cells were seeded in 96-well plates and on polycarbonate filter inserts. Confluent monolayers were exposed to increasing concentrations of 20 reference chemicals for 24-h and 72-h. Cytotoxicity was determined using MTT and NRU cell viability assays in 96-well plates. Transepithelial electrical resistance (TEER) for PP was measured in culture inserts. Inhibitory concentrations 50% (IC50s) suggest that there were good correlations between 24-h and 72-h exposures. NRU IC50 values correlated better with TEER, which is consistent with the Registry of Cytotoxicity (RC; ICCVAM) database report. Both cell viability assays were more sensitive than TEER measurements. In fact, 24-h and 72-h NRU assays, and 72-h TEER measurements displayed the highest correlations with established rodent LD50s. In addition, [<sup>3</sup>H]- and [<sup>14</sup>C]-mannitol, lucifer yellow (low mw indicators), and FITC-dextran (higher mw indicator) were used to fully understand the influence of chemical agents on PP. In our experiments, passive paracellular transport of the tight junction markers parallels the IC50s determined with the viability assays and TEER measurements. Our AT/PP model thus allows for the differentiation between the concentrations necessary for AT and those needed to interfere with PP. Development of an *in vitro* test system for PP, in combination with acute toxicity, strengthens the reliability of the intestinal cell assay. Thus, we propose that the AT/PP model be used to compute a formula that can "normalize" and improve the predictive ability of *in vitro* acute cytotoxicity assays for *in vivo* lethality. (Supported by NIH/NIEHS/AREA R15 ES012170-01).

## 1628 PROTOCOL OPTIMIZATION FOR THE EVALUATION OF *IN VITRO* CYTOTOXICITY ASSAYS FOR ESTIMATING RODENT AND HUMAN ACUTE SYSTEMIC TOXICITY.

M. Paris<sup>1,2</sup>, J. Strickland<sup>1,2</sup>, W. Stokes<sup>1</sup>, S. Casati<sup>3</sup>, R. Tice<sup>1,2</sup>, H. Raabe<sup>4</sup>, C. Cao<sup>5</sup>, R. Clothier<sup>6</sup>, J. Haseman<sup>7</sup>, P. Crockett<sup>8</sup>, M. Wenk<sup>9</sup>, M. Vallant<sup>7</sup>, G. Mun<sup>4</sup>, G. Moyer<sup>4</sup>, J. Madren-Whalley<sup>5</sup>, C. Krishna<sup>3</sup>, M. Owen<sup>6</sup> and N. Bourne<sup>6</sup>. <sup>1</sup>NICEATM, NIEHS, Research Triangle Park, NC, <sup>2</sup>ILS, Inc., Research Triangle Park, NC, <sup>3</sup>JRC, ECVAM, Ispra, Italy, <sup>4</sup>IIVS, Gaithersburg, MD, <sup>5</sup>ECBC, USArmy, Aberdeen Proving Ground, MD, <sup>6</sup>University of Nottingham, Nottingham, United Kingdom, <sup>7</sup>NIEHS, Research Triangle Park, NC, <sup>8</sup>Constella Group, Research Triangle Park, NC and <sup>9</sup>BioReliance, Rockville, MD.

NICEATM and ECVAM initiated a three-phase multi-laboratory validation study to evaluate the usefulness of two *in vitro* basal cytotoxicity assays for estimating human acute toxicity and starting doses for acute rodent lethality testing. Seventy-two coded chemicals exhibiting a wide range of toxicity were tested in mouse 3T3 fibroblasts and normal human keratinocytes (NHK) using neutral red uptake (NRU) to assess cytotoxicity. A phased approach optimized the protocols between phases to enhance intra- and inter-laboratory reproducibility. Phase Ia established historical databases for the positive control for each of the 3 labs. Protocols were modified to prevent NR crystal formation and improve cell growth. Following Phase Ib testing of 3 coded chemicals, NR concentration was further reduced in the 3T3 assay to prevent crystals. Phase II testing of 9 coded chemicals prompted adoption of plate sealers to improve testing of volatile chemicals and more rigorous solubility procedures to dissolve less soluble chemicals. For Phase III, a procedure to prequalify NHK medium to assure it promoted adequate cell growth was added. As the phased data were evaluated, test acceptance criteria were also revised. This study highlights the value of a phased approach that allows data evaluation and protocol optimization prior to each subsequent phase. The authors recommend more and

smaller phases at the beginning of such studies to quickly and efficiently optimize a standard test method protocol for use in the main study. Supported by: NIEHS contracts N01-ES-85424 and N01-ES-75408; EPA IAG DW-75-93893601-0; European Commission contract No. 19416-2002-04 F2ED ISP GB

## 1629 ETHANOL-INDUCED TOXICITY AND APOPTOSIS IN HEPG2 CELLS AND VA-13 CELLS: ROLE OF FATTY ACID ETHYL ESTERS.

H. Wu<sup>1</sup>, K. Bhopale<sup>1</sup>, G. A. Ansari<sup>1</sup> and B. S. Kaphalia<sup>1</sup>. <sup>1</sup>Pathology, University of Texas Medical Branch, Galveston, TX, <sup>2</sup>Pathology, University of Texas Medical Branch, Galveston, TX, <sup>3</sup>Pathology, University of Texas Medical Branch, Galveston, TX and <sup>4</sup>Pathology, University of Texas Medical Branch, Galveston, TX.

Oxidative metabolism of ethanol is primarily catalyzed by hepatic alcohol dehydrogenase (ADH) and cytochrome P450 2E1 (cyp 2E1). Earlier, we reported significantly higher synthesis of fatty acid ethyl esters (FAEEs, nonoxidative metabolites of ethanol) in hepatocellular carcinoma (HepG2) cells (ADH deficient) as well as HepG2 cells transfected with human cyp 2E1 (E47 cells) than that in HepG2 cells transfected with murine ADH I (VA-13 cells). Therefore, we determined apoptosis in HepG2 and VA-13 cells by ELISA and DNA ladder formation after ethanol exposure (100-800 mg %). Individual FAEEs were analyzed at 6 hr (optimal time for FAEE formation) and toxicity was evaluated by MTT assay and lactate dehydrogenase (LDH) leakage. Although no significant change in viability of the cells was observed at all the concentrations of ethanol, apoptosis was significantly higher in HepG2 cells than VA-13 cells exposed to 800 mg % ethanol. Surprisingly, LDH release was diminished with increasing concentration of ethanol in HepG2 cells as compared to none in VA-13 cells. Formation of FAEEs was found to be dose-dependent, and 16:0, 18:0 and 18:1 FAEEs were major FAEEs synthesized in HepG2 cells (5.3, 8.2 and 34.1 nmol/25 million cells, respectively) as compared to only trace amounts in VA-13 cells. The levels of FAEEs in HepG2 and VA-13 cells and extent of apoptosis and diminished LDH release indicate role of FAEEs in ethanol-induced toxicity and apoptosis. Therefore, lack of ADH in HepG2 cells favors nonoxidative metabolism of ethanol to FAEEs and be responsible for the ethanol-induced toxicity and apoptosis in HepG2 cells.

## 1630 OPTIMIZATION OF AN *IN VITRO* LONG TERM CORNEAL CULTURE ASSAY.

H. A. Raabe<sup>1</sup>, L. Bruner<sup>2</sup>, T. Snyder<sup>1</sup>, N. Wilt<sup>1</sup> and J. W. Harbell<sup>1</sup>. <sup>1</sup>Institute for In Vitro Sciences, Gaithersburg, MD and <sup>2</sup>The Gillette Co., Boston, MA.

The long-term culture of corneas has been proposed as an *in vitro* model to evaluate potential eye irritation and post-treatment recovery following chemical exposures. Techniques used were modifications of those of Foreman, DM (1996), Xu, KP (2004) and Boulton, M (2003). Porcine eyes were obtained from Sioux-Preme within 24 hours of sacrifice. The eyes were disinfected by immersion in 1% povidone iodine followed by 0.1% Gentamicin in PBS. Excised corneas were filled with an agar/gelatin gel in M199 medium to support the corneas, and were cultured at 37°C, 5% CO<sub>2</sub>, 90% RH in M199 medium to the limbus, leaving the epithelium exposed to air. The corneas were moistened by brief immersion in medium every 2.7 h using a modified plate rocker. To induce damage, corneas were treated with either 1 or 3% SLS, or H<sub>2</sub>O (controls) for exposures of 2, 5 or 10 min. The corneas were rinsed with PBS, cultured for 6, 24 or 48 h, and then fixed in buffered formalin to determine their responses to damage and potential recovery. H&E-stained preparations of control corneas showed normal morphology throughout the 3-day assay, and were comparable to excised/immediately fixed corneas. Controls were characterized by an intact epithelium with viable squamous, wing, and basal cells. The stroma showed frequent viable keratocytes, and minimal swelling indicative of a functional endothelium. The endothelium was typically intact. Corneas treated with 1% SLS for 2 min showed no pathological changes, while exposure to 3% SLS for 2 min induced just slight hyper-eosinophilia in the squamous epithelium. However, corneas treated with 3% SLS for 5 or 10 min showed complete epithelial cell damage or loss 24 h after treatment, as well as loss of viable keratocytes in the upper stroma. By 48 h after treatment, evidence of epithelial cell sheet migration along the basal membrane into the damaged zone was observed. These results confirm the ability to culture porcine corneas for at least 72 hours, and demonstrate the potential for further optimization for the evaluation of recovery after induction of chemical damage.

## 1631 AN EXPANDED REFERENCE DATA-BASE OF *IN VITRO* OCULAR IRRITATION SCORES FOR MARKETED COSMETIC AND PERSONAL CARE PRODUCTS USING A TISSUE EQUIVALENT MODEL.

R. R. Binetti, M. D. Hines, R. Hamid, S. D. Gettings and B. C. Jones. *Avon Products Inc., Suffern, NY.*

A significant advantage of the MatTek EpiOcular OCL-200 tissue model is that it can be used to discriminate between the eye irritation potential of extremely mild products (e.g., most cosmetic and personal care products). We have previously re-

ported how we have used the MatTek model (comprised of human epidermal keratinocytes which form a stratified squamous epithelium similar to corneal tissue) to establish ranges of *in vitro* ocular irritation scores for several categories of cosmetic and personal care products (McCain et al., 2002). These data provided us with a reference database of *in vitro* ocular irritation scores for a cross-section of their currently marketed cosmetic and personal care products. Comparison of the ET50 for prototype formulations with the appropriate range of ET50 scores for marketed products of similar type has proved a useful benchmark of the anticipated consumer acceptability of new products in development. We now report data resulting from our efforts to expand and refine our database as a result of testing over 80 additional marketed products. As reported previously, materials were tested using either the standard (4 hours) or extended (>20 hours) exposure protocol based on their expected irritation potential (i.e., consideration of formula composition, product type, etc.). Cellular viability was used as a marker for irritation potential and measured at various time points by a MTT metabolism colorimetric assay. MTT was quantitated spectrophotometrically at 570nm and an ET50 (time to 50% loss of viability) calculated for each product and a range of *in vitro* ocular ET50 scores was then determined for each product category. Our results provide additional confidence in the data previously determined and establish ranges of *in vitro* ocular irritation scores for several new categories (e.g., eye makeup removers) and sub-categories of products (e.g., adult shampoos, baby shampoos, dandruff shampoos) which can be used as benchmarks for the evaluation of similar, prototype formulations.

### 1632

#### EFFECT OF THE PROTEASOME INHIBITOR PS-341 ON NEURONAL CELLS *IN VITRO*.

V. Csizmadia, A. Raczyński, J. Rottman, K. Ganley, P. Bouchard and V. Sasseville. *Drug Safety and Disposition, Millennium Pharmaceuticals, Inc., Cambridge, MA*. Sponsor: A. Carl.

Peripheral neuropathy is a common adverse effect of many chemotherapeutic drugs. The proteasome inhibitor PS-341 for treatment of multiple myeloma, has induced peripheral neuropathy in a subset of patients. The mechanism of PS-341-induced peripheral neuropathy is unknown. The objective of this study was to investigate the effect of PS-341 on neuronal cells *in vitro*. Unlike myeloma cells, GT-1 murine neuronal cells that were exposed to high concentrations of PS-341 for 16 hours showed increased cell death via a non-apoptotic mechanism as assessed by TUNEL and DNA fragmentation assays. Immunofluorescence, Western, and Immunostaining analysis showed non-ubiquitinated actin microfilament and microtubule organization and relocation to the perinuclear region in PS-341 treated cells. At the same time, other proteins became ubiquitinated or upregulated including ubiquitin and other stress proteins. In the PS-341 treated cells there was also perinuclear-centrosomal accumulation of  $\gamma$ -tubulin, c-myc, and vimentin, which are known to be regulated by proteasomal degradation. There was also an accumulation of RelA, GRP78,  $\gamma$ 1-adaptin, and LAMP proteins in the perinuclear region. Biochemical analysis indicates that PS-341 induced accumulation of protein aggregates in GT-1 cells are detergent - and mechanical - disruption resistant. Similar results were observed in GT-1 cells treated with Lactacystin. In conclusion, PS-341 causes cytoskeletal reorganization and intracytosolic accumulation of diverse ubiquitinated and non-ubiquitinated proteins in the perinuclear region and potentially overloads the endoplasmic reticulum-dependent quality control mechanism. These processes acting alone or in combination are hypothesized to affect axonal transport or other aspects of cellular homeostasis and thus result in neuropathy.

### 1633

#### DEVELOPMENT OF *IN VITRO* CARDIOTOXICITY ASSAY USING RAT CARDIOMYOCYTES CULTURED ON COLLAGEN GEL.

T. Inoue, A. Shioda and K. Kobayashi. *Pre-Clinical Research Department 2, Chugai Pharmaceutical Co., Ltd., Kamakura, Japan*. Sponsor: R. Nagata.

In early stages of drug discovery, highthroughput *in vitro* culture systems are very important for the evaluation of toxicity. However, the functions of the cells rapidly diminish in conventional monolayer cultures. To establish an *in vitro* cardiotoxicity evaluation system that maintains cardiomyocyte (CMC) functions, collagen gel cultures of rat CMCs were investigated. SD rats (0-day- to 5-week-old) were anesthetized; the ventricle was isolated, minced, and digested by collagenase and trypsin. The prepared CMCs were suspended in culture medium and cultured on non-treated plates (monolayer) or plates with type I collagen gel (CG) or CG + Matrigel (MG). The cultured cells were morphologically observed and immunohistochemically stained with anti-connexin 43 (specific to gap junctions in the heart) to characterize each culture condition. Doxorubicin was added to the cultures and the lactate dehydrogenase in the cells and the supernatant were measured to compare the susceptibility to known cardiotoxic compounds. In the monolayer, fibroblast-like cells gradually proliferated and, within 1 week, became the major population in the culture. In the culture on CG, the proliferation of fibroblasts was less

severe and higher numbers of the cells were beating than in the monolayer. By the addition of MG in the CG, cell-cell contacts were augmented and the number of beating cells increased. The staining patterns of connexin 43 in the cultured CMCs on CG+MG (1-week culture) were similar to the intact heart, but there was very little positive staining in the monolayer. This suggests that the monolayer is not suitable for long term culture of CMCs. The cells were more susceptible to doxorubicin in CG and CG+MG than in monolayer. These results show that rat CMC cultures on the CG (+MG) would be effective to maintain cellular functions of CMCs. This culture condition would be suitable for the evaluation of cardiotoxicity as it more resembles *in vivo* conditions than the monolayer.

### 1634

#### EVALUATION OF CIGARETTE SMOKE CYTOTOXICITY UNDER *IN VITRO* CONDITIONS.

H. E. Hartman, F. Sheabar, G. Holloway, J. Ye and S. Millett. *Toxicology Arista Laboratories, Inc., Richmond, VA*.

*In vitro* assays could be used to examine toxicity of cigarette ingredients, design, and prototypes. Several accepted smoking regimens (i.e., ISO and Canadian Intense (CINT) are used to prepare extracts that could be used to determine their biological effects. The first goal of this study was to compare the cytotoxicity of frozen cigarette smoke condensate (CSC) as determined by the neutral red uptake (NRU) assay in 3 different types of mammalian cell lines (HepG2 and BALB/c 3T3 and CHO) under *in vitro* conditions. The second goal was to compare the cytotoxicity of fresh CSC (also referred to as particulate phase or PP), gas vapor phase (GVP), and whole smoke (WS) fractions, prepared under ISO and CINT smoking regimens, in HepG2 cells. Samples were generated on a smoking machine. The PP was collected on a filter pad and extracted in DMSO. GVP was smoke fraction that was trapped in phosphate buffered saline after passing through a filter pad. WS was collected by trapping cigarette smoke in PBS and DMSO. Smoke samples were used to expose cells 1h following extraction. NRU assay was performed after 24 and 48 h incubation for HepG2 and 3T3 cells, respectively. NIH has established a standard operating protocol for the NRU using BALB/c 3T3 cells, however, it did not exclude the use of other cell lines. CSC was more cytotoxic in HepG2 cells than in 3T3 and CHO cells. Comparing cigarette smoke fractions obtained under ISO and CINT conditions showed that smoking under the later conditions has resulted in a more cytotoxic extract than ISO. PP was more toxic than GVP or WS under both regimens. No significant differences between the GVP and WS under the ISO regimen were seen. Under CINT regimen WS was only moderately more cytotoxic than the GVP. Much of this may be attributable to the collection method. Chemical analysis of the gas vapor phase indicated that the majority of the volatile compounds were not captured in the PBS solution. New trapping solutions will be developed in order to enhance capture of volatile and semi-volatile compounds without adversely affecting cell growth.

### 1635

#### *IN VITRO* MODEL FOR VASCULAR DEVELOPMENT IN MOUSE EMBRYONIC STEM CELLS.

G. RHEE<sup>1</sup>, G. Kim<sup>1</sup>, J. Seok<sup>1</sup>, S. Kim<sup>1</sup>, S. Kwack<sup>1</sup>, R. Lee<sup>1</sup>, S. Lee<sup>1</sup>, H. Chung<sup>2</sup> and D. Cho<sup>1</sup>. <sup>1</sup>*Department of Toxicology, National Institute of Toxicological Research, Seoul, South Korea* and <sup>2</sup>*Cell and Gene Therapy Research Institute, Pochon CHA University, Seoul, South Korea*.

Embryonic stem (ES) cells serve as a most popular model system to study early mammalian development. The objective of this study is to drive more simple and efficient vascular development without genetically modified ES cells and to examine the specific gene expression pattern during the differentiation, finally to finding biomarker can be applied for toxicological evaluation. To induce vascular development, embryoid body was formed for 3 days by hanging drop culture and replated on gelatin-coated plate in EGM-2 medium containing VEGF, ascorbic acid, bFGF, IGF, and EGF. When placed in matrigel, these mouse ES cell-derived endothelial cells formed networks similar to vascular structures and observed the expression of Flk1, PECAM1 and VE-cadherin by immunocytochemical analysis within 4-11 days. The gene expression of Flk1, PECAM1 and VE-cadherin were confirmed by RT-PCR analysis. At different time points during the differentiation process, cell surface differentiation antigen such as Flk1 and PECAM1 expression were analyzed by flow cytometric analysis. When sorted Flk1+ cells were replated in 10 % FBS medium containing VEGF(50ng/ml), Flk1+ cells formed vessel-like structure in three-dimensional culture. These preliminary data suggest that Flk+ cells are suitable candidate for studying specific marker genes during vascular development.

#### HISTOPATHOLOGICAL BACKGROUND FINDINGS IN THE COMMON MARMOSET (CALLITHRIX JACCHUS).

S. Friderichs-Gromoll, J. Kaspareit and E. Buse. *Covance Laboratories GmbH, 48163 Muenster, Germany*. Sponsor: G. Weinbauer.

The marmoset model is being used increasingly in toxicological studies with biotech compounds as a second non-rodent species. Compared to other non-rodent species the benefits of this primate model are its small size, and easy and less

hazardous handling. Whereas much information is available for cynomolgus monkey and rhesus monkey, little is known about the incidence and occurrence of spontaneous histopathological lesions in marmosets used in toxicological research. In total, 110 marmosets from 10 different toxicological studies performed during 1995 - 2000, were examined. All animals were control animals. A complete necropsy was performed on all animals and organs were examined histopathologically. Spontaneous histopathological lesions in marmosets that were not seen in cynomolgus monkeys or rhesus monkeys included: Extramedullary haematopoiesis in brain, lung, adrenals, liver, spleen, kidney; C-cell hyperplasia in thyroid; ectopic parathyroid gland in thymus; myocardial fibrosis in heart; osseous metaplasia in lung; microgranuloma in liver; Ito-cell vacuolation in the liver; cholecystitis in the gallbladder; Brunner's gland dilatation in duodenum; chronic enteritis in large intestine and luteal hyperplasia in ovary. The interpretation of the histopathological results of toxicological studies requires a precise knowledge of the background pathology of the laboratory animal species used. It is important for the study pathologist working with marmosets to know the background lesions described, to avoid misinterpretation as treatment-related changes. In conclusion, marmosets show a number of spontaneous histopathological background findings that appear restricted to this laboratory primate species.

**1637 HISTOPATHOLOGY DATABASE FOR CARCINOGENICITY STUDIES WITH SPRAGUE-DAWLEY RATS.**

A. Babb, V. Price, M. Milligan, K. Davis, R. D. Jones and J. Seng. *Toxicology, Charles River Laboratories - DDS - Arkansas Division, Redfield, AR.*

From recent carcinogenicity studies in Sprague-Dawley (SD) rats, Charles River Laboratories DDS - Arkansas Division has compiled the incidence of neoplasms in routinely examined tissues. The SD is an outbred strain that is meant to change over time. Therefore, more recent studies with adequate statistical power were selected to reveal such trends. Neoplastic data were exported from a validated pathology software (LABCAT 4.33) as alpha-numeric fields, imported into linked-query tables (Microsoft ACCESS 2003) then sorted using organ name as the primary key. The results were reported as tissue/organ, histopathologic classification, number of rats, total number of neoplasms and incidence. The tissue/organ incidence was calculated for each sex. In males (n = 330) the highest incidences of background histopathologic neoplasms were pituitary gland adenoma (61.8%), adrenal gland benign pheochromocytoma (13.0%), and pancreas islet cell adenoma (7.2%). In females (n = 260) the highest incidence of background histopathologic neoplasms were pituitary gland adenoma (90.4%), mammary gland fibroadenoma (40.4%), and mammary gland adenocarcinoma (29.2%). Laboratory-specific incidences of neoplasms from recent studies are important for distinguishing background lesions from test article-related findings in toxicology studies with outbred animals.

**1638 A COMPARISON OF PATHOLOGICAL CHANGE AND SURVIVAL IN DIFFERENT RODENT STRAINS OVER A TWO-YEAR STUDY DURATION.**

J. Noakes, R. W. Lewis and J. A. Wright. *Syngenta Central Toxicology Laboratory, Alderley Park, Macclesfield, United Kingdom. Sponsor: R. Dearman.*

We have undertaken a comparison of a number of rat and mouse strains commonly used in the assessment of oncogenicity and chronic toxicity. Specifically, two mouse strains (CD-1 and B6C3F1 from Charles River UK) and two rat strains (HsdBrHan<sup>TM</sup>:WIST and Hsd:Sprague-Dawley<sup>®</sup> SD<sup>®</sup> from Harlan UK) have been evaluated along side the most frequently used strains at these laboratories (C57BL10JAlpk mouse and the Alpk:APrSD Wistar Rat). The purpose of this work was to describe and understand the spontaneous biology of a variety of rodent strains in order to be able to use them in toxicology studies in our laboratory. The strains were assessed over a two-year study duration using routine toxicological parameters that included clinical observation, bodyweight, food consumption and ophthalmoscopy. For rats functional observation battery assessments and motor activity were also assessed. At a number of intervals, corresponding to routine regulatory study durations (28 and 91 days, 6 months, 80 and 104 weeks for mice, and 28 and 91 days, 52 and 104 weeks for rats), animals were killed and blood samples collected for clinical pathology evaluation. A full list of organs was weighed and a detailed examination post mortem was completed. Tissues were also examined by light microscopy. Overall there were no significant differences in clinical condition and husbandry requirements from those of the most frequently used strains at our laboratory. Although there were differences in the absolute bodyweights of each strain, overall the strains had good bodyweight development. The survival of both rat strains was as good or better than that of the Alpk:APrSD Wistar. The survival of the B6C3F1 mouse was better than that of the C57BL10JAlpk mouse, and although the survival of the CD-1 mouse was generally poorer, it was generally within the range of survival reported by Charles River. This data provides a unique description of the survival characteristics and comparison of pathological change seen over time in these rat and mouse strains.

**1639**

**IN-LIFE PARAMETERS AND TUMOUR DATA FROM CHARLES RIVER CRL:CD-1 ® (ICR) BR MOUSE DIETARY AND ORAL GAVAGE TUMORIGENICITY STUDIES TERMINATED AFTER TWO YEARS.**

W. Hooks<sup>1</sup>, C. J. Groom<sup>1</sup> and J. K. Stewart<sup>2</sup>. *<sup>1</sup>Toxicology, Huntingdon Life Sciences, Huntingdon, Cambridgeshire, United Kingdom and <sup>2</sup>Pathology, Huntingdon Life Sciences, Huntingdon, Cambridgeshire, United Kingdom. Sponsor: C. Hardy.*

The in-life and tumour data have been analysed from the control groups of up to 25 tumorigenicity studies to confirm the profile of the Charles River Crl:CD-1 ® (ICR) BR mouse and to compare any possible differences between dietary and oral gavage routes of administration. The mice were housed one or two per cage and the studies were completed over 1995 to 2001. Previous analyses showed mortality values at 2 years of  $52 \pm 10.4\%$  for males and  $56 \pm 8.1\%$  for females, with the values being similar for dietary and oral gavage studies (1). Analysis of bodyweight gain over the first year revealed lower values for oral gavage studies (both sexes) when compared with dietary studies. There was no similar difference in food consumption. Assessment of the tumour profile, from studies terminated at 2 years, has shown that the most prevalent tumours were hepatocellular adenoma/adenocarcinoma (higher in males, with a notably higher incidence of adenoma in dietary studies), bronchioalveolar adenoma/adenocarcinoma and Harderian gland adenoma (males and females), haemopoietic tumours (higher in females), and uterine polyps (females). With the exception of the latter, these tumours were also the major factors contributory to death (FCTD). Other major FCTD included urinary tract lesions (males) and ovarian haemorrhagic cysts (females), with a slightly higher incidence of these findings in oral gavage studies. Additionally, when dietary studies terminated at 18 or 24 months were compared, the longer duration studies showed a higher incidence of the major tumour types and in the total number of tumour types identified. In conclusion, although there were some differences in the in-life parameters, tumour profile and FCTD between the routes of administration, the profiles were largely similar and that continuing the studies to 2 years results in an acceptable, and perhaps a more developed, tumour profile. (1) Hooks, W.N. *The Toxicologist*, 72: 1863 (2003).

**1640**

**SPONTANEOUS LESIONS IN CRJ:CD-1(ICR)-NU/NU MICE BY 106 WEEKS OF AGE DURING THE OBSERVATION PERIOD.**

T. Nakamura<sup>1</sup>, T. Shibanushi<sup>1</sup>, T. Satoshi<sup>1</sup>, K. Kuzutani<sup>1</sup> and M. Takahashi<sup>2</sup>.

*<sup>1</sup>Safety Research Department, Kaken Pharmaceutical Co., Ltd, Sizuoka, Japan and <sup>2</sup>Pathology Peer Review Center, Tokyo, Japan.*

[Backgrounds] Spontaneous lesions of nude mice, especially those in the life-span period, have not been fully reported. We examined the incidences and types of spontaneously developed lesions of Crj:CD-1(ICR)-nu/nu nude mice in the lifetime periods. One hundred and sixteen male and 117 female nude mice of five weeks of age were purchased from Charles River Japan, Inc. and were kept in the air-conditioned barrier system room. All the animals were allowed free access for the food (radiation sterilized CRF-1 LID6, Oriental Yeast Co.) and sterilized water. Mice were monitored for body weight, survival period, clinical signs, and post-mortem pathology. [Results] Body weights increased for 31 weeks, and attained at plateau thereafter. Mean survival time was  $65.3 \pm 1.8$  weeks in the males and  $61.3 \pm 8.8$  weeks in the females and 94% of males and 99% of females died in 106 weeks of age. Moribund animals showed emaciation, abdominal distension and subcutaneous mass or nodule. Swelling of spleen, lymph node and liver and discoloration of kidneys were observed in the autopsy. In the histopathological observation, these lesions were diagnosed as malignant lymphoma or glomerular lesions. In the course of the observation period, incidences of malignant lymphoma attained to 71% in males and 80% in females. Moreover, hepatocellular adenoma and carcinoma in the liver, glandular dilatation in the seminal vesicle, glandular hyperplasia and polyp in the uterus, atrophy and follicular cyst in the ovaries also increased in number with age. [Conclusion] In the present study, predominant neoplastic lesion was found as malignant lymphoma in the higher frequency from Crj:CD-1 (ICR) mice (8% in the males and 22% in the females, in the literature), which strongly suggests the close relevance with T-cell deficiency in the nude mice.

**1641**

**THROMBOCYTOPENIC PURPURA IN GOTTINGEN MINIPIGS.**

C. Auletta, H. F. Bolte, S. J. Gosselin and C. Willard-Mack. *Huntingdon Life Sciences, East Millstone, NJ.*

Thrombocytopenic purpura syndrome has been reported to occur spontaneously in sexually mature Gottingen minipigs at a low incidence (0.1%, 11/11, 637) in a closed breeding colony. [Carasco et al, 2002]. Thrombocytopenic purpura, also referred to as hemorrhagic syndrome, is of unknown etiology and is also seen in the normal pig. The corresponding syndrome in humans is von Willebrands disease. In

our laboratory, this syndrome was noted in two Gottingen minipigs of 306 (0.65%) tested between 2000 and 2002, a high incidence relative to that reported in the literature. The minipig is a non-rodent laboratory animal used extensively in safety evaluation of dermally-administered materials and is increasingly being used as an alternative to dogs and non-human primates for evaluation of drugs administered by a variety of routes. The Gottingen minipig is popular for safety evaluation because of its small size, slow growth rate and non-pigmented skin. Therefore, as use of this animal increases, it is likely that an increasing number of cases of thrombocytopenic purpura will be observed. This poster describes observations for the two cases seen in Gottingen minipigs in our laboratory. The disease had a rapid onset and was characterized by disseminated hemorrhage associated with marked reductions in numbers of circulating thrombocytes (platelets). Both animals were 5 month-old females. Clinical signs included pallor, lethargy, coalescing petechiae on the abdomen, face, neck and limbs, palpable swelling under the jaw and blood beneath the cage. Both animals showed rapid deterioration and were euthanized shortly after the first appearance of signs. Clinical pathology evaluations revealed marked thrombocytopenia, anemia, hematuria, proteinuria and glycosuria. Microscopically, interstitial hemorrhages were present in most organs and most lymph nodes contained large amounts of free erythrocytes in the subcapsular and medullary sinuses. The bone marrow was hypercellular and had numerous degenerating megakaryocytes with granulocytic hypereosinophilic cytoplasm and pyknotic nuclei. Kidneys had minimal focal membranous glomerulonephritis.

## 1642

### CLINICAL PATHOLOGY DATABASE FOR NON-CLINICAL GLP STUDIES WITH LANDRACE -CROSS SWINE.

T. Gartner, P. Powell, V. Price, J. Seng, R. D. Jones and K. Davis. *Toxicology, Charles River Laboratories - DDS - Arkansas Division, Redfield, AR.*

The objective of this study was determine the clinical pathology reference ranges for control male and female Landrace-Cross swine used on non-clinical GLP studies conducted at Charles River Laboratories Discovery and Development Services - Arkansas Division. The Landrace-cross pig has been used as a biomedical research model for urolithiasis, myocardial disease and transplantation, bone and cartilage repair, phototoxicity, and many other conditions. The pig has been used on a limited basis as a non-rodent regulatory model in non-clinical drug toxicity studies. Clinical pathology data were exported from a validated pathology software (LAB-CAT 4.43) as alpha-numeric fields, imported into query tables then sorted by parameter name and individual reference ranges were calculated. Six studies were selected with animals of approximately 2 – 6 months of age (males 8 to 60 kg, females 9 to 55 kg). The hematology (n = 85), coagulation (n = 40) and clinical chemistry (n = 93) parameters were reported for each sex as a range of two standard deviations from the mean along with total number of pigs sampled. Laboratory specific background of clinical pathology reference values for the Landrace-cross pig, provides guidance for interpreting test article-related findings in toxicology studies and to determine the appropriateness of this species for regulatory risk.

## 1643 DEVELOPMENTAL TOXICOLOGY OF THE LUNG.

J. M. Rogers. *Developmental Biology Branch, USEPA, Research Triangle Park, NC.*

Respiratory problems account for a large proportion of hospital admissions to pediatric wards, and the incidence of childhood asthma is increasing for unknown reasons. A number of toxicants have been demonstrated to adversely affect lung development in humans and/or laboratory animals. Lung development begins early in gestation and continues well after birth. The molecular control of normal lung development has been intensely studied and is becoming well elucidated, involving multiple complex signaling networks. In contrast, mechanisms of toxicity to the developing lung are poorly understood. This symposium will present an overview of normal lung development and examples in humans and laboratory animal species of chemicals and conditions that adversely affect lung development. Effects of tobacco smoke and constituents have been well-studied and will be highlighted. Possible modes of action for developmental toxicity to the lung will be presented and research needs will be discussed.

## 1644 GENETIC PATHWAYS CONTROLLING LUNG MORPHOGENESIS.

J. A. Whitsett. *Pulmonary Biology, Cincinnati Children's Hospital, Cincinnati, OH.*  
Sponsor: J. Rogers.

The respiratory tract begins as an outpouching of foregut endoderm on day 9-10 of mouse development. Respiratory tubules undergo stereotypic branching to form the bronchi, bronchioles, and acinar regions of the lung. Sacculations, septation, and vascularization ultimately produce the alveolar gas exchange region typical of

the mammalian lung. Transgenic mice were developed in which lung epithelial cell specific gene addition or deletion is accomplished under conditional control of doxycycline, using the reverse tetracycline transactivator protein expressed by SP-C or CCSP promoters. Conditional expression of cre-recombinase was accomplished in transgenic mice using alkaline phosphatase or green fluorescent protein (GFP) as reporters. Highly efficient recombination of lung progenitor cells was observed prior to lung bud formation on PC6.5-8.5, resulting in the lung-specific gene targeting of virtually all peripheral lung cells. Distinct subsets of proximal and distal lung progenitor cells were identified by the Cre-dependent labeling experiments, demonstrating that the establishment of proximal-distal subsets of cells had occurred remarkably early in foregut endoderm development, commitment being established even before lung bud formation. Gene addition and deletion experiments were then utilized to clarify the role of epithelial mesenchymal interactions involved in lung morphogenesis. FGF signaling was required at precise times during development for lung morphogenesis, supporting the concept that FGF signaling is required for commitment of subsets of stem cells but is not required for ongoing proliferation of epithelial cells in the postnatal lung. The roles of signaling molecules and transcription factors involved in lung morphogenesis, including beta-catenin, Shh, TTF-1, Stat-3 and Foxa2 were studied after Cre-dependent gene targeting. We hope that the ability to precisely control gene expression in the lung will provide insights into the pathogenesis of acute and chronic lung diseases in neonates and adults.

## 1645 EFFECTS OF ENVIRONMENTAL TOBACCO SMOKE (ETS) ON THE DEVELOPING LUNG.

K. E. Pinkerton, J. L. Peake and J. P. Joad. *Center for Health and the Environment, University of California, Davis, CA.*

Infants raised in homes of smokers have more cough and wheeze. These symptoms may arise as a result of abnormal neural and epithelial development of the airways. One study examined whether perinatal exposure to ETS alters the innervation and epithelial composition of the trachea. Rhesus monkeys were exposed to filtered air (FA) or ETS (1 mg/m<sup>3</sup> total suspended particulates, 6 hr/day, 5 days/week) from day 50 of gestation to 75 days postnatal age (n=4 each group). All mothers gave birth to infants within the normal gestational period (165+/-10 days). The trachea of each infant was examined for epithelial composition and mucin content. Innervation of the trachea was determined using protein gene product 9.5 (PGP9.5), a general nerve marker, and substance P (SP), a marker for a subset of nerves including C-fibers. Four areas of the trachea immediately above the carina were imaged and morphometric analysis performed. Epithelial volume/basal lamina surface area (um<sup>3</sup>/um<sup>2</sup>) was 31.6+/-3.4 for infants exposed to FA and 22.6+/-1.3 for infants exposed to ETS (p<0.05). The percentage of epithelial mucin was significantly increased following exposure to ETS (41.6+/-3.3%) compared to FA (23.0+/-3.4%). The volume percent of PGP9.5-immunoreactive (IR) nerve fibers within the tracheal epithelium was unchanged following ETS exposure. In contrast, ETS exposure significantly increased the volume percent of SP-IR fibers in the epithelium (4.0+/-0.1x 10<sup>-3</sup>) compared to FA (1.0+/-0.4x10<sup>-3</sup>). This study demonstrates that exposure of rhesus monkeys to ETS during the perinatal period significantly alters the epithelial composition, mucin content, and presence of SP-IR nerves in the neonatal trachea.

## 1646 EFFECT OF MATERNAL NICOTINE EXPOSURE DURING DIFFERENT PHASES OF LUNG DEVELOPMENT ON LUNG GROWTH IN THE OFFSPRING: PROTECTIVE EFFECT OF COPPER.

G. S. Maritz. *Medical Biosciences, University of the Western Cape, Bellville, Western Province, South Africa.* Sponsor: J. Rogers.

Development of the lung is "programmed" to go through distinct phases of growth. Maternal smoking increases the incidence of respiratory disease in the offspring and some of the adverse effects are associated with nicotine, probably due to interference with "programming" of lung growth. A study was conducted to determine the effect of maternal nicotine exposure during different phases of lung development on the integrity of the lungs of the offspring, and to develop strategies to prevent the adverse effects of nicotine. Pregnant Wistar rats were given nicotine subcutaneously (1mg/kg/day) during (a) all the phases of lung development, that is from day 4 of gestation and throughout lactation ( gestation was 22 days and weaning 21 days), and, (b) from postnatal day 3, one day before the onset of the alveolar phase of lung development. This means that the latter group received nicotine only via the mother's milk. After weaning on postnatal day 21 the offspring received no nicotine. Lungs from 14, 21, and 42 day old neonates were evaluated from at least 9 rats from at least 3 litters of each age group. Maternal nicotine exposure during all the phases of lung development, as well as from the onset of alveolarisation had no effect on lung parenchyma up to postnatal day 21. On postnatal day 42, that is 3

weeks after weaning, the lungs of all the nicotine exposed animals showed signs of premature aging. Changes included a decrease in alveolar number and internal surface area, and an increase in alveolar volume. Microscopic emphysema also occurred. On postnatal day 42 no significant differences occurred between the groups exposed to nicotine during all the phases of lung development and those exposed from one day before the onset of the alveolar phase of development. Maternal copper supplementation (1mg/kg/day) during all the phases of lung development prevented all the adverse effects of maternal nicotine exposure on lung development. Copper supplementation from one before the onset of alveolarisation did not prevent the development of microscopic emphysema. Lung volume and body weights were not affected by maternal nicotine exposure. Therefore, it appears that maternal nicotine exposure changes the "programming" of the lungs of the offspring and thereby induce premature aging which renders the lungs more susceptible to damage. It appears that copper supplementation may prevent the premature aging phenomenon by maintaining the connective tissue framework of the lungs.

 **1647** PRENATAL PERFLUOROOCTANE SULFONATE EXPOSURE AFFECTS PERINATAL LUNG DEVELOPMENT AND CAUSES RESPIRATORY DISTRESS IN RATS.

R. C. Grasty. *Toxicology, UNC Chapel Hill, Research Triangle Park, NC.*

Perfluorooctane sulfonate (PFOS) is an environmentally stable industrial and household compound used as a protectant and surfactant. Prenatal exposure to PFOS at cumulative dosages of 50-100 mg/kg in rats leads to offspring mortality within hours to days after birth; the underlying pathophysiology remains unknown. Studies have shown that a critical period occurs late in gestation, with treatment on gestation days 19-20 (25 or 50 mg/kg/d) sufficient to induce neonatal death. Rat pups exposed to PFOS prenatally presented with labored breathing that worsened until death. The lungs of PFOS-exposed pups were pale and unable to expand fully upon perfusion. Histology and morphometry suggested that the lungs of the treated pups were immature. Therefore, it was hypothesized that PFOS lead to respiratory distress in the rat neonates. Attempts were made to rescue with therapeutic agents (dexamethasone and retinoic acid) to accelerate lung maturation and to combat the PFOS effects. These agents lengthened the time to death, but all exposed animals died, indicating that lung immaturity was not the major defect. Transmission electron microscopy of lungs of PFOS-treated pups revealed that surfactant was present in the alveolar type II cells, with an increase in lamellar bodies present in the 50 mg/kg/d group. Additionally, the alveolar cell membranes in the treated animals were irregular and lacked cell-cell contact. In addition, pronounced filamentous structures were located within the type II cells of treated animals. Further studies will identify the components of these structures and determine whether these structures block surfactant secretion. Microarray studies indicate changes in fatty acid synthesis. Investigations are ongoing to assess the integrity of surfactant in PFOS-exposed rat pups by measuring the ratios of various phospholipid species. The developing lung appears to be a primary target of PFOS, and further studies contribute to elucidating the mechanisms underlying this toxicity.

 **1648** EFFECTS OF ENVIRONMENTAL AIR POLLUTANTS ON POSTNATAL LUNG DEVELOPMENT.

M. Fanucchi. *School of Veterinary Medicine, University of California, Davis, CA.*

The respiratory system is a target for a wide range of toxic environmental contaminants. While the acute and chronic effects of a large number of these substances have been well characterized for the respiratory system of adult mammals, there is significantly less known about the impact of these lung-targeted compounds on the developing respiratory system. The pattern of lung development itself may play a significant role in modulating toxic responses, since significant portions of lung morphogenesis and cytodifferentiation occur postnatally. The risk of injury from an environmental contaminant which is known to target the lung in adults must be evaluated with two considerations: (1) the toxicant may have its impact by altering the processes of morphogenesis and cytodifferentiation resulting in differential expression or organization of the lung in the adult and (2) the stage of morphogenesis and differentiation of various lung subcompartments at the time of exposure may significantly modulate the severity of the toxic response. While there is extensive literature on the toxic potential of a wide range of environmental contaminants when the exposure is directed towards adults, it is obvious that there is a dearth of information regarding the toxic response of the respiratory system during development. The majority of studies suggest that: 1) the respiratory system in pre- and postnatal animals is more susceptible to injury from lung-directed toxicants than it is in adults of the same species; 2) the differences in toxic response to respiratory-targeted compounds among species are amplified when responses are evaluated during lung development.

 **1649** ROLE OF CELL-CELL AND CELL-MATRIX INTERACTIONS IN REGULATION OF TOXICANT-MEDIATED CELL DEATH.

R. Roberts<sup>1</sup> and R. Tjalkens<sup>2</sup>. <sup>1</sup>*Safety Assessment, AstraZeneca, Alderley Park, United Kingdom* and <sup>2</sup>*Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO.*

Cell-cell interactions are key for the regulation of cell survival, cell death and cell proliferation. Thus, an understanding of the interdependency between different tissue cellular compartments is key to elucidating mechanisms of cell death in response to toxicants. This symposium will provide a timely update on the molecular mechanisms of cell death and its regulation, including the role played by cell-cell and cell-matrix interactions. This will be illustrated by three examples of the role these pathways play in toxicant response in diverse tissues. The first speaker will consider how hepatic Kupffer cells are implicated in normal homeostasis and in hepatocarcinogenesis and can mediate both hepatocyte survival or cell death, depending on the toxic insult. The second speaker will address how gap junctional intercellular communication and cell adhesion are interrelated processes using the example of hexachlorobenzene which induces a down-regulation of connexins and E-cadherin in the liver of female but not male rats. The third speaker brings an external perspective and will discuss how the cell detects and signals damage leading to survival or cell death. The fourth speaker will address how neuronal trophic and communication functions are maintained by intricate coupling with associated astroglial cells with emphasis on neurotoxicants that selectively target astroglial cells, rendering neurons vulnerable to both physiologic and pathophysiologic stresses. The forth speaker will also summarise the symposium by uncovering similarities and common themes in the role of the cellular environment in determining cell fate after toxicant insult. This symposium will be of interest both to non-experts looking to understand this field and those with a specific interest in cell biology, carcinogenesis, neurotoxicology, apoptosis or cell-cell communication.

 **1650** CELL-CELL INTERACTIONS AND THEIR ROLE IN TOXICANT-INDUCED HEPATIC CELL DEATH.

R. Roberts. *Safety Assessment, AstraZeneca, Alderley Park, United Kingdom.*

Diverse hepatotoxins induce differing responses; peroxisome proliferators (PPs) induce hepatocyte proliferation, suppression of apoptosis and ultimately liver tumors. In contrast, acetaminophen causes oxidative stress, cell death and irreversible necrotic liver damage. How are these different responses orchestrated and controlled? Increasing evidence suggests that hepatic nonparenchymal cells (NPCs), particularly Kupffer cells, play a major role in directing the response of the hepatocyte via synthesis, storage and release of cytokines such as tumor necrosis factor  $\alpha$  (TNF $\alpha$ ), Interleukin 1L1 $\alpha$  (IL1 $\alpha$ ) and interleukin 6 (IL6). In the case of TNF $\alpha$ , binding to a specific receptor can activate death-signalling pathways leading to apoptosis but also others that lead to survival via p38 MAP kinase and NF- $\kappa$ B. The choice of outcome depends on cellular context; for example, inhibition of translation switches the TNF $\alpha$  signal from survival to death. Additionally, there may be a role for an excessive release from Kupffer cells and adjacent endothelial cells of reactive oxygen species and/or nitric oxide that cause oxidative damage in neighbouring hepatocytes and other liver cells. Although the responses of the rodent liver to PPs are entirely dependent on the PP activated receptor, (PPAR $\alpha$ ), the removal of NPCs abrogates the response to PPs both *in vivo* and *in vitro*, demonstrating that cell-cell interactions and cytokine release plays a key role. Interestingly, NPCs isolated from PPAR $\alpha$  null mice, like those isolated from the wild type NPCs, can restore the hepatocyte response to PPs. However, as expected, PPAR $\alpha$  null hepatocytes remained non-responsive to PPs, irrespective of the genotype of the added NPCs. These data support a role for NPCs in facilitating a response of hepatocytes to PPs that is ultimately dependent on the presence of PPAR $\alpha$  in the hepatocyte. Overall, hepatic Kupffer cells are implicated in normal homeostasis, in acute response to toxicants and in hepatocarcinogenesis and can mediate both hepatocyte survival or cell death, depending on the toxic insult and the cellular context.

 **1651** MODULATION OF CELL-CELL INTERACTIONS BY EPIGENETIC HEPATOCARCINOGENS.

M. Charbonneau, I. Plante, N. Raynal and D. G. Cyr. *INRS-Institut Armand-Frappier, Universite du Quebec, Pointe-Claire, Montreal, QC, Canada.*

Mechanisms of epigenetic carcinogenesis involve disruption of cell or tissue homeostasis, such as cell-cell interactions mediated by various types of junctions. Gap junctions are formed by channels that allow direct communication between cells (GJIC), while adhering junctions maintain tissue integrity by linking cells together. Gap and adhering junctions are physically and functionally interrelated membrane structures. Connexins and cadherins are key proteins in gap and adhering junctions, respectively. While the effects of hepatocarcinogens on these proteins in ro-

dent livers are well documented and will be discussed in this presentation, the pathways involved in their regulation are less understood. Consequently, a particular emphasis will be made on hexachlorobenzene (HCB), an important environmental contaminant, that modulates intracellular pathway involved in cell junctions. HCB causes liver tumor formation and down-regulation of connexins and E-cadherin in the liver of female but not male rats. A sexual dimorphism in the activation of the ILK pathway is believed to be responsible for these down-regulations; inactivation of GSK3- $\beta$  and nuclear translocation of both Akt and  $\beta$ -catenin are important events. *In vitro* studies, using specific inhibitors and overexpression systems confirmed not only the role of ILK pathway in cell-cell interactions, but also the functional interrelationships between connexins and cadherins. Down-regulation of proteins forming gap and adhering junctions allow initiated cells to escape control from neighboring cells, thus promoting their clonal expansion. The importance of such mechanisms in carcinogenesis is illustrated by the fact that human tumors of various origins show low levels of immunoreactive connexins and cadherins. Moreover, studies suggest that loss of cell-cell interaction proteins is an early event in the carcinogenesis process. Overall, data support the contention that gap and adhering junctions are at the basis of important cell-cell interactions disrupted in epigenetic hepatocarcinogenesis.

duces progressive dyskinesia, emotional lability, and certain neurological deficits resembling Parkinsons disease. It is postulated that astroglial-derived NO mediates neuronal injury induced by manganese exposure and that manganese potentiates the effects of pro-inflammatory cytokines on induction of nitric oxide synthase in astroglial cells. This hypothesis is tested utilizing: 1) subchronic *in vivo* exposure to manganese in mice; 2) an astroglial-neuronal co-culture system; and 3) primary astrocyte cultures to examine molecular signaling events relevant to inflammatory gene expression. Manganese potentiates cytokine-induced expression of nitric oxide synthase in astrocytes that increases apoptosis in co-cultured neurons in an NF- $\kappa$ B-dependent fashion. Dysregulation of intracellular calcium and mitochondrial dysfunction in astroglia mitochondria appear to be pivotal to induction of nitric oxide production. Thus, therapeutic strategies that target the molecular signaling pathways regulating expression of nitric oxide synthase in astroglia may be effective in mitigating neuronal injury in degenerative conditions of the basal ganglia.

## 1652 THE REGULATION OF APOPTOSIS: SURVIVAL SIGNALLING AND THE IMPORTANCE OF CELL TO CELL COMMUNICATION.

C. Dive<sup>1,2</sup>, J. T. Erler<sup>1</sup>, I. J. Stratford<sup>2</sup>, D. A. Tennant<sup>1,3</sup> and D. R. Tomlinson<sup>3</sup>. <sup>1</sup>*Cellular and Molecular Pharmacology Group, Cancer Research UK Paterson Institute, Manchester, United Kingdom*, <sup>2</sup>*School of Pharmacy and Pharmaceutical sciences, University of Manchester, Manchester, United Kingdom* and <sup>3</sup>*School of Biological Sciences, University of Manchester, Manchester, United Kingdom*. Sponsor: R. Roberts.

Apoptosis is a physiological death process that is conserved from worms and flies to man. All cells will undergo apoptosis by default if not supplied with appropriate survival signals, ensuring that the correct numbers of healthy cells are found in the right place at the right time. Two general pathways to apoptosis have been characterised. The extrinsic pathway, activated by ligation of plasma membrane death receptors (e.g. Fas), drives the formation of a Death Initiating Signaling Complex (DISC) that in turn activates a proteolytic caspase cascade. The intrinsic pathway is activated by drug-induced damage and via loss of cell-cell or cell-matrix contacts. These apoptotic signals are relayed to mitochondria where interactions between pro- and anti-apoptotic proteins of the Bcl-2 family determine the release of apoptotic factors including cytochrome c and Smac. Cytosolic cytochrome c activates the apoptosome complex and a caspase cascade and Smac binds to inhibitor of apoptosis proteins (IAPS) to remove their restraint on caspase activity. The cellular microenvironment plays a major role in regulating the induction of apoptosis. For example, the hypoxia experienced by tumour cells within a solid mass has an impact on the Bcl-2 family of proteins with consequences for tumour cell survival and resistance to therapy. Specifically, the role of hypoxia inducible factor  $\alpha$  in promoting cell survival will be examined *in vitro* and *in vivo*. A second example is provided by studies that ask how the Schwann cell population is lost in patients with diabetic neuropathy. Given the intimate interplay between Schwann cells and the axon they surround, we ask how this Schwann cell loss influences the observed axonopathy associated with this disease. Specifically, the impact of chronic hypoxia combined with hyperglycaemia on Schwann cell Bcl-2 family proteins and apoptosis will be examined.

## 1653 NEURO-GLIAL INTERACTIONS IN BASAL GANGLIA DYSFUNCTION: INSIGHTS FROM MANGANESE NEUROTOXICITY.

R. Tjalkens. *Toxicology Section, Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO*.

During periods of stress or injury, astroglia can undergo phenotypic transformation into an activated state whereupon expression of inflammatory mediators is dramatically increased, to the detriment of associated neurons. Neuronal injury in several disorders of the basal ganglia, including manganism and Parkinsons disease, is associated with regional increases in expression of inflammatory mediators and activation of astroglia, with subsequent overproduction of nitric oxide (NO). The present studies explore the role of astroglial activation in basal ganglia dysfunction by examining a prototypic neurotoxicant of the basal ganglia, manganese, and its capacity to elicit expression of inflammatory genes in astroglia. Although playing various essential physiological roles in the central nervous system, manganese in excess is the cause of an extrapyramidal neurodegenerative disorder in humans that pro-

## 1654 THE UBIQUITIN-PROTEASOME SYSTEM AS A BIOLOGICAL TARGET IN TOXIC RESPONSES AND DISEASE.

R. S. Pollenz. *Biology, University of South Florida, Tampa, FL*.

The ubiquitin-proteasome system is an essential pathway involved in covalently modifying proteins to influence their function and turnover. The cascade is initiated by an activating enzyme (E1), that binds to the 76 amino acid ubiquitin protein (UB). The E1 then transfers the UB to an E2 carrier protein. Following this transfer, a UB ligase enzyme (E3) covalently links the UB to a target protein. It is the E3, or E3/E2 complex that supplies the target specificity of the ubiquitination event. Genome mining has identified 530 possible genes encoding E1, E2, E3, UB and deubiquitinating enzymes (DUB). Ubiquinated substrates are usually recognized by the 20S or 26S proteasome complexes and destroyed, although recent studies suggest that UB or UB-like modification does not always result in destruction. The proteasomes are huge multiprotein complexes that can be found in both the cytoplasm and nucleus. Overall, the proteasome accounts for 1% of a cells protein. Due to the number of gene products required for the ubiquitin-proteasome system, it is a prime target in various human diseases states and cancer. Defects in the system have been implicated in neurodegenerative diseases such as Parkinsons and Alzheimers. In addition, studies continue to suggest that that the various enzymes of the pathway may be targets for toxicologically relevant compounds typified by arsenic, cadmium, TCDD and ethanol. In addition, the ubiquitin-proteasome system is implicated in the ligand mediated degradation of important transcription factors such as p53, steroid hormone receptors and the aryl hydrocarbon receptor (AHR). Due to these findings, the enzymes of the ubiquitin-proteasome pathway have become important targets in toxicology screens and in drug discovery paradigms.

## 1655 TOXICANT AFFECTS ON UBIQUITIN-PROTEOSOME SYSTEMS: LESSONS FROM CROSS-COMPOUND AND CROSS-SYSTEM ASSESSMENTS.

E. Faustman, X. Yu, J. Sidhu and J. Robinson. *Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA*.

This talk will highlight mechanistic research from our laboratory which examines the similarities and dissimilarities of metal effects on the Ubiquitin-proteasome (UB) pathway. The effects of three metals were evaluated in mouse embryonic fibroblast cells (MEF) using environmentally relevant concentrations of MeHg (2.4  $\mu$ M), Cd (5.0  $\mu$ M) and As (5.0  $\mu$ M) for 24 hours. MG132 (0.5  $\mu$ M), a classical proteasome inhibitor, was also included to compare the effects of these metals with a well-characterized inhibitor of the UB pathway. These concentrations were chosen as they were consistent with our previous studies where minimal impacts were observed on cytotoxicity, stress signaling and apoptotic pathways under these treatment conditions. Gene expression array analysis was done using CodeLink Mouse Uniset 10K oligonucleotide based platforms. To determine the role that specific cell signaling pathways might play in mediating these metal effects, we evaluated these responses in both wild-type as well as P53 knockout cells. We developed pathway specific analysis approaches using GenMAPP (Gene MicroArray Pathway Profiler) on normalized data. Our results have allowed us to compare both molecular and cellular level responses across these four agents and have facilitated our identification of common and unique targets within the UB pathway for these agents. The dependence of these targets upon the P53 cell cycle control checkpoint pathway was determined. These studies were supported by USEPA and NIEHS ES08601, ES07033, ES 11387, ES 10613 and R 826882.

## 1656 ENVIRONMENTAL FACTORS, UBIQUITIN-PROTEOSOME DYSFUNCTION AND PARKINSON'S DISEASE.

A. G. Kanthasamy, *Biomedical Sciences, Iowa State University, Ames, IA.*

Exposure to pesticides and metals has been linked to the etiopathogenesis of Parkinson's disease. Recently, we showed that the organochlorine pesticide dieldrin induces apoptosis in dopaminergic cells via caspase-3-dependent proteolytic activation of the proapoptotic kinase PKC $\delta$ . Abnormal accumulation and aggregation of  $\alpha$ -synuclein and impairment of the ubiquitin-proteosome system have been suggested to contribute to the dysfunction, degeneration and ultimate death of dopaminergic neurons in PD. To further understand the cellular mechanisms underlying dieldrin-induced dopaminergic neurodegeneration, we examined the effects of dieldrin on the ubiquitin-proteosomal function in rat mesencephalic dopaminergic cells overexpressing human  $\alpha$ -synuclein ( $\alpha$ -SYN cells). Low dose (30 microM) dieldrin induced time-dependent cytotoxicity over a 24 hr period in  $\alpha$ -SYN cells compared to vector expressing cells.  $\alpha$ -SYN cells were slightly resistant to dieldrin toxicity up to 12 hr post exposure but were more sensitive at 24 hr. Dieldrin treatment for 24 hr also resulted in a significant increase in caspase-3 enzyme activity in  $\alpha$ -SYN cells. Dieldrin treatment significantly increased the proteosomal activity at 3 hr in vector cells but not in  $\alpha$ -SYN cells. At a later time point (24 hr), a significant reduction in proteosomal activity was observed in both vector and  $\alpha$ -SYN cells, however, the impairment of proteosomal function was more pronounced in  $\alpha$ -SYN cells than in vector cells. Dieldrin also increased the accumulation of ubiquitin. Immunocytochemical analysis of dieldrin-treated  $\alpha$ -SYN cells showed aggregation of  $\alpha$ -synuclein in a time-dependent manner, with small aggregates appearing as early as 6 hr and progressively increasing over a 24 hr. The proteosomal inhibitor lactacystin also induced a profound aggregation in  $\alpha$ -SYN cells. Overall, these results suggest that impairment of the ubiquitin-proteosome function following environmental neurotoxin exposure may play a role in  $\alpha$ -synuclein aggregation in Parkinson's Disease [NIH grants NS 045133 and ES 10586].

## 1657 EFFECT OF ETHANOL ADMINISTRATION ON PROTEASOME ACTIVITY IN LIVER AND IN CULTURED HEPATOMA CELLS.

T. M. Donohue, N. A. Osna and D. L. Clemens. *Research, VA Medical Center, Omaha, NE.* Sponsor: R. Pollenz.

Chronic ethanol consumption by heavy drinkers and alcoholics or exposure of liver cells to ethanol *in vitro* can cause liver cell death and liver injury, leading to the complications of hepatic fibrosis and cirrhosis in humans and laboratory animals. The loss of cell viability has been associated with a decline in proteasome function in cells, because of the pivotal role of this proteolytic enzyme in cell regulation and function, including cell proliferation, enzyme regulation and antigen presentation. Ethanol is a hepatotoxin that, when administered to animals to produce blood ethanol levels of 40 mM (i.e 184 mg/dL) or more results in a 36-40% decline in liver proteasome activity. Our aim is to determine the mechanism(s) responsible for the alcohol-elicited decline in proteasome activity and its association with liver injury. Our studies to date have revealed that ethanol-induced oxidative stress contributes significantly to this decline in enzyme activity and that the level of oxidative stress correlates with the severity of liver pathology. Oxidative stress is regulated not only by the levels of ethanol and its metabolism but also by the type of dietary fat that is included in the diet of ethanol-fed experimental animals. At this time, we know that the ethanol-elicited decline in proteasome activity is correlated with liver damage, but we do not know whether such a decline is causally related to liver injury. However, because the proteasome degrades the majority of oxidized proteins and proteins modified by ethanol-derived aldehydes and reactive oxygen and nitrogen species, we hypothesize that the partial loss of proteasome activity would augment the accumulation of potentially cytotoxic proteins to enhance the onset of cell death. In this presentation, I will provide evidence from both *in vivo* and *in vitro* studies to suggest that proteasome activity and proteolytic systems in general, influence cell viability in response to ethanol consumption *in vivo* or ethanol exposure *in vitro*.

## 1658 THE UBIQUITIN-PROTEASOME SYSTEM IN REGULATION OF NUCLEAR TRANSCRIPTION FACTORS AND SIGNAL TRANSDUCTION PATHWAYS.

R. S. Pollenz, J. Popat, M. de la Pena and J. McQuown. *Biology, University of South Florida, Tampa, FL.*

The concentration or subcellular location of the key proteins involved in signal transduction pathways have been shown to impact gene regulation. The aryl hydrocarbon receptor (AHR) is one protein that appears to be controlled by the ubiquitin-proteasome system. It is clear that binding of ligands typified by 2, 3, 7, 8 tetra-

chlorodibenzo-p-dioxin (TCDD) result in nuclear accumulation and degradation of the AHR. However, the sequence of events following ligand binding that specify degradation are poorly understood. Studies indicate that there is a 60-minute lag between ligand exposure and the detection of AHR degradation. This implies a regulatory event. Analyses of receptors that are defective in nuclear import reveal that the lag time is not reduced and the kinetics of degradation are not changed when compared to wild type AHR proteins. AHRs that are nuclear prior to ligand exposure also are degraded along the same time frame as wild type receptors. During the first 60 minutes of exposure, the AHR becomes localized within the nucleus and appears to exist as either a dimer with ARNT or in a complex with hsp90 and XAP2. Since the AHR is a phosphoprotein, studies were initiated to determine whether changes in the phosphorylation state were important in the degradation events. The analysis of endogenous AHR turnover in the presence of phosphatase inhibitors did not reveal any reductions in AHR turnover. Interestingly, stimulation of various cell lines with TCDD, results in a transient reduction in estrogen receptor protein levels and gene-chip studies suggest that several genes of the ubiquitin-proteasome system are upregulated by TCDD. Thus, while the degradation switch of the AHR remains elusive, it is intriguing to consider that enzymes of the ubiquitin-proteasome system may be impacted by ligands typified by TCDD to affect other pathways. Supported by NIEHS 10991.

## 1659 WHY METALS BECOME NEUROTOXIC.

W. Zheng. *School of Health Sciences, Purdue University, West Lafayette, IN.*

Neurodegenerative diseases are characterized by progressive atrophy and dysfunction of anatomically or physiologically related neurological systems. Cumulative evidence suggests a role of metals in the etiology of numerous such diseases. For example, excess manganese (Mn) and iron (Fe) in particular brain regions have been associated with Parkinsonism; copper (Cu) and zinc (Zn) have been implicated in extracellular deposits of amyloid plaques in Alzheimer's brains; overload of aluminum (Al) in the brain has also been controversially related to Alzheimer's disease. Moreover, exposure to organic metals such as methylmercury (MeHg) has been linked to persistent psychomotor disturbances. However, the imminent question remains as to what factors may render metals, either essential or xenobiotic, more prone to being harmful in sporadic or hereditary neurodegenerative diseases. Understandably, interactions of these metals with genetic components, proteins, metal transport machineries, and cellular redox mechanisms, may signify some of the key factors in metal-induced neurotoxicities. This symposium will address the current understanding of biochemical characteristics of metals that are implicated in neurodegenerative disorders, including (1) metal-protein interaction such as Cu and Zn in beta-amyloid aggregation, (2) metal-metal interaction such as Mn in alteration of brain Fe functions, (3) metal-subcellular structure interaction such as MeHg and microtubules, (4) metal-transporter interaction such as Al speciation in brain Al metabolomics, and (5) metal-redox pathway interaction implicated in metal-induced oxidative stress. The symposium will be of interest to those who are engaged in metal toxicology, neuroscience, neurotoxicology, risk assessment, regulatory management, occupational health, and toxicology education.

## 1660 SELECTIVE BLOOD-BRAIN BARRIER TRANSPORT OF ALUMINUM, MANGANESE, AND OTHER METALS IN METAL-INDUCED NEURODEGENERATION.

R. A. Yokel. *College of Pharmacy, University of Kentucky Medical Center, Lexington, KY.*

Excessive concentrations of aluminum (Al), copper (Cu), iron (Fe), mercury (Hg), manganese (Mn), tin (Sn) and zinc (Zn) have been shown or hypothesized to contribute to one or more neurodegenerative diseases, including Alzheimer's disease (AD), Parkinson's disease (PD), Wilson's disease (WD) and Friedreich's ataxia. The uptake of metals into the brain is often mediated by selective carriers or transporters localized at the blood-brain barrier (BBB). Thus, the regulation of metal transport by the BBB is fundamental to subsequent metal-induced neurotoxicities. This presentation will first review the evidence supporting and refuting roles of Mn in PD and Al in AD, including disparities between Mn-induced Parkinsonism and idiopathic PD, epidemiological evidence of Al neurotoxicity, clinical studies of brain Al in AD patients, and biochemical effects produced by Al that mimic AD. It will then focus on the selective metal transporters at the BBB as a key factor in the potential for metals to produce neurotoxicity. The specific interaction of a unique chemical species (form) of a neurotoxic metal with a particular membrane transporter at the BBB serves as a good example of selective transport of metals by the BBB. The ability of the methyl-Hg-cysteine complex to mimic methionine and to serve as a substrate for an amino acid transporter illustrates this mechanism of brain metal entry. Another mechanism that may mediate brain entry of several metals is transferrin-receptor mediated endocytosis. This presentation will further discuss the role of similar mechanisms in Al and Mn brain influx and efflux. The evidence for carrier-

mediated influx and efflux of Al across the BBB will be presented, as will the evidence for carrier-mediated influx, but only diffusion-mediated efflux, of Mn. Our incomplete knowledge of the mechanisms mediating Al and Mn flux across the BBB will be contrasted to the understanding of the Cu transporter that plays a central role in WD and the paucity of data on BBB flux of Sn and Zn.

#### 1661 INTERACTION OF COPPER AND ZINC WITH $\beta$ -AMYLOID IN PATHOGENESIS OF ALZHEIMER'S DISEASE.

A. I. Bush. *Genetics and Aging Research Unit, Harvard Medical School and Massachusetts General Hospital, Charlestown, MA.* Sponsor: W. Zheng.

$\beta$ -Amyloid ( $\text{A}\beta$ ) is a ubiquitous metalloprotein with selective high-affinity binding sites for zinc (Zn) and copper (Cu). Studies have shown an elevation of Zn and Cu in the plaques in AD. Furthermore, genetic ablation of the ZnT3 transporter abolishes amyloid deposition in the Tg2576 mouse model for AD.  $\text{A}\beta$  binds Cu and Zn through a site that involves oligomeric peptide assembly, and resembles the structure of SOD1. When synthetic  $\text{A}\beta$  binds Cu in the absence of Zn, it is highly redox active. Biological reducing agents such as dopamine, cholesterol and vitamin C can act as a reservoir of electron donation, so that the  $\text{A}\beta/\text{Cu}$  complex acts as a catalyst generating  $\text{H}_2\text{O}_2$  ( $\text{Km}=5 \mu\text{M}$ ,  $\text{Vmax}=30 \text{nM}/\text{min}$ ). The toxicity of  $\text{A}\beta$  species is proportional to the peptide's ability to reduce Cu or iron (Fe) and generate  $\text{H}_2\text{O}_2$  ( $\text{A}\beta42 > \text{A}\beta40 > \text{rat A}\beta$ ).  $\text{H}_2\text{O}_2$  is a freely permeable pro-oxidant and is the chemical source of much of the oxidation damage that is abundantly evident in AD brain. Where cholesterol is the substrate for  $\text{H}_2\text{O}_2$  production, it is specifically oxidized by  $\text{A}\beta/\text{Cu}$  complexes into forms that are markedly increased in AD post-mortem brain tissue compared to age-matched normal and neurological disease control tissue. Chelators of Cu and Zn both disaggregate  $\text{A}\beta$  deposits from post-mortem human brain and also inhibit redox activity and  $\text{H}_2\text{O}_2$  production. We have found that one such orally bioavailable chelator, clioquinol, markedly inhibits brain amyloid pathology in Tg2576 mice. This compound has recently completed a successful pilot Phase 2 clinical trial in AD, where plasma  $\text{A}\beta$  levels were lowered and cognitive decline significantly arrested. Cu and Fe levels rise in several tissues with aging for reasons that are still unclear. We hypothesize that some metalloproteins are liable to becoming abnormally decorated with extra Cu and Fe ions leading to a gain of redox-activity. The interactions described for  $\text{A}\beta$  may be applicable to other protein targets implicated in other age-related degenerative diseases such as cataracts, Parkinson's disease, and amyotrophic lateral sclerosis.

#### 1662 BINDING TO SUBCELLULAR STRUCTURES IN METHYLMERCURY-INDUCED NEURODEGENERATIVE DAMAGE.

K. R. Reuhl. *Pharmacology & Toxicology, Rutgers University, Piscataway, NJ.*

Binding of metals to subcellular structures represents a crucial factor in the molecular and cellular events that prompt metals to generate neurotoxicities, such as in the case of methylmercury (MeHg). MeHg is a potent neurotoxicant. During the last three decades, studies have attempted to identify organelar targets within neurons to account for the compound's regional selectivity. Two organelles - the mitochondrion and the microtubule (MT) - have been shown to be highly vulnerable to MeHg. Recent studies indicate that these structures have a complex pattern of structural and functional co-dependency. Exposure of mature neurons to MeHg results in a rapid disassembly of perikaryal microtubules and almost coincident loss of mitochondrial membrane potential and increases in cytosolic markers of oxidative stress. A subpopulation of tyrosinated MTs immediately adjacent to the mitochondria is first to disassemble, followed by other perikaryal MT and later, axonal MTs. The slow degeneration of axonal MTs likely contributes to the delay in the clinical expression of neuronal dysfunction in adults. Pretreatment with taxol, a microtubule stabilizing agent, protects against MeHg damage and inhibits loss of mitochondrial membrane potential. Inhibition of mitochondrial activity slows, but does not prevent, MT disassembly. In contrast, MeHg treatment of undifferentiated neurons causes a prompt and extensive loss of MT in neurons, but only modest increases in mitochondrial permeability and oxidative stress. However, as the neuron develops neurites, it rapidly assumes an adult pattern of response, including increasing reliance on mitochondrial respiration. Taken together, these data suggest that MT represent an early target of MeHg in both immature and mature neurons, while mitochondria are most vulnerable once they assume mature respiratory function. (Supported by NIH ES-05022, ES11256 and USEPA R829391).

#### 1663 METAL-METAL INTERACTIONS IN MANGANESE-INDUCED PARKINSONISM.

W. Zheng. *School of Health Sciences, Purdue University, West Lafayette, IN.*

Metals, by their chemical nature, share many similarities, such as the valence charge, ionic radius, and electronic polarity. These characteristics comprise the molecular basis on which one metal can interact with another in biological reactions.

For example, lead toxicity has been linked to its interaction with calcium; arsenate, by mimicking phosphate, causes a disruption in energy production. This presentation will discuss how the chemical similarity between manganese (Mn) and iron (Fe) leads to a distorted Fe homeostasis in the CNS following Mn exposure, which may contribute to the etiology of Mn-induced Parkinsonism. Systemic and cellular Fe metabolism is regulated by the iron regulatory protein-1 (IRP1), which binds to the iron responsive element (IRE) in mRNAs of transferrin receptor (TfR) and ferritin via the [4Fe-4S] structure of IRP1's active center. Mn competes with Fe for the binding of IRP1, resulting in an altered binding affinity of IRP1 to IRE-containing mRNAs. A gel shift assay demonstrated that Mn exposure increased the binding of IRP1 to the stem loop-containing mRNAs encoding the TfR and the divalent metal transporter (DMT1) in cultured choroidal epithelial cells, which constitute the blood-cerebrospinal (CSF) barrier. Consequently, a real-time PCR analysis revealed an increased density of TfR and DMT1 mRNAs after Mn treatment, with the subsequent elevated cellular protein concentrations of TfR and DMT1 in cultured choroid plexus cells. Studies utilizing RT-PCR and nuclear run off techniques further showed that Mn treatment did not affect the level of heterogeneous nuclear RNA (hnRNA) encoding TfR and DMT1, nor did it affect the level of nascent TfR mRNA. Taken together, these results suggest that Mn-Fe interactions at the blood-CSF barrier prompt Fe transport at the blood-CSF barrier; the effect is likely due to Mn action on translational events relevant to the production of TfR and DMT1, but not due to its action on transcriptional, gene expression of TfR. The disrupted Fe homeostasis in the brain upon Mn exposure may explain Mn-induced neurodegenerative toxicity. (Supported by ES08146)

#### 1664 ADVANCES IN MATERIAL SAFETY DATA SHEET COMMUNICATION.

M. McDiarmid<sup>1</sup> and L. Frazier<sup>2</sup>. <sup>1</sup>*Occupational Health Project, University of Maryland, Baltimore, MD* and <sup>2</sup>*Department of Preventive Medicine, University of Kansas School of Medicine, Wichita, KS.*

OSHA is currently reviewing its Material Safety Data Sheets (MSDS) requirements, as is the American National Standards Institute (ANSI). Employers using hazardous chemicals are required by OSHA's Hazard Communications Standard to have MSDSs available to workers. Developing and providing effective communication is a major challenge within the public health and occupational health communities. Some MSDSs are difficult for workers to read; some MSDSs are outdated; and some MSDSs omit needed health information. On the other hand, some manufacturers produce what might be considered examples of "best practice" MSDS writing: excellent, readable, and timely information. Another source of information, the New Jersey Hazardous Substances Fact Sheets, covers only about 1, 600 workplace chemicals. However, the program receives 80, 000 hits per month on its website for its fact sheets, which are considered by many environmental and labor advocates to be good sources of essential health and safety information. The message that reproductive health includes both men and women, and that it can be affected by their workplace exposures, needs to reach the workers and their employers through MSDS communication. Paul and Kurtz surveyed Massachusetts MSDSs in 1994 for products containing two known reproductive toxicants, lead and glycol ethers, and found that over 60% did not mention possible reproductive health effects. They also found that where reproductive hazards were mentioned in MSDSs, they were 18 times more likely to address developmental effects than male reproductive risks. How can MSDS writing be improved to a best practice standard while avoiding national or international standards conflicts? The NIOSH Reproductive Health Research Team is interested in finding ways to improve the quality of MSDSs in general, and particularly the quality of reproductive health information. Representatives from NIOSH, industry, academia, and the New Jersey Right to Know Program will present and discuss multiple facets of this issue.

#### 1665 ISSUES WITH MSDS COMMUNICATION OF REPRODUCTIVE HAZARDS.

L. Frazier<sup>1,2</sup>, M. J. Rall<sup>2</sup> and D. B. Fromer<sup>1</sup>. <sup>1</sup>*Preventive Medicine and Public Health, University of Kansas School of Medicine-Wichita, Wichita, KS* and <sup>2</sup>*Obstetrics and Gynecology, University of Kansas School of Medicine-Wichita, Wichita, KS.* Sponsor: M. McDiarmid.

MSDS have multiple audiences, ranging from professionals with technical expertise to workers. To help improve the readability of MSDS, the American National Standards Institute emphasizes communication principles in its newly revised standard (ANSI Z400.1). OSHA plans to provide guidance on preparing MSDS, and has partnered with the Society for Chemical Hazard Communication. Implementation of the Globally Harmonized System (GHS) of Classification and Labeling of Chemicals is being considered. The GHS International Chemical Safety (ICS) Cards contain standardized risk phrases for 1600 chemicals. These phrases may need further development to ensure that male reproductive hazards are stated. For dibromochloropropane (DBCP), the reproductive risk phrases on the

ICS card are "Avoid exposure to (pregnant) women" and "Causes toxicity to human reproduction or development." The reading grade levels of these phrases are 9.9 and 14.04 (college level), respectively. Reading grade levels can be calculated using software like MS Word or calculated manually. The following sentence has a reading grade level of 18.7, PhD level: "DBCP is a specific male gonadotoxicant in humans and laboratory animals, leading at high doses to azoospermia which may not be reversible." The following are examples of simpler language: "At high levels, this chemical may cause damage to the male reproductive system" (reading grade level 8.5; source: ToxFAQ from the Agency for Toxic Substances and Disease Registry). "Reproductive Hazard. DBCP may damage the testes (male reproductive glands). DBCP may decrease fertility in males and females. Infertility and lack of sex drive have been noted in exposed males" (reading grade level 7.3, source: New Jersey Right to Know Hazardous Substances Fact Sheets). In conclusion, chemical toxicity phrases on MSDS need to be both accurate and comprehensible. Efforts to develop simpler language about health hazards for MSDS are similar to efforts in the medical field to improve patient education.

## 1666 DEVELOPING GOOD MSDS COMMUNICATIONS IN INDUSTRY.

J. S. Bus. *The Dow Chemical Company, Midland, MI.*

Material Safety Data Sheets (MSDS) are an important mechanism by which the potential developmental and reproductive health hazards of chemicals are communicated to workers and other health professionals. Generation and maintenance of consistently and clearly worded MSDS documents by industry is supported by internal processes that encompass several key functions. These functions include: 1) generation, archiving and retrieval of relevant toxicology and human health information from standardized, globally accessible database(s). The data may be from both company- and literature generated studies; 2) designated Subject Matter Experts (SMEs) use professional judgment to interpret toxicological data gathered from a broad spectrum of sources, tapping additional specific expertise from with the laboratory research functions as necessary; 3) SMEs from disciplines of toxicology, industrial hygiene and occupational medicine develop standardized policies, practices and descriptive phrases that promote globally consistency language describing effects within and between documents. The OSHA Hazard Communication Standard and ANSI Z400.1-2004 provide valuable guidance in preparation of such standardized descriptors. Consistency in application of appropriate standardized MSDS descriptor phrases to specific developmental or reproductive toxicity responses is facilitated by SME cross-reference to rationale guidance statements for selection of specific phrases. For example, selection of the standardized phrase *Has been toxic to the fetus in laboratory animal tests* is guided by the rationale statement *Fetotoxic; no information as to maternal toxicity available. Does not address birth defects (teratogenicity). May be used with standardized statement XXX.* Additional guidance is available to SMEs on standardized definitions such as *fetotoxicity, birth defects, maternal toxicity*, etc. Thus, effective and consistent communication of MSDS health information is facilitated by SME access to well-maintained databases whose basic toxicology findings are accurately linked to standardized communication phrases.

## 1667 MSDS IN CANADA AND THE COMMUNICATION OF REPRODUCTIVE TOXICITY.

P. Demers. *School of Occ/Env Hygiene, University of British Columbia, Vancouver, BC, Canada.* Sponsor: M. McDiarmid.

In Canada the content and availability of Material Safety Data Sheets (MSDSs) is regulated under Hazardous Products Act (HPA) and the associated Controlled Products Regulations (CPR). The program is administered by the Workplace Hazardous Materials Information System (WHMIS), a federal program housed within Health Canada. However, actual enforcement and responsibility of workplace inspection is delegated to the 13 provinces and territories, which are also responsible for other health and safety regulation in Canada for the great majority of workplaces. Disclosure is required for toxicological information regarding both reproductive and developmental toxicity. For the purpose of MSDS disclosure, any indication of an adverse effect on fetal development or reproductive parameters must be disclosed on the MSDS irrespective of whether or not there is an adverse effect on the pregnant female. However, the guidelines state "it is important to focus on any effects that were found at low doses or in the absence of maternal toxicity." In general, the Hazardous Products Act requires chemical ingredients to be specifically listed if they are present at 1.0% or more in a product. However, that threshold is reduced to 0.1% or more for teratogens, embryotoxins, and reproductive toxins (as well as carcinogens, respiratory tract sensitizers and mutagens). While regulations list the areas that must be covered on MSDSs, there is no approval mechanism or systematic review of the content or completeness of the information on the sheets. Enforcement focuses on the availability of MSDSs at the workplace and meeting of training requirements. While enforcement of violations in omitting

information from the sheets is in theory possible, there is no well-established process or program for doing so. Because of this the content is highly variable. For example, in a recent review of Canadian MSDSs for products containing toluene diisocyanate it was discovered that 25% of sheets failed to indicate the asthma was a potential effect of exposure.

## 1668 STRENGTHS OF THE NJ HAZARDOUS SUBSTANCE FACT SHEET PROGRAM: HOW TO WRITE A BETTER MSDS.

R. Willinger, JD MPH and A. Sobieszczyk, MD PhD. *Right to Know Program, New Jersey Department of Health and Senior Services, Trenton, NJ.* Sponsor: B. Grajewski.

The New Jersey Department of Health and Senior Services, Right to Know Program, pursuant to the Worker and Community Right to Know Act, prepares Hazardous Substance Fact Sheets on individual chemicals. They are similar to Material Safety Data Sheets (MSDS). This effort is unique among the States. The Fact Sheet Group includes a toxicologist, physician, industrial hygienist, word processor and editor. The Fact Sheets are prepared in a standardized format and use standardized phrases that are written in a language understandable to non-health professionals. Under the section entitled Health Hazard Information, the toxicologist prepares the Chronic Health Effects subsection that includes Reproductive Hazards. Staff conducts a comprehensive search for information about reproductive hazards using a variety of authoritative textbooks and databases. Hazards searched for include teratogenicity, fetotoxicity, embryotoxicity, and damage to the male and female germ cells and reproductive systems in general. Teratogenicity is defined by regulation and requires "epidemiological evidence of teratogenicity in humans or positive teratogenic evidence in at least two different animal species." A Decision Logic determines the use of eleven standard reproductive hazard phrases. If no standardized phrase is applicable, text specific to the hazard is written. When reproductive hazard or teratogenicity is present, standardized questions and answers about reproductive hazard and teratogenicity also appear in the Question and Answer section of the Fact Sheet. Since the inception of this effort in 1984, over 1,700 Fact Sheets have been prepared (and revised) and included on the Department's website. The Fact Sheets are used by public and private employers, employees, emergency responders, health care providers and agencies, and members of the public for hazard communication.

## 1669 THE SAFETY ASSESSMENT OF NUTRITIONALLY IMPROVED FOOD AND FEED CROPS.

B. G. Hammond. *Product Safety Center, Monsanto Company, St. Louis, MO.*

The first generation of food and feed crops developed through modern agricultural biotechnology were designed to improve agronomic characteristics such as control of noxious weeds (herbicide tolerance) or protection against insect pests. The next generation of products under development include crops that have improved nutritional characteristics. Speakers for this workshop will discuss (1) various biotechnology approaches that are being used to improve nutritional characteristics of feed/food crops, (2) a case study for the safety and nutritional assessment of a nutritionally improved food/feed crop (3) recommendations of the EU ENTRANSFOOD working group on safety assessment of foods derived from genetically modified crops (4) conclusions from a recent ILSI workshop entitled Nutritional and Safety Assessments of Foods and Feeds Nutritionally Improved through Biotechnology. At the end of the presentations, a panel discussion will compare and contrast recommendations from the SOT, ENTRANSFOOD and ILSI work-groups regarding the safety assessment of nutritionally improved crops.

## 1670 IMPROVED NUTRITION THROUGH MODERN BIOTECHNOLOGY.

M. Newell - McGloughlin. *University of California Systemwide Biotechnology Research and Education Program, U.C. Davis, Davis, CA.* Sponsor: B. Hammond.

Innovation is essential for sustaining and enhancing agricultural productivity. Biotechnology has introduced a new dimension to such innovation, offering efficient and cost-effective means to produce a diverse array of novel, value-added products and tools. It has the potential to improve qualitative and quantitative aspects of food, feed and fiber production, reduce dependency on chemicals, and lower the cost of raw materials, in a sustainable manner. Commercialization of the products of recombinant DNA technology is just another facet in a long history of human intervention in nature and as such the same parameters of risk-based assessment should apply. It must be undertaken within a regulatory framework that ensures adequate protection of the consumer and the environment while not

stymieing innovation. The first generation of such crops focused largely on input agronomic traits, the next generation will focus more on value-added output traits such as improved nutrition and food functionality. Functional foods are defined as any modified food or food ingredient that may provide a health benefit beyond basic nutrition. From a health perspective, plant components of dietary interest can broadly be divided into four main categories, macronutrients (proteins, carbohydrates, lipids [oils], and fiber), micronutrients (vitamins, minerals, phytochemicals), anti-nutrients (substances such as phytate that limit bioavailability) and allergens & toxins. Developing plants with improved quality traits involves overcoming a variety of technical challenges inherent to metabolic engineering. Both traditional and biotechnology techniques are needed to produce plants carrying the desired quality traits. Continuing improvements in molecular and genomic technologies are contributing to the acceleration of product development. These new products and new approaches on the horizon require a reassessment of appropriate criteria to manage risk while insuring that the development of innovative technologies and processes is encouraged to provide value-added commodities for the consumer.

## 1671 CASE STUDY FOR THE SAFETY ASSESSMENT OF A NUTRITIONALLY IMPROVED FEED/FOOD CROP.

B. G. Hammond, T. Reynolds, G. Hartnell, E. Rice, R. McCoy and K. Glenn. *Product Safety Center, Monsanto Company, St. Louis, MO.*

Corn is deficient in lysine requiring supplementation with this essential amino acid in certain animal diets. When added to diets at nutritional levels, lysine is Generally Recognized As Safe (GRAS) by the FDA and is used as a human food additive when provided at nutrient levels. To increase lysine levels, the coding sequence for the dihydrodipicolinate synthase (cDHDPS) enzyme from *Corynebacterium glutamicum*, was introduced into corn. This enzyme is not feedback inhibited by lysine leading to increased free lysine in grain. Lysine maize, provides an alternative to addition of lysine to animal diets. Lysine maize will be identity preserved for use in poultry and swine diets. This safety assessment focuses on its intended use and inadvertent use should it enter human food. Bioinformatic analyses showed no structural or immunological similarities of cDHDPS to known allergens or toxins. It is structurally and functionally related to similar DHDPS enzymes that are involved in lysine biosynthesis in a wide range of organisms. When incubated *in vitro* with simulated gastric fluid, cDHDPS protein was readily degraded. No adverse effects were observed in mice fed an acute, high dose (800 mg/kg) of cDHDPS protein. An acute oral mouse study is appropriate to assess potential toxicity since most protein toxins act through acute mechanisms. The composition of grain and forage grown at different locations were analyzed as outlined in the OECD consensus document. Targeted metabolites in the lysine synthetic and catabolic pathway were also analyzed. Gain, feed efficiency, and carcass yield of broilers fed diets containing Lysine maize were not different from broilers fed lysine supplemented diets and were superior to broilers fed conventional maize and no added lysine. No meaningful changes in body wt, clinical or microscopic pathology were observed in rats fed Lysine maize for 90 days. Food and feed products derived from Lysine maize are as safe as those derived from conventional corn and produce the intended nutritional benefits.

## 1672 SAFETY ASSESSMENT OF NUTRITIONALLY IMPROVED CROPS THROUGH MODERN BIOTECHNOLOGY.

H. A. Kuiper, G. A. Kleter and E. J. Kok. *RIKILT, Institute of Food Safety, Wageningen University and Research Center, Wageningen, Netherlands.* Sponsor: B. Hammond.

Food crops developed through modern biotechnology, with improved nutritional or health beneficial characteristics demand a rigorous assessment of their safety and nutritional impact. The question has been addressed whether the safety assessment framework as developed for genetically modified (GM) foods with improved input traits, equally applies to these new types of foods (European Network on the Safety Assessment of GM Food Crops, ENTRANSFOOD, Food and Chemical Toxicology 42, 2004, 1043-1202) and the Task Force of the ILSI International Food Biotechnology Committee (Comprehensive Reviews in Food Science and Food Safety 3, 2004, 36-104). In case of nutritionally enhanced food crops, particular attention must be paid to the choice of the appropriate comparator for safety evaluation. In certain cases not the parent crop, but the food component which level is intentionally high in the GM crop, will be the appropriate comparator. Toxicological and nutritional testing of these types of foods in animals should carefully be considered, in particular with respect to optimised diet composition. Moreover the estimation of anticipated intake levels of these types of foods is important, for certain foods systematic post market monitoring may be considered. The possible occurrence and assessment of unintended effects in GM food crops as result of the genetic modification is a key element in the safety assessment and may be of particular relevance for those crops with specific metabolic pathways modified through the insertion of multiple genes. Detection relies basically on a targeted ap-

proach i.e. comparative analysis of crop specific compositional parameters in the GM and non-GM crop. In order to increase the chances of detecting unintended effects, new profiling techniques like transcriptomics, proteomics and metabolomics have the potential to extend the comparative analyses (non-targeted approaches).

## 1673 SAFETY AND NUTRITIONAL ASSESSMENT OF FOODS AND FEEDS NUTRITIONALLY IMPROVED THROUGH BIOTECHNOLOGY.

I. C. Munro. *CANTOX Health Sciences International, Mississauga, ON, Canada.*

A newly emerging class of biotechnology-derived crops is being developed with a focus on improved nutritionally quality. Nutritionally improved foods should be evaluated for their potential impact on human/animal nutrition and health regardless of the technology used to develop them. The evaluation includes assessing both the change in the composition of the individual foods/feeds or ingredients and the impact of the changes on the overall composition of the diets of the projected population(s). The safety assessment begins with a comparative assessment of the new food/feed with an appropriate comparator that has a history of safe use. Compositional analysis is the starting point for this assessment. Current approaches of targeted compositional analysis are recommended for the detection of any alterations. Biosynthetic and catabolic pathways of the newly expressed trait should be compared for the improved crop and the appropriate conventional counterparts. For nutritionally enhanced or altered products, the dietary exposure to nutrient(s) whose content is changed should be estimated and the appropriate set of studies carried out to assess the nutritional quality and the safety of any newly expressed protein(s) and metabolites. Examples of such studies are structure-activity relationships, *in vitro* determinations of digestibility of the proteins and animal feeding studies with the relevant target species. It is concluded that the food safety and diet-health assessment methods currently employed are sufficiently robust to be applied to nutritionally improved foods.

## 1674 VINYL CHLORIDE: LEGACY AND LESSONS LEARNED.

R. O. McClellan. *Toxicology and Human Health Risk Analysis, Albuquerque, NM.*

Vinyl chloride is a major commodity chemical that has been extensively studied relative to its toxicological and carcinogenic properties. Early research conducted by producers and users of vinyl chloride focused on its toxicological properties. The research results were used in a standard safety factor framework to derive threshold limit values for occupational exposure. Long-term rodent inhalation studies were initiated to investigate the potential for chronic toxicity and carcinogenicity. Almost concurrently, carcinogenic responses were observed in the rodent studies and case reports were published on a finding of a rare cancer, hepatic angiomas in workers exposed to high levels of vinyl chloride. More stringent occupational exposure limits were instituted and further research on vinyl chloride initiated. This included epidemiological studies of workers, animal carcinogenicity bioassays and mechanistic investigations. The initial results, while confirming the carcinogenicity of vinyl chloride in humans and rodents, appeared to yield marked differences in carcinogenic potency in humans and rodents. Further research on the metabolic kinetics and molecular dosimetry of vinyl chloride and its metabolites provided a basis for reconciling the original apparent species differences in potency and provided a mechanistic basis for the very specific carcinogenic response, hepatic angiomas. The more stringent exposure standards have been effective in protecting workers. In retrospect, the research conducted on vinyl chloride may be viewed as a success story for how mechanism-based findings can be used to establish appropriate health protective standards. Moreover, the research approach used with vinyl chloride has served as a template for evaluating the toxicity and carcinogenicity of other chemicals.

## 1675 METABOLISM OF VINYL HALIDES AND REACTIONS OF ELECTROPHILIC PRODUCTS.

F. P. Guengerich. *Biochemistry and Center in Molecular Toxicology, Vanderbilt University, Nashville, TN.*

Interest in vinyl chloride (VC) began >35 years ago with reports of unusual liver tumors in some workers. Our own group began studies on the role of metabolism of VC in collaboration with Drs. Gehring and Watanabe of the Dow group. Cytochrome P450 enzymes, particularly 2E1, oxidize VC to an epoxide, which rearranges to 2-chloroacetaldehyde. The epoxide reacts with DNA to form N7-guanyl and etheno adducts, and the haloacetaldehyde preferentially reacts with proteins. These paradigms have been extended, with consideration of roles of acyl

halides as well, to other important vinyl halides including vinylidene chloride, trichloroethylene, and perchloroethylene. Questions still exist about the halide order in the toxicities of vinyl halides. The work with VC stimulated interest in etheno DNA adducts, which have now been identified as products of oxidation of endogenous lipids. These studies provide perspective on the balance of cancer attributable to xenobiotics vs. endogenous processes in risk assessment. (Supported in part by USPHS R01 ES02205, R35 CA44353, R01 ES10546, and P30 ES00267)

## 1676 VINYL CHLORIDE: ESTABLISHING THE ROLE OF DOSIMETRY IN RISK ASSESSMENT.

M. E. Andersen. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Non-linear clearance of drugs such as aspirin and ethanol became well-established in the 1960s. High doses routinely used in long term toxicity testing were expected to cause saturation of clearance pathways, accumulation of test compounds, and toxic consequences. Scientists at Dow Chemical Company, led by Dr. Perry Gehring, began routine evaluations of the metabolism and kinetics of test commodity compounds in the early 1970s and also developed pharmacokinetic (PK) models. The highlight of this body of work was association of the carcinogenic responses of vinyl chloride (VC) with amounts of vinyl chloride (VC) metabolized. Studies with <sup>14</sup>C-VC estimated total amount metabolized and a novel closed atmosphere metabolism chamber permitted assessment of metabolic rate constants. In addition to use of dosimetry to infer the mode of action of VC metabolites, the PK tools developed were subsequently applied by other Dow scientists, their collaborators, and external groups of toxicologists to create more complete physiologically based pharmacokinetic (PBPK) models for inhaled and ingested toxicants that supported dose, dose-route and interspecies extrapolations of kinetics. The expansion of PK and PBPK approaches in dose-response assessment and chemical risk assessment over the past 3 decades owe much to the initial applications of these tools with VC. This talk provides a personal overview of the history of PK modeling in toxicology and dose-response assessment tracing the relationship of the applications of the methods with VC to present more widespread applications of PBPK models with many different types of chemicals, including inhaled organic chemicals, persistent organic pollutants, respiratory tract irritants, metals, and endocrine active compounds.

## 1677 VINYL CHLORIDE: TOXICOLOGICAL AND CARCINOGENIC RESPONSES IN HUMANS AND LABORATORY ANIMALS.

R. O. McClellan. *Toxicology and Human Health Risk Analysis, Albuquerque, NM.*

Vinyl chloride monomer (VCM) is a major commodity chemical. In the 1930s, it was discovered that VCM could be polymerized to polyvinyl VC (PVC), a discovery that led to world-wide production and use of PVC. Using approaches that were contemporary for 1950-1960 the acute toxicity of VC was investigated in multiple species. Results on non-cancer endpoints were used in a traditional safety factor approach to set threshold limit values. In the rapidly developing PVC industry some exposures occurred at levels sufficient to cause scleroderma, e.g. coldness and numbness of the hands and acro-osteolysis of the terminal phalanges. In 1973, an astute physician observed three cases of a rare cancer, hepatic angiosarcoma, and determined that all three patients worked in a PVC production facility as cleaners of polymerization autoclave reactors. Almost concurrently, preliminary results from high level VCM inhalation studies with rats and mice indicated that VCM was carcinogenic. The finding of a carcinogenic response in both workers and laboratory animals immediately triggered extensive new research including clinical and epidemiological studies on VCM workers, carcinogenicity studies in laboratory animals and mechanistic studies. These studies soon confirmed the carcinogenicity of VCM and shifted attention to understanding the site-specificity of the cancers and the nature of the exposure-cancer response relationship. The studies are remarkable in many ways; collaboration of industrial, academic and government scientists, use of state-of-the-art techniques, study of a wide range of exposure concentrations, introduction of kinetic modeling that facilitated a shift from an exposure to a dose metric, attention to inter-species extrapolations and a move from definition of hazard to quantification of cancer risk. Findings in each area will be reviewed to gain insight into lessons learned from evaluating risks of exposure to VCM and how VCM experience has impacted the field of chemical toxicology and risk assessment. Opportunities will be identified for further use of the VCM experience to advance these fields.

## 1678 CONFLICT OF INTEREST.

J. P. Maurissen<sup>2</sup> and S. G. Gilbert<sup>1</sup>. <sup>1</sup>INND, Seattle, WA and <sup>2</sup>Neurotoxicology, Dow Chemical Company, Midland, MI.

The conflict of interest issue has recently been the subject of much attention from the points of view of editorial policy and electoral policy to scientific advisory boards. The perception is that some scientists performing or evaluating research

may be tempted to overlook an adverse effect in a research project (hoping to please the sponsor and to secure future funding from the same source); likewise, other scientists may be tempted to overemphasize the significance of a positive result in their research (to gain access to additional grant support from private or institutional foundations or to favor donations from the general public). A number of scientific journals (including Toxicological Sciences) have recently addressed or reviewed the issue of conflict of interest. Similarly, a number of institutions have also codified their policy to help in the selection of members for scientific advisory boards. A number of questions can be asked around several themes: What is a financial conflict of interest? What about grant renewal, university tenure? What is the importance of non-financial conflicts of interest in the decision process, e.g., number of publications, academic competition, public/professional visibility, satisfaction of accomplishment, loyalty? When does a conflict start and stop being a conflict, apparent or real? Should a scientist with a real conflict of interest be prevented from publishing an editorial or a review paper on the basis of a conflict of interest? What if the conflict is not real but perceived? Should a perceived conflict of interest be enough to disqualify an otherwise competent scientist from election to a panel? What is the role of full disclosure in a successful conflict of interest policy? A group of five panelists (from diverse backgrounds) will present their views concerning the conflict of interest.

## 1679 WHAT IS A "CONFLICT OF INTEREST"?

T. L. Beauchamp. *Kennedy Institute of Ethics, Georgetown University, Washington, DC.* Sponsor: S. Gilbert.

What is a "conflict of interest"? It is too vague to say that it is "A conflict between private interests and official responsibilities of a person in a position of trust." However, it is very difficult to construct a definition that is not at once both too broad (prohibiting too much) and too narrow (allowing too much). Many definitions are also impracticable. A better definition will appeal to the need for impartiality in acting on duties of loyalty to protect certain interests when those interests come into conflict with a personal interest or a duty of loyalty to act in the interests of a different person, group, or institution. No definition will escape the need to construct practical rules of COI. Most institutions now have some rules governing financial COI, but none (or very few) regarding nonfinancial COIs. The following relationships are examples of relationships in large institutions that constitute a conflict of interest when one person is in a position to hire, promote, or advance another person: 1. They have entered into a personal financial relationship with each other. 2. Their relationship is more than professional (regardless of whether the relationship is a positive or a negative one); this includes but is not limited to ...close personal friendship; ...family connection (spouse, domestic partner, parent, son or daughter, cousin to the second degree); ...romantic relationship; ...relationship of trust (lawyer, doctor, trustee, consultant and the like). 3. They have collaborated on a grant or have coauthored or coedited a paper/article/book together. 4. Either has served as a mentor to the other. It is controversial how to implement COI rules and who should determine whether there really is a conflict, by contrast to a perceived conflict. Many believe that it should be left up to each individual person who potentially has a COI. Recusal is often handled in the same manner. But this "personal disclosure" solution is too subjective. Policies so constructed have generally failed to be serious monitors of COI.

## 1680 CONFLICT OF INTEREST IN THE PUBLICATION PROCESS.

L. D. Lehman-McKeeman. *Bristol Myers Squibb Co., Princeton, NJ.*

Conflicts of interest may occur in scientific research in situations where financial or other personal considerations may bias the professional judgment of an author conducting or reporting research or a reviewer involved in the peer review process. Conflicts may be real or perceived, harmful or insignificant. Whereas such conflicts may represent the potential for compromised judgment, they do not necessarily indicate the likelihood that such bias will occur. However, there is increasing sensitivity to the subject of conflict of interest disclosures relative to the publication of peer-reviewed manuscripts, and over the past several years, many biomedical journals including Toxicological Sciences, have adopted policies governing the need for full disclosure of potential conflicts of interest. The International Committee of Medical Journal Editors (ICMJE) has published uniform requirements for manuscripts submitted to biomedical journals, and Toxicological Sciences ascribes in principle to this policy (<http://www.icmje.org/index>). The need for the conflict of interest policy is not driven by the sense that the integrity of toxicological research has been compromised. Rather it is based on the recognition that such disclosures serve to inform readers about any special interests, enabling them to make informed judgments about the potential significance or lack of significance of a disclosure. Similarly, disclosures by reviewers serve to inform the Editor regarding any conflict of interest that could bias their opinions of a manuscript, and reviewers are asked to

disqualify themselves when they believe it is appropriate to do so. For all manuscripts, authors and reviewers are asked to state explicitly whether any conflicts exist. When noted by authors, these disclosures are indicated in the published article. Disclosing conflicts of interest does not ensure a faultless publication process. However, providing such information helps to authors, reviewers and readers to focus on the quality and reliability of the data, and ultimately to collectively benefit the scientific integrity of the journal.

## 1681 ROLE OF GOVERNMENT OVERSIGHT.

*B. A. Schwetz, Office for Human Research Protections, Rockville, MD.*

Conflicts of interest have undermined the trust of the public in research involving animals and humans, whether real or perceived. Many government and nongovernment institutions have developed guidelines to identify and handle competing interests that could compromise the integrity of decisions made by their employees or constituents. Financial conflicts of interest have received more attention than either institutional or professional conflicts of interest, because of available guidelines or perhaps because they are easier to document and quantify, not because they are necessarily more important than institutional or professional conflicts of interest. Many, but not all, institutions have developed internal guidance on conflicts of interest. Federal and state agencies and departments have regulations and guidances that relate to conflicts of interest, primarily for conduct of research involving animals and humans and participation in federal advisory committees. Conflicts of interest are not inherently wrong and are hard to avoid. However, special steps are needed to assure that conflicting and competing interests do not interfere with the responsible conduct of research and other professional and scientific activities.

## 1682 MANAGING CONFLICTS OF INTEREST: DOES DISCLOSURE GO FAR ENOUGH?

*M. Goozner, Cntr for Sciences. in the Public Instrst, Washington, DC. Sponsor: S. Gilbert.*

The laws designed to protect the public in environmental, health, nutrition and related areas recognize that sound regulatory policy depends on sound science. At the same time, businesses subject to regulatory decision making seek to minimize regulatory costs and limit the level of government intervention in the economy. Business interests seek to intervene in the regulatory process by funding scientists whose conclusions are in line with their desired regulatory outcomes. The influence of funding sources on outcomes of scientific research has been well documented. Industry-funded science is more likely to reflect the economic interests of funders. Findings that negatively influence funders' interests are less likely to appear in the literature. Researchers with industry-backing are better positioned in terms of financial support and other benefits to serve on government scientific advisory committees, appear before regulatory bodies and testify before Congress. Gatekeepers of scientific integrity have opted for conflict of interest disclosure policies as the best way to manage these competing interests. Leading scientific journals have adopted disclosure policies. Government agencies are supposed to prohibit conflicts of interest on scientific advisory panels and balance the points of view on committees. Evidence is mounting that disclosure is a failed policy for managing conflicts of interest. Government agencies increasingly waive or overlook conflicts of interest in staffing their advisory committees. Regulatory agencies like the FDA are increasingly funded by industry through user fees and depend on industry-funded science in making regulatory decisions. New strategies are needed to mitigate the effects of scientific conflicts of interest on the regulatory process. Government agencies must adopt new standards of scientific independence for its in-house staff. Congress must provide increased funding for independent scientists to conduct the studies that will determine regulatory decisions. The legal structure must be changed so that decision makers are mandated to rely on independent science when making regulatory decisions.

## 1683 CONFLICT OF INTEREST AND BIAS: A VIEWPOINT FROM INDUSTRY.

*C. Barrow, Dow Chemical Company, Washington, DC.*

In recent years, some groups have questioned the reliability and credibility of public health and environmental research conducted and/or sponsored by industry. Some have even suggested that all industry conducted or funded science be barred from use in weight-of-the-evidence risk assessment decisions and industry scientists be barred from peer review panels. Despite such allegations, industry conducted and funded scientific studies have long been and continue to be recognized by government agencies, many NGOs, and the scientific community at large as necessary and valuable contributions to the understanding of human health and environmental effects of chemical substances. It is clear that in many instances, there is an under-

appreciation of the exceptional measures employed by industry to assure the quality and credibility of scientific studies and data. These include for example: • conducting studies under Good Laboratory Practice (GLP) regulations which entails full availability of the raw, quality-assured data files, • the use of approved national and international protocols and test guidelines, • publication in the peer-reviewed literature, service on editorial boards, and participation on government sponsored peer review boards and committees. Further confidence in the scientific standards and processes of industry generated information is underpinned by the recognition of the EPA that of the various types of data and information employed in risk assessment, GLP derived data will most readily meet the requirements of the Information Quality Act<sup>1</sup>. As appropriately stated by the Society of Toxicology research should be judged on the basis of scientific merit, without regard for the funding source or where the studies are conducted (e.g. academia, government, or industry)<sup>2</sup>. <sup>1</sup>USEPA 260/R-02-008. Guidelines for Ensuring and Maximizing the Quality, Objectivity, Utility, and Integrity of Information Disseminated by the Environmental Protection Agency, October, 2002. <sup>2</sup>Principles for Research Priorities in Toxicology. Adopted by the Society of Toxicology, January 1998.

## 1684 DOSIMETRY AND REPRODUCTIVE/DEVELOPMENTAL STUDY DESIGN AND INTERPRETATION FOR RISK OR SAFETY ASSESSMENT.

*E. Carney<sup>2</sup> and H. A. Barton<sup>1</sup>. <sup>1</sup>USEPA, Research Triangle Park, NC and <sup>2</sup>Toxicology & Environmental Research & Consulting, Dow Chemical Company, Midland, MI.*

Reproductive and developmental toxicity studies in animals are utilized in assessing the potential adverse effects of chemicals and drugs in pregnant women, nursing infants, and children. The results of these studies are extrapolated to humans primarily based on the dose or the exposure in the mother due to the complexity of describing the dose, pharmacokinetics, and tissue dosimetry of chemicals during pregnancy, lactation, and postweaning periods. Transporters are increasingly recognized as a key factor in dosimetry during early life along with development of metabolism and other clearance processes. For pharmaceuticals, measurement of maternal blood levels, and sometimes placental and lactational transfer, are addressed for safety assessment. Classical and physiologically-based pharmacokinetic analyses are increasingly being applied across these life stages of reproduction. Identification of the critical window of sensitivity, and how this critical period and its associated pharmacokinetics correlates with humans, is a significant challenge. This workshop will present approaches to characterizing measures of internal dose in reproductive and developmental toxicity studies, and how this impacts study designs and applications for safety and risk assessment.

## 1685 LIFE-STAGE DEPENDENT DOSIMETRY AND POTENTIAL IMPACTS ON RISK ASSESSMENT.

*H. A. Barton, USEPA, Research Triangle Park, NC.*

Risk assessments for environmental chemicals are typically based on exposures in the mother when effects are observed in reproductive or developmental toxicity studies in animals. Knowledge of the windows of susceptibility and pharmacokinetic changes occurring during development facilitate the use of measures of internal dose in risk assessments. Issues and approaches, including pharmacokinetic modeling, will be described for selected chemicals including perfluorooctanoic acid (PFOA). Evaluation of potential differences in susceptibility to cancer with early life exposures requires distinguishing between differences in exposure and response. For a number of chemicals acting through mutagenic modes of action, specific experimental designs use defined injection doses to the animals at different ages. Therefore, in the absence of adequate pharmacokinetic modeling or experimental data, it is unclear to what extent the differences in tumor incidences reflect differences in exposure or response. Effects were observed in offspring in one-generation studies in rats exposed to perfluorooctanoic acid. One compartment pharmacokinetic analyses were undertaken to describe the average daily area under the curve in blood of PFOA for pregnancy, lactation, post-weaning pups, and male and female adults following gavage dosing. PFOA urinary clearance changes dramatically with age likely due to developmental changes in an organic anion transporter in rat kidney. These estimates were compared to maternal dosing to gain insight into the range of risk estimates that would be obtained depending upon when the critical window occurred. (This abstract does not represent EPA policy.)

## 1686 INCORPORATING DOSIMETRY IN DEVELOPMENTAL TOXICITY ASSESSMENTS: STUDY DESIGN AND DATA INTERPRETATION.

*E. Mylchreest and S. A. Gannon, DuPont Haskell Laboratory, Newark, DE.*

Standard developmental toxicity testing of chemicals generally does not include determination of maternal and developmental dosimetry. Generally, the need for developmental dosimetry data is prompted by the prior observation of developmental

toxicity, and the design of a useful dosimetry study in developing animals is facilitated by prior knowledge of the critical window of exposure during development as well as some knowledge of the toxicokinetics of the chemical. Unfortunately, for most chemicals such information is rarely available, particularly the critical window of exposure and the active metabolite(s) are not known, and selection of sample time points is based on technical feasibility (e.g. whole embryos can be harvested at early time points; placental and fetal blood samples can be obtained at later stages). In the case of perfluorooctanoic acid (PFOA), dosimetry studies were prompted by the observation of a small increase in offspring mortality in the first generation of a two-generation reproduction study. Previous toxicokinetic data indicated that PFOA is not readily metabolized and has a short half-life in adult female rats, but little or no data was available in pregnant or lactating rats. The concentration of PFOA was determined in maternal milk and plasma, placenta, amniotic fluid, and conceptus (embryo, fetus, pup, and fetal and pup plasma) following repeated oral dosing of the dam using 3 graded dose levels during gestation and lactation. PFOA in maternal milk was ten times less than maternal plasma (steady state), which was twice that in fetal plasma near term. Milk levels were generally comparable to pup plasma, which decreased from postnatal day 3 to 7, and were similar thereafter. PFOA was detected in the early embryo, amniotic fluid and placenta. Statements can be made about the relative concentration of PFOA in mother and conceptus but interpretation of the data is challenging due to the lack of a known critical developmental period for induction of offspring mortality.

## 1687 TRANSPORTERS DURING DEVELOPMENT.

C. D. Klaassen. *Pharmacology, U Kansas Med. Ctr, Kansas City, KS.*

Xenobiotics have been thought to distribute into and out of tissues by simple diffusion of the lipid soluble chemicals. However, it has not been clear how xenobiotics could efflux from tissues after they are made much more water soluble by phase I and II biotransformation enzymes. It is now known that there are transport proteins in cell membranes that can transport xenobiotics and their metabolites out of cells. Two important family of transporters that perform these efflux functions are the Multidrug Resistance Proteins (Mdrs) and Multidrug Resistance Associated Proteins (Mrps). These proteins are most abundant in liver and kidney for excreting chemicals, and in brain capillaries where they prevent many chemicals from entering the brain. In addition to these efflux transporters, there are also uptake transporters that aid in the distribution of xenobiotics into cells. Three families of transporters are especially important for uptake: namely Organic Anion Transporters (Oats), Organic Anion Transporting Polypeptides (Oatps), and Organic Cation Transporters (Octs). These transporters are especially predominant in liver and kidney for the elimination of xenobiotics. Some of these transporters are expressed in the placentae similarly to that in liver and kidney, suggesting they might protect the fetus from xenobiotics. The Mdr transporter has been shown as one of those transporters that protect the fetus from xenobiotics.

## 1688 PHARMACEUTICAL PERSPECTIVE ON DOSIMETRY IN REPRODUCTIVE AND DEVELOPMENTAL STUDIES AND THE IMPACT ON DRUG DEVELOPMENT.

G. Pastino. *Drug Metabolism and Pharmacokinetics, Schering Plough Research Institute, Lafayette, NJ.*

Over the past decade, the FDA and others have become increasingly concerned about the safety and efficacy of drugs in the pediatric population. Federal regulations have been developed which mandate pharmaceutical companies to provide information on the safe use of drugs in this population. Exceptions may be made on a case by case basis but only in instances in which children will not be exposed to the drug. Information that may guide the safe and effective use in children can be obtained during pre-clinical drug development through the conduct of reproductive and developmental toxicity studies or studies in juvenile animals. However, these studies generally do not characterize the pharmacokinetic profile and dosimetry. Clinical trials are also conducted in children, the nature and timing of which depends on the specific drug being developed. At a minimum, studies are required to determine the dose that produces similar exposure to that in adults at the recommended dose taking into consideration formulation issues. This is true when the indication, the disease process and the outcome of therapy are similar between adults and children. However, when a drug will be used to treat a disease primarily affecting children, or if the disease is life threatening and there are no other therapeutic options, more extensive safety and efficacy information in children is required. There are several empirical limitations in the conduct of clinical PK studies in children, such as small blood volumes and bioanalytical assays requiring extreme sensitivity. There are also many differences between adults and children in physiological and biochemical processes that may alter the PK profile in children (i.e., absorption, metabolism, protein binding, excretion) all of which need to be considered si-

multaneously in order to accurately assess safety in children. A potentially useful tool for accomplishing this task is the development and appropriate application of physiologically based pharmacokinetic models in juvenile animals and children.

## 1689 PBPK MODELING OF EARLY LIFESTAGES AND ESTIMATION OF DOSIMETRY FOR RISK ASSESSMENT.

H. Clewell<sup>1</sup> and R. Clewell<sup>2</sup>. <sup>1</sup>*ENVIRON, Ruston, LA* and <sup>2</sup>*CIIT Centers for Health Research, Research Triangle Park, NC.*

The purpose of dosimetry in human health risk/safety assessment is to provide a quantitative estimate of an exposure concentration or dose in the human population of interest that would be equivalent, from the viewpoint of tissue exposure, to a particular exposure concentration or dose (e.g., NOAEL) derived from toxicity studies. Over time, risk assessment dosimetry has evolved from methods based solely on administered dose or exposure concentration to methods that attempt to define equivalent exposures of a specific target tissue to a chemical or its active metabolite. Recently, there have also been increasing efforts to extend dosimetric methods to early lifestages, focusing on the exposure of the fetus or neonate rather than just the exposure of the mother. This presentation will describe the use of physiologically based pharmacokinetic (PBPK) modeling to provide dosimetric evaluation of gestational, lactational, and neonatal exposures. Specifically, early life PBPK modeling will be discussed from the viewpoint of elucidating the principal factors that must be considered in performing dosimetry for perinatal exposures. Appropriate early life dosimetry is critically dependent on several factors: the lifestage at which the effect of the chemical occurs (gestation, lactation, post-weaning), the kinetic characteristics of the chemical (persistence, bioaccumulation), and the mode of action for the chemical interaction with the target tissue. A categorical default approach for early life dosimetry is proposed, based on equivalent body burden (average tissue concentration) during the window of developmental susceptibility, and using simple compartmental modeling constructs (intake, volume of distribution, clearance). Examples of the approach are provided for both non-persistent (perchlorate) and persistent (Mirex) chemicals.

## 1690 SKIN MODEL SELECTION FOR SAFETY ASSESSMENT OF TOPICAL DRUG PRODUCTS: REGULATORY AND INDUSTRY PERSPECTIVES.

G. G. Qiao. *CVM and CDER, USFDA, Rockville, MD.*

Improper skin model selection in drug R&D and regulatory approval may under- or over-estimate systemic toxicity risk of a topical drug, resulting in significant resource and public health costs. Comparison and careful selection of *in vitro* versus *in vivo*, animal versus human, healthy versus diseased skin models under various exposure conditions during topical drug development and approval are critical. However, our knowledge base in chemical dermal absorption is mainly built on the healthy skin absorption data. For this reason, the regulatory evaluation of drug safety profile has been largely based on healthy skin study data submitted by drug sponsors, especially in the animal drug sector. FDA, per its general guidelines, requires target animal safety profiles to be tested in healthy subjects for veterinary drug products including topical drugs to be applied to diseased skin. Human dermal drug safety testing employs a wider range of animal models for various purposes. The question is whether the healthy skin data can predict what happens in patients with compromised skin and whether our testing methods are reflecting the most recent progresses in this field. Data have suggested diseased or damaged skin can compromise skin barrier function, and thus enhance systemic as well as local toxicity risk. Those issues deserve closer research and regulatory attention. Through this workshop, impact of compromised skin barrier function by skin diseases or by other exposure variables on systemic versus local, short term versus long term risk are addressed from academic research, industrial R&D, and regulatory approval perspectives. Comparative skin histology, skin biology, skin barrier function assessment, dermal absorption, cutaneous drug disposition, and government guidelines for safety testing of human and animal dermal drugs are to be discussed with research data. Inputs from the scientific community on those issues are helpful for future government guideline revisions.

## 1691 COMPARATIVE MODEL SELECTION BETWEEN SPECIES AND ABNORMAL SKIN: MORPHOLOGY, DERMAL DRUG DELIVERY, AND OVERALL BARRIER FUNCTION.

N. A. Monteiro-Riviere. *Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.*

The focus of this presentation is to overview the basic anatomy, biology and barrier functions of human and animal skin in the context of chemical and drug absorption. Several anatomical and physiological factors that can influence the penetra-

tion of a compound demonstrate species and body site differences, making correct selection of the animal model an extremely important component in assessing the penetration of a compound. What animal models may serve as surrogates for humans? The epidermal stratum corneum with its lipid bilayers serves as the rate limiting barrier to absorption for most topically applied chemicals. Skin permeability may be increased or decreased depending on the condition of the skin. Certain skin diseases, as well as vehicle selection, may have an effect on compound penetration. Any disease process that alters the normal anatomical integrity would be expected to modulate chemical percutaneous absorption. Repeated dermal exposure of some compounds can influence the rate of penetration of these compounds through modification of these barrier structures. These factors will be thoroughly discussed in this presentation.

## 1692 SKIN MODEL SELECTION IN TOPICAL DRUG R&D AND REGULATORY APPROVAL: CHALLENGES AND SOLUTIONS IN DRUG SAFETY ASSESSMENT.

G. G. Qiao<sup>1</sup> and A. C. Jacobs<sup>2</sup>. <sup>1</sup>CVM, USFDA, Rockville, MD and <sup>2</sup>CDER, USFDA, Rockville, MD.

Dermal model selection for dermal drug safety testing is complicated by the fact that skin is the application site, the target site, and the port of entry for both systemic activity and toxicity. A careful configuration of a dermal test system regarding its biological, drug-related, and environmental (temperature and relative humidity) variables is essential for successful R&D and regulatory approval of a topical drug. This presentation is to focus on various factors influencing local disposition, systemic absorption, and thus toxicity of a topically applied drug along with supporting research data. Skin pathological condition (disease type/stage and skin pH), skin surface preparation (cleaning, tape stripping, and pre-exposure), dosing site selection (location, site number, and total area), skin barrier function assessment (TEWL and skin hydration), dose formulation and dosage, application procedure (alternative route, occlusion), drug-drug interaction, environmental variables, and dermal data interpretation are among the most relevant factors for assessing local and systemic safety profiles of a drug. Blood AUC may serve as a key parameter in selecting an *in vivo* model if correct extrapolations can be made. For example, if the targeted clinical patients with skin diseases have a risk of larger dermal absorption, the drug may need to be tested for systemic safety in a skin model that gives enhanced dermal absorption (e.g., by removal of the stratum corneum or via subcutaneous injection of the dose when another test model/species is not proper). Similarly, different safety tests require different test models, approaches, and study designs. Gaps between FDA target animal safety guidelines and the latest progress in dermal toxicology research along with potential solutions or alternatives are to be discussed while balancing the R&D and regulatory approval needs.

## 1693 TEST METHODS AND MODELS USED IN THE DEVELOPMENT OF TOPICALLY-APPLIED PRODUCTS.

J. F. Nash. *Central Product Safety, Procter & Gamble Company, Cincinnati, OH.*

A unique aspect of the toxicological evaluation of topically applied products is that the application and target tissue are clearly visible. As such, the health status of the application site, i.e., skin, and the intended use/benefits of the product are important factors when considering human health risk assessment. Preclinical models, *in vitro* or *in vivo*, used to evaluate dermal toxicity, e.g., irritation, utilize ideal skin in combination with exaggerated exposures to the chemical of interest. Beyond such local effects, establishing bioavailability of topically applied compounds is critically important since progression to systemic evaluations is in many cases predicated on the dermal penetration of the chemical. *In vitro* penetration studies using skin explants or more detailed *in vivo* animal pharmacokinetic studies are used to determine absorption into and through the skin. These experiments also utilize non-compromised skin and a range of doses. Later stages of safety testing may include the evaluation of product on targeted lesions or diseased skin. For OTC drug or cosmetic products, human safety evaluations may use subjects with skin disorders or sensitive skin. For example, to establish the human safety of a topically applied facial moisturizer containing salicylic acid, human pharmacokinetic studies were conducted in subjects with normal, acneogenic and photoaged skin. The latter two cohorts were considered to be skin conditions of targeted users of this product. In this example, there was no difference in the systemic bioavailability of salicylic acid among these groups after single or repeated application. Barrier function was uncompromised in these subjects which may account for the similarities among these groups. Thus, there is the need to consider the barrier status of the skin when considering irritation, sensitization, and photo-mediated toxicities. Human safety assessment of topically applied products should include the impact of the health status of skin either empirically, i.e., experimentally, or with the incorporation of conservative safety margins.

## 1694 GUIDANCE AND ANIMAL MODEL SELECTION FOR SAFETY ASSESSMENTS FOR DERMAL DRUG PRODUCT DEVELOPMENT AND APPROVAL.

A. Jacobs<sup>1</sup> and G. Qiao<sup>2</sup>. <sup>1</sup>CDER USFDA, Rockville, MD and <sup>2</sup>CVM USFDA, Rockville, MD.

The International Conference on Harmonization (ICH) Guidelines describe in general when nonclinical studies are needed to support human and animal drug development. These can be followed for general aspects of studies on safety pharmacology, genotoxicity, developmental/reproductive toxicity, and carcinogenicity. However, there are a number of dermal drug-specific issues that need to be addressed, including local tolerance, hypersensitivity, photo effects, and excipients, as well as the appropriate animal model selection. The Center for Drug Evaluation and Research (CDER)/FDA has separate guidances for photosafety testing, immunotoxicity testing, testing of excipients, and juvenile studies. Dermally administered human drugs may be applied to healthy skin, atopic skin, broken skin, psoriatic skin, or ulcerated skin. Although the skin of minipigs best mimics normal human skin, many nonclinical studies for dermal drug products are conducted in other species for a variety of reasons. For example, study of the systemic effects of a dermally applied drug in rats or rabbits may be appropriate for drugs to be applied to the skin of persons with atopic dermatitis. The most appropriate animal model will depend on the endpoint being evaluated (e.g., irritation, sensitization, systemic absorption/toxicity, reproductive/developmental effects, photo effects, or wound-healing effects), the formulation (e.g., patches vs creams vs solution), and the indication (e.g., wound-healing vs atopic dermatitis vs acne). Similarly, the same considerations are widely applicable to animal dermal drug development although a target species is often used since it is simply the best test model and is readily available. However, the impact of skin conditions and exposure variables on systemic and local toxic risk in animal dermal drug development and approval has been largely ignored.

## 1695 CONDUCTING A COMPREHENSIVE TOXICOLOGICAL AND SAFETY EVALUATION OF NANOMATERIALS: CURRENT CHALLENGES AND DATA NEEDS.

M. P. Holsapple<sup>1</sup> and W. H. Farland<sup>2</sup>. <sup>1</sup>HESI, Washington, DC and <sup>2</sup>USEPA, Washington, DC.

Nanomaterials are currently being used in a variety of commercial products including fabrics for clothing, circuitry for electronic components, and delivery systems for pharmaceuticals. In addition, nanotechnology could have a dramatic impact on a number of additional applications such as energy generation and distribution, food processing, and building construction. In light of numerous potential societal benefits of nanotechnology, a systematic approach needs to be developed to conduct a comprehensive toxicological and safety evaluation for nanomaterials. The goal of this Roundtable will be to present the current state-of-the-science associated with a characterization of the safety of nanomaterials. The key points to be addressed will be what kinds of data are needed with an emphasis on testing strategies for exposure assessment and hazard identification. The discussion of exposure assessment will highlight inhalation as a critical route of exposure as well as address the importance of dermal and other routes of exposure. The discussion of hazard identification will balance the need for new approaches as a result of the unique modes of action of nanomaterials with the ability to capitalize on existing methods. This roundtable will also explore how the unique properties associated with nanomaterials should be integrated into the testing strategies, the distinctive environmental and human exposures that result from nanomaterials, and the current challenges with regard to conducting a comprehensive toxicological and safety evaluation of nanomaterials.

## 1696 INHALATION AS A CRITICAL EXPOSURE ROUTE FOR EVALUATING NANOMATERIALS.

T. D. Landry. *Toxicology and Environmental Research and Consulting, The Dow Chemical Company, Midland, MI.*

Discrete particles in the nanoscale size range will predominantly deposit in the respiratory tract by diffusion. Once deposited, nanoparticles (NP, particles < 100nm) may cross biological membranes and access tissues to a substantially greater extent than would occur with larger particles. Inflammation has been observed with some NPs in the respiratory tract, likely reflecting the relatively large surface area of NPs. The accentuated inflammation may reflect physiologic conditions similar to studies in which there was particle overload of (rat) pulmonary clearance. Effects beyond the respiratory tract may also occur, with current investigations directed towards cardiovascular effects. Understanding the exposure and effects of discrete nanoparticles will be an important task for toxicologists. However, with the broad applications of nanomaterials for nanotechnology, a simple focus on discrete nanoparticles

is not adequate. Very high forces draw the NPs to aggregate and agglomerate, markedly affecting their propensity to become airborne, as well as their aerodynamic diameter. Many uses of nanomaterials in composites and structures severely limit or preclude airborne exposure. However, disaggregation, deagglomeration, and dissolution in biological fluids are other considerations that may influence health effects. Although inhalation will be a critical route of exposure in some cases, a full understanding of exposure and fate requires consideration of the technology applications and physical state of the nanomaterials.

#### 1697 DERMAL EXPOSURE ROUTE FOR EVALUATING NANOMATERIALS.

N. A. Monteiro-Riviere, *Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.*

Skin can serve as a primary route of exposure to toxicants including novel nanoparticles (NP). Skin is unique because it is a potential route of occupational and /or environmental exposure to NP and also provides an environment within the avascular epidermis where particles could potentially lodge and not be susceptible to removal by phagocytosis. Can manufactured nanoparticles gain access to the epidermis? Would such particles preferentially locate in the lipids of the stratum corneum after topical exposure? Can keratinocytes exposed to NP elicit an early inflammatory response?

#### 1698 THE VALUE OF EXISTING TESTING STRATEGIES FOR EVALUATING NANOMATERIALS.

J. M. Carter, *Central Product Safety, Procter & Gamble, Cincinnati, OH.*

Information regarding the potential adverse effects of nanomaterials is currently limited. Although engineered nanoparticles have not been systemically tested, a few inhalation and epidemiology studies using ambient ultrafine particles have yielded some results for which preliminary conclusions can be drawn. Additionally, several studies using nano-sized particles have shed some light on the biokinetics and biodistribution of nanomaterials once inhaled or ingested. Pharmaceutical applications have also been a source of information regarding the potential translocation of nanoparticles from the site of exposure to remote areas throughout the body. While much speculation exists regarding the unique hazard of nanomaterials compared to bulk materials of like chemistry, current traditional toxicity testing methods have been used to identify hazards for nanomaterials. Effects from inhalation of micron-sized particles are generally restricted to the lung, or portal of entry, with no systemic distribution. Therefore, traditional inhalation toxicology studies have been typically restricted to studying effects directly related to the lung. Because more is known today regarding the kinetics and distribution of nanoparticles functional endpoints can be expanded beyond the traditional route of entry effect to include systemic effects. Using a combination of short-term mechanistic studies, *in vitro* studies and ultrafine-particle epidemiological studies represent important enhancements to the traditional inhalation toxicity assays. Integrating these traditional tools increase our ability for hazard identification of nanomaterials, a key first step in the risk assessment process.

#### 1699 MODE OF ACTION CONSIDERATIONS IN THE EVALUATION OF SAFETY OF ENGINEERED NANOSCALE MATERIALS.

N. J. Walker, *NIEHS, Research Triangle Park, NC.*

Nanoscale materials can be broadly defined as materials that have at least one critical dimension less than 100nm. While there has been considerable research on ambient ultrafine particles, the characterization of the potential health impact of engineered nanoscale materials that are produced through nanotechnology is an emerging issue of considerable discussion and debate. The diversity of size, aspect, chemical composition, surface chemistry and coating for engineered nanoscale materials raises multiple issues for the evaluation of their potential health impact. Namely (1) what are some of the anticipated modes of action and are there unique physicochemical properties that translate into novel modes of action for these materials? (2) what are the best experimental strategies to address recognized and novel modes of action? (3) can evaluation of a core set of properties or test substances be used for the prediction of effects for a broader set of nanoscale materials? (4) Can key parameters be identified to help ensure the development of safe nanoscale materials?

#### 1700 SUPPORT VECTOR MACHINE ALGORITHM FOR THE PREDICTION OF GENE FUNCTION USING A LARGE CHEMOGENOMIC REFERENCE DATABASE.

G. Natsoulis, M. Fielden, W. Hu, S. Dunlea, B. Eynon and K. Kolaja, *Chemogenomics and Toxicology, Iconix Pharmaceuticals Inc., Mountain View, CA.*

Interpretation of toxicogenomic studies are often hampered by the large proportion of genes of unknown function in the rat genome. While unsupervised clustering of genes across many experimental conditions can be used as a means of inferring gene function through guilt by association, such a method is highly dependent on the variables used and suffers from a lack of predictive power. To more accurately ascribe a function to previously uncharacterized genes, a support vector machine (SVM) algorithm was used. Unlike unsupervised classification methods, the robust and sparse SVM algorithm employed herein identifies a small number of variables which best predict gene function. The variables were derived from over 3700 dose-time point-tissue combinations from rats treated with 600 reference drugs, toxicants and biochemical standards in triplicate short term repeat dose studies. Signatures were derived using training sets consisted of genes with known functions related to oxidative stress, acute phase response, PXR activation, cell cycle as well as other toxicological mechanisms of interest. Iterative split-sample cross validation confirmed that these signatures were capable of positively identifying genes known to play a role in these processes, as well as uniquely identifying other genes and ESTs not previously ascribed with the identified function. In total, we were able to assign a putative gene function to over 1200 uncharacterized genes on the CodeLink RU1 microarray. Application of the gene function signatures to genes representing known drug targets revealed putative new roles for these targets, thus suggesting new uses for small molecule inhibitors of these targets. The methodology could also be extended to identify new drug targets in disease related pathways, and for annotating genes in other organisms. These results illustrate the use of supervised classification algorithms and a large reference database of expression profiles for the functional annotation of gene products to aid drug discovery and development.

#### 1701 A MULTIVARIATE DATA ANALYSIS TECHNIQUE FROM THE SYNTHESIS OF A PRIORI KNOWLEDGE AND EMBEDDED STATISTICAL STRUCTURE.

P. Wilson, *Air Force Research Laboratory, Wright-Patterson AFB, OH.* Sponsor: L. Schlagler.

The application of computer technology and statistical techniques in biological research has become necessary when processing high-dimensionality data sets generated from genomic, proteomic and metabolomic research; usually applying multivariate statistical analysis to reduce the data dimensionality to help with visualization of experimental results or to uncover relationships between experimental parameters and biological response. Previous work in multivariate data analysis used optimization techniques like principle component analysis (PCA) or independent component analysis (ICA), which seek out the statistical dependence structure that optimizes variance or statistical independence, respectively. Many reduction techniques rely largely on a priori assumptions about the underlying statistics of the biological process, often resulting in models with dubious suitability. More recently, a technique called network component analysis (NCA) in biological systems has been offered, which uses expert knowledge of the system's pathways to construct a model for optimization in the least-squares sense to the experimental results. A technique is purposed here that combines the advantages of using the NCA approach, which increases the likelihood of a model's veracity, and the advantages of assuming a general statistical structure to the data, which can elucidate new knowledge about a system's topology, or the connectivity between input parameters and output results. By assuming an underlying Markovian process to the data, the next higher order assumption to statistical independence, additional pathways can be conjectured based on optimizing the entropy.

#### 1702 PROBING ALTERATIONS OF THE MITOCHONDRIAL MEMBRANE PROTEOME IN A MURINE MODEL OF PARKINSON'S DISEASE USING LIQUID CHROMATOGRAPHY-TANDEM MASS SPECTROMETRY.

D. R. Cawthon<sup>1</sup>, J. A. Gant<sup>2</sup>, M. B. Goshe<sup>2</sup>, Z. A. Xu<sup>1</sup>, W. Slikker<sup>1</sup> and S. F. Ali<sup>1</sup>. <sup>1</sup>*Neurotoxicology, USFDA/NCTR, Jefferson, AR* and <sup>2</sup>*Molecular and Structural Biochemistry, NC State University, Raleigh, NC.*

An important murine model of Parkinson's Disease utilizes the neurotoxicant 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP). The mechanism of MPTP toxicity is thought to involve accumulation of the MPP<sup>+</sup> (1-methyl-4-phenylpyridinium) metabolite into mitochondria. A wide variety of mitochondrial membrane proteins can then be affected by oxidative damage, post-translational modifications, and/or altered production/degradation. Our understanding of this model of neuro-

toxicity requires in-depth analyses of the mitochondrial membrane proteome, but this has been complicated by their extreme hydrophobicity. Consequently, a method was developed to isolate mitochondrial membrane proteins from brain tissue for analysis by multidimensional liquid chromatography-tandem mass spectrometry. Mice (C57BL/6N) were treated with 2 x 10 mg/kg i.p. doses of MPTP two hours apart and were sacrificed 24 hours after the last dose. Mitochondrial fractions were isolated from murine forebrains following homogenization and centrifugation through Percoll gradients. Mitochondrial membranes were enriched using a sodium carbonate procedure before further purification and analysis. Membrane proteome profiles were obtained for both control and treatment groups. Based on the collected MS/MS spectra, 853 proteins (from ~ 9, 500 peptides) were detected in the sample obtained from the MPTP-treated mice whereas 784 proteins (from ~ 6, 500 peptides) were identified in the control. A total of 422 proteins were common to both samples, which included numerous proteins comprising complex I of the respiratory chain and the subunits of complexes II, III, IV, and V ( $F_0F_1$  ATP synthase). Analysis of the proteins unique to the control or the treated samples revealed alterations in the mitochondrial membrane proteome following MPTP administration. Changes in post-translational modifications, including phosphorylation and oxidative damage, are also being conducted.

#### 1703 NOVEL NETWORK ANALYSIS FOR TOXICOLOGY USING KEYMOLNET.

H. Sato, M. Fukuda, M. Shigetaka, N. Iwasaki, Y. Inoue, Y. Kikushima, K. Nakanishi, M. Ogura, Y. Wakamatsu, H. Kuriki, Y. Mizoguchi, R. Taniguchi, T. Nanba, Y. Ozeki, A. Nogi and A. Itai. *Bioinformatics, Institute of Medicinal Molecular Design, Inc. (IMMD), Tokyo, Japan.* Sponsor: Y. Aoki.

We developed a comprehensive information platform for toxicological, medical, pharmaceutical and life science research in the post-genome era, named KeyMolnet. Using KeyMolnet, we show new approaches to network analysis for DNA microarray data. Thanks to the rapid progress of technology in recent years, it is now possible to obtain very large quantities of gene expression data at a time. However, difficulties still remain in extracting meaningful information from such large quantities of data and in analyzing the relationship between the data and biological function. We therefore developed an advanced tool, which can generate molecular networks upon demand, and can bind them to physiological events, disease and drug information. Here we show novel approaches to the mechanism analysis of the relationship between the effects of cigarette smoke on human airway epithelial cells and lung cancer, using the public DNA microarray data (GEO accession#GSE994, Proc National Acad Sciences US A. 2004 6;101(27):10143-8., PMID: 15210990) and KeyMolnet. In this analysis, the different molecular mechanisms which occur in the airway epithelial cells of current and ex-smokers are discussed, by comparing the networks generated by up-regulated or down-regulated genes, using our original logical operation function without recourse to cluster analysis. KeyMolnet is suggested to be a powerful tool to enable practical approaches to research into biological and toxicological mechanisms, which in turn contributes to discovery in medical, pharmaceutical and life sciences.

#### 1704 BIOINFORMATICS METHODS FOR LIVER CANCER ANALYSIS USING CROSS SPECIES MAPPING BASED ON RAT GENE EXPRESSION PROFILING.

W. Tong<sup>1</sup>, H. Fang<sup>2</sup>, R. Perkins<sup>2</sup>, L. Shi<sup>1</sup>, S. H. Yim<sup>3</sup>, J. M. Ward<sup>3</sup> and Y. P. Dragan. <sup>1</sup>*Systems Toxicology, National Center for Toxicological Research, Jefferson, AR*, <sup>2</sup>*Division of Bioinformatics, Z-Tech, NCTR, Jefferson, AR* and <sup>3</sup>*Center for Cancer Research, National Cancer Institute, Bethesda, MD.*

Liver cancer is a public health concern in many parts of the world. We used albumin-SV40 transgenic rats, which spontaneously develop hepatic neoplasms within 6-9 months, as a model for the liver cancer study. We performed microarray studies on tumor samples obtained from the transgenic rats. Gene expression profiles were generated from two control, two adenoma and two carcinoma samples with a 10K mouse chip using a dye flip approach. Data from microarray analysis of liver tumors from these animals demonstrated an altered gene expression. Our analysis found that 2223 genes were differentially expressed across the sample sets using an F test with  $P < 0.05$ . A wide range of bioinformatics methods was used to determine the relevance of the findings in rat to human with respect to chromosomal aberration, pathways and functions (Gene Ontology). Using these bioinformatics tools, particularly ArrayTrack that is developed in house and available to the public, we found that genes related to cell cycle control, cell proliferation, apoptosis, transcriptional regulation, and protein metabolism were altered. We also closely examined gene expression in regions of previously identified chromosomal aberrations associated with early hepatic neoplasms in this transgenic rat model using a novel visualization tool. The utility of ArrayTrack was demonstrated in this project for analysis of gene expression data derived from microarray experiment. Analysis indicates that the altered gene expression associated with rat liver tumor development may be useful in the analysis of human liver cancer.

#### 1705 ASSESSMENT OF SPECTRAL INTEGRATION AND NORMALIZATION IN NMR-BASED METABONOMIC ANALYSES.

B. Webb-Robertson<sup>1</sup>, D. F. Lowry<sup>1</sup>, K. H. Jarman<sup>1</sup>, S. J. Harbo<sup>2</sup>, Q. R. Meng<sup>2</sup>, J. G. Pounds<sup>1</sup> and K. M. Lee<sup>2</sup>. <sup>1</sup>*Pacific Northwest National Laboratory, Richland, WA* and <sup>2</sup>*Toxicology Northwest, Battelle Memorial Institute, Richland, WA.*

Metabonomics involves the quantitation of the dynamic multivariate response of an organism to a pathological event or genetic modification. The analysis of this data involves the use of appropriate multivariate statistical and chemometric techniques to search for patterns. The premise is that changes in this profile of endogenous molecules can be used as a rapid screen for human risk assessment or as a tool to diagnose disease and monitor treatment outcomes. The most common approach in Nuclear Magnetic Resonance (NMR)-based metabonomics is to align the spectra to an internal reference standard, remove regions of endogenous peaks, spectral integration to reduce the number of variables, and normalization. The last two, the size of spectral integration regions and normalization, have not been well studied. We assess the classification accuracy on two distinctly different datasets via principal component analysis (PCA) and a leave-one-out cross-validation approach under an array or spectral integration regions and two normalization schemes. The first dataset consists of urine collected at five time points from 15 young male Wistar-Hannover rats exposed to -naphthylisothiocyanate (ANIT). The second consists of serum collected at two time points from young male C57BL/6 mice with intra-tracheal instillation to porcine pancreatic elastase or saline. This study indicates that independent of the normalization method the classification accuracy is not highly sensitive to the size of the spectral integration region. In addition, for both datasets, it was observed that the data scaled to mean zero and unity variance (auto-scaled) has higher within classification accuracy variability over spectral integration window widths than the data scaled to the total intensity of the spectrum that is mean-centered. (Funded by Battelle BSTI IR&D fund)

#### 1706 THE COMPARATIVE TOXICOGENOMICS DATABASE (CTD).

C. Mattingly<sup>1</sup>, M. Rosenstein<sup>1</sup>, G. Colby<sup>1</sup>, J. N. Forrest<sup>2,1</sup> and J. L. Boyer<sup>2,1</sup>. <sup>1</sup>*MDI Biological Laboratory, Salisbury Cove, ME* and <sup>2</sup>*Yale University School of Medicine, New Haven, CT.* Sponsor: W. Toscano.

Most human diseases involve the interactions between genetic and environmental factors. We are developing the publicly available Comparative Toxicogenomics Database to promote understanding about the effects of environmental chemicals on human health (<http://ctd.mdbi.org>). Our resource supports hypothesis-driven research about the molecular mechanisms of chemical actions by: 1) identifying gene-chemical interactions in diverse organisms through literature curation and integration of toxicologically relevant -omics data; and 2) facilitating cross-species comparative analyses of toxicologically important genes and proteins through the curation of Gene Sets, which group relevant sequences from diverse organisms and provide multiple alignment and phylogenetic analysis results. Gene Sets greatly assist the identification of conserved, functional regions and are providing important insights into the role of these genes in modulating chemical actions. Approximately 85, 000 chemicals are listed in the USEPA Toxic Substances Control Act Chemical Substances Inventory (USEPA 2003); however, the molecular mechanisms underlying their actions are not well understood. The diverse model organisms used in toxicology studies and the increasing quantity of sequence data available from such organisms present new opportunities for structure-function studies that may lead to improved prediction and prevention of toxicity. CTD is cultivating collaborations among toxicologists and other biological resources, encouraging data submission and participation by investigators worldwide that will contribute to the development of CTD, facilitating the integration of diverse, toxicologically relevant data sets, and supporting critical curation of toxicologically important genes and gene-chemical interactions. These features will make CTD an important resource for the toxicology community and help scientists explore the complex relationship between the environment and human health.

#### 1707 WITHIN- AND BETWEEN-ANIMAL VARIATION, AND REFERENCE RANGES OF HEMATOLOGICAL AND SERUM BIOCHEMICAL PARAMETERS IN CYNOMOLGUS MONKEYS.

T. Koga<sup>1,2</sup>, K. Kanefuji<sup>2</sup> and R. Nagata<sup>3</sup>. <sup>1</sup>*SNBL, Kagoshima, Japan*, <sup>2</sup>*The Institute of Statistical Mathematics, Tokyo, Japan* and <sup>3</sup>*SNBL, Tokyo, Japan*.

[Purpose] Cynomolgus monkeys, one of a number of primates phylogenetically close to humans, are commonly used in animal studies. Basic information obtained from cynomolgus monkeys nourished and maintained under artificial conditions largely contributes to the improvement of an evaluative health condition index, and improves the accuracy of studies in this genus. The purpose of this study is to assess

biological variations and reference ranges of hematological and serum biochemical parameters in cynomolgus monkeys. [Methods] Data from 73 male and 81 female Chinese-bred cynomolgus monkeys aged 3 to 7 years showing no abnormalities during the breeding period were used. After performing suitable transformation, the overall reference range was calculated as mean +/- 1.96SD. To assess within- and between-animal variations, analysis of variance (ANOVA) was applied. A simple method, which applies prior information, was also proposed to estimate individual reference ranges. [Results] Reference ranges of hematological and serum biochemical parameters in cynomolgus monkeys were estimated for males and females separately. Between-animal variances were also evaluated and parameters including MCV, MCH, PT, ALP, T.Chr., and CRNN appeared to show a large between-animal variation. [Conclusion] It is essential to use accurate reference ranges to assess health condition, biological variations, or effects of drugs or endocrine-disrupting chemicals in the study system. For that purpose, we have presented reference ranges for hematological and serum biochemical parameters in cynomolgus monkeys. We also evaluated within- and between-animal variation and found that some parameters show large between-animal variation. Individual reference ranges of these parameters for each animal estimated by the proposed method would make it possible to assess biological variation or effects of drugs or endocrine-disrupting chemicals more accurately.

### THEORETICAL TARGET SEQUENCE FOR THE INTERACTION BETWEEN AFLATOXIN B1 AND PROTEINS.

J. Olivero-Verbel, I. Lans, I. Ospino, R. Vivas, E. Martínez and A. Padilla. *Environmental and Computational Chemistry Group, University of Cartagena, Cartagena, Bolívar, Colombia.*

Aflatoxin B1 (AFB1) is one of the most potent human carcinogens. After CYP-mediated activation to the carcinogenic metabolite AFB1 8, 9-epoxide (AFBO), this reactive compound can form adducts with both proteins and nucleic acids, leading to alterations in protein function and mutations, respectively. The goal of this study was to determine the molecular characteristics that can be considered to predict if a particular peptide sequence might bind to exo-AFBO. Using quantum chemical calculations, the structure of conjugates exo-AFBO-peptide were energetically optimized using the semiempirical method AM1, whereas different molecular properties were calculated at the DFT/B3LYP/631G level. Starting sequences were constructed using cysteine and lysine as covalent bridges and new aminoacids were added once an energetically favorable conjugate was found. Free energies of the reactants and the products, as well as their molecular reactivity descriptors such as global softness, hardness and electronegativity were used to select candidate peptides. Preliminary results have shown that several peptides derived from the sequence MGCES have good tendency to form adducts with AFBO. The conjugate stability increases with the number of intramolecular hydrogen bonds and the geometrical and chemical nature of each peptide, clearly suggesting that the reaction between AFBO and proteins is driven by specific structure-activity relationships. Supported by the University of Cartagena (Cartagena) and Colciencias (Bogota), Colombia. Grant 1107-05-14663.

### A DATABASE FOR TRACKING TOXICOGENOMIC SAMPLES AND PROCEDURES WITH GENOMIC, PROTEOMIC AND METABONOMIC COMPONENTS.

W. Bao<sup>1</sup>, J. Fostel<sup>2</sup>, M. D. Waters<sup>2</sup>, B. Merrick<sup>2</sup>, D. Ekman<sup>1</sup>, M. Kostich<sup>1</sup>, J. Schmid<sup>1</sup> and D. J. Dix<sup>1</sup>. <sup>1</sup>*Office of Research and Development, USEPA, Research Triangle Park, NC* and <sup>2</sup>*National Center for Toxicogenomics, National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

Toxicogenomics generates massive amounts of molecular data in parallel with traditional toxicological endpoints in various formats produced by researchers from different scientific disciplines. Conventional toxicology includes biochemical, histopathological and physiological endpoints, as well as information on treatments, tissues and experimental procedures. The molecular data generated by 'omic technologies are the result of a complex series of experimental and analytical procedures. Thus, data storage and management is essential to toxicogenomics, and requires a more sophisticated system than lab notebooks and electronic spreadsheets. We developed a database for tracking Toxicogenomic Samples and Procedures (TSP) based on the MIAME-Toxicology guidelines and relational database theory. We report here the extension of TSP beyond genomics, to include proteomics and metabolomics components. TSP has a hierarchical structure, capturing information on study design, animal treatments, toxicological endpoints, tissue and biofluid specimens, sample characteristics and quality metrics, and linkage to subsequent toxicogenomics data. The user-friendly interface enables researchers to easily add, edit, save, delete, and navigate different records. TSP is implemented in Microsoft Access software, permitting distribution to any laboratory running Microsoft Office. TSP creates standardized data annotation and entry systems sup-

porting complete reporting and information exchange between researchers from different scientific disciplines. Finally, TSP facilitates exporting data, including corresponding toxicological endpoints and details relevant to study design, into public databases such as CEBS, the Chemical Effects in Biological Systems Knowledgebase. This abstract does not necessarily reflect EPA policy.

### INFLUENCE OF PROTEIN ALLERGENS ON DENDRITIC CELL ACTIVATION.

S. M. George<sup>1</sup>, M. Cumberbatch<sup>2</sup>, C. Portsmouth<sup>2</sup>, A. Destrument<sup>2</sup>, R. J. Dearman<sup>2</sup>, D. Archer<sup>1</sup>, M. Alcocer<sup>1</sup> and I. Kimber<sup>2</sup>. <sup>1</sup>*School of Biological Sciences, Nottingham University, Nottingham, United Kingdom* and <sup>2</sup>*Immunology, Syngenta CTL, Macclesfield, United Kingdom.*

The induction of immune responses, including allergic responses, by dendritic cells (DC) is dependent not only upon the provision of appropriate antigenic peptides for T lymphocyte recognition, but also upon concomitant delivery of costimulatory signals. We have demonstrated that the major allergens from egg, brazil nut and potato (ovalbumin; OVA, ber e 1 and sol t 1) each induce specific IgE production following systemic administration to BALB/c strain mice. The effects of these proteins on the activation status of cultured mouse (BALB/c) bone marrow derived DC have now been examined. Endogenous endotoxin content of the proteins was 0.53 endotoxin units (EU)/ $\mu$ g (OVA), 0.05EU/ $\mu$ g (ber e 1) and 1.5EU/ $\mu$ g (sol t 1). DC were cultured for 24h with protein (0 to 100 $\mu$ g/ml) prior to assessment of surface marker expression associated with DC maturation (MHC class II, CD40, CD54, CD80 and CD86) by flow cytometry and cytokine content (interleukin [IL]-1 $\alpha$ , IL-1 $\beta$ , IL-6, IL-10, IL-12, IL-17 and tumor necrosis factor  $\alpha$ ) of culture supernatants by cytokine microarray. Incubation of DC with either OVA or sol t 1 caused dose dependent increases in membrane marker expression and cytokine secretion, similar effects to those caused by treatment of DC with bacterial lipopolysaccharide (LPS). In contrast, Ber e 1 failed to up-regulate any of the maturation markers examined and did not stimulate cytokine secretion. To evaluate the potential contribution of endogenous endotoxin to DC activation, cells were cultured with OVA or sol t 1 in the presence of polymyxin B (PmB) to neutralize endotoxin. Under conditions where PmB inhibited completely DC maturation and cytokine secretion caused by 100ng LPS (163EU), PmB inhibited only partially DC activation provoked by 100 $\mu$ g OVA (53EU) or 100 $\mu$ g sol t 1 (150EU). These data suggest that while endotoxin contamination may represent an important consideration for the immunogenicity of these proteins *in vivo* and *in vitro*, allergen-specific effects on DC require further investigation.

## 1711

### CUTANEOUS CYTOKINE SECRETION PROFILES INDUCED IN MICE FOLLOWING EXPOSURE TO IRRITANTS OR CHEMICAL ALLERGENS.

M. Cumberbatch, R. J. Dearman and I. Kimber. *Immunology, Syngenta CTL, Macclesfield, United Kingdom.*

Chemical contact and respiratory allergens induce in mice upon repeated topical exposure divergent immune responses characteristic of T helper (Th1) and Th2 cell activation, respectively. Although, the mechanistic basis for the development of polarized immune responses to these chemicals remains unresolved, we have speculated that the pattern of cytokines induced in the skin upon first exposure to chemical may be important for skewing such responses. Using a skin explant assay we have now compared the cytokine secretion profiles induced following single topical exposure of BALB/c strain mice to the contact allergens dinitrochlorobenzene (DNCB, 1%) and oxazolone (Ox, 0.5%), with the respiratory allergen trimellitic anhydride (TMA, 25%) and the skin irritant sodium lauryl sulfate (SLS, 10%). Groups of mice were exposed on the dorsum of both ears to chemical 2 to 4h prior to preparation of dorsal ear explants for culture for 16h on medium. Analysis of culture supernatants by cytokine array revealed that exposure to DNCB (n=20) or to Ox (n=10) was associated with significant increases in interleukin (IL)-1 $\beta$  release by 4h of treatment (5.4-fold and 6-fold, respectively) compared to treatment with vehicle alone. No significant changes in this cytokine were observed following topical application of TMA (1.2-fold, n=20) or SLS (1.4-fold, n=4). Furthermore, only exposure to DNCB or Ox resulted in early (2h) IL-17 secretion (4.0-fold and 4.8-fold, respectively), which had declined significantly for both chemicals by 4h. In contrast, treatment with TMA promoted a marked early (2h) elevation in IL-10 release (2.8-fold) relative to vehicle, compared with DNCB (0.8-fold), Ox (1.8-fold) or SLS (0.6-fold). Other cytokines such as IL-6, IL-12p40 and IL-12p70 remained largely unchanged. These results suggest that single exposure of mice to irritants or chemical allergens may be associated with the stimulation of a distinct cutaneous cytokine secretion profile and that early production of IL-1 $\beta$  and IL-17 may be indicative of the development of Th1 responses to contact allergens.

## VALIDATION OF A MURINE MODEL OF CHEMICAL-INDUCED ASTHMA IN MICE, USING TRIMELLITIC ANHYDRIDE AND 1-CHLORO-2, 4-DINITROBENZENE.

J. Vanoirbeek<sup>1</sup>, M. Tarkowski<sup>2</sup>, N. Ben<sup>1</sup> and P. Hoet<sup>1</sup>. <sup>1</sup>Lab. of Pneumology - Lungtoxicology, K.U.Leuven, Leuven, Belgium and <sup>2</sup>Department of Immunotoxicology, Institute of Occupational Medicine, Lodz, Poland.

Testing the validity of our model of immunologically mediated asthma in mice, developed with toluene diisocyanate, using trimellitic anhydride (TMA), a known respiratory sensitizer and 1-chloro-2, 4-dinitrobenzene (DNCB), a known dermal sensitizer. On day 1, BALB/C mice received the chemical (20  $\mu$ l/ear, TMA 5% and DNCB 0.2%) or vehicle (acetone/olive oil) on each ear. On day 7 they received a dermal boost with the same concentration of the chemical (20  $\mu$ l/ear). On day 10, the mice were intranasally challenged with the chemical (TMA 1% or DNCB 0.02%, 10  $\mu$ l/nostril) or vehicle. Lung function was monitored by whole body plethysmography for 40 min after challenge. Pulmonary inflammation was assessed 24 h after challenge by bronchoalveolar lavage (BAL) and histology. TNF- $\alpha$  and MIP-2 were measured in BAL. Immunological parameters included total IgE serum levels, lymphocyte populations in auricular (AurLN) and superficial cervical lymph nodes (CervLN), IL-4 and IFN- $\gamma$  levels in supernatants of LN cells with or without concanavalin A (ConA) stimulation. Mice sensitized with TMA, boosted with TMA or vehicle and challenged with TMA experienced markedly increased Penh immediately after the intranasal challenge. DNCB treated mice did not show any ventilatory changes after intranasal challenge. 24 h after challenge a neutrophil influx (5-10%) and increase of MIP-2 and TNF- $\alpha$  levels were found in BAL in both TMA and DNCB treated mice. AurLN cells of mice treated with TMA or DNCB showed an increase in CD19+ B-cells. An increased level of IL-4 and IFN- $\gamma$  was found in supernatants of ConA stimulated AurLN and CervLN cells of TMA or DNCB treated mice. Serum total IgE was increased in TMA treated mice only. Both compounds induced a mixed Th1-Th2 response, but only TMA induced a pulmonary immunological response. These results confirm that the model we developed is potentially suitable to specifically screen for pulmonary allergens. DWTC PS/01/43 and FWO-Vlaanderen

## CCL2 KO MICE DEMONSTRATE ENHANCED TH2 RESPONSES FOLLOWING DERMAL SENSITIZATION.

L. P. Myers<sup>1</sup>, P. Simeonova<sup>2</sup> and B. J. Meade<sup>1</sup>. <sup>1</sup>Agriculture and Immunotoxicology Group, NIOSH, Morgantown, WV and <sup>2</sup>Health Effects Laboratory Division, NIOSH, Morgantown, WV.

Host resistance studies have demonstrated the importance of CCR2 (C-C chemokine receptor 2) in Th1 responses and CCL2 (ligand of CCR2) in Th2 responses. These studies were undertaken to evaluate the role of CCR2 and CCL2 in the development of skin sensitization. To begin this evaluation, CCL2 and CCR2 knockout (KO) mice or C57BL/6 wild-type (WT) control mice were dermally exposed to 2% 2, 4-toluene diisocyanate (TDI), 30% alpha-hexylcinnamaldehyde (HCA), or vehicle (acetone). Their response to chemical exposure was evaluated using a modified LLNA (local lymph node assay), analysis of serum IgE, and phenotypic analysis of draining lymph node cells. CCR2 KO mice demonstrated a reduced stimulation index (SI) in the LLNA to 2% TDI, as compared to the WT controls (35.8 & 70.6, respectively) with little difference observed in the response to HCA (SI = 4.5 for CCR2 KO and SE = 5.1 for WT mice). Serum IgE levels after 2% TDI exposure were also significantly lower in CCR2 KO ( $5918 \pm 877$  ng/ml) compared to WT ( $8156 \pm 632$  ng/ml) mice. In contrast, CCL2 KO mice demonstrated an increased SI following exposure to 2% TDI as compared to WT controls (44.8 & 47.4, respectively), as well as a slight increase in proliferation to HCA (7.5 & 5.2, respectively). Moreover, CCL2 KO mice had a significant increase in serum IgE levels after TDI exposure ( $24542 \pm 5651$  ng/ml) when compared to WT treated with TDI ( $9345 \pm 2959$  ng/ml). Consistent with published studies in host resistance, where CCR2 KO mice demonstrated a Th1 defect, CCR2 KO demonstrated a slight decrease in their response to HCA, a Th1 inducing chemical. In contrast to observed effects on host resistance (Th2 defect) in CCL2 KO mice, the CCL2 KO mice demonstrated an enhanced Th2 response following exposure to the dermal sensitizer, TDI.

## DOSE-DEPENDENT INCREASE IN THE PRODUCTION OF NERVE GROWTH FACTOR, NEUROTROPHIN-3, AND NEUROTROPHIN-4 IN A *PENICILLIUM CHRYSOGENUM*-INDUCED ALLERGIC ASTHMA MODEL.

Y. Chung<sup>1</sup>, A. Farraj<sup>2</sup>, N. H. Coates<sup>3</sup>, S. H. Gavett<sup>3</sup> and M. D. Ward<sup>3</sup>. <sup>1</sup>Environmental Sciences and Engineering, UNC/USEPA, Chapel Hill, NC, <sup>2</sup>CVM, NCSU, Raleigh, NC and <sup>3</sup>ORD, NHEERL, USEPA, Research Triangle Park, NC.

Increased levels of neurotrophins (nerve growth factor [NGF], brain-derived neurotrophic factor [BDNF], neurotrophin [NT]-3, and/or NT-4) have been associated with asthma as well as in animal models of allergic asthma. In our mouse

model for fungal allergic asthma, repeated pulmonary challenge with *Penicillium chrysogenum* extract (PCE) induced dose-dependent allergic asthma-like responses in mice. The aim of this study was to investigate whether exposures to PCE could increase the production of neurotrophins in bronchoalveolar lavage fluid (BALF) of PCE challenged mice. Mice were exposed to 10, 20, 50, or 70  $\mu$ g of PCE by involuntary aspiration four times over one month. BALF was collected before (Day 0), and at Day 1 and 3 following the final exposure. The levels of NGF, NT-3, and NT-4 were determined by ELISA. Lungs collected at Day 0, 1, and 3 were perfusion-fixed and processed for immunohistochemical examination of NGF production. PCE-exposed mice had dose-dependent increases in NGF, NT-3, and NT-4. A single exposure to PCE did not significantly increase the production of the neurotrophins. Exposures to PCE caused an increase in positive immunohistochemical staining for NGF in epithelial and smooth muscle cells in addition to infiltrated cells such as mononuclear cells and macrophages. Taken together, mice that received multiple exposures to PCE had dose-dependent increases in NGF, NT-3, and NT-4 in BALF. This is the first study to link fungal allergic asthma in an experimental model with enhanced production of neurotrophins in the airways. (Supported by UNC/EPA Cooperative Training Agreement CT829471. This abstract does not reflect EPA policy.)

## CYTOKINE, ANTIBODY AND PULMONARY RESPONSES IN BALB/C MICE FOLLOWING DERMAL EXPOSURE TO SELECTED DIISOCYANATES.

E. H. Boykin<sup>1</sup>, N. H. Coates<sup>1</sup>, L. M. Plitnik<sup>2</sup>, D. L. Doerfler<sup>1</sup>, S. H. Gavett<sup>1</sup> and M. K. Selgrade<sup>1</sup>. <sup>1</sup>ETD, USEPA, Research Triangle Park, NC and <sup>2</sup>Merck and Co., Inc., West Point, PA.

Exposure to certain low molecular weight chemicals is associated with asthma. A simple test is needed to identify chemicals that pose this hazard. Increases in total serum IgE or Th2 cytokines in draining lymph nodes following dermal exposure have been pursued as means to screen potential asthmagens. Previously, we developed cytokine mRNA profiles using the RNase protection assay for 6 isocyanates, (1% TDI, 2% MDI, 2% HMDI, 2% IDPI, 1% TMI, 1% TMXDI), and for 1% DNCB. The isocyanates could be divided into two groups (high & low responders) based on expression of Th2 cytokines. We hypothesized that dermal exposure to the high responders would result in enhanced pulmonary hyperresponsiveness to methacholine challenge. BALB/c mice received 10 dermal exposures over a period of 4 wks. Treatment groups included 6 isocyanates, DNCB and acetone:olive oil (vehicle). Mice were then challenged with increasing doses of methacholine; responsiveness was assessed using whole body plethysmography (Buxco). Serum, bronchoalveolar lavage fluid (BALF), and lymph nodes were collected for total IgE & IgG subclasses, cell counts, and cytokine profiling. There were no changes in total or differential cell counts for any of the exposure groups compared to vehicle. Significant increases in serum IgE & IgG1 were apparent for all treatment groups compared to vehicle. The cytokine mRNA profile in lymph nodes assessed by real time PCR produced the same pattern of high and low responders seen previously. Mice exposed to HMDI, TMI, and TMXDI (but none of the other treatment groups) showed significant hyperresponsiveness to methacholine. Also, hyperresponsiveness occurred after dermal exposure for only one of the 3 known asthmagens. This data suggests a disconnect between total serum IgE response, cytokine message and hyperresponsiveness. (This abstract does not reflect EPA policy.)

## IN UTERO EXPOSURE TO GENISTEIN (GEN) BY GAVAGE INCREASES IGE AND IGG1 PRODUCTION BY ADULT B6C3F1 MICE FOLLOWING TREATMENT WITH RESPIRATORY ALLERGEN TRIMELLITIC ANHYDRIDE (TMA).

T. L. Guo, R. P. Chi, W. Auttachao, D. M. Hernandez and K. L. White, Jr. Virginia Commonwealth University, Richmond, VA.

It has been reported that there is an increase in the use of asthma or allergy drugs in young adults who were fed soy formula during infancy as compared to those who were fed cow milk formula. The objective of the present study was to determine if *in utero* exposure to GEN had any effects on TMA-induced production of total IgE or IgG subclasses by adult B6C3F1 mice. Both male and female mice were exposed to GEN by dosing their dams, e.g. the pregnant C57BL/6 mice ( $\times$  male C3H), with GEN (20 mg/kg) via gavage from day 14 of gestation to post natal day (PND 3). The offspring were weaned at PND 22, and the sensitization to TMA was achieved by treating individual mice with 50  $\mu$ L of 10% TMA on the shaved backs in acetone:olive oil (3:1) at PND 70. Seven days later, the mice were challenged with 25  $\mu$ L of TMA on the dorsal side of both ears. In addition to evaluating the immunoglobulin content in the sera, other immunological responses including the natural killer (NK) cell activity and anti-CD3 antibody-mediated splenocyte proliferation were performed on PND 84. In males, *in utero* exposure to GEN had no effects on the terminal body weight, spleen weight, relative spleen weight, spleen cell

number, NK activity or anti-CD3 antibody-mediated splenocyte proliferation. However, a significant increase in serum levels of IgG1, but not total IgE and IgG, was observed when compared to the vehicle control mice. In females, no effects on the terminal body weight, spleen weight, relative spleen weight, or total spleen cell number were produced. However, a significant increase in serum levels of total IgE, but not IgG1 or total IgG, was observed. Furthermore, an increase in NK cell activity, but not anti-CD3 antibody-mediated splenocyte proliferation, was observed in female mice. Overall, the results demonstrate that GEN modulates the developing immune system in such a way that more IgG1 or IgE is produced upon exposure to TMA in adult mice (Supported by NIEHS R21 ES012286).

DIFFERENTIAL EXPRESSION OF ARGINASE IN OVALBUMIN (OA) AND TRIMELLITIC ANHYDRIDE (TMA) INDUCED ASTHMA.

J. F. Regal<sup>1</sup>, A. L. Greene<sup>1</sup>, R. R. Regal<sup>2</sup>, M. Rutherford<sup>4</sup>, C. Giulivi<sup>3</sup>, G. Flickinger<sup>4</sup>, J. Hendrickson<sup>4</sup> and M. Mohrman<sup>1</sup>. <sup>1</sup>*Biochemistry & Molecular Biology, University of Minnesota, Duluth, MN*, <sup>2</sup>*Mathematics & Statistics, University of Minnesota, Duluth, MN*, <sup>3</sup>*Molecular Biosciences, University of California-Davis, Davis, CA* and <sup>4</sup>*Veterinary & Biomedical Sciences, University of Minnesota, St. Paul, MN*.

Both TMA, a small molecular weight chemical, and OA, a reference protein allergen, cause occupational asthma. To determine if different mechanisms are responsible for lung eosinophilia in asthma depending on the allergen, Balb/c mice were sensitized with TMA or OA, followed by intratracheal challenge with TMA conjugated to mouse serum albumin (TMA-MSA) or OA, respectively, to elicit the allergic phenotype. MSA challenge was control. 72 hr later, measurement of eosinophil peroxidase in lung demonstrated the same significant increase in eosinophilia with both allergens. RNA was isolated from lung lobes of 6-8 animals in the 4 treatment groups and hybridized with Affymetrix U74Av2 microarrays. Statistical analysis used RMA-normalized, log scale intensities from GeneTraffic. False discovery rates (q-values) were calculated from an overall F test to identify candidate genes with differences in expression for the 4 groups. With a q-value cutoff of 0.1, 855 probe sets were identified as differentially expressed in OA vs TMA induced asthma. 287 genes of the 855 probe sets had a 1.2 fold increase or greater over control for either OA or TMA treated animals. Confirming studies of others, gene expression for arginase 1 was significantly increased in OA induced asthma. However, increased arginase expression was not detected in TMA induced asthma. RT-PCR analysis confirmed the microarray findings. In addition, arginase 1 enzyme activity was significantly increased in OA but not TMA induced asthma. Increased arginase 1 may reduce arginine availability for nitric oxide production in OA, but not in TMA induced asthma. The data suggest that pathways of arginine metabolism and the importance of nitric oxide in asthmatic inflammation may differ in OA and TMA induced asthma. 4-HYDROXYNONENAL MODIFICATION OF MOLECULAR CHAPERONES IN A RAT MODEL OF CHRONIC ALCOHOLIC LIVER INJURY.

D. L. Carbone<sup>1</sup>, J. A. Doorn<sup>2</sup>, Z. Kiebler<sup>1</sup> and D. R. Petersen<sup>1</sup>. <sup>1</sup>*University of Colorado Health Sciences Center, Denver, CO* and <sup>2</sup>*University of Iowa, Iowa City, IA*.

Aldehydic lipid peroxidation products formed in excess under conditions of oxidative stress have a documented ability to modify proteins, DNA, and other important biomolecules, likely exacerbating any existing pathological condition. A proteome-wide scan was employed to detect hepatic proteins modified by 4-hydroxyneonenal (4-HNE) in a rat model of chronic alcoholic liver injury. Specifically, in subcellular fractions isolated from the livers of rats fed a combination high fat and ethanol diet, the molecular chaperones Hsp72, Hsp90, and Hsp60 were identified as targets for 4-HNE adduction using two-dimensional electrophoresis, immunoblot, and LC-MS/MS techniques. To test the hypothesis that 4-HNE modification of these heat shock proteins inhibits chaperone-mediated protein refolding, purified recombinant Hsp72, Hsp90, and Hsp60 were treated with 10  $\mu$ M 4-HNE, resulting in a 47%, 68%, and 25% reduction in protein refolding efficiency, respectively. Tryptic digest of 4-HNE-modified Hsp72 and LC-MS/MS peptide analysis demonstrated consistent modification of Cys 267 in the ATPase domain of the protein. The significance of Cys 267 modification was demonstrated using bacterial DnaK which lacks Cys 267 and was completely resistant to inactivation with 10  $\mu$ M 4-HNE. A significant decrease in ATP affinity following modification of Hsp72 with 10  $\mu$ M 4-HNE was demonstrated using ATP-linked agarose beads, and a corresponding decrease in substrate binding was confirmed by co-immunoprecipitation of the Hsp72/luciferase complex. The data presented here demonstrate modification and inhibition of Hsp72, Hsp60, and Hsp90 by micromolar concentrations of 4-HNE, along with a mechanism for Hsp72 inactivation. Inhibition of these chaperones may contribute to the progression of alcoholic liver disease by limiting the ability of a cell to efficiently repair mis-

folded or otherwise damaged proteins. This work was supported by NIH/NIAAA RO1AA09300 and NIH/NIEHS RO1ES09410 (DRP), NIH/NIEHS F32 ES11937 (JAD), and NIH/NIAAA F31 AA014308 (DLC).

TOXICITY ASSESSMENT OF SILVER NANOPARTICLES (AG 15, 100 NM) IN ALVEOLAR MACROPHAGES.

S. Hussain<sup>1</sup>, K. Hess<sup>2</sup>, J. M. Gearhart<sup>1</sup>, K. T. Geiss<sup>3</sup> and J. M. Schlager<sup>3</sup>.

<sup>1</sup>*Mantech Environment Technology, Inc., Wright-Patterson AFB, Dayton, OH*, <sup>2</sup>*Geo-Centers, Inc., Wright-Patterson AFB, Dayton, OH* and <sup>3</sup>*Human Effectiveness Directorate, Wright-Patterson AFB, OH*.

The present study was conducted to evaluate the acute toxicity of Ag 15nm and 100 nm nanoparticles in rat alveolar macrophages. For toxicity evaluations, cellular morphology, mitochondrial function (MTT assay), membrane leakage of lactate dehydrogenase (LDH assay), neutral red uptake (NR), reduced glutathione (GSH) levels, reactive oxygen species (ROS), and mitochondrial membrane potential (MMP) were assessed at 24 h under control and exposed conditions. The morphological appearance of control and Ag (15, 100 nm) exposed cells were observed by phase contrast microscope. The morphology of cells exposed to Ag 15 and 100 nm nanoparticles at 15 and 50  $\mu$ g/ml doses displayed cellular shrinkage, and an abnormal size and irregular shape. It was also noted that Ag 15 and 100 nm nanoparticles were surrounded by macrophages, some of these attached to the membrane. The results of biochemical studies showed that mitochondrial function decreased significantly in cells exposed to Ag nanoparticles at dose exposure from 10-50  $\mu$ g/ml. LDH leakage significantly increased in cells exposed to Ag nanoparticles (10-50  $\mu$ g/ml). Further, results demonstrated significant depletion of GSH level, reduced mitochondrial membrane potential, and increases in ROS levels in Ag (15 and 100 nm) exposed cells at 25 and 50  $\mu$ g/ml. A significant depletion of GSH levels appeared to create an overwhelming imbalance between antioxidants and ROS, thus resulting in cellular damage. The results suggest that silver nanoparticles likely to induce oxidative stress in macrophages. The potential activation of an inflammatory response in macrophage cultures will be further investigated by quantifying the levels of cytokines that include TNF- $\alpha$ , MIP-2, and IL-6.

1720

LIPIDOMIC ANALYSIS OF THE EFFECT OF INHIBITION OF  $Ca^{2+}$ -INDEPENDENT PHOSPHOLIPASE A<sub>2</sub> ON OXIDANT-INDUCED NEURONAL CELL DEATH.

B. Peterson, K. Guthrie and B. S. Cummings. *Pharmacology and Biomed. Sciences., University of Georgia, Athens, GA*.

Recent studies in renal cells have demonstrated that inhibition of  $Ca^{2+}$ -independent phospholipase A<sub>2</sub> (iPLA<sub>2</sub>) increased oxidant-induced cell death. However, no research has examined the effect of iPLA<sub>2</sub> inhibition on oxidant-induced neuronal cell death. Accordingly, we tested the hypothesis that iPLA<sub>2</sub> mediates neuronal cell death induced by oxidants in A172 glioblastomas, a human brain cell line. Reverse transcriptase polymerase chain reactions, immunoblot analysis and activity assays indicated that A172 cells expressed both cytosolic (iPLA<sub>2</sub> $\beta$ ) and microsomal (iPLA<sub>2</sub> $\gamma$ ) isoforms of iPLA<sub>2</sub>. Measurement of annexin V (apoptotic cell marker) and propidium iodide (PI, oncotic cell marker) staining using flow cytometry demonstrated that the oxidants hydrogen peroxide ( $H_2O_2$ ; 0-1000  $\mu$ M) and tert-butylhydroperoxide (TBHP; 0-400  $\mu$ M) induced time- (0-48 hr) and concentration-dependent increases in cell death. Treatment of A172 cells with 2.5  $\mu$ M bromoenol lactone (BEL), a specific iPLA<sub>2</sub> inhibitor, prior to exposure to 500  $\mu$ M  $H_2O_2$  for 12 hr significantly increased oncosis compared to cells exposed to only  $H_2O_2$ . Similarly, treatment of cells with BEL prior to exposure to 200  $\mu$ M TBHP for 12 hr decreased apoptosis and increased oncosis. Analysis of forward and side scatter using flow cytometry was used to verify alterations in the mode of cell death morphologically. We further investigated the hypothesis that iPLA<sub>2</sub> mediates oxidant-induced neuronal cell death by determining the effect of BEL on the phospholipid profile of A172 cells. Common phospholipids expressed in A172 cells included 32:2, 36:3, and 36:4 phosphatidylcholine (PtdCho). Treatment with  $H_2O_2$  alone reduced 32:2 PtdCho 20% compared to untreated cells. BEL alone caused a 10% increase in 36:4 and 36:3 PtdCho but did not alter  $H_2O_2$ -induced decreases in 32:2 PtdCho. These data demonstrate that both microsomal and cytosolic iPLA<sub>2</sub> are expressed in neuronal cell cultures and suggest that iPLA<sub>2</sub> mediates oxidant-induced neuronal cell death, possibly by mechanisms involving phospholipid turnover.

1721

IDENTIFICATION AND CHARACTERIZATION OF SMALL MOLECULE ACTIVATORS OF THE ANTIOXIDANT RESPONSE ELEMENT.

J. T. Kern<sup>1</sup>, H. Luesch<sup>2</sup>, P. G. Schultz<sup>2,3</sup> and J. A. Johnson<sup>1</sup>. <sup>1</sup>*University of Wisconsin-Madison, Madison, WI*, <sup>2</sup>*The Scripps Research Institute, La Jolla, CA* and <sup>3</sup>*Genomics Institute of the Novartis Research Foundation, San Diego, CA*.

We have performed ultra high-throughput chemical screening involving over 1.16 million compounds to identify a number of unique small molecule activators of the antioxidant response element (ARE). The ARE is a transcriptional element respon-

sible for the production of phase II detoxification enzymes that protect cells against oxidative stress. Alternatively, small molecule activators of the ARE may inhibit histone deacetylases and induce caspase activity leading to cell death, both mechanisms having consequences in anticancer chemotherapy. Ligands were identified using an ARE-luciferase reporter construct transiently transfected into IMR-32 human neuroblastoma cells and validated in murine primary neurocortical cultures expressing an ARE-human placental alkaline phosphatase (ARE-hPAP) transgene. Compounds activating the reporters greater than 5 fold were selected for additional study. At 5 and 10 micromolar concentration these compounds protect against acute hydrogen peroxide toxicity in the neuroblastoma and primary cortical cell lines. To validate the ARE activating potential and toxicological effects of the compounds *in vivo*, preparations of the ligands were injected into ARE-hPAP transgenic reporter mice and various tissues were analyzed for hPAP activity. Histochemical analysis of the injected animals also demonstrates the activity. An abbreviated ADMETox profile (bone marrow and hepatotoxicity, cytochrome P450 specificity) further characterizes each compound. These validated compounds serve as lead molecules for explorations intending to identify therapeutically relevant small molecules for use in oxidative stress-related disorders.

## 1722 PI3 KINASE/AKT, A SURVIVAL PATHWAY AGAINST CYP2E1 DEPENDENT TOXICITY.

A. A. Caro and A. I. Cederbaum. *Pharmacology and Biological Chemistry, Mount Sinai School of Medicine, New York, NY*. Sponsor: D. Petersen.

AKT deactivation has been proposed as a causal mediator of cell death in several models, including oxidative stress. The objective of this work was to evaluate the possible role of PI3 kinase/AKT as a survival pathway against CYP2E1- and oxidative stress- dependent toxicity. E47 cells (HepG2 cells transfected with human CYP2E1 cDNA) exposed to 25 uM Fe-NTA + 5 uM arachidonic acid (Fe+AA) developed higher toxicity than C34 cells (HepG2 cells transfected with empty plasmid). Toxicity was associated with increased oxidative stress, and activation of calcium-dependent hydrolases calpain and phospholipase A2 (PLA2). LY294002, a specific inhibitor of PI3 kinase, but not LY303511, an inactive analog, increased the toxicity of Fe+AA in E47 cells. LY294002 did not significantly affect PLA2 or calpain activation, CYP2E1 activity, or lipid peroxidation elicited by Fe+AA. Thus, the increased toxicity promoted by LY294002 is downstream of the CYP2E1-dependent oxidant stress and activation of calcium-dependent hydrolases. Fe+AA treatment of E47 cells, but not C34 cells, led to a small decrease in phosphorylation of AKT (-24% at 2h), with no change in total AKT levels. LY294002, but not LY303511, produced a further decrease of phosphorylated AKT in Fe+AA treated E47 cells (-77% at 2h), with no change in total AKT. LY294002 produced a small decrease in phosphorylated AKT in E47 cells not exposed to Fe+AA (-12% at 2h). Transient transfection with active AKT in E47 cells partially inhibited the toxicity by Fe+AA. On the contrary, another chemical PI3 kinase inhibitor, wortmannin, did not affect Fe+AA toxicity in E47 cells. While wortmannin did not affect calpain or CYP2E1 activity, or lipid peroxidation, it significantly inhibited PLA2 activation by Fe+AA in intact cells. Since PLA2 plays such a critical role in the Fe+AA toxicity in E47 cells, use of wortmannin as PI3 kinase inhibitor is complicated in models where PLA2 activation is involved. These results suggest that PI3 kinase/AKT may serve as a survival pathway against CYP2E1 dependent toxicity.

## 1723 INHIBITION OF HUMAN MITOCHONDRIAL ALDEHYDE DEHYDROGENASE BY 4-HYDROXYNON-2-ENAL AND 4-OXONON-2-ENAL.

J. A. Doorn<sup>1</sup>, T. D. Hurley<sup>2</sup> and D. R. Petersen<sup>3</sup>. <sup>1</sup>*Medicinal and Natural Products Chemistry, University of Iowa, Iowa City, IA*, <sup>2</sup>*Biochemistry, Indiana University, Indianapolis, IN* and <sup>3</sup>*Pharmaceutical Sciences, University of Colorado, Denver, CO*.

Previous studies demonstrated 4-hydroxynon-2-enal (4HNE) to be both a substrate and inhibitor of mitochondrial aldehyde dehydrogenase (ALDH2). Enzyme inactivation by 4HNE is reversible at low  $\mu$ M but could be irreversible at higher concentrations. Structurally analogous to 4HNE is the lipid peroxidation product 4-oxonon-2-enal (4ONE), which has higher reactivity than 4HNE toward protein nucleophiles. Because it is similar in structure to 4HNE but more reactive, 4ONE could be a suicide substrate for ALDH2. The goal of this work was to determine whether 4ONE is a substrate or inhibitor of human ALDH2 (hALDH2) and elucidate the mechanism of inactivation by 4HNE and 4ONE. At  $[4\text{ONE}] \leq 10 \mu\text{M}$ , hALDH2 catalyzed oxidation of 4ONE to 4 oxonon-2-enoic acid (4ONEA) with a yield of 5 mol 4ONEA produced per mol of enzyme (monomer). Synthesized 4ONEA and glutathione reacted with a calculated rate constant 87 fold less than that measured for 4ONE but comparable to that of 4HNE. Analysis of hALDH2 activity toward propanal revealed both 4ONE and 4ONEA to be potent, irreversible inhibitors of the enzyme. Plots of hALDH2 inactivation by 4ONEA were log-linear, and pseudo-first-order rate constants varied linearly with  $[4\text{ONEA}]$ , indicating that experimental  $[4\text{ONEA}] \ll$  dissociation constant. In contrast,

hALDH2 inhibition by 50  $\mu\text{M}$  4HNE was reversible. hALDH2/NAD was incubated with 4HNE, 4ONE and 4ONEA, and mass spectral analysis of tryptic peptides revealed modification of hALDH2 by 4ONE and 4ONEA. In particular, the peptide containing active site Cys 302 was adducted, and results of MS/MS analysis confirmed Cys 302 to be the site of modification. These data indicate that hALDH2 catalyzes oxidation of 4ONE to 4ONEA; however, 4ONEA is a reactive electrophile. Furthermore, both 4ONE and 4ONEA but not 4HNE are potent, irreversible inhibitors that can modify the active site Cys 302.

## 1724 INDUCTION OF OXIDATIVE STRESS IN HUMAN LUNG CELLS BY THE ESTROGEN METABOLITE, 4-METHOXYESTRADIOL.

Y. J. Cheng<sup>1</sup>, P. Lin<sup>2</sup> and L. W. Chang<sup>1</sup>. <sup>1</sup>*Division of Environmental Health and Occupational Medicine, National Health Research Institutes, Kaohsiung, Taiwan* and <sup>2</sup>*Institute of Toxicology, Chung Shan Medical University, Taichung, Taiwan*.

Epidemiological studies have demonstrated significantly high incidences of pulmonary dysfunctions and diseases, including lung cancer, in populations exposed to dioxins. Animal studies further showed that lung pathology and cancer could be induced in female rats treated with 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD). In our previous studies, we demonstrated a significant elevation of 4-methoxyestradiol (4-MeOE2), a second stage estradiol (E2) metabolite, together with a suppression on cell growth in TCDD-treated human lung cell (H1355 and BEAS-2B) cultures. As suppression of cell growth may lead to a reduction of cellular repair and regeneration of lung epithelial cells, it becomes important to further explore the role of 4-MeOE2 in pulmonary toxicity. In our present study, we found that 4-MeOE2 induced significant production of ROS in the H1355 cells with an induction of SOD activity in a dose and time dependent manner. At dose of 100nM, we also found that 4-MeOE2 decreased intracellular GSH as well as inhibited the aconitase activity and reduced the ATP level in the cells. Concomitantly, suppression of cell growth was also observed at the same time. Such phenomena (induction of SOD activity, reduction of intracellular GSH, inhibition of aconitase activity, reduction of cellular ATP, and suppression of cell growth) were not observed in cells treated with 2-methoxyestradiol (2-MeOE2), the other second stage E2 metabolite. Our studies provided strong evidence that interaction of TCDD and estrogen (E2) in human lung cells would uniquely elevate a E2 metabolite, 4-MeOE2, which in turn would induce oxidative stress and a series of cellular events leading to an eventual adverse change (suppression of cell growth) in the lung epithelial cells. These findings help to explain and elucidate the high incidences of pulmonary diseases in both humans and animals, especially females, when exposed to dioxins.

## 1725 PROTEOMIC IDENTIFICATION OF NONLETHAL OXIDATIVE INJURY BIOMARKERS.

L. Xie and Q. M. Chen. *Pharmacology, University of Arizona, Tucson, AZ*.

Oxidants are byproducts of aerobic metabolism and have been shown to mediate the toxicity of a large number of environmental chemicals. Under most circumstances, the level of oxidants produced inside our body is low and not sufficient to harm cells. Despite this harmlessness, cellular maladaptation to nonlethal doses of oxidants contributes to various diseases including cancer and cardiovascular disease. Detecting cellular injury induced by low dose oxidants becomes important for early diagnosis of these diseases. We have used ESI-LC-MS/MS based proteomics to identify protein factors induced and secreted due to oxidative stress in several cell types. We found that  $\text{H}_2\text{O}_2$  at sublethal doses caused increased secretion of IGFBP-6 and cystatin C from normal human fibroblasts and rat cardiomyocytes. Using doxorubicin to induce oxidative stress *in vivo*, we found increased levels of IGFBP-6 and cystatin C in the plasma of treated mice, suggesting that these two proteins can serve as biomarkers of cellular injury *in vivo*. Proteomic analysis of human fibroblast whole cell lysates detected increased levels of thioredoxin reductase, actin, proteasome alpha2 subunit, proteasome beta2 subunit, tropomyosin 1 and beta-galactoside-binding lectin. cDNA microarray was used to verify our proteomic data and found increased levels of mRNA encoding the proteins listed above. In this study, we have established two biomarkers, IGFBP-6 and cystatin C, that can be used to detect nonlethal doses of oxidative stress injury *in vitro* and *in vivo*. Proteomics of cell lysates combined with cDNA microarray will likely generate additional biomarkers that can potentially serve to diagnose different stages of cellular injury.

## 1726 GR-DEFICIENT MICE (GR1(A1NEU)) ARE SUSCEPTIBLE TO DIQUAT-INDUCED HEPATIC INJURY.

L. K. Rogers, X. Meng, M. S. Augustine, S. E. Welty and C. V. Smith. *Center for Developmental Pharmacology and Toxicology, Columbus Children's Research Institute, Columbus, OH*.

GR1(a1Neu) mice are genetic knockouts for glutathione reductase (GR) [Rogers, Toxicol Sciences, 2004]. GR catalyzes the reaction of glutathione disulfide (GSSG) to glutathione (GSH) by using the reducing equivalents of cellular NADPH, thus

maintaining the availability of GSH for antioxidant functions. We tested the hypothesis that mice deficient in GR activities would be more susceptible to oxidant injury by administration of the redox-cycling oxidant, diquat. Neu and C3H/HeJ (control) mice were given 0 to 50  $\mu$ mol/kg of diquat and sacrificed between 0.5 and 6 h. Neu mice exhibited hepatic necrosis by histology and elevated plasma ALT activities at doses as low as 5  $\mu$ mol/kg (Neu vs C3H, 429 $\pm$ 26 vs 20 $\pm$ 13 IU/L, at 6 h). Diquat doses of 10 and 50  $\mu$ mol/kg caused substantial mortality in Neu mice by 4 and 2 h, respectively. Elevated plasma ALT activities (140 $\pm$ 69 IU/L) were observed as early as 0.5 h after 7.5  $\mu$ mol/kg of diquat, but C3H mice showed no injury or mortality at doses to 50  $\mu$ mol/kg (19 $\pm$ 6 IU/L) through 6 h. No diquat-dependent changes in hepatic GSH levels were observed in either strain. Basal levels of GSSG are greater in Neu than in C3H mice (138 $\pm$ 30 vs 38 $\pm$ 5  $\mu$ M), and increases in GSSG were only observed in the Neu mice and at the highest doses of diquat (444 $\pm$ 91  $\mu$ M, at 2 h after 50  $\mu$ mol/kg). Histological evaluations indicated moderate hepatic necrosis in diquat-treated Neu mice, and preliminary observations indicate marked renal necrosis. Heterozygous mice (Neu/C3H/HeJ) exhibited half of the hepatic GR activities observed in the wild type C3H/HeJ mice (2.3 $\pm$ 0.9 vs 4.8 $\pm$ 0.9 U/g tissue), but demonstrated no hepatic injury with doses as high as 100  $\mu$ mol/kg (29 $\pm$ 12 IU/L). The markedly greater sensitivity to diquat-induced hepatic injury in the GR-deficient mice reflects the critical contributions that GR makes to the antioxidant defense mechanisms.

CAN THE HERSHBERGER ASSAY SPECIFICALLY DETECT AN ANDROGENIC OR ANTI-ANDROGENIC ACTIVITY OF CHEMICAL? -RELATIONSHIP BETWEEN *IN VITRO* AND *IN VIVO* ASSAYS.

M. Nakai<sup>1</sup>, S. Noda<sup>1</sup>, M. Iida<sup>2</sup>, M. Takeyoshi<sup>1</sup>, Y. Minobe<sup>1</sup>, K. Yamasaki<sup>1</sup>, Y. Yakabe<sup>1</sup> and M. Takahashi<sup>3</sup>. <sup>1</sup>Chemicals Evaluation and Research Institute, Kitakatsushika-gun, Japan, <sup>2</sup>Otsuka Pharmaceutical Co., Ltd., Tokushima, Japan and <sup>3</sup>Pathology Peer Review Center, Tokyo, Japan.

The rodent Hershberger assay was originally developed to detect myotrophic effects of steroids and has been used for the screening of endocrine disrupting chemicals, which function via androgen receptor (AR)-mediated mechanism. Both AR-binding and AR-mediated transactivational assays were also utilized for the simple *in vitro* screening of them or for providing of the mechanism data. In order to evaluate the applicability and performance limitations of these *in vivo* and *in vitro* assays for the mechanism-specific screening of endocrine disruptors, it is very important to analyze the relationships among them. In this study, we performed the comparison between AR-binding or AR-mediated transactivational assays and the rodent Hershberger assay and explored their mechanism-specific performances. Only 33 chemicals of 65 test chemicals showed the same results in both the AR-binding and the Hershberger assays, and the concordance of both assays was 51%. In particular, 29 chemicals of 44 AR-binders (66%) were "negative" in the Hershberger assay. On the other hand, there were only three AR-non-binders, which were judged as "positive" in the Hershberger assay. They were two phthalates and an organo-tin compound. The concordance between the transactivational and the Hershberger assays for the detection of androgenic activity was 85% (55/65 chemicals), while that for the detection of anti-androgenic activity was considerably low (55%) as in the case with the relationship between the AR-binding and the Hershberger assays. To improve such low concordances, a classification of chemicals based on the receptor-binding characteristics of chemicals was studied. Consequently, the concordance between *in vitro* and *in vivo* assays was successfully increased when test chemicals were separated into two categories, ER-binders and ER-non-binders.

**1728**

ABILITY OF THE MALE RAT PUBERTAL ASSAY TO DETECT ENVIRONMENTAL CHEMICALS THAT ALTER THYROID HORMONE HOMEOSTASIS.

T. E. Stoker, S. C. Laws, J. M. Ferrell and R. L. Cooper. EB, RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.

The U.S EPA Endocrine Disruptor Screening Program Tier 1 male pubertal protocol was designed to detect alterations in reproductive development and thyroid function. However, little is known about the efficacy of this protocol as a screen for thyrotocicants with different mechanisms of action. We evaluated three environmental chemicals which reported to alter thyroid hormones: DE-71, thiram, and ammonium perchlorate. DE-71, a polybrominated diphenyl ether mixture which increases the clearance of thyroid hormone, was administered from postnatal day 23 to 53 by gavage to male Wistar rats. DE-71 decreased T4 (3, 30 and 60 mg/kg) and T3 (30 and 60 mg/kg) and increased TSH (30 and 60 mg/kg). The altered homeostasis of thyroid hormone by DE-71 was accompanied by altered histopathology of the thyroid tissue (decreased colloid area, increased follicular cell height) following exposure to 60 mg/kg. Thiram, a dithiocarbamate fungicide reported to inhibit thyroperoxidase activity (T4 to T3) *in vitro*, was administered at doses of 12.5 to 50 mg/kg. Thiram decreased T4 at 50 mg/kg and decreased TSH

at 25 and 50 mg/kg. No differences in T3 or thyroid histology were observed. Thiram also decreased luteinizing hormone at 50 mg/kg and testosterone at all doses. The decreased LH was likely due to the ability of thiram to inhibit norepinephrine synthesis, which is important for normal GnRH function. Perchlorate, an ingredient in rocket fuel, paints, and lubricants and a competitive inhibitor of iodide uptake by the thyroid gland, was administered at 62.5, 125, 250, and 500 mg/kg. Perchlorate decreased T4 and increased TSH at doses of 125 to 500 mg/kg. Thyroid histology was altered at all doses. These results demonstrate that the male pubertal protocol is sensitive to the effects of thyrotocicants that act through a variety of mechanisms. This abstract does not necessarily reflect EPA policy.

GENE EXPRESSION PROFILING REVEALS COMMON TARGETS FOR VARIOUS ANDROGEN RECEPTOR ANTAGONISTS IN DEVELOPING FETAL RAT TESTIS.

X. Mu, K. Liu and K. W. Gaido. CIIT Centers for Health Research, Research Triangle Park, NC.

*In utero* exposure to androgen receptor (AR) antagonists elicits male reproductive tract deficits in rats similar to those attributed to human testicular dysgenesis syndrome. Although these AR antagonists can compete with androgen at the receptor level *in vitro*, the specific gene and signaling pathway targeted by these compounds during androgen-mediated male reproductive tract development remain to be determined. The present study was performed to examine global gene expression patterns in rat fetal testis following *in utero* exposure to various AR antagonists. Pregnant Sprague-Dawley rats were treated with flutamide (50 mg/kg/day), linuron (50 mg/kg/day), vinclozolin (200 mg/kg/day), p, p'-DDE (100 mg/kg/day) or corn oil vehicle by gavage daily from gestation day (GD) 12 to 19. Dose levels were selected to maximize fetal response with minimal maternal toxicity. Testes were isolated on GD 19, and global changes in gene expression were determined by microarray analysis. Of the approximately 30, 000 genes queried, 90, 142, 81, and 109 genes were significantly altered following exposure to flutamide, linuron, vinclozolin, and p, p'-DDE, respectively. Seventeen genes were commonly altered by all four AR antagonists, with 10 genes up-regulated and 7 genes down-regulated. Changes in mRNA expression of selected common responsive genes were confirmed by real-time RT-PCR. In all treatments but flutamide, there was a decrease in mRNA expression of various genes involved in cholesterol synthesis and steroidogenesis evidenced by both microarray and real-time RT-PCR analysis. However, the testicular testosterone level remained unchanged in all treatments. We conclude that *in utero* exposure to diverse AR antagonists could cause common alterations in certain gene expressions in developing fetal rat testis. Considering the relatively small number of significant genes, low magnitude of alterations in gene expression and lack of pathological effect of AR antagonists, we suspect that fetal testis is not a primary target for AR activity.

**1730**

APPLICATION OF GENE EXPRESSION ANALYSIS OF MANNOSE 6-PHOSPHATE/INSULIN-LIKE GROWTH FACTOR-II RECEPTOR (M6P/IGF2R) IN VENTRAL PROSTATE FOR SCREENING OF CHEMICALS WITH ANDROGEN-MEDIATED ACTIVITIES IN THE RAT HERSHBERGER ASSAY.

T. Yamada, K. Bando, S. Kawamura, Y. Okuno and T. Seki. Environmental Health Science Laboratory, Sumitomo Chemical Company, Ltd., Osaka, Japan.

The M6P/IGF2R functions as a cell growth suppressor because of its ability to activate the inhibitory activity of TGF $\beta$  and internalize and degrade extracellular IGF2. Castration leads to the activation of the programmed death of the androgen-dependent prostatic epithelial cells in rat ventral prostate. In order to clarify the potential contribution of M6P/IGF2R of this programmed cell death, steady state levels of mRNA of M6P/IGF2R together with TGF $\beta$  and IGF2 were determined by Real-Time PCR analysis. Expression of M6P/IGF2R mRNA in ventral prostate (VP) and seminal vesicles (SV) was higher than that of liver in intact males. Four days after castration, expression of M6P/IGF2R mRNA was increased in VP and SV but not in liver. Time-course analysis for 10 days demonstrated that weights of VP and SV were significantly decreased 3 and 4 days after castration. Within the first day after castration there was an increase in the levels of mRNA of M6P/IGF2R (8-fold) and TGF $\beta$  (18-fold) in VP, and they continued until the 10th day after castration. SV showed a less than 5-fold increase in M6P/IGF2R and TGF $\beta$  mRNA from 3 days after castration. IGF2 mRNA in VP and SV were increased, but the degree of increase was not consistent. These alterations were attenuated by testosterone propionate (1mg/kg), indicating that expressions of M6P/IGF2R, TGF $\beta$  and IGF2 in VP and SV are under negative androgenic regulation. Liver showed no significant changes in the expression of these genes. Furthermore, the rat Hershberger assay with M6P/IGF2R mRNA analysis detected antiandrogenic effects of flutamide (10mg/kg) and p, p'-DDE (100mg/kg) after at least 4 days of treatment. In contrast, colchicine, a known microtubule disruptor

(0.54 mg/kg) had no affect on the expression of these genes. These findings indicate that M6P/IGF2R expression is a potentially reliable biological endpoint to screen for chemicals with androgen-mediated activity.

### 1731 EFFECTS OF AN ANTIANDROGEN ON PROTEIN AND GENE PROFILES IN ADULT RAT TESTES.

C. Friry-Santini<sup>1,3</sup>, P. Kennel<sup>1</sup>, D. Rouquie<sup>1</sup>, M. Samson<sup>2</sup>, M. Benhamed<sup>3</sup> and R. Bars<sup>1</sup>. <sup>1</sup>Research Center, Bayer CropScience, Sophia Antipolis, France, <sup>2</sup>Unit 638, INSERM, Nice, France and <sup>3</sup>Unit 407, INSERM, Oullins, France. Sponsor: N. Carmichael.

Exposure to antiandrogens have been shown to perturb the endocrine system in rats and lead to testicular toxicity. However little is known about the profile of proteins and/or gene expression altered in the testis following exposure to antiandrogens. To better understand the molecular changes produced by antiandrogens in the testis, we have used a proteomic approach to analyse testicular tissues from rats exposed to the model compound, flutamide. The antiandrogen flutamide prevents testosterone from binding to the androgen receptor and this process leads to the inhibition of the androgen dependent tissue stimulation (testes, prostate, seminal vesicles..). *In vivo* 28-day toxicity studies were conducted in male Sprague-Dawley rat by gavage with flutamide [0, 6, 30, 150 mg/kg/day]. At the high dose level, flutamide induced a reduction in the mean body weight gain without any change in mean testis weight (absolute and relative). Leydig cell hyperplasia was observed in a dose-related manner and was the only histopathological changes observed following treatment. Control and treated rat testicular protein were analysed by two-dimensional gel electrophoresis (IPG-IEF/SDS-PAGE). Image analysis using PDQuest software allowed the detection of proteins spots differentially expressed following treatment. A number of proteins were identified by MALDI-TOF analysis providing some information on the metabolic pathways which are altered following flutamide treatment (detoxification mechanism, translation, energy metabolism, signaling pathway..). In parallel, qPCR experiments were performed in order to monitor the level of transcript accumulation corresponding to the identified proteins. Further investigations, using these molecular markers, are ongoing to better characterize the molecular changes observed in the testis following antiandrogens treatment.

### 1732 PROTEIN PROFILING OF ANTIANDROGEN EFFECTS IN THE ADULT RAT VENTRAL PROSTATE.

C. Cayatte<sup>1,3</sup>, C. Pons<sup>1</sup>, J. Guigonis<sup>2</sup>, P. Kennel<sup>3</sup>, D. Rouquie<sup>3</sup>, R. Bars<sup>3</sup>, B. Rossi<sup>1</sup> and M. Samson<sup>1</sup>. <sup>1</sup>Unit 638, INSERM, Nice, France, <sup>2</sup>IFR50 Proteomic platform, INSERM, Nice, France and <sup>3</sup>Research Center, Bayer CropScience, Sophia-Antipolis, France. Sponsor: N. Carmichael.

5-alpha-reductase II is the enzyme which converts testosterone into the more potent androgen, dihydrotestosterone (DHT) which is required for prostate growth and homeostasis. Finasteride, used in therapy of benign prostatic hyperplasia, is an antiandrogenic drug through the selective inhibition of 5-alpha-reductase II. Investigations of antiandrogenic effects in rat ventral prostate of this model compound were approached applying proteomic technologies. Finasteride was daily administered by gavage to young adult Sprague-Dawley rats, at different dose levels (0, 1, 5, 25 and 125 mg/kg per day). After 28 days of treatment, the reproductive tissues including ventral prostates were removed, weighed and examined microscopically. Histopathological changes were observed from 1 mg/kg/day and prostate proteins were separated by two-dimensional gel electrophoresis using isoelectrofocusing (IEF) on immobilized pH gradient strips (pH3-10, pH3-6, pH 5-8, pH7-10) in a first dimension, and SDS-PAGE in a second dimension. Protein patterns of control and treated animals were compared by PD-Quest software analysis and spots were identified by MALDI-ToF mass spectrometry. In the course of this study, several proteins from different cellular compartments were found to be up or down-regulated (chaperones, proteins from mitochondria and cytoskeleton, proteins involved in metabolism and secreted proteins). A similar study is currently under investigation with flutamide (0, 6, 30 and 150 mg/kg per day), an other antiandrogen which prevents testosterone binding to androgen receptor. These investigations are expected to better characterise the molecular changes observed in the prostate following antiandrogen treatment.

### 1733 THE ENDOCRINE PROFILE OF INTACT FEMALE RATS ON THE DAY OF PROESTRUS FOLLOWING EXPOSURE TO ATRAZINE.

R. L. Cooper, A. Buckalew, S. C. Laws and T. E. Stoker. RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.

The chlorotriazine herbicide, atrazine, has been shown to disrupt the neuroendocrine control of reproductive function in both the male and female rat. We reported that atrazine caused a dose-dependent suppression of the estrogen-induced

surge of luteinizing hormone (LH) in the ovariectomized female rat. We also found that this herbicide caused an increase in serum estrone and estradiol in the intact male. The purpose of the present study was to determine whether or not the pituitary and gonadal hormones are affected within the same dose range. Therefore, we examined the effect of atrazine on hormone concentrations in the intact proestrous female rat. LE rats with regular 4-day estrous cycles were gavaged daily for 3 days (diestrus I to proestrus) with 0, 6.25, 12.5, 25 and 75 mg/kg of atrazine. On the day of vaginal proestrus (final day of dosing) females were killed at 1200, 1400, 1600, 1800 and 2000 h. At each time point the brain, pituitary, and blood were collected and processed for subsequent assays. Serum prolactin (PRL), LH, progesterone, corticosterone, estradiol, estrone and androstenedione were measured by radioimmunoassay. The peak concentration of LH was suppressed at all doses of atrazine as compared to the controls. Progesterone and androstenedione were increased at 1600 and 1800 h in the 75 mg/kg group. There were no significant differences in estrone, estradiol or corticosterone, although there was an apparent trend for increased levels as the atrazine dose increased. The results of these experiments demonstrate that atrazine suppresses LH at doses as low as 6.25 mg/kg. However, changes in serum steroid hormones were not observed until doses of 75 mg/kg were administered. Further studies are needed to determine the NOEL for the suppression of LH by atrazine and to better evaluate the apparent alterations in steroids. (This abstract does not necessarily reflect EPA policy.)

### 1734 ESTROGENICITY OF MIXTURES OF CHEMICALS ON UTERINE GROWTH OF PREPUBERAL RATS.

J. V. Meeuwen<sup>1</sup>, A. Piersma<sup>2</sup>, M. van den Berg<sup>1</sup> and J. Sanderson<sup>1</sup>. <sup>1</sup>Biotoxicology, IRAS, Utrecht, Netherlands and <sup>2</sup>RIVM, Bilthoven, Utrecht, Netherlands.

The human diet contains numerous compounds, of which a minority has shown (anti)-estrogenic effects *in vitro* and *in vivo*. The origin of these compounds varies from plant-derived (phytochemicals; PCs) to industrial pollutants and pesticides (xenoestrogens; XEs). It has been postulated that these compounds may act in a non-additive way in combination with endogenous estrogens (e.g. 17 $\beta$ -estradiol=E2). To investigate potential non-additive effects, 2 mixtures were composed that reflected concentrations reported in serum from humans consuming a regular diet. One mixture (PCM) contained coumestrol, genistein, naringenin, (+, -)catechin, (-, -)epicatechin and quercetin the other (XEM) contained, nonyl-, and octylphenol,  $\beta$ -hexachlorocyclohexane, methoxychlor, bisphenol A and dibutylphthalate. Our previous *in vitro* studies, based on cell proliferation and pS2 gene expression in MCF7 cells, demonstrated that observed potency and calculated potency (using estrogen equivalency factors) of combinations of PCM, XEM and E2 did not deviate from the expected additive model. To confirm this additivity in an *in vivo* model, E2, PCM and XEM were tested alone or at various combinations in rat uterotrophic assays. Prepuberal female rats were dosed subcutaneously once every 24 h for 3 days and sacrificed on day 4. The uterine weight served as a measure of estrogenicity. Tested doses for PCs and XEs were within the range reported in plasma of humans consuming a regular diet. ED50 for E2 was found at 1  $\mu$ g/kg bw. ED50s for PCM and XEM were found at doses that are 12 times lower or at least 20 times higher than reported in human plasma respectively. Average uterine weight increase ( $n=5$ /group) of animals dosed with different combinations of PCM or XEM with E2 supported the concept of additivity. Based on our results from uterotrophic assays we conclude that a possible contribution of estrogenic effect caused by PCs from the diet might be more significant than that caused by XEs and that (plant-derived or xeno) estrogenic compounds in human diet could interact with E2 in an additive way.

### 1735 MOLECULAR CHARACTERIZATION OF THE UTEROTROPHIC ASSAY: TEMPORAL GENE EXPRESSION CHANGES IN THE UTERUS FOLLOWING ETHINYLESTRADIOL.

H. J. Ahr, H. Ellinger-Ziegelbauer, A. Freyberger, E. Hartmann, A. Mahringer and F. Kroetlinger. Molecular and Genetic Toxicology, Bayer healthcare AG, Wuppertal, Germany.

The uterotrophic assay is undergoing validation as an *in vivo* screen for estrogenicity. In this study, the temporal changes of gene expression were compared to parameters like uterine wet weight and histology. Groups of five juvenile female Wistar rats were subcutaneously dosed with either ethinylestradiol (3 microgram/kg) or corn oil (solvent control) every 24 hours for three consecutive days. Two, four, eight, and 24 hours after the first, four and 24h after the second, and 24 h after the last application, uteri were taken for histopathological examination and for analysis of the expression profiles. Four and eight hours after the first administration, uterine weight increased to about 1.4-fold, then increased further and reached more than 10-fold of the corresponding control values at final necropsy. The earliest detectable uterine change observed by histology was hypertrophy of stromal cells four hours after the first application. Hypertrophy of the luminal and glandular epithelium and of myometrial cells occurred 24 h after the first

application, whereas dilation of the uterine lumen was observed four hours after the second application. At the gene expression level, prominent time-dependent expression patterns were found which could be related to the histopathological observations. Analysis of the approx.1500 significantly deregulated genes revealed a profound remodeling of the uterine tissue including an early upregulation of genes involved in biosynthetic processes, cytoskeletal rearrangement, and vasculogenesis. The expression of cell cycle progression genes increased abruptly 24 h after treatment. Also suggested from the function of some of deregulated genes is an inflammatory response which could explain earlier observations showing inhibition of estrogen-induced increase in uterine weight by antiinflammatory agents. In summary, the analysis of the expression changes allowed further insight into the mechanisms underlying the uterotrophic response in this model.

COMPARATIVE GENE EXPRESSION ANALYSIS OF THE MOLECULAR EFFECTS OF SYNTHETIC, PLANT-DERIVED AND PHYSIOLOGICAL ESTROGENS IN THE IMMATURE RODENT UTERUS.

J. G. Moggs, H. Tinwell, F. Lim, M. J. David, I. Kimber, J. Ashby and O. George. *Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

The xenoestrogen group of endocrine disruptors have the potential to cause reproductive and developmental effects through stimulation or disruption of estrogen receptor signalling. Whilst the exposure of humans to  $\mu\text{g}/\text{kg}$  levels of synthetic environmental estrogens is assumed to be hazardous, exposure to  $\text{mg}/\text{kg}$  levels of phytoestrogens in foods and dietary supplements is frequently proposed to be life enhancing. Given this apparent paradox, an important question is whether estrogens derived from different sources induce their estrogenic effects through similar mechanisms. To address this question, we gave immature mice three daily subcutaneous injections of 17 $\beta$ -estradiol (E2, 2.5  $\mu\text{g}/\text{kg}$ ), the synthetic estrogen diethylstilbestrol (DES, 2  $\mu\text{g}/\text{kg}$ ) or the phytoestrogen genistein (GEN, 50  $\text{mg}/\text{kg}$ ). Control mice received vehicle alone (arachis oil). These doses induced equivalent gravimetric and histologic uterotrophic effects, using the standard 3-day uterotrophic assay protocol. Gene expression profiles of 72h uterine samples, measured using Affymetrix microarrays, revealed that E2, GEN and DES induce essentially identical changes in gene expression. We conclude that, in the rodent uterus, a synthetic estrogen and a phytoestrogen operate via a molecular mechanism analogous to the physiological estrogen, E2. These data demonstrate that the origin of an estrogen - be it physiological, plant-derived or synthetic - plays no role in determining its biological activity in the uterus. This highlights the need for an holistic approach to safety assessment wherein preconceptions of intrinsic hazard are replaced by an objective assessment of likely perturbations of physiological functions caused by combined exposures to xenoestrogens.

ESTRADIOL PROTECTS AGAINST ETHANOL-INDUCED BONE LOSS IN FEMALE RATS BY PREVENTING OSTEOCLAST ACTIVATION.

R. Haley<sup>2</sup>, M. Hidestrand<sup>1,2</sup>, K. Shankar<sup>1,2</sup>, C. K. Lumpkin<sup>3</sup>, B. Yarberry<sup>2</sup>, T. M. Badger<sup>4,2</sup> and M. J. Ronis<sup>1,2</sup>. <sup>1</sup>*Pharmacology & Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR*, <sup>2</sup>*Arkansas Children's Nutrition Center, Little Rock, AR*, <sup>3</sup>*Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR* and <sup>4</sup>*Physiology & Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR*.

We hypothesized that protection against ethanol-induced bone loss in pregnancy might be due to increased circulating sex steroids. In the current study, 225 g female Sprague-Dawley rats ( $N = 6/\text{group}$ ) were infused liquid diets with or without isocaloric EtOH substitution of carbohydrate calories using total enteral nutrition at a dose of 13  $\text{g}/\text{kg}/\text{d}$  for 21 d. Additional control and EtOH groups were supplemented with 17 $\beta$ -estradiol (E2, 20  $\mu\text{g}/\text{kg}/\text{d}$  via osmotic minipump) or with E2 + progesterone (P, 75  $\text{mg}/\text{kg}/\text{d}$  s.c. in corn oil vehicle). At the end of the study E2 supplementation increased plasma E2 values from  $3 \pm 1$  to  $66 \pm 12 \text{ pg}/\text{ml}$  ( $p \leq 0.05$ ) and P supplementation increased P values from  $12 \pm 6$  to  $225 \pm 31 \text{ ng}/\text{ml}$  ( $p \leq 0.05$ ) in EtOH treated rats, values similar to or higher than those observed in pregnancy. While E2 supplementation had no effect on tibial bone density in control rats, E2 prevented ethanol-induced bone loss. Total tibial bone density and tibial trabecular bone density were greater in the E2 + EtOH than in the EtOH group ( $p \leq 0.05$ ) as measured by peripheral quantitative computerized tomography both *in vivo* and in isolated tibia. In addition, measurement of plasma collagen type I fragments (RatLapsTM) by ELISA as a marker of osteoclast-mediated bone resorption demonstrated increases with EtOH and suppression in the E2 + EtOH group ( $p \leq 0.05$ ). In contrast both EtOH and E2 reduced plasma osteocalcin, a bone formation marker in an additive fashion ( $p \leq 0.05$ ). The E+P group had no significant effects compared to supplementation with E2 alone. These data suggest E2 protects against ethanol-induced bone loss by preventing ethanol-associated osteoclast activation. (Supported by NIH AA12928 M.R.).

ONTOGENY OF P-GLYCOPROTEIN (PGP) IN SELECTED TISSUES OF NEONATAL MALE AND FEMALE CD-1 MICE.

S. Yavanhxay<sup>1</sup>, M. Christian<sup>2</sup>, A. Hoberman<sup>2</sup>, J. C. Eldridge<sup>1</sup> and J. T. Stevens<sup>1</sup>. <sup>1</sup>*Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC* and <sup>2</sup>*Charles Rivers Labs, Horsham, PA*.

The mdrla isoform of P-glycoprotein (pgp) is an essential component in capillary endothelial cell, acting as a transmembrane pump to facilitate removal of drugs and toxicants. Using RT-PCR to measure mRNA, and Western immuno-blotting to measure protein, we have assessed development of PGP expression in female CD-1 mouse brain, kidney, liver, and ovaries, and in brain, kidney, liver, testes, and ventral prostate of male mice, on PND 1, 5, 10, 15, 20, and 60. No remarkable gender differences appeared in PGP ontogeny in brain, kidney, and gonads. Expression of both protein and mRNA generally increased from PND 1 to 60, but they were typically more rapid for protein than message. Protein levels at PND 20 were near adult (PND 60) levels, but were only 20-40% of adult levels at PND 1. An exception was expression in liver, already at approximately 70% of adult level at PND 1. Similarly, mRNA expression was 70-100% of adult level by PND 20 in all organs examined, but was only 10% of adult level at PND 1. It is concluded that the ontogeny of PGP mRNA and protein in brain, kidney, gonad and prostate increases from low, but detectable, expression levels at PND 1 to nearly adult levels at PND 20; while the liver appears nearly complete at birth. For uncertain reasons, mRNA levels appear to rise more slowly, relative to adult expression, than do protein levels. The results also suggest, in concordance with our findings in neonatal rats (Yavanhxay et al., 2004, Toxicologist), that the ontogeny of PGP, in the tissues examined, differs from that of human infants and children, which is completely developed from before birth. It calls into serious question the validity of using neonatal rodent models to assess potential toxic effects of natural hormones, pesticides, and environmental endocrine disruptors that interact with the P-glycoprotein pump, because rodent barriers remain far from completely developed at birth.

TRANSCRIPT PROFILING OF GENE EXPRESSION CHANGES ASSOCIATED WITH AN INCREASED INCIDENCE OF CANCER AFTER EXPOSURE OF NEONATAL MICE TO XENOESTROGENS.

D. J. Moore, F. Lim, H. Tinwell, I. Kimber, J. Ashby, G. Orphanides and J. Moggs. *Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

Epigenetic changes, including altered DNA methylation status, have recently been implicated in the development of human cancers. It is becoming increasingly apparent that toxicant-induced changes in epigenetic status may also play an important role in some mechanisms of toxicity. The potential role of xenobiotic-induced epigenetic changes in developmental toxicity is exemplified by exposure to diethylstilbestrol (DES), a developmental stage-specific non-genotoxic carcinogen. We have used a rodent experimental model for DES-induced carcinogenesis in order to define the early molecular events, including changes in gene expression, that may be associated with the onset of carcinogenesis. Neonatal female mice were given five daily subcutaneous injections of DES during post-natal days (PND) 1-5 at doses (1 and 1000  $\mu\text{g}/\text{kg}$ ) that have been reported previously to result in a high incidence of uterine tumours after 18 months (31% and 90%, respectively). Arachis oil was used as a vehicle control. Gene expression levels, uterine weights and histological parameters were analysed at PND6, PND17, PND30 and PND50. Gene expression profiling using Affymetrix microarrays revealed that DES-induces a complex pattern of dose-dependent gene expression changes in the uterus. A subset of DES-responsive genes, including lactotransferrin and complement component 3, exhibited persistently altered expression levels throughout the 50 day time course, demonstrating that transient exposure to DES during PND 1-5 results in stable changes in gene expression that may be due to epigenetic phenomena. The mechanistic basis for these persistent changes in gene expression is currently being analysed by measuring the DNA methylation status of CpG island sequences within their promoter regions. These studies provide novel insights into the relationships between epigenetic changes in gene expression and chemically-induced carcinogenesis in a rodent model system.

THYROID HORMONE STATUS IN ADULT FEMALE RATS AFTER AN ORAL DOSE OF PERFLUOROOCTANESULFONATE (PFOS).

J. Butenhoff<sup>1</sup>, M. Eastvold<sup>2</sup>, J. Bjork<sup>3</sup>, D. Ehresman<sup>1</sup>, R. Singh<sup>2</sup>, K. Wallace<sup>3</sup> and S. Tanaka<sup>1</sup>. <sup>1</sup>*3M Company, St. Paul, MN*, <sup>2</sup>*Mayo Medical Laboratories, Rochester, MN* and <sup>3</sup>*University of Minnesota, Duluth, MN*.

Perfluorooctanesulfonate (PFOS), a persistent bioaccumulative acid, is widely distributed in humans and wildlife. Prior studies have observed decreased total and free thyroid hormones (TH) in serum without a compensatory rise in thyrotropin

(TSH). However, we have recently demonstrated that measurement of free thyroxine (FT4) by analog methods in serum containing PFOS is prone to negative bias in that PFOS competes with FT4 for binding. We also observed that hepatic malic enzyme (ME) and  $\alpha$ -glycero-3-phosphate-dehydrogenase ( $\alpha$ G3PD), which are responsive to TH, were either increased (ME) or unchanged ( $\alpha$ G3PD) after treatment with PFOS. To test the hypothesis that PFOS increases free TH availability and the hepatic response to TH, the effects of PFOS on TH status were investigated over a 24-hour time period following a single oral dose of PFOS. Adult female SD rats (5/group) were given 15 mg/kg PFOS or vehicle and sacrificed at 2, 6, and 24 hours post-dose. Sera and liver were harvested and flash frozen immediately. Chemiluminescent (CL) methods were used to measure serum total thyroxine (TT4), total triiodothyronine (TT3), FT4, reverse triiodothyronine (rT3) and TSH. FT4 was also measured by a reference method, equilibrium dialysis RIA (ED-RIA). In addition, translational and transcriptional expressions of ME were evaluated. Compared to controls, TT4, TT3, FT4, and rT3 by CL method were significantly reduced over the 24 hours duration with PFOS. However, FT4 by ED-RIA was significantly increased at 2 (68%) and 6 (90%) hours and returned to control value at 24 hours. TSH activity was comparable to controls at 2 and 24 hours, and was apparently reduced at 6 hours. ME activity was increased by 4, 12, and 43% of control at 2, 6, and 24 hours, respectively. Thus, these results demonstrate that thyroid status was enhanced rather than suppressed following PFOS administration.

**1741**

THE EFFECTS OF POLYCHLORINATED BIPHENYLS ON THYROID HORMONE RECEPTOR MEDIATED ACTION *IN VIVO* AND *IN VITRO*.

K. J. Gauger, S. Giera and R. Zoeller. *Biology Department, Program in Molecular and Cellular Biology, University of Massachusetts, Amherst, MA.*

Polychlorinated biphenyls (PCBs) are ubiquitous environmental contaminants routinely found in human and animal tissues. Prenatal exposure to PCBs is associated with neuropsychological deficits, which may be produced by PCBs altering thyroid hormone (TH) action in the brain. In the present study, we first tested whether maternal exposure to a commercial PCB mixture, Aroclor 1254 (A1254), affects TH signaling in the fetal rat brain. Dams were dosed daily with 0, 1, or 4 mg/kg A1254 which significantly reduced their circulating levels of TH, but increased the expression of several TH-responsive genes in the fetal cortex of their offspring, including NSP-A, RC3/Neurogranin, and Oct-1. Additionally, the expression of malic enzyme (ME), a known TH-responsive gene in the liver, was elevated in animals treated with 4 and 8 mg/kg of 6 parent PCB congeners that represent specific classes of PCBs prevalent in A1254, including PCBs 77, 105, 118, 126, 138, and 153. These findings are consistent with a direct action of PCBs on TH receptors (TRs). However, this agonistic effect does not appear to involve interaction with the ligand binding domain of the TR because none of the 6 PCBs utilized in the *in vivo* study competitively bound to rat TRs isolated from hepatic nuclei. Therefore, in order to elucidate the molecular mechanism by which these specific PCB congeners activate TH-responsive gene expression, we are testing each congener independently in an *in vitro* cell culture system. For this congener specific analysis, we are employing H4IE cells to determine the effect PCBs on endogenous ME expression and GH3 cells to examine the effects of PCBs on endogenous growth hormone (GH) expression. Finally, the promoter regions of these TH-responsive genes have been well characterized and contain a TH response element (TRE). Therefore, we are utilizing ME and GH promoters that are linked to a luciferase reporter gene to further establish how PCBs interfere with TR mediated action.

COMPARISON OF INHIBITORY EFFECTS OF ETHANOL AND METHYL T-BUTYL ETHER (MTBE) ON RAT LEYDIG CELL TESTOSTERONE PRODUCTION.

R. Shuto, B. B. Goldberg and A. de Peyster. *Graduate School of Public Health, San Diego State University, San Diego, CA.*

Ethanol (EtOH) is an alternative motor fuel oxygenate proposed to replace MTBE, which is being phased out but persists in the environment. Both are reported to produce some type of testicular toxicity, possibly through inhibition of testosterone synthesis. Is one a more potent steroidogenesis inhibitor? and if so, what are the implications of substituting EtOH for MTBE in motor fuels? Leydig cells from adult Harlan Sprague-Dawley rats isolated using Percoll gradients were exposed for 3 hr to equimolar concentrations of ethanol or MTBE without hCG (baseline) or with hCG stimulation. Total testosterone (T) produced was measured by radioimmunoassay (DPC, Los Angeles). Aminoglutethimide was included routinely as a positive control. When equimolar concentrations of EtOH or MTBE up to 100 mM were compared in the same experiments, both caused similar inhibition of hCG-stimulated cells, whereas only MTBE consistently inhibited baseline T production. Less than 25 mM EtOH had no measurable effect in this system (legal blood alcohol concentration limit is ~17 mM). Different potencies and/or other

dissimilar modes of action of MTBE and EtOH or their metabolites in Leydig cells might be predicted by previously reported effects of each. For example, MTBE (but thus far not EtOH) has been reported to cause Leydig cell tumors in rats, whereas chronic consumption of high doses of EtOH reduces spermatogenesis and fertility and causes testicular atrophy, none of which has yet been reported in rodent reproductive toxicity studies of MTBE. We have also observed in Leydig cell exposure systems that formaldehyde, a metabolite of MTBE, is a more potent T inhibitor than acetaldehyde, an EtOH metabolite. The implications and contributions of these findings to comparative risk assessments will also be presented.

CHANGES IN FETAL TESTIS GENE EXPRESSION AND STEROID HORMONE SYNTHESIS INDUCED IN MALE OFFSPRING AFTER MATERNAL TREATMENT WITH DEHP (DI-N-ETHYLHEXYL PHTHALATE).

V. S. Wilson<sup>1</sup>, C. Lambright<sup>1</sup>, J. Furr<sup>1</sup>, K. Bobseine<sup>1</sup>, C. Wood<sup>1</sup>, K. Hosdeshell<sup>2</sup> and L. E. Gray<sup>1</sup>. *Reproductive Toxicology Division, USEPA, ORD, NHEERL, Research Triangle Park, NC and<sup>2</sup> NC State University, Raleigh, NC.*

Phthalate esters are high production volume, ubiquitous environmental chemicals some of which induce reproductive malformations in rats when administered during sexual differentiation. Recently we have shown that malformations in gubernacular ligament development induced by high doses of DEHP are associated with decreased *insl3* gene expression, a gene critical for proper gubernacular ligament formation. In study one, DEHP (0, 100, 300, 600, or 900 mg/kg/day) was administered orally to Sprague-Dawley dams on gestation days (GD) 8 through 18. On GD18, fetal testes were evaluated for hormone production and changes in gene expression. Results indicate that DEHP induced a dose dependent linear decrease in testosterone production that was significant at 300, 600 and 900 mg/kg. Progesterone production was decreased at 900 mg/kg. *Ins3* gene expression was also decreased in a dose dependent manner. To investigate the ontogeny of gene changes associated with these effects, a second study dosed dams orally with 0 (vehicle only) or 750 mg/kg/day DEHP beginning on GD8. Testes RNA was prepared from fetuses of 3 litters each on GD 16.5, 17, and 18. Microarray analysis was conducted on these samples using Affymetrix gene chips. Preliminary results indicate significant ( $p < 0.05$ ) changes in several genes associated with Leydig cell steroidogenesis and peptide hormone production such as CYP17, StAR and *Ins3* beginning, in some cases, as early as GD 16.5. A more thorough analysis of gene chip results is underway but, thus far, the changes demonstrated are consistent with the malformations previously observed in male offspring after *in utero* exposure to similar doses of DEHP. Disclaimer: This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

MECHANISM OF PHTHALATE-INDUCED DEVELOPMENTAL REPRODUCTIVE TOXICITY: INHIBITION OF TESTOSTERONE AND INSULIN-LIKE 3 HORMONE PRODUCTION BY FETAL LEYDIG CELLS.

L. E. Gray, N. Noriega, C. Lambright, J. Furr and V. S. Wilson. *ORD, NHEERL, RTD, EB, USEPA, Research Triangle Park, NC.*

While the phthalate esters (PE) are a diverse class of chemicals, several PEs appear to induce reproductive toxicity via a common mode of action (CMOA). *In utero* DEHP, BBP, and DBP reduce testis testosterone (T) production and *insl3* mRNA levels inducing a syndrome of reproductive malformations unique to PEs. For DEHP, reproductive effects are seen at 11 mg/kg/d and above. Having a CMOA, it is not surprising that combined PE exposures during pregnancy produce dose-additive cumulative toxicity. When PEs are coadministered with an androgen receptor (AR) antagonist, some of the effects also are cumulative. In the pubertal male rat, DEHP, DBP and BBP delay puberty. For DEHP, this delay is associated with lower serum T and reduced T production *ex vivo*. In contrast to their effects on hormone production, the PEs do not appear to be significant AR antagonists *in vitro* or *in vivo*. In a Hershberger assay, a protocol that primarily detects AR antagonists, DEHP, DBP and BBP only cause weak positive to negative responses at a high dosage level (1 g/kg/d) suggesting that AR antagonism is not a major mechanism of PE-induced reproductive toxicity. We suspect that the PEs are altering fetal Leydig cell differentiation, delaying the onset of hormone production during sexual differentiation. The fact that both steroid and peptide hormones are altered *in utero* indicates that mechanism of action does not involve a direct effect on steroidogenic enzymes. In addition, the fact that growth of the liver is induced by DEHP but not DBP at low doses suggests that effects on the liver are not caused by the same CMOA as are effects on the developing male rat reproductive tract. Until the mechanism for PE-induced reproductive toxicity in the rat is fully characterized, uncertainty will exist in the extrapolation of these effects to other mammalian species, including humans. Disclaimer: This is an abstract of a proposed presentation and does not reflect Agency policy.

REPRODUCTIVE SUCCESS AND AROMATASE ACTIVITY IN THE FISH CUNNER (*TAUTOGOLABRUS ADSPERSUS*) EXPOSED TO ATRAZINE OR OCTYLPHENOL IN THE LABORATORY.

L. J. Mills<sup>1</sup>, R. E. Gutjahr-Gobell<sup>1</sup>, S. C. Laws<sup>2</sup>, D. Borsay Horowitz<sup>1</sup> and G. E. Zarogian<sup>1</sup>. <sup>1</sup>USEPA, NHEERL, Atlantic Ecology Division, Narragansett, RI and <sup>2</sup>USEPA, NHEERL, Reproductive Toxicology Division, Research Triangle Park, NC.

This study was conducted to test the hypothesis that reproduction in fish is altered by exposure to endocrine-disrupting chemicals (EDCs) that modify aromatase activity. Aromatase, a product of the CYP19 gene, is an enzyme complex that catalyzes the conversion of the androgens androstenedione and testosterone to the estrogens estrone and estradiol. Atrazine and octylphenol are EDCs common in aquatic environments, and both have been reported to alter estrogen concentrations in fish or rats. During our laboratory experiments, cunner in spawning condition were monitored daily to determine egg production, egg fertility and egg viability both before and after exposure to atrazine (nominal concentrations 0.1-5 ppm) or octylphenol (nominal concentrations 1-100 ppm). After one week of monitoring pre-exposure reproduction, treatments were delivered by subcutaneous implantation of the test chemical or solvent (controls) in a slow-release matrix of Ethocel® and coconut oil just below the dorsal fin of each fish. Reproduction was monitored for two more weeks, and then fish were euthanized and dissected. Brain, gonad and liver samples were flash-frozen and archived for later analysis. Results of these experiments indicate that atrazine and octylphenol had very little effect on egg production, egg fertility, egg viability, or ability of eggs to hatch. Only fish imprinted with the highest concentration of atrazine (5 ppm) showed a significant reduction in egg production compared to controls. All males, regardless of treatment, produced milt and motile sperm. Preliminary analysis of brains from fish exposed to atrazine showed a significant elevation of aromatase activity in male cunner, and a complete analysis of tissues is now underway. Our results to date suggest short-term exposure to an EDC that modifies aromatase activity does not necessarily translate into an impact on reproductive success of exposed fish once spawning has begun.

AROMATASE INHIBITION: LINKING BIOCHEMICAL MECHANISM OF ACTION TO OUTCOME IN THE SHORT-TERM FATHEAD MINNOW REPRODUCTION ASSAY.

D. L. Villeneuve, K. M. Jensen, M. D. Kahl, E. J. Durhan, E. A. Makynen, A. L. Linnun, B. C. Butterworth and G. T. Ankley. *Mid-Continent Ecology Division, USEPA, Duluth, MN.* Sponsor: J. Mata.

A 21 d fathead minnow (*Pimephales promelas*) reproduction assay has been proposed as one of five *in vivo* tests to be used for tier 1 screening of endocrine disrupting chemicals (EDCs). Previous studies with the pharmaceutical aromatase inhibitor fadrozole defined a profile of responses consistent with exposure to a potent aromatase inhibitor. In this study fathead minnows were exposed to two fungicides, prochloraz and fenarimol, that were suspected to act as EDCs through inhibition of aromatase activity and/or weak antiandrogenic effects. The purpose was to examine whether weak aromatase inhibitors, with potentially mixed mechanisms of action, would yield a profile of responses consistent with those observed for fadrozole. *In vitro* experiments with fathead minnow brain and ovary homogenates demonstrated that prochloraz could inhibit fathead minnow aromatase activity (IC50s = 7.2-11.4  $\mu$ M). Fenarimol concentrations greater than 5  $\mu$ M caused a significant decrease in aromatase activity *in vitro* but IC50s could not be determined. *In vivo*, both chemicals significantly decreased fecundity and depressed plasma vitellogenin concentrations in females. Additionally, prochloraz caused a concentration dependent decrease in plasma estradiol. Brain aromatase activity was significantly reduced in males exposed to 0.3 mg prochloraz/L, but neither chemical decreased brain aromatase activity in females, *in vivo*. Results of this study help define predictive relationships between *in vitro* biochemical actions of these chemicals and their ecologically relevant *in vivo* effects. *The contents of this abstract do not necessarily reflect official EPA policy.*

EFFECTS OF VARIOUS LACTONE-DERIVATIVES ON AROMATASE (CYP19) ACTIVITY IN H295R HUMAN ADRENOCORTICAL CARCINOMA CELLS AND (ANTI)ANDROGENICITY IN TRANSFECTED LNCAP HUMAN PROSTATE CANCER CELLS.

T. Sanderson<sup>1</sup>, S. Nijmeijer<sup>1</sup>, D. Scholten<sup>1</sup>, M. van den Berg<sup>1</sup>, S. Cowell<sup>2</sup>, E. Guns<sup>2</sup>, C. Nelson<sup>2</sup> and S. Ruchirawat<sup>3</sup>. <sup>1</sup>Institute for Risk Assessment Sciences, Utrecht University, Utrecht, NL, Netherlands, <sup>2</sup>The Prostate Centre, Vancouver General Hospital, Vancouver, BC, Canada and <sup>3</sup>Laboratory of Medicinal Chemistry, Chulabhorn Research Institute, Bangkok, Thailand.

Certain lactone-containing secondary plant metabolites display potent biological activities, such as anti-inflammatory or anti-tumor. Aromatase (CYP19) is a key enzyme in the synthesis of estrogens from androgens. Over-expression has been asso-

ciated with increased risk of estrogen-dependent mammary tumors, and aromatase inhibitors are effective in their treatment. Thirteen synthetic lactone-derivatives were evaluated for effects on aromatase activity in H295R cells. Cells were exposed to lactones (0.1-100  $\mu$ M) dissolved in DMSO (0.1% in medium) for 24 h prior to measurement of aromatase activity using the tritiated water-release assay. Also, (anti)androgenic effects of the lactones were assessed in LNCaP cells transfected with human androgen receptor (AR) and an AR-responsive luciferase reporter gene. Three (competitive) inhibitors of aromatase activity were identified (potencies in decreasing order): 3-(3, 4-dimethoxyphenyl)-4-(4-methoxyphenyl)-5H-furan-2-one (TM-7; IC50=1  $\mu$ M; Ki=1.0  $\mu$ M), 3, 4-bis-(3, 4-dimethoxyphenyl)-5H-furan-2-one (TM-8; IC50=2  $\mu$ M; Ki=1.2  $\mu$ M) and 3-(3, 4-dimethoxyphenyl)-4-(3, 4, 5-trimethoxyphenyl)-5H-furan-2-one (TM-9; IC50=3  $\mu$ M; Ki=6.8  $\mu$ M). Concentration-dependent inducers of aromatase (>2fold) were 3, 4-diphenyl-5H-furan-2-one (TM-1), 3-phenyl-4-(4-methylsulfonylphenyl)-5H-furan-2-one (TM-4; Viox), 3-(3, 4-difluorophenyl)-4-(4-methylsulfonylphenyl)-5H-furan-2-one (TM-11) and 3-(2, 4-difluorophenyl)-4-(4-methylsulfonylphenyl)-5H-furan-2-one (TM-13). In transfected LNCaP cells, the three inhibitors TM-7, 8 and 9 appeared to be weakly androgenic below 1  $\mu$ M; they were antiandrogenic above 1  $\mu$ M in the presence of 100 pM dihydrotestosterone. The other lactones showed no consistent pro- or anti-androgenic effects in this system.

IN VITRO EFFECTS OF BROMINATED FLAME RETARDANTS ON THE ADRENOCORTICAL ENZYME CYP17. A NOVEL ENDOCRINE MECHANISM OF ACTION?

R. Fernandez Canton<sup>1</sup>, T. Sanderson<sup>1</sup>, S. Nijmeijer<sup>1</sup>, A. Bergman<sup>2</sup> and M. van den Berg<sup>1</sup>. <sup>1</sup>Institute for Risk Assessment Sciences, IRAS, Utrecht, Netherlands and

<sup>2</sup>Department of Environmental Chemistry and Analytical Chemistry, Stockholm University, Stockholm, Sweden.

Fire incidents have decreased over the last 20 years partly due to regulations requiring addition of flame retardants (FRs) to materials. The five major BFRs are hexabromocyclododecane (HBCD), tetrabromobisphenol-A (TBBPA) and three commercial mixtures of polybrominated diphenyl ethers (PBDEs) (penta, octa, deca), which are extensively used as FRs. Furthermore, concentrations of PBDEs have been rapidly increasing during the last 10 years in human breast milk and a number of endocrine (*in vitro*) effects have been reported. We used the human adrenocortical carcinoma cell line (H295R) to assess possible effects of some of these BFRs (PBDEs, several of their metabolites (OH-BDEs, MeO-BDEs), TBBPA, HBCD and brominated phenols (BP)) on CYP17 activity. This enzyme catalyzes an important step in the sex steroidogenesis and is responsible for the biosynthesis of dehydroepiandrosterone (DHEA). In order to study this interaction, a novel method was developed. HBCDD, BDE99 and 100 showed significant inhibition of CYP17 activity at the highest concentrations (10  $\mu$ M) used with no signs of cytotoxicity. A strong inhibition of CYP17 activity was found when the cells were treated with BDE47 (6OH-BDE47) causing a concentration dependent decrease of almost 90% at 10  $\mu$ M but with a concurrent decrease in cell viability at the highest concentration. Replacement of the 6OH group by a methoxy group eliminated this cytotoxicity, while still DHEA production was significantly inhibited. Other OH or their methoxy derivatives were used to explain possible structural properties behind this inhibition of CYP 17 and possible associated cytotoxicity. In the case of 4OH-BDE49, CYP17 activity was significantly reduced and replacement of 4OH group by a methoxy group abolished CYP17 inhibition.

ESTROGENIC ACTIVITY OF THE POLYBROMINATED DIPHENYL ETHERS FLAME RETARDANTS.

M. Mercado Feliciano<sup>1</sup> and R. M. Biggs<sup>2</sup>. <sup>1</sup>Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN and <sup>2</sup>Obstetrics and Gynecology, Indiana University School of Medicine, Indianapolis, IN. Sponsor: L. Kamendulis.

Recent studies suggest that polybrominated diphenyl ethers (PBDEs), used as flame-retardants in textiles and electronics, may act as endocrine disruptors. While PBDEs have been found worldwide in air, foodstuff, wildlife and human tissue, the full impact of exposure to these chemicals on tissue development and cancer is not known. The overall goal is to identify the mechanisms by which PBDEs behave as hormones and thereby perturb the cellular physiology of development and cancer. The commercial PBDE mixture DE-71 was incubated with female rat microsomes in a buffer containing NADP<sup>+</sup> and glucose-6-phosphate dehydrogenase (G6PDH) for different time periods (30 min to 24 hours). The pesticide methoxychlor was used as a positive control. The metabolites generated were tested for estrogenic activity using an Estrogen Response Element (ERE) - luciferase gene construct. Other tests in progress include estrogen receptor (ER) binding assay and MAPK phosphorylation assays to determine nongenomic estrogen-like activity. PBDE oxidative metabolites produced *in vitro* during 24 hours incubation induce gene expression

of ERE-luciferase. On average, incubations with NADP<sup>+</sup> increased PBDE estrogenic activity about 6-fold in the ERE-luciferase assay, compared with vehicle control and about 3-fold compared with control PBDE incubations without NADP<sup>+</sup>. Preliminary results from binding assays indicate that neither PBDE nor its 24-hour metabolites bind the ER. Our data confirms findings by Meerts et al. showing that *in vitro* P450 metabolism of PBDEs produces hormonally-active metabolites (2000; *Toxicology Sciences* 56:95) and that such metabolites have estrogenic activity *in vitro* (2001; *Env. Health Pers.* 109(4):399). Ongoing experiments will assess the ability of PBDEs and their metabolites to bind the estrogen receptor and to activate MAPK phosphorylation associated with non-genomic estrogen effects.

**1750** SCREENING ASSAYS FOR ANDROGENIC ACTIVITIES OF XENOBIOTICS.

S. O. Mueller and S. Simon. *Toxicology, Merck KGaA, Darmstadt, Germany.*

The androgen receptor (AR) is a member of the nuclear receptor superfamily and mediates the physiological effects of androgens. The AR binds to specific DNA sequences, so-called androgen response elements (ARE) leading to transcription of androgen-dependent genes. Interference of the AR signalling pathway by xenobiotics may lead to endocrine disruption. The objective of this study was therefore to establish assays in human cells that enable the analysis of androgenic activities of xenobiotics. Since the activity of the AR is modulated by the cellular environment and the AREs of the target genes, we generated reporter plasmids containing either the consensus steroid response element derived from the MMTV promoter (SRE), a human, or a rat ARE. In addition, we cloned the human AR derived from LNCaP cells. We then analysed several well known androgens for their activity in human prostate carcinoma LNCaP cells with endogenous AR as well as in the human HepG2 cells that lack AR. In LNCaP cells, the activities of R1881, testosterone, dihydrotestosterone (DHT) and cyproterone acetate were low on the SRE reporter, whereas no response at all was observed on the human and rat ARE. In contrast, when we transfected AR into HepG2 cells, all androgens tested exerted strong induction on all reporter plasmids tested. For comparison, we also employed the MMTV long-terminal repeat promoter that showed equal responses as the SRE and ARE reporters in HepG2 cells. The androgenic potencies of the compounds tested were comparable in LNCaP and HepG2 cells with the exception of DHT, which showed a 100-fold lower potency in HepG2 cells when compared to LNCaP cells. Since we were unable to obtain high activities in LNCaP cells, we employed another human prostate cell line, RV1 that expresses endogenous AR. In RV1 cells, DHT exerted potencies at sub-nanomolar doses similar to LNCaP cells and displayed high efficiencies that were comparable to the results obtained in HepG2 cells. In conclusion, the potency of DHT depends highly on the cellular environment. Based on these results, RV1 cells are a highly sensitive and appropriate model to screen for androgenic compounds.

**1751** EVALUATION OF POTENTIAL ESTROGENIC AND ANDROGENIC ACTIVITY OF OCTAMETHYLCYCLOTETRAZILOXANE (D4) AND DECAMETHYLCYCLOPENTASILOXANE (D5).

A. L. Quinn, S. D. Crofoot, J. M. Tobin, J. M. Regan, J. M. McMahon and K. P. Plotzke. *Dow Corning Corporation, Midland, MI.*

The estrogenic activity of D4 and D5 was evaluated in ovariectomized Sprague-Dawley (SD) and Fischer 344 (F-344) rats exposed to the highest achievable vapor concentration of D4 (700 ppm) or D5 (160 ppm) via whole body inhalation for 16 hours/day for 3 days. Immediately following exposure animals were euthanized and the effect of test article on uterine weight (wet and blotted) was evaluated. Exposure to D4 resulted in a significant increase in both absolute and relative uterine weights (wet and blotted), and significant increases in luminal and glandular epithelial cell height in both strains of rats. Exposure to D5 did not result in an increase in any of the estrogenic endpoints measured in either strain of rat. Subsequently, D4 and D5 were evaluated for their ability to bind to the estrogen receptor alpha. In a typical competition experiment, D4 (700 ppm) was able to displace ~20% of the 3H-estradiol. Under identical conditions, D5 (160 ppm) did not displace any of the estradiol indicating that this material does not compete for the receptor-binding site. In an *in vitro* luciferase reporter gene assay using MCF-7 cells transiently transfected with a plasmid for estrogen receptor alpha and the luciferase gene, 10μM D4 resulted in an activation of the reporter gene (6-fold increase over baseline controls). D5 did not activate the reporter gene at the same dose range, while 17β-estradiol resulted in the expected increase (35-fold increase at 10 nM dose range). Using *in vitro* and *in vivo* assays, D4 has consistently resulted in a weak estrogenic response, while D5 has not elicited any estrogenic responses. Castrated male F-344 rats were exposed to D4 or D5 for 16 hours/day for 10 days. Typical Hershberger

assay endpoints were evaluated. Neither material resulted in any significant increase in any of the accessory sex organ weights, indicating that neither D4 nor D5 is associated with any androgenic activity. Sponsored by the Silicones Environmental, Health and Safety Council of North America.

ESTROGENIC ENDOCRINE DISRUPTOR POTENCY OF ORGANOCHLORINE PESTICIDES DETECTED USING THE LUMI-CELL™ ER BIOASSAY.

J. D. Gordon<sup>1</sup>, A. C. Chu<sup>1</sup>, M. D. Chu<sup>2</sup>, M. S. Denison<sup>3</sup> and G. C. Clark<sup>1</sup>.

<sup>1</sup>*Xenobiotic Detection Systems, Inc., Durham, NC*, <sup>2</sup>*Alta Analytical Perspectives Inc., Wilmington, NC* and <sup>3</sup>*Department of Environmental Toxicology, University of California, Davis, Davis, CA*.

Organochlorine pesticides are found in many ecosystems worldwide, which have resulted in the contamination of the food chain. Endocrine disruptor compounds (EDCs) can have a significant detrimental effect on the endocrine and reproductive systems of both humans and animals. Identification of EDC pesticides requires a relevant bioassay, which can detect these chemicals, and provide a relevant estimate of their endocrine disrupting potency. To detect EDCs, BG-1 cells were stably transfected with an estrogen-responsive luciferase reporter gene plasmid (pGudLuc7ere). The resulting cell line, the LUMI-CELL™ ER bioassay, responds to estrogenic chemicals in a time-, dose dependent- and chemical-specific manner with the induction of luciferase gene expression. Thirteen organochlorine pesticides suspected of possessing estrogenic endocrine disrupting potential were tested. All of the compounds with historical data demonstrating estrogenic activity were shown to possess estrogenic activity. When comparing the estrogenic potency of the pesticides, the order of induction of activity with respect to their EC50 values is: α-Chlordane > Kepone > DDD > pp' DDT > Methoxychlor > Ψ-Chlordane > pp' DDE > Fenarimol > 2, 4, 5-Trichlorophenoxyacetic Acid > Dieldrin > Linuron > Mirex = Vinclozolin. The average minimal effective dose for organochlorine pesticides in animals appears to be 5 ppm or greater. The LUMI-CELL™ ER bioassay is capable detecting organochlorine pesticides at <1 ppm (with a lower limit of detection of <0.1 ppm). This data clearly demonstrates that the LUMI-CELL™ ER high-throughput bioassay system is a fast, reliable, and relatively inexpensive method for detection of environmental EDCs, and could refine, reduce or replace animals in many tests. Meeting requirements mandated by the EPA and ICCVAMs Tier I requirements for EDC detection assays. Supported by NIEHS SBIR grant ES10533-03 and Superfund Basic Research Grant ES04699.

**1753**

SENSITIVE METHOD FOR DETERMINING PESTICIDE ESTROGENIETY AT PICOMOLAR LEVELS USING A SERUM-FREE BG-1 OVARIAN CELL MODEL.

P. Wong and F. Matsumura. *Ctr for Health and the Environment, UC Davis, Davis, CA.*

Most xenobiotic estrogenicity assay methods rely on their direct agonist action on the estrogen receptor (ER). Often, ligand binding assays are used to approximate their ER activation potential. Such methods, however, do have drawbacks since most pesticides activate the ER via a "ligand independent activation" (LIA) by being only weak or non-agonistic with the ER. Therefore, there is a need to develop an assay method that will detect the estrogenic actions of a pesticide regardless of its ER ligand binding ability. Using a serum-free BG-1 ovarian cell model, we investigated the ability of several organochlorine (OC) pesticides to stimulate known estrogenic actions such as increased proliferation, and upregulation of estrogen response element (ERE) dependent proteins. These effects were abolished using ICI 164, 384 (ICI), a pure ER antagonist, thus implicating the requirement of ER for these events. Using these methods, we observed concentration dependent (10pM-100nM) ER mediated cell proliferation in BG-1 cells using the OCs heptachlor epoxide (HE), β-hexachlorohexane (βHCH), and endosulfan I (ENDO). In addition, we were able to observe upregulation of the ERE dependent proteins progesterone receptor and PS2. EMSA studies for ERE binding further supported these OC's ERE activating abilities. Using the same culture conditions, we tested the blocking action of growth factor antibodies for erbB2 (9G6) and insulin-like growth factor (IGF-Ab) receptors and discovered they to inhibit BG-1 proliferation by HE (9G6), βHCH (9G6) and ENDO (IGF-Ab). This experiment confirms the existence of a possible crosstalk between ER and growth factor receptors in OC LIA. In conclusion, we were able to develop a sensitive method for determining both ligand dependent and independent estrogenic activity of selected pesticides. Secondly, we demonstrated the ability of OCs to activate the estrogenic system in BG-1 cells independent of direct ER binding; and third, our data implicates a possible crosstalk component between the ER and growth factor receptor systems for OC LIA.

GENE EXPRESSION PATTERNS OF THE AMPHIBIAN HPT-AXIS IN NORMAL DEVELOPMENT AND AFTER EXPOSURE TO THE MODULATORS METHIMAZOLE, PERCHLORATE AND PROPYLTHIOURACIL.

J. J. Korte, H. M. Kerr, S. L. Batterman, G. W. Holcombe, P. A. Kosian, J. E. Tietge and S. J. Degitz. *MED, NHEERL, ORD, USEPA, Duluth, MN*. Sponsor: J. Nichols.

In response to the Endocrine Disruptor Screening and Testing Program Advisory Committee recommendations, the USEPA has developed a screening assay capable of detecting the effects of chemicals on the hypothalamus-pituitary-thyroid (HPT) axis in *Xenopus laevis*. The primary endpoints of the screen are developmental rate and thyroid gland histology. However, we are currently developing biochemical (thyroid hormone concentrations), and molecular (gene and protein) measurements to improve diagnostic capability of the assay. In this study, we determined developmental expression patterns of key genes from stages 51 to 66 in the pituitary (thyroid stimulating hormone (TSH) and deiodinases type II and III (DII and DIII)) and thyroid gland (thyroid transcription factor I (TTF I), thyroid peroxidase (TPO), thyroglobulin (TG), and sodium-iodide symporter (NIS)). Measurements were made by quantitative real-time RT-PCR (Q-PCR). Significant patterns of stage-specific gene expression were observed. In the baseline pituitary samples, expression of TSH and DII tracked together peaking at stage 59, while DIII did not peak until stage 62, a pattern which is consistent with a regulatory role in metamorphic climax. Concentrations of methimazole, perchlorate, and propylthiouracil which have been shown to significantly affect metamorphosis and thyroid gland morphology did not result in changes in the expression of TSH, DII, and DIII in the pituitary within 48 h. Additionally, some samples were used to generate amplified RNA probes for use in a focused gene array. The array contains nearly 100 genes of importance to the HPT axis. Results from the two methods for detecting changes in gene expression showed unique advantages: While gene arrays examine many genes in one experiment, the quantitative data from Q-PCR experiments allows more robust statistical comparisons. This abstract does not necessarily reflect EPA policy.

PROTEIN PROFILING OF *XENOPUS LAEVIS* BRAIN CELLS FOLLOWING EXPOSURE TO T4 SYNTHESIS INHIBITORS: POTENTIAL APPLICATION TO THE ASSESSMENT/DIAGNOSIS OF XENOBIOTICS THAT PERTURB THE THYROID PATHWAY.

J. Serrano<sup>1</sup>, B. Witthuhn<sup>2</sup>, L. Higgings<sup>2</sup>, J. Tietge<sup>1</sup>, J. Korte<sup>1</sup>, P. Kosian<sup>1</sup>, G. Holcombe<sup>1</sup> and S. Degitz<sup>1</sup>. <sup>1</sup>*ORD/NHEERL/MED, USEPA, Duluth, MN* and <sup>2</sup>*Biochemistry and Molecular Biology, University of Minnesota, St. Paul, MN*.

Sponsor: J. Nichols.

Development of a cost-effective, non-mammalian screening assay for thyroid axis disrupting chemicals is a goal of the USEPA. To address this need, we are applying a multi-endpoint strategy that combines molecular and *in vivo* methods using the amphibian model, *Xenopus laevis*. As part of this effort, we report the use of a proteomic approach to assess the effects of xenobiotics on the thyroid hormone axis. Differential protein profiling was applied to investigate specific expression patterns produced by a suite of model T4 synthesis inhibitors in pre-metamorphic *Xenopus*. Gel electrophoresis and Mass Spectrometry were used to evaluate the effects of methimazole, perchlorate and propylthiouracil upon protein expression in brain tissue cells. Briefly, proteins were isolated/separated by 2D-PAGE, stained and quantitated by image analysis. Spots showing quantitative differences between control and treated samples were excised robotically and identified by LCMS. Over 20 proteins were found to be differentially regulated by these compounds. To date, we have characterized 4 proteins showing the most consistent/unique changes across chemicals tested. These proteins fell into various functional groups comprising gene expression modulation (hnRNP A1), targeted membrane fusion (SNAP-25), lipid raft formation (flotillin 1), and metabolism (aldolase). Results indicated that SNAP-25, a t-SNARE complex protein, is upregulated by all T4 inhibitors assessed. This finding is consistent with reports of SNAP-25 upregulation in the adenohypophyses of thyroidectomized rats, and downregulation in the adrenal gland by T4. Overall, these data demonstrate the utility of protein profiling to establish characteristic expression patterns which can be used as diagnostic elements for thyroid active chemicals. (This abstract does not necessarily reflect USEPA policy)

PHENOBARBITAL AFFECTS THYROID HISTOLOGY AND LARVAL DEVELOPMENT IN THE AFRICAN CLAWED FROG, *XENOPUS LAEVIS*.

M. J. Chowdhury, G. W. Holcombe, P. A. Kosian, J. E. Tietge and S. J. Degitz. *Mid-Continent Ecology Division, USEPA, Duluth, MN*. Sponsor: J. Nichols.

The USEPA (EPA) has recently proposed an amphibian-based assay intended for screening chemicals abilities to disrupt the thyroid axis. To develop this assay, a number of chemicals have been tested which have well defined mechanism of pitu-

itary-thyroid axis disruption. The objective of the present study was to determine if *Xenopus* is sensitive to chemicals which act by inducing the biotransforming enzyme uridine diphosphate glucuronosyltransferase (UDPGT). In mammals, phenobarbital is known to induce microsomal UDPGTs resulting in increased thyroid hormone glucuronidation and elimination. However, it is not clear if amphibians are sensitive to this mode of thyroid axis disruption. In this study, we exposed stage-54 *Xenopus laevis* tadpoles to a range of phenobarbital concentrations (0, 125, 250, 500, 1000, and 1500 mg/L) via the water. At day 21, we characterized morphology, thyroid gland histology and larval development. Treatment resulted in a concentration dependent increase in mortality and thyroid gland changes, although dramatic effects on developmental rate were not observed. Tadpole mortalities at the experimental concentrations were 0, 0, 2.5, 13, 27, and 45 % respectively over 21 days. Phenobarbital treatment resulted in thyroid hypertrophy, colloid reduction, enlarged irregular follicles, and follicular cell hypertrophy and hyperplasia. These results are consistent with those observed in mammals, thus indicating *Xenopus* tadpoles are sensitive to the thyroid axis disrupting effects of phenobarbital via UDPGT-mediated pathways. Molecular investigation of UDPGT genes is currently underway in our laboratory to further understand the mechanism in *Xenopus* tadpoles. (M. J. Chowdhury is a US National Research Council Associate. This abstract does not necessarily reflect USEPA policy).

SUBLETHAL EFFECTS OF CADMIUM ON DEVELOPMENT IN *RANA PIPIENS* AND *XENOPUS TROPICALIS*.

J. A. Gross<sup>1,2</sup>, T. Chen<sup>2</sup> and W. H. Karasov<sup>2</sup>. <sup>1</sup>*Animal Sciences, University of Wisconsin - Madison, Madison, WI* and <sup>2</sup>*Wildlife Ecology, University of Wisconsin - Madison, Madison, WI*.

While there have been many studies characterizing acute responses in amphibian adults, embryos and larvae to heavy metals such as cadmium the responses of amphibians to chronic exposure to this metals is generally unstudied. Some metals are putative endocrine disruptors and affect sexual development, reproduction, and metamorphosis but the sensitivity of amphibians to these effects are also unstudied. We exposed embryos and tadpoles of northern leopard frogs (control, 0.25, 5.0, 20.0 µg/l, as CdCl<sub>2</sub>; static renewal system) and African clawed frogs (control, 6.25, 25.0, 100.0, 400.0 µg/l, as CdCl<sub>2</sub>; flow-through diluter system) to sublethal doses of cadmium from embryonic stages to complete tail resorption. Survival of embryos (Gosner stage (GS) 17 to 25 for *R. pipiens* and Neiwenkoop and Faber stage (NFS) 29 to 43 for *X. tropicalis*) was > 94% in all treatments for both species. *Rana pipiens* tadpole mortality was positively correlated with dose and was significantly higher in the 20.0 µg/l treatments than all other treatments by week 8 (P<0.05). Tadpole survival was >80% through GS 42, forelimb emergence for all other treatments. Tadpoles exposed to 0.25 and 5.0 µg/l Cd demonstrated increased size by week 7 (P<0.05 and P=0.07 respectively) and were significantly younger at GS 42 (P<0.001 and P<0.05 respectively) relative to control. Swimming speed of tadpoles in 0.25 µg/l treatments was significantly higher than other treatments (p < 0.05). No differences were seen in *X. tropicalis* tadpole survival (>70%) to NFS 65, complete tail resorption. *Xenopus tropicalis* exposed to 6.25, 100.0 and 400.0 µg/l Cd were larger at NFS 65 relative to other treatments. This is the first chronic sublethal Cd study for both *R. pipiens* and *X. tropicalis*. Cadmium was shown to alter growth and development in a native and model amphibian species at ecologically relevant concentrations.

MECHANISMS OF GERMINAL VESICLE BREAKDOWN (GVBD) INHIBITION BY PHENYL-SUBSTITUTED GLYCOL ETHERS IN *XENOPUS OOCYTES IN VITRO*.

D. J. Fort<sup>1</sup>, R. L. Rogers<sup>1</sup>, J. H. Thomas<sup>1</sup>, P. D. Guiney<sup>2</sup> and J. A. Weeks<sup>2</sup>. <sup>1</sup>*Fort Environmental Laboratories, Stillwater, OK* and <sup>2</sup>*Product Safety & Environmental Assessment, SC Johnson & Son, Racine, WI*.

Under normal conditions, *Xenopus* oocytes undergo final maturation which is induced by progesterone via a membrane bound receptor (OMPR) or androgens via a classical intracellular receptor (AR). The progestin/antiprogestin activities of a series of substituted glycol ethers including: ethylene glycol monomethyl ether (EGME), -monoethyl ether (EGEE), -monopropyl ether (EGPE), -monobutyl ether (EGBE), -monophenyl ether (EGPhE), diethylene glycol monomethyl ether (DGME), and triethylene glycol monomethyl ether (TGME) were screened using an *in vitro* *Xenopus* oocyte germinal vesicle breakdown (GVBD) assay. Results suggested that each of the ethylene glycol ethers, but not DGME or TGME were capable of inhibiting GVBD *in vitro* in a concentration dependent manner. Potency, expressed as an IC<sub>25</sub>, ranged from 1.0 µg/L for EGPhE to >10 mg/L for TGME. Results from additional studies suggested that the inhibitory effects of EGME, EGEE, EGPE, and EGBE on GVBD may be mediated primarily through the OMPR, whereas the unanticipated potency of EGPhE is postulated to be a result of bimodal inhibition of both the OMPR and AR pathways. This unexpected potency

of EGPhE based structure activity assessment suggested that additional phenyl-substituted glycol ethers including, EG-monobenzyl ether (EGBeE), EG-diphenyl ether (EGDPhE), and propylene glycol monophenyl ether (PGPhE) should be evaluated in an attempt to establish their relative potencies compared to the EGPhE. The monophenyl-substituted GEs were most capable of inhibiting GVBD producing relative GVBD inhibition potencies: EGPhE > PGPhE > EGME >> EGEE > EGBeE > EGPE >> EGBE >> EGDPhE >> DGME = TGME. These results suggest a remarkable structural specificity of mono-substituted phenyl ethers (EGPhE and PGPhE) to inhibit Xenopus oocyte maturation and warrant additional receptor binding studies.

NON-ADDITIVE DOSE DEPENDENT GENE EXPRESSION PATTERNS EXHIBITED BY A MIXTURE OF 17-ALPHA ETHYNYLESTRADIOL AND GENISTEIN *IN VIVO*.

R. Gupta<sup>2, 3, 4</sup>, L. D. Burgoon<sup>1, 3, 4</sup>, A. Harney<sup>2, 3, 4</sup>, D. R. Boverhof<sup>2, 3, 4</sup>, J. Kwekel<sup>2, 3, 4</sup>, C. Gennings<sup>5</sup> and T. R. Zacharewski<sup>2, 3, 4</sup>. <sup>1</sup>*Pharmacology & Toxicology, Michigan State University, East Lansing, MI*, <sup>2</sup>*Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI*, <sup>3</sup>*Center for Integrative Toxicology, Michigan State University, East Lansing, MI*, <sup>4</sup>*National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI* and <sup>5</sup>*Biostatistics, Virginia Commonwealth University, Richmond, VA*.

Human populations are generally exposed to subthreshold doses of the phytoestrogen genistein, however there are concerns regarding non-additive interactions with other exogenous and endogenous estrogens. Coadministration of submaximal doses of 17-alpha ethynylestradiol (EE) and genistein (GEN) were studied to identify non-additive gene expression interactions. Immature, ovariectomized mice were gavaged with 3, 10, 30, 100, or 300ug/kg EE; 0.3, 0.9, 3, 9, or 30mg/kg GEN; a 1:100 mixture of EE and GEN (same doses as above), or sesame oil vehicle. Animals were sacrificed 24hrs following administration and uterotrophic effects and hepatic gene expression was examined. All doses of EE and selected doses (3/0.9; 10/3; 30/9; 100/30 ug/kg / mg/kg) EE/GEN induced uterine wet weight; while GEN failed to elicit a significant ( $P = 0.05$ ) uterotrophic response. Custom cDNA microarrays with 13, 824 features representing 8661 unique genes were used to monitor changes in hepatic gene expression from EE, GEN, or mixture treated mice. EE and mixture samples clustered together, while GEN samples clustered separately. Eighty genes exhibited a monotonic response in either EE or GEN treated hepatic samples. Of these, 23 exhibited non-additive interactions as assessed by the single chemical required (SCR) method. Gene functions represented by these 23 genes included steroid metabolism and biosynthesis and response to oxidative species, and are localized to the endoplasmic reticulum and the mitochondria. Results from these studies demonstrate non-additive interactions between EE and GEN that warrant further investigation. Supported by NIH Grants R01 ES11271 and \*T32 ES07255.

TEMPORAL GENE EXPRESSION ANALYSIS OF MOUSE HEPA-1C1C7 CELLS TREATED WITH 17 $\beta$ -ESTRADIOL BY CDNA MICROARRAY.

C. J. Fong, L. D. Burgoon, R. Gupta, D. G. Humes and T. R. Zacharewski. *Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI*.

cDNA microarrays, containing 6376 clones representing 4858 unique genes, were used to examine temporal changes in gene expression in the mouse Hepa-1c1c7 hepatoma cell line following treatment with 10 nM 17 $\beta$ -estradiol (E2) or vehicle (DMSO) in serum free media at 1, 2, 4, 8, 12, 24, and 48 hours. MTT and direct cell count assays indicated that cells were viable in serum free media but at a significantly reduce proliferation rate. Model-based t-statistical analysis identified significant changes in the expression of 213 unique genes representing functions associated with lipid metabolism, glucose metabolism and oxidative stress with seven k-means clusters representing the major temporal patterns. Overall gene-specific changes in expression between *in vitro* and *in vivo* models were poor. However, the induction of LDL receptor genes (*Vldlr*, *Sorl1*) and the cholesterol-ester synthesis gene (*Soat1*), and the down-regulation of HDL receptor (*Scarb1*) are in agreement with liver responses in C57BL/6 mice following oral ethynylestradiol exposure and consistent with the reported *in vivo* decreases in serum LDL/HDL ratios elicited by estrogens. Estrogenic regulation of the hepatic liver X receptor (*LXR*), a cholesterol regulator, may also be a contributing factor of activating these events. In contrast, DMSO elicited only 95 early changes in gene expression representing functions associated with cell proliferation, solute homeostasis and xenobiotic metabolism which could be described by two k-means clusters indicating that it is not a significant contributor to the changes observed upon exposure to estrogen. This study shows that although Hepa-1c1c7 cells may not be an appropriate model for overall *in vivo* hepatic effects of estrogen, it may be suitable for more define studies investigating specific mechanisms such as those affecting cholesterol transport and metabolism. Supported by R01 ES11271.

1761

CONSTITUTIVE ANDROSTANE RECEPTOR (CAR)-DEPENDENT HEPATIC INDUCTION OF UDP-GLUCURONOSYLTRANSFERASES (UGTs) IN WISTAR-KYOTO RATS BY CYP2B INDUCERS.

M. K. Shelby<sup>1</sup>, A. L. Slitt<sup>1</sup>, N. J. Cherrington<sup>2</sup> and C. D. Klaassen<sup>1</sup>. <sup>1</sup>*University of Kansas Medical Center, Kansas City, KS* and <sup>2</sup>*University of Arizona, Tucson, AZ*.

UGTs catalyze the glucuronidation of numerous endogenous and xenobiotic compounds. UGT activity is increased by phenobarbital (PB) and other compounds that induce cytochrome P450 2B (CYP2B). Induction of CYP2B by PB is mediated via CAR binding to phenobarbital response element modules (PBREM). The purpose of this study was to determine: 1) CAR dependence of UGT induction by the CYP2B inducers PB, diallyl sulfide (DAS), polychlorinated biphenyl 99 (PCB99), and trans-stilbene oxide (TSO), and 2) whether CYP2B inducers activate PBREM in a CAR-dependent manner *in vivo*. Wistar Kyoto (WK) rats have male-predominant expression of CAR in liver. Thus, a more robust induction of UGTs or activation of PBREM-luciferase reporter activity in male WK rats compared to females would indicate CAR dependence. UGT mRNA levels were examined in livers of male and female WK rats treated with PB, DAS, PCB99 and TSO using the branched DNA assay. UGT1A1, 1A5, and 2B1 mRNA levels were induced in male WK rats by all four CYP2B inducers. However, in female WK rats, induction was either absent or diminished suggesting induction of UGT1A1, 1A5, and 2B1 by CYP2B inducers is CAR-dependent. UGT1A6 mRNA was increased only by TSO, and induction occurred to the same extent in both male and female WK rats, suggesting induction of UGT1A6 by TSO is independent of CAR expression. Hepatic injections of PBREM-luciferase reporter construct into male and female WK rats and subsequent luciferase reporter assays were conducted to examine CAR-dependent activation of PBREM by CYP2B inducers. PB and DAS treatment of male WK rats produced a 20- and 10-fold increase, respectively, in luciferase activity relative to controls; whereas in females, luciferase activity was increased 7 and 3 fold respectively. Together these results indicate that induction of UGT1A1, 1A5, and 2B1 by CYP2B inducers is mediated via CAR. Additionally PB and DAS activate PBREM in a CAR-dependent manner. (Supported by NIH Grants ES-08156 and ES-07079)

1762

HEPATIC INDUCTION OF MOUSE UDP-GLUCURONOSYLTRANSFERASE (UGT) MNRA EXPRESSION BY PROTOTYPICAL ACTIVATORS OF VARIOUS TRANSCRIPTION PATHWAYS.

D. B. Buckley, J. S. Petrick and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS*.

UGTs catalyze the addition of UDP-glucuronic acid to endo- and xenobiotics, enhancing their water solubility and excretion. Many exogenous compounds, such as microsomal enzyme inducers (MEIs), alter gene expression through xenobiotic-responsive transcription factors, namely the aryl hydrocarbon receptor (AhR), constitutive androstane receptor (CAR), pregnane X receptor (PXR), peroxisome proliferator-activated receptor alpha (PPAR $\alpha$ ), and NF-E2 related factor 2 (Nrf2). These transcription factors regulate xenobiotic-inducible expression of hepatic biotransformation enzymes and transporters. The purpose of this study was to determine the hepatic inducibility of mouse Ugt isoforms by MEIs. Male C57BL/6 mice were treated for four consecutive days with activators of AhR (TCDD, PCB126, and  $\beta$ -naphthoflavone), CAR (TCPOBOP, phenobarbital, and diallyl sulfide), PXR (pregnenolone-16 $\alpha$ -carbonitrile, spironolactone, and dexamethasone), PPAR $\alpha$  (clofibrate, ciprofibrate, and diethylhexylphthalate), and Nrf2 (oltipipraz, ethoxyquin, and butylated hydroxyanisole), respectively. Mouse hepatic Ugt mRNA expression was determined using the branched DNA signal amplification assay. Ugt1a isoforms predominantly expressed in liver were inducible by MEIs. Ugt1a1 mRNA expression was induced by activators of all five transcription factor pathways, Ugt1a5 was induced by Nrf2 activators, Ugt1a6 was induced by AhR ligands, and Ugt1a9 was induced by AhR, CAR, PXR, and PPAR $\alpha$  activators/ligands. Although liver-predominant, mouse Ugt2b isoforms analyzed did not exhibit hepatic mRNA induction by any class of inducer. Results indicate that among the 11 mouse Ugts examined, four isoforms, Ugt1a1, 1a5, 1a6, and 1a9, are inducible in liver. These results suggest that MEIs can work through at least 5 different xenobiotic-responsive transcription factor pathways to induce Ugt1a isoforms in mouse liver. (Supported by NIH Grants ES-08156 and ES-07079)

1763

INDUCIBILITY OF MOUSE TRANSCRIPTION FACTORS THAT REGULATE HEPATIC METABOLISM AND TRANSPORT.

J. S. Petrick, D. B. Buckley and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS*.

Aryl hydrocarbon receptor (AhR), constitutive androstane receptor (CAR), pregnane X receptor (PXR), peroxisome proliferator-activated receptor alpha (PPAR $\alpha$ ), and NF-E2 related factor 2 (Nrf2) are transcription factors that coordinately induce expression of biotransformation enzymes and transporters in response to

xenobiotics. Treatment of mice with activators of AhR, CAR, PXR, PPAR $\alpha$ , and Nrf2 induces expression of their associated marker genes: cytochrome P450 (Cyp) 1a1, 2b10, 3a11, 4a14, and NADPH quinone oxidoreductase 1 (Nqo1), respectively. The purpose of this study was to determine whether AhR, CAR, PXR, PPAR $\alpha$ , and Nrf2 activators induce mRNA expression of these transcription factors concomitantly with induction of their corresponding marker genes. Male C57BL/6 mice were treated for four days with activators of AhR (TCDD, PCB126, and  $\beta$ -naphthoflavone), CAR (TCPOBOP, phenobarbital, and diallyl sulfide), PXR (pregnenolone-16 $\alpha$ -carbonitrile, spironolactone, and dexamethasone), PPAR $\alpha$  (clofibrate, ciprofibrate, and diethylhexylphthalate), or Nrf2 (oltipraz, ethoxyquin, and butylated hydroxyanisole). All marker genes were induced by activators of their associated transcription factors. In addition, some marker genes were induced by multiple classes of activator compounds, as 1) Cyp2b10 was induced by CAR, PXR, PPAR $\alpha$  and Nrf2 activators, 2) Cyp3a11 was induced in response to both CAR and PXR activators, and 3) Nqo1 expression was induced by activators of AhR, PPAR $\alpha$  and Nrf2. Of the transcription factors, only PPAR $\alpha$  was induced by more than one of its own ligands. Furthermore, CAR was induced by AhR ligands, and PXR was induced by two of three PPAR $\alpha$  ligands. Overall, the magnitude of transcription factor induction was modest, indicating that their expression is tightly regulated, even in the presence of compounds that markedly induce expression of their marker genes. These data indicate that P450 and Nqo1 induction by xenobiotics occurs with minimal induction of their associated transcription factors. (Supported by NIH Grants ES-09716, ES-09649, ES-08156, and ES-07079)

#### 1764

#### VITAMIN D-INTERACTING PROTEIN 150 (DRIP150) COACTIVATION OF ESTROGEN RECEPTOR $\alpha$ (ER $\alpha$ ) IN ZR-75 BREAST CANCER CELLS IS INDEPENDENT OF LXXLL MOTIFS.

J. Lee<sup>1</sup>, K. Kim<sup>1</sup> and S. Safe<sup>1,2</sup>. <sup>1</sup>*Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX* and <sup>2</sup>*Institute of Biosciences & Technology, Texas A&M University System Health Science Center, Houston, TX*.

Vitamin D receptor-interacting protein 150 (DRIP150) has been identified as part of mediator-like complexes that enhance transcriptional activation of the estrogen receptor (ER) and other nuclear receptors (NRs). DRIP150 coactivates ligand-dependent ER $\alpha$ -mediated transactivation in ZR-75 and MDA-MB-231 breast cancer cells transfected with a (luciferase) reporter construct (pERE $\alpha$ ) regulated by three tandem estrogen responsive elements (EREs). Coactivation of ER $\alpha$  by DRIP150 in ZR-75 cells was activation function 2 (AF2)-dependent and required an intact helix 12 that typically interacts with LXXLL motifs (NR-box) in p160 steroid receptor coactivators (SRCs). DRIP150 contains C- and N-terminal NR-boxes (amino acids 1186-1182 and 73-69, respectively), and deletion analysis of DRIP150 showed that regions containing these sequences were not necessary for coactivation of ER $\alpha$ . Analysis of multiple DRIP150 deletion mutants identified a 23 amino acid sequence (811-789) required for coactivation activity. Analysis of the protein crystal structure data base identified two regions at amino acids 789-794 and 795-804 which resembled  $\alpha$ -helical motifs in Lanuguinosa lipase/histamine N-methyl transferase and hepatocyte nuclear factor 1, respectively. Using a squelching assay and specific point mutations into proline residues within each  $\alpha$ -helix, the NZF-SEVRVYN (795-804) region was identified as the critical sequence required for the activity of DRIP150. These results demonstrate that coactivation of ER $\alpha$  by DRIP150 in ZR-75 cells is NR-box independent and requires a novel sequence with putative  $\alpha$ -helical structure. #### 1765

#### GLUCOCORTICOID RECEPTOR AND STEROID AND XENOBIOTIC RECEPTOR (SXR) REGULATION OF SXR PROMOTER ACTIVITY.

L. M. Tompkins and A. D. Wallace. *Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC*.

In recent years, it has been established that steroid and xenobiotic receptor (SXR) or pregnane X receptor (PXR), plays a novel role as a xenosensor by binding a wide spectrum of xenobiotics and altering metabolism by induction of cytochrome P450 enzymes, specifically 3A4. Xenobiotics capable of inducing SXR expression and subsequent CYP3A4 expression can alter metabolic pathways and potentiate drug-drug interactions. Of the three SXR protein isoforms, preliminary experiments demonstrate selective induction of one isoform following glucocorticoid treatment. To study the regulation of SXR gene expression, we cloned a 2kb fragment of the SXR promoter region into the pGL3 luciferase reporter vector (SXR2kb-luc). The SXR2kb-luc construct was transiently transfected into the human hepatoma cell line HepG2, along with human glucocorticoid receptor (hGR) expression vector and treated with the glucocorticoid dexamethasone (Dex). Surprisingly, SXR2kb-luc reporter activity was repressed 40% by hGR alone compared to empty vector controls, and Dex treatment caused an additional ligand-dependent decrease in re-

porter activity. Zhang et al. (1999) demonstrated pregnenolone 16 $\alpha$ -carbonitrile (PCN), a rat SXR ligand, was capable of inducing SXR mRNA expression, suggesting SXR may regulate its own promoter. HepG2 cells were then co-transfected with SXR2kb-luc and either pSG5 empty vector or hSXR expression vector. hSXR expression caused an 60-80% decrease in reporter activity when compared to empty vector controls. When hSXR transfected cells were treated with the hSXR ligand rifampicin, repression of SXR2kb-luc activity was observed to 30% of the vehicle treated controls. These experiments demonstrate significant reporter activity from the binding of endogenous HepG2 cellular proteins to response elements in the SXR2kb promoter. Repression mediated by both GR and SXR suggests a common mechanism may be responsible. Repression of SXR promoter reporter activity, while not the expected outcome, hints at a more complex and dynamic profile of SXR gene expression.

#### 1766

#### HEPATOCYTE RXRALPHA REGULATES THE EXPRESSION OF THE GLUTATHIONE S-TRANSFERASE GENES AND MODULATES ACETAMINOPHEN-GLUTATHIONE CONJUGATION IN MOUSE LIVER.

Y. Y. Wan, N. Chou, L. He, M. Gyamfi, A. J. Mendy and G. Dai. *Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS*.

Retinoid X receptor alpha (RXR $\alpha$ )-mediated pathways play a critical role in xenobiotic detoxification. Our previous report showed that RXR $\alpha$  modulates acetaminophen (APAP)-induced hepatotoxicity. The present study further elucidates the role of hepatocyte RXR $\alpha$  in detoxification of APAP. Wild type and hepatocyte RXR $\alpha$ -deficient mice were injected with a toxic dosage of APAP (i.p., 500 mg/kg). Liver injury was monitored by measuring serum alanine aminotransferase (ALT) and sorbitol dehydrogenase (SDH) activities and liver histology. Our data demonstrated that hepatocyte RXR $\alpha$ -deficient mice were protected from the hepatotoxic effect of APAP, even though the liver basal glutathione (GSH) levels were significantly lower than wild type mice. To further analyze the mechanism, HPLC analysis of APAP metabolites was performed. Our data revealed a significantly higher amount of APAP-GSH conjugate in the liver and bile of RXR $\alpha$ -deficient mice compared with that of wild type mice. APAP overdose causes accumulation of the toxic electrophile N-acetyl-p-benzoquinone imine (NAPQI), which is detoxified by conjugation with reduced GSH to form the 3-S-glutathionyl conjugate of APAP (APAP-GSH) via the action of glutathione S-transferases (Gsts). Therefore, northern blot analyses were performed to measure the gene expression of Gst family members in APAP-treated and untreated mice for both genotypes. The mRNA levels of seven Gst family members were up-regulated in RXR $\alpha$ -deficient mice, whereas Gstpi was down-regulated. After APAP treatment, Gst theta3 was up-regulated, while Gst alpha1 and 3 were down-regulated in RXR $\alpha$ -deficient mice. It is likely that the alteration of the gene expression profile of Gst family in the liver of RXR $\alpha$ -deficient mice enhances APAP-GSH conjugation, which in turn contributes to the protection of RXR $\alpha$ -deficient mice from APAP-induced hepatotoxicity.

#### 1767

#### P38 MITOGEN-ACTIVATED PROTEIN KINASE IS INVOLVED IN CONSTITUTIVE ANDROSTANE RECEPTOR SIGNALING TO REGULATE CYP2B INDUCTION BY XENOBIOTICS.

F. Zhang, H. B. Hoffman and L. You. *CIIT, Research Triangle Park, NC*.

The constitutive androstan receptor (CAR) is a member of the nuclear receptor (NR) superfamily. CAR activation causes induction of genes encoding xenobiotic and steroid-metabolizing enzymes CYP2B. In contrast to classic endocrine NRs that show very selective ligand binding, CAR displays relatively low affinities for its ligands. CAR also differs from most other NRs in having a strong constitutive activity in the absence of ligand. Like NRs, the mitogen-activated protein kinase (MAPK) signaling pathways play critical roles in regulating gene expression and control diverse cellular responses to internal and external stimuli. MAPK pathways have been implicated in numerous NR-regulated functions since the NRs and their transcriptional coregulators are often among the downstream substrates of the kinases. In this study, we investigated the role of MAPK in CAR-mediated CYP2B gene induction by examining the three main MAPK pathways, ERK, p38, and JNK. Real time RT-PCR analyses of CD-1 mouse primary hepatocytes showed that while blocking the ERK and JNK MAPK pathways did not have significant effects on the induction of CYP2B10, inhibition of the p38 MAPK pathway not only reduced endogenous CYP2B10 gene expression, but also minimized the induction of CYP2B10 by TCPOBOP, a potent CAR activator. Examination of kinase activation showed that TCPOBOP treatment increased the level of phosphorylated p38 in mouse primary hepatocytes. Also, transient transfection assays in HepG2 cells demonstrated that inhibition of the p38 MAPK pathway repressed CAR transactiva-

vation, but that blocking the ERK and JNK pathways did not inhibit CAR activation. These results indicate that p38 MAPK activity is required for CAR-mediated induction of the CYP2B gene in response to xenobiotics.

## 1768

### EVIDENCE FOR CAR-DEPENDENT HEPATOCELLULAR PROLIFERATION IN TCPOBOP-TREATED CONSTITUTIVE ANDROSTANE RECEPTOR KNOCKOUT (CAR<sup>-/-</sup>) MICE.

D. M. Nelson, V. Bhaskaran, B. Gemzik, B. D. Car and L. D. Lehman-McKeeman. *Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ.*

TCPOBOP (1, 4-bis[2-(3, 5-dichloropyridoxyl)] benzene), a potent agonist of CAR, is a mitogen and liver tumor promoter in mice. In this study, male and female wildtype (C57BL/6) and CAR<sup>-/-</sup> mice were treated with TCPOBOP (3 mg/kg) for 4 days, and hepatic gene expression was determined with Affymetrix murine genome U74Av2 microarrays. Data were analyzed with Rosetta Resolver (statistical significance of  $p \leq 0.01$ ). A total of 232 hepatic transcripts were altered by TCPOBOP in a sex-independent, CAR-dependent manner. As expected there was no evidence of CYP2B induction in CAR<sup>-/-</sup> mice, whereas Cyp2b10 increased 100- and 25-fold, in male and female WT mice, respectively. TCPOBOP treatment increased liver weight 2-fold and caused marked hepatic hyperplasia and hypertrophy in WT mice, but was without effect in CAR<sup>-/-</sup> mice. The hyperplastic response in WT mice was associated with increased expression of Ki-67 and PCNA. Furthermore, cyclins A2, B1 and B2 were increased at least 4-fold in both sexes along with induction of cyclin dependent kinase 1 (8-fold), suggesting increased mitotic activity, with particular effects in S-phase and the G2 to M transition. Induction of genes controlling cytokinesis (Ect2, 8-fold) and nucleotide metabolism (ribonucleotide reductase M2, 5-fold; thymidine kinase, 2.5-fold) was evident. In opposition to changes associated with increased cell cycle kinetics, there was a marked increase in expression of genes that stimulate terminal differentiation, growth suppression and apoptosis including growth arrest and DNA-damage inducible (Gadd) genes, particularly Gadd45 $\alpha$  (15-fold), Gadd45 $\beta$  (25-fold) and growth-differentiation factor-15 (4-fold). These results indicate that TCPOBOP treatment alters expression of genes involved in the regulation of cell cycle control and DNA synthesis, with the balance skewed to favor cell proliferation. As no similar changes were observed in CAR<sup>-/-</sup> mice, the results also indicate that TCPOBOP-induced alterations in hepatic cell cycle regulation are CAR-dependent.

## 1769

### EFFECTS OF 2, 2', 4, 4, ' -TETRABROMODIPHENYL ETHER ON CAR AND PXR REGULATED GENE EXPRESSION IN WEANLING FEMALE RATS.

V. M. Richardson<sup>1</sup>, K. M. Crofton<sup>2,1</sup> and M. J. DeVito<sup>1</sup>.  
<sup>1</sup>*ORD/NHEERL/ETD/PKB, USEPA, Research Triangle Park, NC* and  
<sup>2</sup>*ORD/NHEERL/ETD/NTD, USEPA, Research Triangle Park, NC.*

The polybrominated diphenyl ether (PBDEs) mixture, DE-71 causes endocrine disruption by altering thyroid function via the induction of hepatic uridinediphosphate-glucuronosyltransferases, (UGTs). DE-71 also induces ethoxresorufin-O-deethylase (EROD), and pentoxyresorufin-O-deethylase (PROD). These studies suggest that DE-71 is a mixed inducer of Ah receptor (AhR), pregnane X receptor (PXR) and constitutive androstane receptor (CAR) regulated genes. There are no definitive conclusions on the ability of PBDE-47, a major congener in DE-71, to act as a CAR/PXR agonist. This study examined the ability of PBDE-47 and DE-71 to activate genes in the AhR, CAR, and PXR pathways by quantitative real-time PCR. Female Long-Evans rats (28 day old) were orally administered 3, 10, 30, or 100 mg PBDE-47/kg/day or 30 mg DE-71/kg/day for 4 days. Animals were sacrificed 24 hours after the final dose; livers were collected and stored at -80 degrees Celsius until analyzed. PBDE-47 caused a dose-dependent increase in PROD activity starting at 10mg/kg/day, and only a slight increase in EROD activity at the highest dose (100mg/kg/day). Neither PBDE-47 nor DE-71 affected CAR, PXR, RXR, Mrp2, Oatp2, or UGT2B mRNA expression. DE-71 significantly increased AhR, CYP2B1, CYP2B2, UGT1A6, and UGT1A7 mRNA levels, while significantly decreasing Mdr1A, and UGT1A1 mRNA levels. PBDE-47 significantly increased AhR mRNA at 100mg/kg/day. Significant increases were also seen in CYP2B1 and 2B2 mRNA at 30 and 100mg/kg/day PBDE-47. DE-71 induced CYP1A1 over 90-fold, while PBDE 47 only induced CYP1A1 12 fold at the highest dose tested. CYP2B1 was induced 350-fold by DE-71 and 1100-fold by 100 mg PBDE-47/kg/day. The data indicate that PBDE-47 and DE-71 alter AhR and CAR/PXR regulated genes, although PBDE-47 is more efficacious as a CAR/PXR activator than DE-71. The AhR activated genes suggests that PBDE-47 may be a weak AhR agonist or contains minor dioxin-like contaminants. (This abstract does not necessarily reflect USEPA policy).

## 1770

### TRANSCRIPTIONAL ACTIVATION OF CREATINE KINASE GENE EXPRESSION BY INSULIN-LIKE GROWTH FACTOR (IGF-I).

F. Wang<sup>1</sup> and S. Safe<sup>2</sup>. <sup>1</sup>*OB/GYN, The State University of New York, Buffalo, NY* and <sup>2</sup>*Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Previous studies from this laboratory revealed that IGF-I increased cathepsin D mRNA level and reporter gene activities in breast cancer cells transfected with a plasmid containing chloramphenicol acetyltransferase (CAT) reporter gene linked to a cathepsin D gene promoter. This study investigated the mechanism of IGF-I regulation of creatine kinase B (CKB) gene expression in breast cancer cells. IGF-I increased CAT activities (4- to 8-fold) in cells transfected with the constructs containing CKB promoters -2897 to +5, -1434 to +5, -1201 to +5, -528 to +5, -228 to +5, and -195 to +5. CKB promoter sequence -568 to -523 contains two Sp1 binding sites and one estrogen responsive element (ERE), and previous studies showed that both the Sp1 binding sites and ERE were involved in CKB induction by estrogen in breast cells. Indeed, IGF-I induced CAT activities in cells transfected with reporter constructs containing CKB promoter sequence -568 to -523, and mutation of either Sp1 binding sites or ERE did not decrease the CAT activity. However, mutation or truncation of both the Sp1 binding sites and ERE abolished the IGF-I-induced CAT activities. In MDA-MB-231 breast cancer cells, cotransfection with wild-type ER restored the IGF-I-induced CAT activities in cells transfected with the constructs containing CKB promoter sequence -568 to -523, but not with the ER containing a mutation of serine at 118. The IGF-I-induced CAT activities were decreased in MCF-7 cells transfected with reporter constructs containing CKB promoter -568 to -523 and treated with PD 98059, a MAPK inhibitor. In addition, cotransfection of dominant negative ras or MAPK expression plasmids abolished the IGF-I-induced CAT activities in MCF-7 cells transfected with reporter constructs containing CKB promoter -568 to -523. These results suggested IGF-I activated CKB gene expression through activation of ER via the ras-MAPK pathway. (Supported by ES09106 and ES09253)

## 1771

### ANALYSIS OF GENE EXPRESSION DURING UTERINE INDUCTION AND REGRESSION IN IMMATURE, OVARIECTOMIZED RATS FOLLOWING TREATMENT WITH ETHYNODIOL ESTRADIOL.

J. C. Kwekel, H. A. Dagleish, L. D. Burgoon, J. R. Harkema and T. R. Zacharewski. *Department of Biochemistry and Molecular Biology, National Food Safety and Toxicology Center, Center for Integrative Toxicology, Michigan State University, East Lansing, MI.*

Changes in uterine physiology, cell type morphology and gene expression were evaluated in a comprehensive time course study after oral administration of 100  $\mu$ g/kg bw ethynodiol estradiol (EE) to immature, ovariectomized SD rats. Animals were dosed once or once daily on 3 consecutive days and uteri were harvested 2, 4, 8, 12, 18, 24, 72, 84, 96, 120, 144, or 168 hrs after treatment. Animals in the histological study received an i.p. injection of 5-bromo-2-deoxyuridine (BrdU, 50  $\mu$ g/kg bw) 2 hours prior to sacrifice. Uterine wet weight, a classical marker of estrogen exposure, was maximally induced ~6-fold at 72 hrs. Global changes in gene expression were examined using custom rat cDNA microarrays consisting of 8, 567 clones representing 5, 818 unique genes. 1, 755 genes exhibited a significant change at one or more time points as determined using a model-based t-statistic/Empirical Bayes approach. In order to phenotypically link these changes in gene expression to the physiological alterations observed in the uterotrophic response, complementary histological and morphometric assessment of uterine mid-horn sections stained with eosin and hematoxylin were performed. Additional histological slides were stained with anti-BrdU for assessments of proliferation. Pathological findings included indications of edema, eosinophil infiltration, hypertrophy, hyperplasia, angiogenesis and apoptosis consistent with the temporal changes in gene expression at time points preceding or overlapping these phenotypic markers. These assessments provide baseline data characterizing estrogen elicited responses in the rodent uterus, as a comparator for future estrogenic endocrine disruptor studies. Funding provided by NIH grant: ES011271 and ES07255-16

## 1772

### EFFECTS OF ESTROGEN ON IMMATURE, OVARIECTOMIZED MICE: A MULTI-APPROACH, TISSUE-BY-TISSUE COMPARISON.

J. W. Burt<sup>1,2</sup>, L. D. Burgoon<sup>2</sup>, D. G. Humes<sup>1</sup>, J. C. Kwekel<sup>1,2</sup>, A. S. Harney<sup>1</sup>, J. R. Harkema<sup>3</sup> and T. R. Zacharewski<sup>1,2</sup>. <sup>1</sup>*Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI*, <sup>2</sup>*Center for Integrative Toxicology, Michigan State University, East Lansing, MI* and <sup>3</sup>*Pathobiology & Diagnostic Investigation, Michigan State University, East Lansing, MI.*

17 $\alpha$ -Ethynodiol estradiol (EE) elicited gene expression and histological changes in the uterus, mammary gland, liver, femur and kidney were examined in immature, ovariectomized C57BL/6 mice. Mice were gavaged with 100 $\mu$ g/kg EE and tissues

were harvested after 2, 4, 8, 12, 18, and 24 hrs or at 72 hours following three consecutive 24 hr doses. cDNA microarrays containing 13361 clones (7810 unique, annotated genes) were used to compare gene expression profiles of EE treated animals to time-matched, vehicle controls. Active gene lists were compiled for each tissue using a model-based t-value/empirical Bayes method based upon filtering by P1(t) values. Clustering of responses indicate that mammary and bone exhibit comparable changes in expression with kidney displaying the most divergent responses. Comparisons of active gene lists indicate that EE regulates common biological processes (i.e. proliferation and xenobiotic metabolism), in addition to tissue-specific responses (i.e. lipid metabolism in the liver). Genes associated with proliferation were highly represented in all tissues examined but showed tissue specificity suggesting a lack of a common proliferative mechanism elicited by EE. The temporal expression of growth factors, transcription factors and cell cycle regulators was consistent with the 7.5-fold increase in uterine blotted weight at 72 hrs, and the concomitant increases in uterine luminal epithelial cell height and BrdU incorporation. These comprehensive studies measuring multiple endpoints allow for the phenotypic anchoring of the observed gene expression changes and facilitate distinguishing adaptive responses from changes associated with a physiological effect. Results from these studies indicate that EE does not elicit a common, tissue-independent expression profile. Supported by NIH grants ES 011271 and T32 ES07255.

REGULATION OF TRANSCRIPTIONAL ACTIVATION OF LARGEMOUTH BASS ESTROGEN RECEPTORS ALPHA, BETA 1 AND BETA 2 BY ESTRADIOL AND THE CONTAMINANTS NONYLPHENOL AND METHOXYCHLOR IN HEPG2 CELLS.

N. Denslow<sup>1</sup>, J. Blum<sup>1</sup> and T. Sabo-Attwood<sup>2</sup>. <sup>1</sup>*University of Florida, Gainesville, FL* and <sup>2</sup>*University of Vermont, Burlington, VT.*

The purpose of this study was to measure the activation of the three estrogen receptor (ER) isotypes found in the largemouth bass (*Micropterus salmoides*) (LMB) by 17 $\beta$ -estradiol (E2), nonylphenol (NP) and methoxychlor (MXC). NP is a deterrent that has been found to be present in the environment and has been shown to act as a disruptor of the estrogen receptor mediated signaling pathway by virtue that it up regulates vitellogenin in largemouth bass *in vivo*. MXC is a less environmentally persistent analog of DDT that has also been shown to act as an estrogen. Using transient transfection assays in human HepG2 cells we find that each receptor type is responsive to the endogenous ligand E2 in a dose-dependent manner. When cells were treated with E2, ER $\alpha$  activity becomes distinguishable from control at 0.1  $\mu$ M and continues rising through 1.0  $\mu$ M, while ER $\beta$ 2 and  $\beta$ 1 begin to rise between 0.05 and 0.075  $\mu$ M, but reach a maximal response at 0.5  $\mu$ M. For NP, both ER $\alpha$  and ER $\beta$ 2 were activated by 5  $\mu$ M and continue to rise through 10  $\mu$ M. However, higher concentrations of NP are cytotoxic. No response was seen for ER $\beta$ 1 upon treatment with NP. Preliminary data for MXC show that as with human ER $\alpha$ , the LMB ER $\alpha$  is activated between 0.5 and 1.0  $\mu$ M MXC. The similarity of the E2 dose response curves obtained for ERs  $\beta$ 1 and  $\beta$ 2 supports the view that the two subtypes are recent duplicates in teleosts, as has been suggested in the literature. The lack of responsiveness to NP for ER $\beta$ 1 indicates that this receptor isotype may have its own function and suggests that *in vivo* responses to NP is through activation of either ER $\alpha$  or ER $\beta$ 2.

ESTROGEN INFLUENCES THE GROWTH OF CELLS THROUGH MODULATING THE INTRACELLULAR REDOX STATE.

Q. Felty and D. Roy. *Environmental & Occupational Health, Florida International University, Miami, FL.*

The intracellular redox state is characterized by a balance between oxidant production and reducing equivalents which allow reactive oxygen intermediates (ROI) to function as second messengers. The primary effect of ROI signaling molecules is the reversible oxidation of proteins that cause a change in protein function resulting in signal transduction. Growth factors rapidly stimulate the production of low to intermediate levels of intracellular ROI which signal cell proliferation. Therefore, we investigated whether estrogen mediated changes of cellular redox state influenced the growth of cells. The data presented here lead to the following major findings: 1) physiological concentrations (100 pg/ml) of estrogen rapidly modulate cellular redox state and 2) estrogen-induced phosphorylation and binding of transcription factors (i.e. AP-1), and cell cycle gene expression (i.e. cyclin D1) are modulated by cellular redox state. Our results suggest that a nongenomic pathway(s) is involved in the support of estrogen-dependent growth. The biological significance of our findings from this study provide the basis for the development of novel antioxidant-based drugs or gene therapy targeted for the prevention and treatment of estrogen-dependent cancer.

THE EFFECT OF POLYCHLORINATED BIPHENYLS (PCBs) ON THYROID HORMONE RECEPTOR (TR) AND CO-REGULATOR INTERACTIONS ON DNA.

S. You<sup>1</sup>, K. Gauger<sup>1</sup> and R. Zoeller<sup>2, 1</sup>. <sup>1</sup>*Molecular & Cellular Biology Program, University of Massachusetts, Amherst, MA* and <sup>2</sup>*Biology, University of Massachusetts, Amherst, MA.*

PCBs may exert adverse effects, especially in the developing brain, by interfering with thyroid hormone (TH) signaling. Previous studies have clearly documented that PCB exposure can reduce circulating levels of TH. Thus, one hypothesis is that PCBs can exert adverse effects by causing hypothyroxinemia. However, we find that developmental exposure to PCBs can cause TH-like effects on the expression of TH-responsive genes in the developing brain. Thus, there is a very clear difference between the effect of PCB exposure on circulating levels of TH, and the effect of PCB exposure on TH signaling. While the simplest explanation for this observation is that PCB congeners or PCB metabolites bind to the TR and activate gene expression, we have failed to identify such congeners or metabolites in extensive studies. To determine the extent to which PCBs directly affect TH signaling through its receptor, we have begun to characterize the ability of PCB exposure to increase TH-responsive genes in liver, heart, and *in vitro*. In the heart, we find that PCB exposure does not affect the expression of MHC- $\alpha$ , MHC- $\beta$ , or SERCA-2 (all TH-responsive genes), despite causing a significant reduction in serum TH. Thus, the effect of PCB exposure has different effects on TR-mediated gene expression in different tissues. To further investigate this issue, we are using the Chromatin Immunoprecipitation (ChIP) assay. This approach will allow us to test whether PCB exposure influences the ability of TR to bind to DNA regulatory elements of TR-regulated genes as well as to determine whether TR associates with different coregulators (NCoR or SRC-1).

GENETIC TOXICOLOGY AND BONE MARROW CYTOTOXICITY STUDIES OF THE CORTICOTROPIN-RELEASING HORMONE (CRH) RECEPTOR ANTAGONIST, ANTALARMIN.

P. T. Curry<sup>1</sup>, M. Nagabhushan<sup>1</sup>, D. L. McCormick<sup>1</sup>, R. E. Parchment<sup>2</sup>, K. Calis<sup>3</sup>, P. W. Gold<sup>3</sup>, G. Cizza<sup>3</sup>, D. Charney<sup>3</sup>, E. R. Glaze<sup>4</sup> and J. E. Tomaszewski<sup>4</sup>. <sup>1</sup>*IIT Research Institute, Chicago, IL*, <sup>2</sup>*SciTech Development LLC, Grosse Pointe, MI*, <sup>3</sup>*National Institute of Mental Health, Bethesda, MD* and <sup>4</sup>*National Cancer Institute, Bethesda, MD.*

Antalarmin (AA; N-butyl-N-ethyl-[2, 5, 6-trimethyl-7-(2, 4, 6)-trimethylphenyl]-7H-pyrido[2, 3-d]pyrimidin-4-yl amine) is a CRH type 1 receptor antagonist being developed as a treatment for stress-related pathologies, including depression and anxiety. Genetic toxicology studies were conducted to identify mutagenic or clastogenic effects of AA, and a multi-species bone marrow cytotoxicity study was performed to investigate possible species specificity in AA toxicity. AA was not mutagenic in bacterial mutagenesis assays conducted using Ames tester strains TA 98, TA 100, TA 102, TA 1535, and TA 1537; Ames assays were conducted both with and without metabolic activation. AA was also negative in the L5178Y TK $+$ -mammalian cell mutagenesis (mouse lymphoma) assay conducted both with and without metabolic activation. Micronucleus evaluations demonstrated that AA was not clastogenic in bone marrow cells harvested from CD rats (6/sex/group) receiving oral exposure to AA at doses of up to 1000 mg/kg/day for 14 days. These data demonstrate that AA is not genotoxic in standard preclinical genetic toxicology bioassays. *In vitro* cytotoxicity studies were performed using CFU-GM neutrophil progenitors harvested from rat, dog, and human bone marrow to determine whether the rat or the dog more closely predicts human bone marrow responses to AA. AA was cytotoxic to canine bone marrow cells; by contrast, both rat and human bone marrow cells were insensitive to AA cytotoxicity. Because significant bone marrow toxicity was observed in subchronic toxicity studies in dogs but not in rats, these *in vitro* data suggest that the bone marrow cytotoxicity of AA in the dog may not be a good predictor of bone marrow toxicity in humans. The rat appears to be the more appropriate species for prediction of human bone marrow responses to this drug. (N01-CM-87102)

SUBCHRONIC ORAL TOXICITY OF THE CORTICOTROPIN-RELEASING HORMONE (CRH) RECEPTOR ANTAGONIST, ANTALARMIN, IN DOGS.

W. D. Johnson<sup>1</sup>, J. Harder<sup>1</sup>, D. L. McCormick<sup>1</sup>, R. L. Morrissey<sup>2</sup>, K. Calis<sup>3</sup>, P. W. Gold<sup>3</sup>, G. Cizza<sup>3</sup>, D. Charney<sup>3</sup>, E. R. Glaze<sup>4</sup> and J. E. Tomaszewski<sup>4</sup>. <sup>1</sup>*IIT Research Institute, Chicago, IL*, <sup>2</sup>*Pathology Associates, Chicago, IL*, <sup>3</sup>*National Institute of Mental Health, Bethesda, MD* and <sup>4</sup>*National Cancer Institute, Bethesda, MD.*

Antalarmin (AA; N-butyl-N-ethyl-[2, 5, 6-trimethyl-7-(2, 4, 6)-trimethylphenyl]-7H-pyrido[2, 3-d]pyrimidin-4-yl amine) is a CRH type 1 receptor antagonist being developed as a treatment for stress-related pathologies, including depression

and anxiety. In a 14-day range-finding oral toxicity study, AA doses of 0, 10, 50, 100, and 200 mg/kg/day were evaluated in beagle dogs (1/sex/group). AA doses of 50, 100, and 200 mg/kg/day induced dose-related decreases in body weight and food consumption; these effects were associated with repeated emesis and duodenal inflammation. AA doses  $\geq$ 50 mg/kg/day induced bone marrow and lymphoid suppression, thymic atrophy, hepatic toxicity (hepatocyte degeneration; cholestasis), and renal toxicity (cortical cell necrosis). At 10 mg/kg/day, AA toxicity was limited to decreased WBC and reticulocyte counts, lymphoid depletion, and minimal hepatic changes. In a 90-day oral toxicity study in beagle dogs (5/sex/group), AA doses of 0, 4, 8, and 16 mg/kg/day had no effect on survival, body weight, food consumption, electrocardiographic measures, or a Functional Observational Battery. The bone marrow and lymphoid system were primary sites of AA toxicity: at 16 mg/kg/day, AA induced significant bone marrow and lymphoid depletion, with only minimal liver toxicity (hepatocyte degeneration and cholestasis). All AA doses decreased reticulocyte counts. No evidence of renal toxicity was present in any dose group. After a 30-day recovery period, hematologic and microscopic findings had normalized. The Maximum Tolerated Dose (MTD) for AA in dogs is  $>$ 200 mg/kg/day ( $>$  4000 mg/m<sup>2</sup>/day). Based on the bone marrow and lymphoid toxicity observed at 16 mg/kg/day, the No Observable Adverse Effect Level (NOAEL) for AA in dogs is 8 mg/kg/day (160 mg/m<sup>2</sup>/day). (N01-CM-87102)

## 1778

### SUBCHRONIC ORAL TOXICITY OF THE CORTICOTROPIN-RELEASING HORMONE (CRH) RECEPTOR ANTAGONIST, ANTALARMIN, IN RATS.

T. L. Horn<sup>1</sup>, W. D. Johnson<sup>1</sup>, D. L. McCormick<sup>1</sup>, R. L. Morrissey<sup>2</sup>, K. Calis<sup>3</sup>, P. W. Gold<sup>3</sup>, G. Cizza<sup>3</sup>, D. Charney<sup>3</sup>, E. R. Glaze<sup>4</sup> and J. E. Tomaszewski<sup>4</sup>. <sup>1</sup>*IIT Research Institute, Chicago, IL*, <sup>2</sup>*Pathology Associates, Chicago, IL*, <sup>3</sup>*National Institute of Mental Health, Bethesda, MD* and <sup>4</sup>*National Cancer Institute, Bethesda, MD*.

Antalarmin (AA; N-butyl-N-ethyl-[2, 5, 6-trimethyl-7-(2, 4, 6-trimethylphenyl)-7H-pyrrolo[2, 3-d]pyrimidin-4-yl] amine) is a CRH type 1 receptor antagonist being developed as a treatment for stress-related pathologies, including depression and anxiety. AA doses of 0, 25, 50, 100, 250, 500, and 1000 mg/kg/day were evaluated in a 14-day range-finding oral toxicity study in CD rats (5/sex/group). AA doses of 500 and 1000 mg/kg/day induced mortality, and thus clearly exceeded the Maximum Tolerated Dose (MTD); clinical pathology and histopathologic evaluation of tissues identified hepatic and renal toxicity at these doses. By contrast, no limiting toxicity was seen in rats receiving AA at doses of  $\leq$ 250 mg/kg/day for 14 days. Plasma AA peaked at 2 hours, and remained detectable at 24 hours; plasma AA levels did not increase with increasing duration of exposure. In a 90-day oral toxicity study in CD rats (20/sex/group), AA doses of 0, 30, 100, and 300 mg/kg/day had no effects on survival, body weight, food intake, clinical signs, or a Functional Observational Battery. Clinical pathology assays and histopathologic evaluation of tissues identified the liver and kidney as primary targets of AA toxicity; no evidence of bone marrow toxicity was observed. At 300 mg/kg/day, modest increases in GGT were correlated with hepatocellular necrosis, chronic inflammation, and bile duct hyperplasia and fibrosis. Renal pathology at 100 and 300 mg/kg/day included inner cortical necrosis, inflammation, hypertrophy, and nephrophy. After a 30-day recovery period, clinical chemistry and most microscopic changes had normalized; however, minimal to mild hepatic fibrosis and minimal to mild renal cortical inflammation remained. The MTD for AA in rats is 300 mg/kg/day (1800 mg/m<sup>2</sup>/day). The No Observable Adverse Effect Level (NOAEL) for AA in rats is 30 mg/kg/day (180 mg/m<sup>2</sup>/day). (N01-CM-87102)

## 1779

### CYPROHEPTADINE AND CYCLIZINE INHIBIT INSULIN SECRETION IN RIN5F CELLS BY INHIBITING CALCIUM CHANNELS.

M. Otieno<sup>1</sup>, N. Bavuso<sup>1</sup>, A. Katein<sup>1</sup>, T. Kelly<sup>1</sup>, J. Milano<sup>1</sup> and F. Pognan<sup>2</sup>. <sup>1</sup>*Safety Assessment US, AstraZeneca Pharmaceuticals, Wilmington, DE* and <sup>2</sup>*Safety Assessment UK, AstraZeneca Pharmaceuticals, Alderley Park, United Kingdom*.

Cyproheptadine and cyclizine induce vacuolation of  $\beta$ -cells in rat pancreas. Vacuolation by cyproheptadine is associated with loss of insulin while that by cyclizine is accompanied by insulin secretion. The purpose of this study is to characterize the effect of these compounds on insulin in the pancreatic cell line RIN5F and to test the hypothesis that calcium channels mediate the effect on secreted insulin. Cells were treated with compound (10nM to 10 $\mu$ M) for 16h and insulin was measured by ELISA. Cyproheptadine caused a dose-dependent decrease in secreted and intracellular insulin with a maximal inhibition of 80-90% at 10 $\mu$ M. Inhibition of intracellular insulin was due to decreased insulin2 mRNA. Treatment with cyclizine led to a biphasic increase in secreted insulin of 20% at low doses followed by a 30% decrease at 10 $\mu$ M; inhibition of intracellular insulin by cyclizine, however, was dose-dependent with a maximal inhibition of 80% at 10 $\mu$ M. KCl was used to activate calcium channels and nimodipine, a calcium channel antagonist, was used as a positive control. Cyproheptadine inhibited KCl-mediated calcium entry into

cells with a maximal inhibition of 100% at 10 $\mu$ M. Cyclizine enhanced KCl-mediated calcium entry at low doses followed by a 50% inhibition at 10 $\mu$ M. The magnitude of inhibition of calcium entry by both compounds corresponded well with their effect on insulin secretion. Cyproheptadine (IC50;1.6 $\mu$ M) was as potent as nimodipine (IC50;0.7 $\mu$ M) in its inhibition of KCl-induced calcium entry, suggesting that it may be a calcium channel antagonist. Nimodipine, like cyproheptadine, also mediated a dose-dependent decrease in secreted insulin, further arguing for the role of calcium channels in insulin secretion. In summary, cyproheptadine and cyclizine inhibit both secreted and intracellular insulin and inhibition of secreted insulin may be due to inhibition of calcium channels.

## 1780

### REPEAT DOSE TOXICITY STUDIES IN RATS AND DOGS WITH TH0318, A DPP IV-RESISTANT ANALOG OF NATURAL GLP-1.

S. Fennell<sup>1</sup>, H. Loughrey<sup>1</sup>, M. Garino<sup>1</sup>, S. Abdullah<sup>1</sup>, M. Stilianesis<sup>2</sup>, K. Arjah<sup>2</sup>, B. Vu<sup>2</sup> and E. Ferdinand<sup>1</sup>. <sup>1</sup>*Theratechnologies, Inc., Saint Laurent (Montreal), QC, Canada* and <sup>2</sup>*CTBR Bio-Research Inc., Senneville, QC, Canada*. Sponsor: C. Banks.

TH0318 is a modified natural GLP-1 analog, having a hydroxybenzoyl moiety conjugated to the N-terminal end of the natural GLP-1 sequence, that is under development for the treatment of Type 2 Diabetes Mellitus. The repeat dose toxicity of TH0318 was evaluated in 14-day repeat-dose studies in rats (10-15/sex/group) given twice daily (3 to 4 hours apart) subcutaneous doses of 0, 0.5, 2 or 8 mg/kg bid (0, 1, 4 or 16 mg/kg/day) and in dogs (3-5/sex/group) given twice daily (3 to 4 hours apart) subcutaneous doses of 0, 0.1, 0.4 or 1.2 mg/kg bid (0, 0.2, 0.8 or 2.4 mg/kg/day). There was no evidence of systemic target organ toxicity in either species. Pharmacodynamic effects of TH0318 included reductions in body weight gain/ slight body weight loss and/or reductions in food intake at 4 mg/kg/day and greater in rats and at 0.8 mg/kg/day and greater in dogs. In both species, a local irritant reaction at the injection site was attributed primarily to the vehicle (pH 3.9) and showed partial reversibility following a 14-day off-dose period. Plasma toxicokinetic data (C<sub>max</sub> and AUC) demonstrated that animals were exposed to TH0318 and related C-terminal immunoreactive peptides in a dose-related manner; values on Day 14 were higher than Day 1. The no-observed-adverse-effect-level for systemic toxicity was 16 and 2.4 mg/kg/day in rats and dogs, respectively, representing 266- to 516-fold the maximum anticipated human dose. These results, together with those obtained from a battery of safety pharmacology and genetic toxicology studies, indicate that TH0318 has an appropriate toxicological profile in animals for the conduct of clinical safety evaluations in humans.

## 1781

### CARCINOGENICITY EVALUATION OF ATAZANAVIR IN MICE.

T. A. Mably<sup>1</sup>, T. P. Sanderson<sup>1</sup>, C. D. Houle<sup>2</sup>, B. E. Schilling<sup>1</sup> and M. A. Dominic<sup>1</sup>. <sup>1</sup>*Drug Safety Evaluation, Bristol-Myers Squibb Co., Mt. Vernon, IN* and <sup>2</sup>*Experimental Pathology Laboratories, Inc., Research Triangle Park, NC*.

The tumorigenic potential of atazanavir (ATV) was evaluated in a 2-year oral carcinogenicity study in CD-1 mice at doses of 20, 40, and 80 mg/kg/d in males and 40, 120, and 360 mg/kg/d in females. At the end of treatment, the incidence of hepatocellular adenomas was increased in females at 360 mg/kg/d; no other drug-related tumors were observed. As ATV was previously shown to cause hepatocellular necrosis in mice at high doses and was not genotoxic (weight of evidence), a 3-month timecourse study was conducted to investigate whether the increase in liver adenomas was a result of increased hepatocellular proliferation secondary to cytotoxicity and/or decreased apoptosis. In this study, ATV doses of 40 and 80 mg/kg/d in males and 120 and 360 mg/kg/d in females were administered for 2 weeks and 1 and 3 months. In males, generally minimal hepatic effects occurred at multiple timepoints, principally at 80 mg/kg/d, and included increased ALT and liver weights, hepatocellular hypertrophy, and low incidences of hepatocellular vacuolation and single-cell necrosis (high dose only). There was no stimulation of hepatocellular proliferation as measured by increased 5-bromo-2'-deoxyuridine (BrdU) nuclear labeling or inhibition of apoptosis as measured by decreased terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) in high-dose males. Hepatotoxicity was more pronounced in females, particularly at 360 mg/kg/d, and characterized by minimal to marked increases in ALT and/or AST and liver weights, hepatocellular vacuolation, and high incidences of single-cell hepatic necrosis at all time points. In females, hepatotoxicity was accompanied by dose-related increases (3-15X) in BrdU labeling; TUNEL was also increased (2-7X). In conclusion, these data indicate that the increase in hepatocellular adenomas in ATV-treated female mice was likely due to increased hepatocellular proliferation secondary to cytotoxicity. These results are consistent with a well-recognized nongenotoxic mechanism of tumor formation in rodents.

## MULTIPLE DOSE TOXICITY STUDY OF IMEXON IN FISCHER 344 RATS.

Y. Chen<sup>1</sup>, E. Glaze<sup>2</sup>, J. Tomaszewski<sup>2</sup>, R. Morrissey<sup>3</sup> and A. Lyubimov<sup>1</sup>.

<sup>1</sup>Toxicology Research Laboratory, University of Illinois at Chicago, Chicago, IL,

<sup>2</sup>Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD and <sup>3</sup>Pathology Associates Division, Charles River Laboratories, Chicago, IL.

This study was conducted to determine the target organ toxicity and reversibility of imexon, a potential anticancer agent, in Fischer 344 rats treated intravenously through the tail vein daily for 5 consecutive days in weeks 1 and 3. Target dose levels studied were 0, 50, 100 and 150 mg/kg/day. No mortality occurred. Dehydration, slight diarrhea, dark material around eyes, and tail lesions were seen during the dosing periods in a dose-dependent manner. Body weight gains and food consumption in all dose groups were lower compared to the control group by the end of weeks 1 and 3. Imexon-induced anemia and leukocytopenia were seen in all test article-treated groups, and neither anemia nor leukocytopenia were completely reversed after a two week recovery period (day 37). This was possibly due to myelosuppression caused by this cytotoxic anticancer agent, which suppressed all hematopoietic cell lines (except platelets). The increases in total protein levels and significant decreases in serum alkaline phosphatase (ALKP) levels in the 100 and 150 mg/kg/day dose groups were seen in males and females. These changes were completely reversed on day 37. The organ weights of liver, lungs/bronchi and spleen were dose-dependently decreased and spleen weights remained lower on day 37. Histopathologic lesions were found on day 22 in the following target organs: kidney, spleen and thymus in both males and females, and vagina and uterus in females in all test article-treated groups. The severity and/or incidence of the majority of lesions were dose-dependent and most of these changes were resolved on day 37, except for the vagina and uterus lesions which were seen on day 37 at all doses including 50 mg/kg/day. Under the conditions of this study, the no-observed-adverse-effect-level (NOAEL) of imexon was not attained. Sponsored by NCI Contract N01-CM-87103.

## SEQUENCE DEPENDENT ANTAGONISM BETWEEN RALOXIFENE, 5-FLUOROURACIL AND PEMETREXED.

E. Fryar<sup>1</sup>, D. H. Jillian<sup>1</sup>, S. M. William<sup>2</sup> and B. Donnell<sup>1</sup>. <sup>1</sup>Pharmacology, Howard University, Washington, DC and <sup>2</sup>Biochemistry, Howard University, Washington, DC.

Raloxifene (RAL), a selective estrogen receptor modulator (SERM) approved for the prevention of osteoporosis and Pemetrexed (MTA) approved for the treatment of mesothelioma are currently under investigation for their antineoplastic effects in breast cancer. In the current study, RAL reduced the cytotoxic effects of high dose MTA in human MCF-7 breast cancer cells *in vitro*. When RAL is given 24 hours prior to a nontoxic dose of 5-fluorouracil (5-FU) and a high dose of MTA, the cytotoxic effects of MTA are antagonized. Antagonism is not observed when cells are exposed to a priming and non-toxic dose of 5-FU and high dose MTA 24 hours prior to RAL. The growth rates of MCF-7 cells administered 10µM MTA, 1µM 5-FU, and 10µM RAL alone were 65.0%± 5.42%, 86.0% ± 10.62%, and 68.3% ± 2.88% of the control, respectively. The combinations of RAL 24 hr prior to 5-FU 2hr prior to MTA and 5-FU 2hr prior to MTA 24 hr prior to RAL exhibited growth rates of 87.6% ± 1.51% and 65.0% ± 0.94% of control respectively. RAL arrests cells in the G1 phase of the cell cycle, thereby preventing the progression of cells to the S phase where 5-FU and MTA exert cytotoxicity therefore, these studies suggest that a) the interactions between RAL, 5-FU and MTA are sequence dependent and b) RAL antagonizes the cytotoxicity of MTA. Acknowledgements- This study was supported by grant RCMI-NIH 5G12RR03048 and Eli Lilly.

## UTILIZATION OF MULTIPLE ENDPOINTS TO INVESTIGATE DIFFERENTIAL TOXICITY PRODUCED BY TOPOISOMERASE II INHIBITORS, DOXORUBICIN AND ETOPOSIDE.

R. T. Dunn, E. S. Galambos, L. Healy, R. Morgan, J. Yamada, H. Hamadeh, A. Kwok, M. E. Cosenza and C. Afshari. Toxicology, Amgen Inc., Thousand Oaks, CA.

Utilization of paradigm compounds can be a powerful tool to investigate differential toxicities. Doxorubicin (Dox) is a well-studied anthracycline antibiotic topoisomerase II inhibitor used to treat certain kinds of cancer. Doxorubicin is associated with cardiotoxicity and this effect is observed in multiple species including human. Etoposide (Eto), similar to Dox, inhibits topoisomerase II. However, Eto is not linked to cardiotoxicity. Therefore, Dox and Eto were used as comparator compounds to identify potential differential toxicities through the analysis of multiple toxicity endpoints. Male S-D rats (-300-350 g) were treated, i.v., with up to 5 doses of either Dox (0.5, 5.0 mg/kg) or Eto, (0.5, 5.0 mg/kg) over a two-week period. Rats treated with Dox at 5.0 mg/kg demonstrated substantial body weight loss and dosing was therefore discontinued. The remaining treatment groups continued on

study and appeared clinically similar to controls. Initial results indicated that a number of parameters were affected by the treatments. White cell counts were significantly reduced in animals that received either low or high dose Dox treatment. Conversely, only the high dose of Eto induced changes in white cell counts. Assessment of individual white cell populations indicated that lymphocytes and basophils were the primary targets of both compounds. Other white cells including neutrophils, eosinophils, and monocytes were resistant to treatments. Thymus to body weight ratios were significantly altered by the high dose of Dox and Eto. Other organ weights, including the heart, were similar to controls. Histological changes in high dose groups included marked bone marrow depletion (Dox and Eto), marginal zone depletion in spleen (Dox only) and marked increases in hepatocyte mitotic figures (Eto only). In addition to the above parameters, cytokine and gene expression changes for certain target tissues were assessed.

## ORAL TOXICITY STUDY OF A RETINOIC ACID ANALOGUE, 9-CIS-UAB-30, IN RATS.

R. Krishnaraj<sup>1</sup>, A. Lyubimov<sup>1</sup>, C. Detrisac<sup>2</sup>, I. Kapetanovic<sup>3</sup>, J. Crowell<sup>3</sup>, W. Brouillette<sup>4</sup> and D. Muccio<sup>4</sup>. <sup>1</sup>Pharmacology, University of Illinois at Chicago, Chicago, IL, <sup>2</sup>Pathology Associates, Chicago, IL, <sup>3</sup>National Cancer Institute, Bethesda, MD and <sup>4</sup>Chemistry, University of Alabama at Birmingham, Birmingham, AL.

9-cis-UAB-30 is a conformationally constrained nuclear retinoid X receptor selective agonist with cancer chemopreventive activity. The toxicity of 9-cis-UAB-30 (0, 3, 15 and 100 mg/kg/day) was studied in CD<sup>®</sup> rats following 28 days of daily oral gavage administration. Plasma drug levels in week 4 were found to increase with the increasing dose. There were no drug-related mortalities, clinical signs of toxicity, or changes in body weight gains, food consumption or ophthalmic parameters in any dose group. Dose-dependent hepatomegaly was seen most significantly in the 100 mg/kg/day dose group females. Significant increases in serum aspartate aminotransferase (36.5% in females) and alkaline phosphatase levels (25.9 and 29.8% in males and females, respectively) were seen in the 100 mg/kg/day dose group. Moderate hypoalbuminemia and hyperglobulinemia resulted in decreased A/G ratio in this dose group females. Histopathology revealed hepatocellular change consistent with hepatic glycogen deposition. Liver appeared as a target tissue. 9-cis-UAB-30 exhibited a small, but statistically significant procoagulant effect as evidenced by decreases in prothrombin time (PT) in the 100 mg/kg/day dose group females (10%) and males (4.9%), and in the 15 mg/kg/day dose group females (3.1%) and males (4.3%). Elevated plasma fibrinogen levels were seen, significantly in the 100 mg/kg/day dose group males. Mild eosinopenia (males) and neutrophilia (females) were the only hematological parameters altered at 100 mg/kg/day. 9-cis-UAB-30 did not exhibit hypertriglyceridemia, a common undesirable effect of retinoids. Under the conditions of this study, the NOAEL for 9-cis-UAB-30 was 3 mg/kg/day primarily due to a small procoagulant effect of uncertain clinical significance. (Supported by NCI Contract No. N01-CN-15119).

## CHANGES IN THE METHYLATION STATUS OF GC-RICH REGIONS OF DNA DURING THE PROMOTION STAGE OF SKIN TUMORIGENESIS.

A. N. Carnell-Bachman<sup>1</sup>, G. M. Curtin<sup>2</sup>, D. J. Doolittle<sup>2</sup> and J. I. Goodman<sup>1</sup>.

<sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI and <sup>2</sup>Research and Development, R. J. Reynolds Tobacco Company, Winston-Salem, NC.

Aberrant DNA methylation, an epigenetic regulator of gene expression, plays a key role in carcinogenesis. In general, the level of methylation and the level of transcription are related inversely. Thus, altered methylation can affect phenotype. Using the SENCAR two-stage mouse skin tumorigenesis model, progressive changes in methylation both gene-specific and in GC-rich regions can be evaluated in a time-dependent fashion during the promotion stage. Mouse skin was initiated with 7, 12-dimethylbenz[ $\alpha$ ]anthracene (DMBA) and then promoted thrice weekly with 27mg of cigarette smoke condensate (CSC) for 4 or 8 wks plus 4 or 8 wk recovery groups. DNA was isolated and GC-rich methylation was assessed using a newly developed, quantitative assay that permits simultaneous analysis of multiple sites of methylation across the genome. This involves the use of methylation sensitive restriction digestion and arbitrarily primed PCR with electrophoretic separation of PCR products. Additionally the methylation of the promoter region of *Ha-ras*, an oncogene frequently implicated in skin tumorigenesis, was assessed using the enzymatic regional methylation assay (ERMA) and bisulfite sequencing. No change in methylation was observed in the 5' promoter region of *Ha-ras*. In GC-rich regions, promotion for 4 wks yielded 21 sites of changed methylation, 20 of these were hypermethylation (HyperMe). The HyperMe decreased to 19 and 13 following a 4 or 8 wk recovery period, respectively. Promotion for 8 wks resulted in 40 total sites of changed methylation, 38 of these were HyperMe and this number decreased to 8 following an 8 wk recovery period. Reversibility is a hallmark of tumor promotion. These data support our hypothesis that progressive, nonrandom changes in methylation are involved in tumor promotion.

DIETHANOLAMINE (DEA) AND PHENOBARBITAL (PB) PRODUCE AN ALTERED PATTERN OF METHYLATION IN GC-RICH REGIONS OF DNA IN B6C3F1 MOUSE HEPATOCYTES SIMILAR TO THAT RESULTING FROM CHOLINE DEFICIENCY.

J. I. Goodman<sup>1</sup>, L. M. Kamendulis<sup>2</sup> and A. N. Carnell-Bachman<sup>1</sup>. <sup>1</sup>*Pharmacology and Toxicology, Michigan State University, East Lansing, MI* and <sup>2</sup>*Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN*.

DNA methylation (5-methylcytosine content of DNA) is an epigenetic mechanism regulating transcription. Disruption of normal methylation patterns can facilitate the aberrant gene expression underlying carcinogenesis. DEA, a nongenotoxic alkylamine, produces liver tumors in mice. Studies suggest DEA inhibits choline uptake and causes biochemical changes consistent with choline deficiency. Rodents fed methyl-deficient diets exhibit altered methylation of hepatic DNA and an increase in liver tumors, e.g., choline deficiency causes liver tumors in B6C3F1 mice. We hypothesize that DEA-induced choline deficiency leads to altered methylation patterns which may facilitate tumorigenesis. B6C3F1 mouse hepatocytes in primary culture were grown in the presence of 4.5mM DEA, 3mM PB or choline-deficient media for 48 hrs. PB, a nongenotoxic rodent liver carcinogen known to alter methylation in mouse liver, was included as a positive control. Global, average, DNA methylation was assessed using the SSI methylase assay which evaluates methylation at CpG sites. The methylation status of GC-rich regions of DNA, often associated with promoter regions, was assessed via methylation sensitive restriction digestion and arbitrarily primed PCR in which PCR products were separated and detected using an electrophoretic method. Global methylation status was not affected. DEA, PB, and choline-deficient treatment resulted in 54, 63, and 54 total sites of change in GC rich regions, respectively, and the majority were hypomethylations. Specific DEA and PB sites of change were very similar to those exhibited by choline deficiency, i.e., 71% of the total alterations, and 84% of the hypomethylations, were identical to those resulting from choline deficiency. These data indicate altered DNA methylation is an epigenetic mechanism involved in DEA-induced mouse liver tumorigenesis.

DNA HYPMETHYLATION INDUCED BY DRINKING WATER DISINFECTION BY-PRODUCTS IN MOUSE AND RAT KIDNEY.

L. Tao<sup>1</sup>, W. Wang<sup>1</sup>, P. M. Kramer<sup>2</sup>, L. Li<sup>2</sup> and M. A. Pereira<sup>1,2</sup>. <sup>1</sup>*Internal Medicine, Ohio State University, Columbus, OH* and <sup>2</sup>*Molecular Biology and Biochemistry, Medical College of Ohio, Toledo, OH*.

Haloacetic acids including dichloroacetic acid (DCA), trichloroacetic acid (TCA) and dibromoacetic acid (DBA), and trihalomethanes including chloroform and bromo-dichloromethane (BDCM) are major organic disinfection by-products (DBPs) found in finished drinking water after chlorination treatment. In male mice and rats, chloroform and BDCM when administered by oral gavage are nephrocarcinogens. In N-methyl-N-nitrosourea-initiated male mice, TCA promoted kidney tumors while DCA promoted kidney tumors only when co-administered with chloroform in drinking water. DBA has been shown to share biochemical and molecular activities in common with DCA and/or TCA. DNA hypomethylation has been proposed as a mechanism for non-genotoxic carcinogens. In this study, we determined the ability of these DBPs to cause hypomethylation of DNA and the c-myc protooncogene in mouse and rat kidney. Male and female B6C3F1 mice were administered 0, 0.3, 3.0 g/L DCA or 0, 0.4, 4.0 g/L TCA concurrently with 0, 0.1, 0.3, 1.0 and 1.6 g/L chloroform in drinking water. In male but not female mice, DCA, TCA and to a less extent chloroform decreased the methylation of DNA and the c-myc gene in the kidney. Co-administering chloroform increased only DCA but not TCA-induced hypomethylation of the gene. Male B6C3F1 mice and Fischer 344 rats were administered DBA at concentrations of 0, 1000 and 2000 mg/L in drinking water, and BDCM at dose levels of 0, 50 and 100 mg/kg by gavage and at concentrations of 0, 350 and 700 mg/L in drinking water for up to 28 days. Both DBA and BDCM caused a time- and dose-dependent hypomethylation of renal DNA in mice and rats. Hypomethylation of the c-myc gene was observed in mice after 7 days of DBA-exposure. In summary, the ability of the disinfection by-products to cause DNA hypomethylation correlated with their carcinogenic activity in mouse and rat kidney. (Supported by USEPA STAR grant R82808301 and NIEHS grant R03 ES10537)

LOSS OF HISTONE ACETYLATION BY NICKEL: AN EPIGENETIC MECHANISM OF NICKEL CARCINOGENESIS.

Q. ke, T. Kluz and M. Costa. *Department of Environmental Health, New York University School of Medicine, Nelson Institute, Tuxedo, NY*.

Although nickel is a potent human and animal carcinogen and occupational exposure to nickel could cause lung and nasal cancers, it is generally not mutagenic in most classical bacterial or mammalian cell assays. We have previously shown that

carcinogenic nickel exhibited its epigenetic effects on silencing expression of a transgenic gpt gene by enhancing DNA methylation and chromatin condensation, as well as by decreasing histone H3 and H4 acetylation on this transgene. In addition, nickel has been shown to cause a global loss of histone H4 acetylation both in yeast and mammalian cells. Histone acetylation occurs at the lysine residues most often located within the N-terminal tails of core histones including H2A, H2B, H3, and H4. The balance of histone acetylation and deacetylation, is regulated by histone acetyltransferase (HAT) and histone deacetylase (HDAC) enzyme activities, and is critical in regulating the dynamics of chromatin and gene transcription. In general, hyperacetylated histones are mostly associated with active genomic regions, whereas hypoacetylation mainly results in gene repression and silencing. Recent studies have shown that the balance of histone acetylation-deacetylation favors hypoacetylation in tumor cells and histone hypoacetylation plays an important role in gene silencing and carcinogenesis. In this study, we show that carcinogenic nickel decreased not only global acetylation of histone H4, but also that of H2A, H2B, and H3. By using our gpt transgene system, we are able to show that the acetylation of H2A and H2B mirror that of H3 and H4 since the acetylation of H2A and H2B was also lost in the nickel-silenced gpt cell clones. Besides its inhibitory effects on HAT activity, nickel may decrease histone acetylation by depleting the cellular acetyl Co-A, the substrate of the protein acetylation in the cell. Our new findings add further information contributing to nickel carcinogenesis and support to the view that nickel is an epigenetic carcinogen. Moreover, they provide insight for histone code hypothesis.

SEXUAL DIMORPHISM IN DNA METHYLATION IN THE LIVER OF HEXACHLOROBENZENE-TREATED RAT : A POSSIBLE MECHANISM FOR TUMOR PROMOTION.

N. J. Raynal, M. Charbonneau, B. Alt, L. Lee and D. G. Cyr. *INRS-Institut Armand-Frappier, Universite du Quebec, Pointe-Claire, QC, Canada*.

Hexachlorobenzene (HCB), a widespread environmental contaminant, causes gender-specific liver tumor promotion in the rat where only females develop liver cancer. We have previously shown that in female but not male rat livers HCB causes significant decreases compared to controls in : i) the total number of expressed genes as measured by microarray analysis, ii) the mRNA and protein levels of the liver gap junction subunits, connexin 26 and connexin 32 (Cx32), which are considered to be tumor suppressive, and iii) gap junctional intercellular communication (GJIC). Modulation of gene expression is the hallmark of epigenetic carcinogens such as HCB. DNA methylation exerts mechanistic control of gene expression. This study aimed to assess the effects of HCB on DNA methylation as a mechanism responsible for the reduction of global, and more specifically Cx32, gene expression. Global DNA methylation was assessed using arbitrarily primed PCR ; total DNA was extracted (N=4), amplified by PCR and digested by RsaI and HpaII. HCB induced DNA hypermethylation of HpaII restriction site. Local DNA methylation on the Cx32 promoter was measured using methylation specific-PCR (MSP) of bisulfite-treated DNA (N=4). Results showed a 2.5-fold increase ( $p<0.05$ ) in the methylation of the Cx32 promoter in HCB-treated female rat livers compared to controls. Moreover, results showed a marked sexual dimorphism in DNA methylation, with males having lower levels ( $p<0.05$ ) compared to control females, which correlated with the gender-difference in Cx32 mRNA levels. Overall, data suggest that by inducing aberrations in global methylation, and more specifically in local hypermethylation of the Cx32 promoter, HCB acts as a tumor promoter by modifying gene expression only in female rat livers. This work brings a better understanding of the modulation of DNA methylation in the reduction of gene expression by HCB in rat livers and strongly supports its role in rat hepatocarcinogenesis.

LOSS OF BRG1 AND LUNG CANCER PATHOGENESIS.

C. Bartlett<sup>1</sup>, G. Rosson<sup>2</sup> and B. Weissman<sup>2,1</sup>. <sup>1</sup>*Curriculum in Toxicology, UNC-CH, Chapel Hill, NC* and <sup>2</sup>*Pathology and Laboratory Medicine, UNC-CH, Chapel Hill, NC*. Sponsor: C. Harper.

The SWI/SNF chromatin remodeling complex uses the energy of ATP to alter nucleosomes to make DNA accessible to transcription machinery. Aberrations in chromatin remodeling can lead to development of cancer, such as loss of the SWI/SNF complex member BAF47 in rhabdoid tumors. BRG1, one of the catalytic subunits in human SWI/SNF complexes, is lost in ~30% of NSCLC cell lines. LOH surrounding the BRG1 loci at 19p13.2, has been shown in human lung tumor tissue. Loss of BRG1/BRM expression was found in ~10% of human primary tumors and correlated with poor prognosis. Similarly, loss of E-cadherin (a metastasis suppressor and cellular adhesion molecule) expression was found in ~10% of NSCLC and correlated with dedifferentiation and decreased survival. E-cadherin is commonly silenced by promoter hypermethylation in NSCLC. We have performed chromatin immunoprecipitation to show BRG1 is at the promoter

of E-cadherin in MCF7 cells that express high levels of E-cadherin. BRG1/BRM deficient cells examined by western blot were found to have significantly reduced levels of E-cadherin protein expression. Transfection of BRG1 into BRG1/BRM deficient cells induces reexpression of E-cadherin protein in a similar manner as treatment with 5-azacytidine. Therefore, loss of BRG1 expression may promote aberrant methylation of the E-cadherin promoter and subsequent silencing of the gene. We are currently screening H522 cells, a lung cancer cell line deficient for BRG1/BRM, for expression of other markers of lung cancer such as; p16 and FHIT. We will then check if transfection of BRG1, and treatment with 5-azacytidine are able to reexpress those markers. Bisulfite sequencing will be performed to see if those markers promoters are demethylated upon transfection of BRG1, and treatment with 5-azacytidine. We will also do chromatin immunoprecipitation to see if BRG1 is present at those promoters. These experiments should help establish a role for BRG1 in maintaining methylation patterns of critical genes in normal lung tissue.

## 1792 SECONDARY GENETIC ALTERATIONS IN LUNG TUMORS POSSESSING A PRIMARY KI-RAS MUTATION.

H. S. Floyd<sup>1</sup>, J. Jennings-Gee<sup>1</sup>, N. D. Kock<sup>2</sup> and M. S. Miller<sup>1</sup>. <sup>1</sup>*Cancer Biology, Wake Forest University, Winston-Salem, NC* and <sup>2</sup>*Comparative Medicine, Wake Forest University, Winston-Salem, NC*.

Mutation of the *Ki-ras* gene is an early event in spontaneous and chemically-induced murine lung tumors. We previously described a mouse lung cancer model whereby the mutant human *Ki-ras*<sup>G12C</sup> allele is expressed specifically in the lung in a doxycycline (DOX)-inducible manner. Mice treated with DOX developed hyperplastic lesions as early as 12 days and adenomas were first visible by 3 months. Adenomas were present up to 12 months with relatively no tumor progression. To identify secondary genetic alterations, lung adenomas from transgenic mice induced by 9 and 12 months of DOX treatment were analyzed for alterations in expression of *p16Ink4a*, *retinoblastoma* (*Rb*), and cyclin D1 by real-time PCR. Adenomas isolated from mice treated for 9 or 12 months with DOX exhibited decreased expression of *p16Ink4a* in 7/22 (32%) and 1/6 (17%) of the adenomas, respectively, and displayed reduced expression of *Rb* in 21/22 (95%) and 6/6 (100%) of the adenomas, respectively. No alterations in expression of cyclin D1 were observed. Analysis of lung adenomas for mutations in *p16Ink4a* by SSCP demonstrated that all the tumors (33) analyzed thus far exhibited the wild type sequence. The *Ki-ras*<sup>G12C</sup> mice display a relatively benign tumor phenotype, exhibiting mostly hyperplasias and adenomas, with few tumors progressing to carcinomas. These data suggest that alterations in *p16Ink4a* and *Rb* play an important role in the early stages of lung tumorigenesis. (Supported by NCI grant CA91909).

## 1793 COMPARISON OF EXPRESSION PROFILES OF ENU-INDUCED FORESTOMACH TUMORS AND URETHANE-INDUCED LUNG TUMORS IN RASH2 MICE.

M. Okamura<sup>1</sup>, A. Unami<sup>2</sup>, Y. Oishi<sup>2</sup>, K. Sumida<sup>3</sup>, Y. Kashida<sup>1</sup>, N. Machida<sup>1</sup> and K. Mitsumori<sup>1</sup>. <sup>1</sup>*Tokyo University of Agriculture and Technology, Tokyo, Japan*, <sup>2</sup>*Toxicology Research Laboratories, Fujisawa Pharmaceutical Co., Ltd., Osaka, Japan* and <sup>3</sup>*Environmental Health Science Laboratory, Sumitomo Chemical Co., Ltd., Osaka, Japan*. Sponsor: M. Takahashi.

Transgenic mice carrying a human prototype c-Ha-ras gene with its own promoter region (rasH2 mice) have been widely used in many 6-month short-term carcinogenicity tests, and have been recognized to be susceptible to genotoxic carcinogens. To clarify the mechanisms underlying the enhancement of carcinogenesis in rasH2 mice, we performed microarray analyses on chemically induced forestomach and lung tumors, and compared their gene expression profiles. Animals were given a single intraperitoneal injection of 120 mg/kg N-ethyl-N-nitrosourea (ENU) or 5-time intraperitoneal injections of 1000 mg/kg urethane at 2-day intervals. Three ENU-induced forestomach squamous cell carcinomas obtained at week 20 and 3 urethane-induced lung adenomas obtained at week 10 were used for the gene expression analysis. Compared with normal forestomach or lung tissue from non-treated mice, we selected up- and down-regulated genes in each tumor. In addition, we analyzed mRNA expression of human c-Ha-ras gene and some molecules involved in the Ras-MAPK pathway in these tumors. In microarray analysis, many genes related to cell cycle and transcriptions were up-regulated in both ENU- and urethane-induced tumors. Furthermore, the genes for extracellular matrix component, cytokines and chemokines were particularly up-regulated in ENU-induced tumors. RT-PCR analysis confirmed the overexpression of human c-Ha-ras mRNA in both tumors. The up-regulation of mouse endogenous ras genes was observed in only ENU-induced tumors. These results suggest that overexpression of transgene is involved in the enhanced carcinogenesis of both ENU- and urethane-induced tumors. Up-regulation of many genes for extracellular matrix component, cytokines and chemokines observed in ENU-induced tumors are considered to reflect tumor progression.

### CYTOCHROME P4502E1 (CYP2E1) MEDIATED METABOLISM IS A PRE-REQUISITE FOR THE PATHOGENESIS OF URETHANE-INDUCED GENOTOXICITY AND CARCINOGENICITY.

U. Hoffler<sup>1,2</sup>, D. Dixon<sup>2</sup>, S. Peddada<sup>2</sup> and B. I. Ghanayem<sup>2,1</sup>. <sup>1</sup>*Department of Pharmacology, Meharry Medical College, Nashville, TN* and <sup>2</sup>*NIEHS/NIH, Research Triangle Park, NC*.

Urethane exposure induces a multiplicity of tumor types in numerous animal species. A by-product of fermentation, human exposure to urethane occurs through the consumption of alcoholic beverages and fermented foods. Studies conducted in this laboratory demonstrated that CYP2E1, CYPs other than CYP2E1, and esterase to be responsible for 96.4%, 3.2%, and 0.4% of urethane metabolism, respectively. Current work was designed to address the hypothesis that CYP2E1-mediated activation is necessary for the development of urethane-induced genotoxicity and carcinogenicity. Therefore, CYP2E1-null and wild-type mice were administered 0, 1, 10, or 100 mg urethane/kg daily (5 days/week) for 6 consecutive weeks. At the end of dosing, half of the animals were euthanized to assess mutagenesis (micronuclei (MN)) and markers indicative of cell proliferation (Ki-67). The remaining animals were kept without exposure for 7 months. A significant dose-dependent increase in MN-polychromatic (PCE) and normochromatic (NCE) erythrocytes in wild-type mice was detected. In contrast, urethane did not induce an increase in MN-NCE at any dose level in CYP2E1-null mice; while a small but significant increase was observed in MN-PCE at the highest administered dose. Ki-67-labeling indices were also significantly higher in the liver and the lungs of wild-type mice given 100mg urethane/kg vs. control and CYP2E1-null mice treated similarly. At the end of the 7-month recovery, significant increases in the incidences of tumors were observed in the liver, lung, and Harderian gland of wild-type mice. However, a significant inhibition in the incidence of urethane-induced tumors was observed in all 3 organs as well in the number of lung tumors/lung of CYP2E1-null vs. wild-type mice. In conclusion, this data proved that CYP-mediated bioactivation is a pre-requisite for the development of urethane-induced genotoxicity and carcinogenicity.

## 1795

### EFFECTS OF AFB<sub>1</sub> ON EXPRESSION OF P53 AND MDM2 AND ON APOPTOSIS IN HUMAN LUNG CELLS.

T. L. Watterson<sup>1</sup>, T. R. Van Vleet<sup>2</sup> and R. A. Coulombe<sup>1</sup>. <sup>1</sup>*Toxicology Graduate Program, Utah State University, Logan, UT* and <sup>2</sup>*Drug Safety Evaluation, Bristol-Myers Squibb Company, Mt. Vernon, IN*.

Aflatoxin B<sub>1</sub> is a potent dietary hepatocarcinogen, and inhalation of AFB<sub>1</sub>-laden grain dusts has been postulated to be a lung cancer risk. Because mutations and altered expression of the tumor suppresser gene p53 have been observed in liver tumors associated with dietary AFB<sub>1</sub> exposure, we examined the effects of this mycotoxin on the expression of p53 and MDM2 in human bronchial epithelial cells (BEAS-2B) transfected with cDNA for cytochromes P450 (CYP) 1A2 (B1A2) or CYP 3A4 (B3A4), two of the isozymes responsible for AFB<sub>1</sub> activation in the liver and possibly the lung. Untreated B1A2 and B3A4 cells constitutively expressed p53, while AFB<sub>1</sub> exposure (0.015–15  $\mu$ M over 30 minutes) caused a concentration-dependent decline in p53 expression over time in B1A2 cells, and to a lesser extent, in B3A4 cells. The AFB<sub>1</sub>-mediated decrease in p53 continued for at least 12 hr after exposure to 1.5  $\mu$ M AFB<sub>1</sub>. Mirroring the decrease in p53 expression was a concentration-dependent increase in the expression of the 76 kDa MDM2 isoform in B1A2 cells. While AFB<sub>1</sub> did not induce DNA laddering, cleavage of procaspase-3 was detected after 4 hours of AFB<sub>1</sub> treatment as well as with the protein kinase inhibitor staurosporine. These data demonstrate that low, environmentally-relevant AFB<sub>1</sub> concentrations alter the expression of p53 and MDM2 as well as trigger apoptotic events in human lung cells. This study also supports the hypothesis that as in human liver, CYP 1A2 in human lung cells appears to play a dominant role in the molecular activation of AFB<sub>1</sub>.

## 1796

### NOVEL LAVENDAMYCINS AND AB RING SYSTEM ANALOGUES: *IN VITRO* CYTOTOXICITY, APOPTOSIS INDUCTION AND METABOLISM BY NAD(P)H:QUINONE OXIDOREDUCTASE 1 (NQO1).

M. Hassani<sup>1</sup>, W. Cai<sup>2</sup>, K. C. Bray<sup>1</sup>, M. Behforouz<sup>2</sup> and H. D. Beall<sup>1</sup>. <sup>1</sup>*Center for Environmental Health Sciences, The University of Montana, Missoula, MT* and <sup>2</sup>*Department of Chemistry, Ball State University, Muncie, IN*.

Lavendamycins and their AB ring system analogues can be bioactivated by cancer cells that overexpress NAD(P)H:quinone oxidoreductase 1 (NQO1) to exhibit selective toxicity. We examined the metabolism of these compounds by recombinant human NQO1 and their cytotoxicity to human colon adenocarcinoma cells with either no detectable NQO1 activity (BE-WT) or high NQO1 activity (BE-NQ). Metabolism was monitored by a spectrophotometric assay that quantifies cytochrome c reduction at 550 nm and toxicity was determined by MTT and clono-

genic assays. The correlation between the chemosensitivity results of the two assays was evaluated for 3 lavendamycin analogues. There was excellent linear correlation between the IC50 values of the two assays for the lavendamycins for BE-WT ( $r=0.999$ ,  $P=0.03$ ), BE-NQ ( $r=0.999$ ,  $P=0.025$ ) and both cell lines ( $r=0.990$ ,  $P=0.0001$ ). Of the 13 lavendamycins examined for cytotoxicity, the best substrates for NQO1 also showed selective toxicity toward BE-NQ cells. However, neither the AB ring system analogues that were also good substrates nor lavendamycin poor substrates showed selective toxicity. Although both lavendamycins and AB ring system analogues can be bioreductively activated by NQO1, only lavendamycins have the beta-carboline moiety that can act as part of a molecular cavity with potential metal binding sites. Therefore, the lack of selective toxicity of the AB ring system analogues might be due to their inability to utilize metals to bind DNA or act as catalysts for the production of reactive oxygen species. The role of NQO1 in lavendamycin-induced apoptosis was also examined. The concentration required to induce apoptosis was 5-20 fold less in BE-NQ cells compared to BE-WT cells for the best substrate suggesting a selective induction of apoptosis in the NQO1-rich BE-NQ cell line. Supported by NIH grant R15 CA78232.

HIGH PERFORMANCE LIQUID CHROMATOGRAPHY ASSAY FOR N-GLUCURONIDATION 4-AMINOBIPHENYL IN MICE LIVER MICROSOMES AND EXPRESSED HUMAN SUPERSOMES.

M. H. Al-Zoughoul, *Environmental Health, University of Cincinnati, Cincinnati, OH*. A new high performance liquid chromatography (HPLC) method has been developed to determine the N-glucuronidation activity of mice liver microsomes and expressed human supersomes toward the carcinogenic 4-Aminobiphenyl (4-ABP). The HPLC method uses a chemically synthesized 4-ABP-N-Glucuronide (4-ABP-G) as a standard to determine the amount of glucuronide formed. 4-ABP-G was synthesized by chemical reaction between D-gucuronic acid and 4-ABP and the product formed was confirmed by mass spectrometry (MS) to be that of 4-ABP-G. This was used as reference to build the standard curve. The method was specific and sensitive. The calibration curve for the 4-ABP-G was linear from 25-500 pmol/200ml. The intra- and inter-day precision and accuracy for 4-ABP-G were 4% and 7% respectively. The lower detection limit was 10 pmol/200ml. The intra- and inter-day precision of the UDP-glucuronosyltransferase (UGT) activity in mice liver microsomes and expressed human UGT1A4 and UGT1A9 were less than 3 and 8 % respectively. The method proved to be very sensitive and it enabled us to determine the kinetics of UGTs without the need to use the radioactive [ $^{14}C$ ]-UDPGA, which is expensive and difficult to handle. We used this method to determine the kinetics of recombinant human UGT1A4 and UGT 1A9 for 4-ABP. The  $K_m$  and  $V_{max}$  of UGT1A4 were 321nM and 133/min/mg protein and 120nM and 145 pmol/min/mg protein respectively for UGT1A9. Therefore, this method is applicable to determine the glucuronidation status towards carcinogenic arylamines. Glucuronidation of arylamines is an important step in bioactivation and distribution of the active metabolites to the target organ(s). The method could be also applicable to study kinetics of nitrogen-containing drugs for evaluation of drug interactions and side effects using small amounts of biological samples.

**1798**

URINARY BLADDER ENDPOINTS IN WORKERS AND RATS EXPOSED TO PERFLUOROOCTANESULFONYL FLUORIDE (POSF) AND RELATED COMPOUNDS.

G. Olsen<sup>1</sup>, B. Alexander<sup>2</sup>, S. Cohen<sup>3</sup> and J. Butenhoff<sup>1</sup>. <sup>1</sup>*3M Company, St. Paul, MN*, <sup>2</sup>*University of Minnesota, Minneapolis, MN* and <sup>3</sup>*University of Nebraska Med. Ctr, Omaha, NE*.

Workers with potential high exposure to POSF-related compounds, including perfluorooctanesulfonate (PFOS), had 3 bladder cancer deaths vs. 0.2 expected (SMR 12.8; 95% CI 2.6 — 37.4). These compounds have not shown genotoxicity, and toxicology studies (including cancer bioassays) with PFOS and related sulfonamides have not shown bladder effects, but repeat-exposure data was not available for POSF. To further study the association of exposure to bladder cancer, we investigated potential bladder effects of POSF in rats and bladder cancer incidence in workers. Rats were exposed by inhalation to 0, 30, 100, or 300 ppm POSF 6 hrs/day, 5 days/week for 4 (0 & 300 ppm) or 13 weeks. Complete urinalysis was done on overnight urines. SEM/X-ray element analysis for crystals/calculi and immediate pH were conducted on fresh morning urines. Sagittal sections of urinary bladder were taken for SEM analysis and assessment of cell proliferation by proliferating cell nuclear antigen (3 sections,  $10^3$  cells/section). Results: There were no treatment-related findings with respect to urinalysis parameters, including pH and solids, nor changes of the urothelium, including no exposure-related increase in cell proliferation. Epidemiology: Because of high survivorship, living members ( $N = 1895$ ) of the study were contacted by mail to answer a questionnaire about bladder cancer, and 74% participated. Validation occurred by medical record or death certificate for those original members deceased ( $N = 188$ ). Incidence of bladder cancer was compared to expected based on NCI SEER data. Results: 11 bladder cancers were identified. The Standardized Incidence Ratio (SIR) for the entire cohort was 1.3 (95% CI 0.6 — 2.3). The SIR for ever working and working for more than one

year in a high exposed job were 1.7 (95% CI 0.6 — 3.8) and 1.1 (95% CI 0.2 — 3.3), respectively. These studies do not support the hypothesis that the excess risk of bladder cancer initially reported was due to exposure to POSF-related materials or PFOS.

**1799**

DNA DAMAGE AND CYTOGENETIC EFFECTS OF OCHRATOXIN A IN RATS *IN VIVO*.

A. Mally<sup>1</sup>, G. Pepe<sup>2</sup>, S. Ravoori<sup>3</sup>, M. Fiore<sup>2</sup>, R. C. Gupta<sup>3</sup>, P. Mosesso<sup>2</sup> and W. Dekant<sup>1</sup>. <sup>1</sup>*Department of Toxicology, University of Wuerzburg, Wuerzburg, Germany*, <sup>2</sup>*Dipartimento die Agrobiologia e Agrochimica, Università degli Studi della Tuscia, Viterbo, Italy* and <sup>3</sup>*Pharmacology & Toxicology, Brown Cancer Center, University of Louisville, Louisville, KY*.

Ochratoxin A (OTA) is a potent nephrotoxin and renal carcinogen in rats, but the mechanism of OTA induced tumor formation is unknown. OTA has been shown to be negative in most genetic toxicology test *in vitro*. However, the potential of OTA to induce genotoxic effects has not been investigated in male rats, the most sensitive species for OTA induced tumor formation. In this study male F344 rats were repeatedly administered OTA (0, 0.25, 0.5, 1.0 and 2.0 mg/kg b.w.) or the non-chlorinated analogue ochratoxin B (OTB; 2.0 mg/kg b.w.) for 2 weeks and DNA breakage was analyzed in target and non-target tissues using the comet assay. DNA strand breaks were evident in liver, kidney and spleen, but a similar degree of DNA damage was observed in rats treated with OTB, despite the lower toxicity of OTB. Moreover, the presence of DNA damage did not correlate with histopathological alterations which were evident in the kidney, but not in the liver, suggesting that additional events may be required for renal tumor formation by OTA. In liver and kidney, the extent of DNA damage was further enhanced in the presence of Fpg-glycosylase, which is known to convert oxidative DNA damage into strand breaks. In contrast, no spots indicative of DNA adducts were observed in kidney DNA extracted from OTA treated animals by 32P-postlabeling analysis. A small, but not significant increase in the incidence of chromosomal aberrations was observed in splenocytes from rats treated with OTA *in vivo* and subsequently cultured *in vitro* to express chromosomal damage. These aberrations are not typically caused by chemical carcinogens which form covalent DNA adducts and together with the lack of evidence for formation of DNA adducts as assessed by postlabeling, these data suggest that OTA may cause genetic damage in target and non-target tissues independent of direct interaction with DNA.

$\alpha_{2u}$ -GLOBULIN AND RENAL TUMORS IN NATIONAL TOXICOLOGY PROGRAM (NTP) STUDIES.

A. M. Doi, G. D. Hill, J. R. Hailey and J. R. Bucher. *NTP, NIEHS, Research Triangle Park, NC*.

Chemical-induced tumors in the kidney tubules of male rats in association with  $\alpha_{2u}$ -globulin nephropathy are not considered predictive of risk to humans by the International Agency for Research on Cancer and some US regulatory agencies. Essential criteria have been outlined to establish the role of  $\alpha_{2u}$ -globulin nephropathy in renal carcinogenesis. Criteria were based on a hypothesized mechanism of action that involves sustained tubular cell proliferation and consequent development of neoplastic lesions resulting from  $\alpha_{2u}$ -induced nephropathy. A review of NTP studies revealed inconsistencies with this proposed mechanism, including, in some cases, far weaker kidney tumor responses than expected, based on the extent of  $\alpha_{2u}$ -globulin nephropathy. Recent NTP studies with Decalin, propylene glycol mono-*t*-butyl ether and Stoddard solvent IIC included extensive evaluations of  $\alpha_{2u}$ -related nephropathy, and were thus used in assessing the linkage between key renal events in prechronic studies with tumors in 2-year studies. This review revealed an apparent association of tumor responses with renal  $\alpha_{2u}$ -globulin concentrations and granular casts, and to a lesser extent with linear mineralization and tubular hyperplasia. However, tumor responses did not agree with hyaline droplet accumulation or cell labeling indices, albeit evaluations at single time points may not represent cell proliferation variations over time. These results suggest that  $\alpha_{2u}$ -globulin nephropathy may be necessary, but not sufficient to induce the development of tumors, with  $\alpha_{2u}$ -associated cell damage playing a more central role in renal tumor development than cell proliferation responses.

THE TSC-2 TUMOR SUPPRESSOR GENE MODULATES MULTIPLE CELL PROLIFERATION PATHWAYS.

M. T. Labenski<sup>1</sup>, X. Wei<sup>1</sup>, A. Hunt<sup>1</sup>, G. Tsaprailis<sup>1</sup>, M. S. Chacko<sup>2</sup>, M. D. Person<sup>2</sup>, J. Shen<sup>2</sup>, S. C. Hensley<sup>3</sup>, T. J. Monks<sup>1</sup> and S. S. Lau<sup>1</sup>. <sup>1</sup>*Pharmacology and Toxicology, University of Arizona, Tucson, AZ*, <sup>2</sup>*Pharmacology and Toxicology, University of Texas at Austin, Austin, TX* and <sup>3</sup>*UTMDACC, Science Park, Smithville, TX*.

The tuberous sclerosis-2 (Tsc-2) tumor suppressor gene, which encodes the protein tuberin, is a renal tumor suppressor gene. The Eker rat, derived from the Long-Evans strain, provides an excellent model for studying renal carcinogenesis. A germline insertion in the Tsc-2 gene, predisposes these rats to the development of 2, 3, 5-tris-(glutathione-S-yl)hydroquinone (TGHQ) induced renal tumors. A single

treatment of primary renal epithelial cells derived from Eker rats with TGHQ transformed these cells into colonies (QT-RREs) that exhibit aneuploidy, anchorage-independent growth *in vitro* and tumorigenicity in nude mice. The remaining functional allele of the Tsc-2 locus in QT-RRE cell lines is lost during TGHQ transformation, resulting in a loss of tuberin expression. To investigate the role of tuberin in tumor suppression we restored tuberin expression by transient transfection of the Tsc-2 gene into the QT-RRE cells. Utilizing 2D gel electrophoresis coupled with MALDI-TOF peptide mass mapping and post source decay, we compared the protein expression of the Tsc-2 null and Tsc-2 positive QT-RRE cells. Both peroxiredoxin 1 and peroxiredoxin 3 showed an increase (~2 fold) in protein expression. Elevated expression of peroxiredoxins can decrease cellular proliferation by altering H2O2 homeostasis. Several proteasome subunits, which negatively regulate cyclin D1, was also elevated (~3 fold) revealing another proliferation pathway affected by tuberin. A substantial decrease in procathepsin expression (~4.5 fold) also occurred in Tsc-2 transfected QT-RRE cells. Cathepsin D is a lysosomal acid proteinase, which participates in the malignant progression of various cancers, including breast, gastric, and ovarian cancers. In combination, the results reveal that tuberin exerts its tumor suppressor effects by modulating several pathways involved in the regulation of cell proliferation. (GM39338, ES06694, ES07784)

GLOBAL EXPRESSION PROFILING OF MALE RAT KIDNEY: CO-ADMINISTRATION OF A SPECIFIC ESTROGEN RECEPTOR (ER) ANTAGONIST INHIBITS A DYNAMIC 17B-ESTRADIOL (E2) RESPONSE.

P. H. Koza-Taylor<sup>1</sup>, G. D. Cappone<sup>4</sup>, J. D. Obourn<sup>3</sup>, J. C. Cook<sup>2</sup> and M. P. Lawton<sup>1</sup>. <sup>1</sup>MIT, Pfizer, Groton, CT, <sup>2</sup>FD & LS, Pfizer, Groton, CT, <sup>3</sup>ED, Pfizer, Groton, CT and <sup>4</sup>Toxicology Sciences, Pfizer, Groton, CT.

Estrogens have been shown to induce renal tumors in carcinogenicity and initiation-promotion studies as well as in renal tumor animal models such as the Syrian hamster. For example, estrogen administration to Syrian hamsters induces an 80-100% incidence of renal carcinomas in males. The mechanisms responsible for tumor formation are unknown, but likely involve ER-mediated mitogenesis, leading to the increased cell turnover via altered growth factor and oncogene expression. To gain further insight into the potential mechanism of ER-mediated carcinogenesis in the kidney, we have used gene expression profiling to identify altered cell growth and regulation pathways. As previously reported (Endocrinology 144:701, 2003), the kidney is indeed transcriptionally responsive to 17b-estradiol (E2), with only the uterus and pituitary gland showing a greater response among 13 tissues profiled. In the current study, male rats were dosed daily for 15 days with 20 mg/kg E2, 5 or 10 mg/kg ICI-182, 780 (ICI) or a combination of 20 mg/kg E2 and 5 or 10 mg/kg ICI. Renal expression profiles were generated using Affymetrix GeneChips and accessory sex glands (ASG) weights were measured to confirm the biological response to estrogen. The relative ASG weight decreased by 70% in animals dosed with E2, and returned to control levels in animals that were co-administered E2 and ICI, confirming the role of the ER in this response. Consistent with the ASG effects, there was also a robust transcriptional response in kidneys from the E2-treated animals (1, 221 differentially regulated with fold change greater than 1.5x at  $p < 0.5$ ) that was almost completely attenuated by co-administration with ICI, again demonstrating the role of the ER in mediating the expression changes. Genes involved in cell cycling, growth hormone signaling and cell proliferation were modulated by E2, consistent with a non-genotoxic mechanism of renal tumor formation.

APOPTOSIS, SENESCENCE AND CYTODIFFERENTIATION IN CARCINOGENIC MODELING.

N. H. Chiu<sup>4</sup>, G. Merlino<sup>2</sup>, K. H. Kim<sup>3</sup>, C. J. Kermp<sup>3</sup> and J. Beaubier<sup>5</sup>. <sup>1</sup>NCEADC, USEPA, Washington, DC, <sup>2</sup>Lab. Molecular Biology, National Cancer Institute, Bethesda, MD, <sup>3</sup>Division Human Biol, Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA, <sup>4</sup>Office Science Technology Office of Water, USEPA, Washington, DC and <sup>5</sup>Office Pesticide Pollution Prevention Toxics, USEPA, Washington, DC. Sponsor: D. Singh.

The hazard function power parameter (k) in failure-time-distribution Weibull models applied to bioassay data, likely represents the number of critical events in multistage-carcinogenesis. We modeled data from experiments in tumor-suppressor-gene-p53-knockout mice (p53<sup>+/-</sup>, p53<sup>-/-</sup>) and found an estimated reduction in critical carcinogenic events to 5 & 4 compared to 6 steps in the wild type controls. This reduction in mechanistic events (steps) occurs in both malignant lymphomas and soft-tissue-sarcomas in the experimental knockout mice. A further reduction in the number of critical events was found in colonies of quadruple knockouts p53<sup>+/-</sup>p27<sup>+/-</sup> compared to p53<sup>+/+</sup>p27<sup>+/+</sup>, p53<sup>+/-</sup>p27<sup>+/+</sup>. These latter results indicate that the number of stages predicted by Weibull and gamma-distribution-gamma- accumulation models show a preemptive loss in steps

controlling cell-cycle progression in these carcinogenesis. Using a similar computer modeling approach, we also estimated the number of steps of rhabdo- myosarcomagenesis in INK4a/ARF<sup>+/+</sup>, INK4a/ARF<sup>+/+</sup> with or without HGF/SF transgene. We found a further reduction of 1-2 steps in cancer development instigated by the loss of this cytodifferentiation-autocrine loop in addition to the cell-cycle control. A reduction in steps apparent from our computation approach was also found in bioassay data from the SMAD3<sup>+/</sup>, p27<sup>+/</sup> colonies in contrast to SMAD3<sup>+/</sup>, p27<sup>+/</sup>; APCMin<sup>+/</sup>, p27<sup>+/</sup>; APCMin<sup>+/</sup>, p27<sup>+/</sup> mice. This leads to the interpretation that in carcinogenesis control of apoptosis and senescence (Cell-Cycle-arrest) likely plays a more important role than autocrine-cytodifferentiation. **1804**

NUMBER OF CRITICAL CELL-CYCLE-EVENTS IN CANCER DEVELOPMENT OF P53-P27 KO MICE.

N. Chiu<sup>3</sup>, K. H. Kim<sup>2</sup>, C. Kemp<sup>2</sup> and J. Beaubier<sup>4</sup>. <sup>1</sup>NCEADC, USEPA, Washington DC, DC, <sup>2</sup>Division Human Biology Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA, <sup>3</sup>Office Science & Technology, Office of Water, USEPA, Washington, DC and <sup>4</sup>Office Pollution Prevention and Toxics, USEPA, Washington, DC. Sponsor: D. Singh.

The power parameter k of the hazard function in Weibull model, failure-distribution models likely represents the number of critical events in multistage-carcinogenesis. We have modeled data from experiments in tumor suppressor gene-p53-knockout mice (p53<sup>+/</sup>, p53<sup>-/-</sup>) colonies with contrasting results to the wild type. Our statistical results estimate a reduction in specific carcinogenic events from 6 in the wild type to either 5 or 4 in the knockout mice. The reduction in mechanistic events (steps) was found in both malignant lymphomas and soft-tissue-sarcomas comparing p53<sup>+/</sup> and p53<sup>-/-</sup> colonies to wild type controls. The genetic load of these animals plays apparently a critical load in determining the number of steps. When the computation was expanded to investigate the effects of p27Kip1 and p27Cip1 in regulating cell-cycle-progression and DNA-damage-repair response with p53, the latencies of tumor development in various experiments in p53<sup>+/</sup>p27<sup>+/</sup>, p53<sup>+/</sup>p27<sup>+/</sup>, p53<sup>-/-</sup>p27<sup>+/</sup> and p53<sup>+/</sup>p27<sup>+/</sup> combinations in mixed (C57BL/6J/C3H/NIH) and uniformed (C57BL/6J) animals were respectively shortened. These latter results indicate that the number of events predicted by Weibull and gamma-distribution-gamma-accumulation models show that genetic mechanisms in these respective carcinogenesis were further reduced by 2 steps. Disclaimer: Opinions and conclusions in this paper are the authors and do not necessarily reflect their affiliated institutions.

ARNT, A PUTATIVE COACTIVATOR OF C-MYC/MAX SIGNALING PATHWAY, INTERACTS WITH C-MYC.

R. Wu, M. Hoagland and H. Swanson. University of Kentucky, Lexington, KY.

ARNT (aryl hydrocarbon receptor nuclear translocator) is the DNA binding partner of the AHR (aryl hydrocarbon receptor) that together are thought to mediate most of the toxic and carcinogenic actions of 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD). By binding to different partners, ARNT is involved in many signaling pathways and plays corresponding roles in embryonic development, the hypoxia response and development of the central nervous system. To delineate the putative role of ARNT in modulating the oncogenic pathway of c-Myc/Max, we performed transient transfection assays using a reporter gene regulated by p53 promoter and c-Myc and ARNT expression plasmids. We discovered ARNT is able to enhance c-Myc induction of the p53 reporter gene and that this effect is independent of DNA binding by ARNT. In addition, we have used yeast two hybrid and mammalian two hybrid assays and found that ARNT and c-Myc are able to directly interact with each other both in yeast and mammalian cells. Confocal imaging indicates that the dominant colocalization of ARNT and c-Myc occurs in the cell nucleus. Our data indicates that ARNT is capable of enhancing p53 promoter activity by modulating the c-Myc/Max pathway and that this effect is mediated by a direct interaction between ARNT and c-Myc. These data also support the idea that TCDD, via activation of AHR, may sequester ARNT from its endogenous role in p53 gene induction and accelerate cell cycle progression and/or inhibition of apoptosis.

A POTENTIAL ROLE FOR C-MYB, BAX AND THE ARYL HYDROCARBON RECEPTOR IN BENZENE-INITIATED TOXICITY.

H. J. Badham<sup>1</sup> and L. M. Winn<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada and <sup>2</sup>School of Environmental Studies, Queen's University, Kingston, ON, Canada.

Benzene is a leukemogen found in agents such as cigarette smoke, industrial solvents, and gasoline. Chronic occupational exposure to benzene has been correlated with oxidative stress and acute myelogenous leukemia. Childhood acute leukemia

has been associated with highly variable expression of the proapoptotic factor bax, which is inhibited by phosphorylation in the presence of reactive oxygen species (ROS) and is involved in controlling cell death particularly in hematopoietic cells. The oncogene c-myb is important in hematopoiesis and its over-expression has been implicated in the pathogenesis of myelogenous leukemias. Our laboratory has demonstrated that chicken erythroblast HD3 cells show an increase in c-Myb activity and an increase in ROS when exposed to the benzene metabolites catechol, benzoquinone, and hydroquinone. Activation of the aryl hydrocarbon receptor (AhR) by environmental toxicants has been associated with carcinogenesis. Interestingly, benzene-initiated hematotoxicity is absent in mice lacking the AhR suggesting an imperative role for this receptor in benzene toxicities. Using mouse hepatoma wild type and AhR null cells we investigated the role of this receptor on metabolite initiated increases in c-Myb activity and bax phosphorylation. Our results illustrated that both cell types showed increases in c-Myb activity when exposed to varying concentrations of catechol and hydroquinone for 24 hr. Interestingly, protein expression of c-Myb was increased after catechol exposure in AhR null cells while decreased in wild type cells. Our results also demonstrated that wild type cells exposed to catechol had decreased phosphorylated bax protein expression and increased dephosphorylated bax protein expression. In contrast, AhR null cells showed an increase in phosphorylated bax and no change in dephosphorylated bax. These results suggest a role for bax and the AhR in the toxicity initiated by benzene metabolites. Support: CIHR

THE ESTROGENIC ACTIVITIES OF ARYL HYDROCARBON RECEPTOR AGONISTS ARE DUE TO DIRECT ACTIVATION OF ESTROGEN RECEPTOR  $\alpha$

M. Abdelrahim<sup>1</sup>, K. Kim<sup>2</sup>, S. Pearce<sup>3</sup>, E. Ariazi<sup>3</sup>, H. Liu<sup>3</sup>, V. Jordan<sup>3</sup> and S. Safe<sup>1,2</sup>. <sup>1</sup>*Institute of Biosciences & Technology, Texas A&M University System Health Science Center, Houston, TX*, <sup>2</sup>*Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX* and <sup>3</sup>*Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL*

A recent study reported that aryl hydrocarbon receptor (AhR) agonists activated estrogen receptor (ER)-mediated signaling through a mechanism in which the ligand-activated AhR complex acts as a coregulator of ER action. This study investigates the Ah- and estrogen-responsiveness of 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), 3-methylcholanthrene (3-MC), and 3, 3', 4, 4', 5-pentachlorobiphenyl (PCB) in MCF-7 cells. All three AhR agonists induced transactivation (up to 20-fold) in cells transfected with a construct (pDRE<sub>3</sub>) containing 3 tandem dioxin-responsive elements (DREs), and small inhibitory RNA for the AhR (iAhR) decreased this response, whereas small inhibitor RNA for ER $\alpha$  (iER $\alpha$ ) had no effect. In a parallel study, 17 $\beta$ -estradiol (E2), PCB and MC (but not TCDD) induced transactivation (3- to 5-fold) in MCF-7 cells transfected with a construct (pERE<sub>3</sub>) containing 3 tandem estrogen response elements (EREs). E2-, 3-MC- and PCB-induced transactivation was significantly decreased in cells cotransfected with pERE<sub>3</sub> and iER $\alpha$ , whereas iAhR had no effect on ligand-induced transactivation. These results suggest that the estrogenic activity of 3-MC and PCB was AhR-independent and due to a direct effect on ER $\alpha$ ; this was also confirmed by showing that the antiestrogen ICI 182, 780 also blocked PCB- and 3-MC-induced activity. These data coupled with results in AhR-negative breast cancer cells show that PCB and 3-MC directly activate ER $\alpha$  independent of AhR expression. (Supported by NIEHS ES09106 and ES04176)

INHIBITION OF ESTROGEN RECEPTOR-NEGATIVE BREAST CANCER CELL GROWTH BY ARYL HYDROCARBON RECEPTOR AGONISTS

L. Kotha and S. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX*

MDA-MB-453 and BT-474 breast cancer cell lines overexpress epidermal growth factor receptor 2 (ErbB2) and represent *in vitro* models for later stage hormone-resistant breast cancer. Treatment of these cell lines with aryl hydrocarbon receptor (AhR) agonists such as 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), diindolylmethane (DIM), and 6-methyl-1, 3, 8-trichlorodibenzofuran (MCDF) inhibit growth of both cell lines with IC<sub>50</sub> values < 10 nM, 2  $\mu$ M and 1  $\mu$ M, respectively. Similar results were obtained for phosphatidylinositol-3-kinase (PI3-K) and mitogen-activated protein kinase (MAPK) inhibitors LY294002 and U0126, respectively, and these compounds also inhibited constitutively-active kinase activities in these cell lines. In contrast, TCDD, MCDF and DIM did not significantly block kinase activities despite their inhibition of cell proliferation. We also investigated the effects of TCDD, DIM and 6-MCDF on expression of critical cell cycle regulatory proteins (cyclin D1, p27 and p21) and on apoptosis. These responses were not

significantly affected by AhR agonists. In contrast, treatment of MDA-MB-453 cells with 10 nM TCDD, 10  $\mu$ M DIM or 2  $\mu$ M 6-MCDF resulted in an 8-, 4.5- and 6-fold increase in HES-1 protein expression in MDA-MB-453 cells. HES-1 protein has previously been identified as an inhibitory transcription factor that is induced by TCDD in ER-positive T47D breast cancer cells. Induction of HES-1 by AhR agonists in MDA-MB-231 suggests that this protein may play a role in the AhR-responsive antimitogenic activity of AhR agonists in ER-negative breast cancer cell lines. (Supported by NIEHS ES09106 and ES04176)

**1809**

CONSEQUENCES OF INTERACTION OF THE EQUINE ESTROGEN METABOLITE, 4-HYDROXYEQUILENIN, WITH ESTROGEN RECEPTOR  $\alpha$

M. Chang and J. L. Bolton. *University of Illinois at Chicago, Chicago, IL*

4-Hydroxyequilenin (4-OHEN) is a redox-active phase I metabolite of several equine estrogens present in Premarin, the most widely prescribed estrogen replacement formulation in North America. It has been shown that 4-OHEN was more toxic and induced considerably more DNA damage in ER $\alpha$  positive breast cancer cells compared to an ER $\alpha$  negative cell line. Coadministration of the antiestrogen 4-hydroxytamoxifen diminishes this differential DNA damage implying that 4-OHEN-mediated oxidative DNA damage could be ER-dependent. It has been shown that 4-OHEN has a very poor binding affinity and weak estrogenic activity in Ishikawa cells using the alkaline phosphatase induction assay. However, it has never been investigated if 4-OHEN is truly estrogenic and interacts with ER leading to ER-dependent DNA damage in other established cell-based assays. In the present study, the ability of 4-OHEN to interact with ER was investigated using the estrogen-responsive element (ERE)-luciferase activity assays in ER-positive MCF-7 cells. Our data showed that 4-OHEN is able to activate ERE-luciferase activity and 4-OHEN-induced luciferase activity was blocked in the presence of a pure antiestrogen. In order to understand the mechanism of 4-OHEN-mediated ER/ERE transactivation, it was investigated if aryl hydrocarbon receptor (AhR) could play a role since 4-OHEN can interact with AhR which then can act as a coactivator to induce ER $\alpha$ -mediated gene transcription. Knockout of AhR mRNA did not affect 4-OHEN-mediated ER/ERE transactivation, implying that AhR is not required for such gene transcription and 4-OHEN may directly interact with ER. In summary, 4-OHEN could act as an estrogen agonist and it may directly interact with the ER. Our data imply that 4-OHEN may be genotoxic as a chemical carcinogen but also as a hormone which could induce cell proliferation-induced mutations.

G2/M BLOCK OF PRIMARY MAMMARY EPITHELIAL CELLS FROM PRE-MENOPAUSAL WOMEN IN RESPONSE TO GENOTOXIC CARCINOGEN EXPOSURE

J. Brooks<sup>1</sup>, J. Wang<sup>1</sup>, A. Humphrey<sup>1</sup>, J. Hearnes<sup>2</sup>, J. Pietenpol<sup>2</sup>, J. Price<sup>2</sup> and S. E. Eltorm<sup>1</sup>. <sup>1</sup>*Pharmacology, Meharry Medical College, Nashville, TN* and <sup>2</sup>*Vanderbilt University, Nashville, TN*

The mammary tissues are targets for many lipophilic environmental chemicals, including organochlorines, polycyclic aromatic hydrocarbons (PAH) and arylamines. Studies were designed to compare the effect of B[a]P and TCDD, prototypic PAHs, on the primary mammary epithelial cells (HMEC) from pre-menopausal women. The response of HMEC to these chemicals exposure on cellular proliferation and differentiation was evaluated using fluorescence-activated cell sorter (FACS) analysis, immunoblotting and immuno-cytological staining coupled-fluorescent microscopy. Exposure to TCDD for 20 hours has no significant effect on the cell cycle distribution. The treatment with B[a]P has resulted in enhanced BrdU incorporation by an average of 7-fold over control. Exposure to B[a]P for 20 hours caused a block in G2/M phase, resulting in cells accumulation in this phase at an average 13 percentage higher than untreated control cells. While no change is observed in the fraction of cells in the S phase, an average of 13 % was depleted from G1/Go phase, indicating the cells ability to transit through S-phase. Western immunoblotting analysis showed that these cells failed to activate P53 and its downstream target in response to the high dose (10  $\mu$ M) of B[a]P. These cells failed to undergo apoptosis and responded by increasing their mitotic activities, as evidenced by the enhanced PCNA staining. Due to their role in bioactivation of B[a]P to the ultimate genotoxic metabolites, CYP1A1 and CYP1B1 expression and induction by B[a]P and TCDD was examined in these cells. The data obtained from real time RT-PCR showed CYP1A1 mRNA to be induced by 100-300-fold with TCDD and about 50-150 folds by B[a]P. The data point to an anomalous cellular response of mammary epithelial cells from these subjects to genotoxic carcinogen. Funded by U54-CA91408-03 and DAMD17-02-01-0483.

CHANGES IN ESTROGEN METABOLISM IN CATECHOL-O-METHYLTRANSFERASE (COMT) DEFICIENT MICE ARE ASSOCIATED WITH INCREASED DEVELOPMENT AND ALTERED GENE EXPRESSION IN THE MOUSE MAMMARY GLAND.

C. Borgeest<sup>1</sup>, C. A. Zahnow<sup>2</sup>, S. O. DaCosta<sup>1</sup>, B. L. McAtee<sup>1</sup>, J. A. Flaws<sup>3</sup>, J. K. Babus<sup>3</sup>, S. Biswal<sup>1</sup> and J. D. Yager<sup>1</sup>. <sup>1</sup>*Environmental Health Science, Johns Hopkins University, Baltimore, MD*, <sup>2</sup>*Cancer Biology, Johns Hopkins University, Baltimore, MD* and <sup>3</sup>*Department of Epidemiology and Preventive Medicine, University of Maryland, Baltimore, MD*.

Estradiol (E2) has two catechol estrogen (CE) metabolites that are inactivated by COMT, a phase II biotransformation enzyme. Studies in our lab demonstrated that a low activity polymorphism for COMT is associated with increased risk for breast cancer and that COMT inhibition leads to increased oxidative DNA damage in MCF-7 cells. Additional studies show that mammary gland cells from COMT knockout (KO) mice metabolize E2 to CEs, but do not produce methoxy estrogen metabolites, which are thought to be anti-mitogenic. Additionally, preliminary experiments show that serum E2 levels (pg/mL) are higher ( $p \leq 0.04$ ) in the KO mice ( $42.1 \pm 13.4$ ;  $n=5$ ) than in their wild-type (WT) counterparts ( $7.0 \pm 1.9$ ;  $n=3$ ). CEs bind to the estrogen receptor, are estrogenic, and are precursors of estrogen quinones that cause DNA damage. Thus, we hypothesized that mammary gland development in the KO mice would be affected by the observed alterations estrogen metabolism. To test this hypothesis, mammary glands were excised from 4 week old KO and WT mice and subjected to whole mount examination of the epithelial tree. Ductal branching was quantified by counting terminal end buds and RNA was isolated for microarray analysis of gene expression. Our results show that the KO mice have ( $p \leq 0.02$ ) more terminal end buds per gland ( $34.30 \pm 5.030$ ;  $n=3$ ) than WTs ( $19.8 \pm 6.9$ ;  $n=5$ ), suggesting greater development. Microarray analysis shows that 15 genes were significantly up-regulated in the KOs (fold change range: 1.5-6.8;  $p \leq 0.05$ ). The up-regulated genes have been associated with cell signaling, growth/proliferation and cancer, suggesting that the alterations in estrogen metabolism might result in changes in gene expression in the mammary gland and may contribute to altered development. (Supported by NIH grants R01 CA77550, T32 ES07141, and P30 ES03819).

INVESTIGATION OF OCTAMETHYLCYCLOTETRAZILOXANE (D4) AND DECAMETHYLCYCLOPENTASILOXANE (D5) AS DOPAMINE D2-RECEPTOR AGONISTS.

P. A. Jean, K. A. McCracken, J. A. Arthurton and K. P. Plotzke. *Dow Corning Corporation, Midland, MI*.

Oncogenicity studies of D4 and D5 have shown uterine adenomas and adenocarcinomas, respectively. Binding of dopamine receptor agonists to dopamine D2-receptors on pituitary lactotrophs inhibits the process of prolactin secretion. In the rat, decreased circulating levels of prolactin induces a decrease in circulating progesterone and consequently, an elevated estrogen:progesterone ratio. The neoplastic effects of dopamine receptor agonists on the uterus have been attributed to this apparent estrogen dominance. Experiments were conducted to evaluate the potential for D4 and D5 to modulate pituitary prolactin secretion as dopamine D2-receptor agonists. Utilizing an *in vitro* cell line, derived from a rat pituitary tumor (MMQ, ATCC #: CRL-10609), 10  $\mu$ M D4 and D5 were each shown to decrease maitotoxin-induced prolactin release by 55% without affecting viability. An *in vivo* model was then used to assess serum prolactin levels in reserpine-treated female Fischer 344 rats following 6-h vapor inhalation exposure to 700ppm D4 or 160ppm D5. In this model, serum prolactin levels were decreased 88% by 700ppm D4 and 50% by 160ppm D5 relative to reserpine control. Pretreatment with sulpiride, a dopamine receptor antagonist, blocked the effect of D4 and D5 suggesting that these cyclic siloxanes were acting on the pituitary as dopamine D2-receptor agonists *in vivo*. These results and the known species differences in reproductive physiology provide support for a potential mode of action that is not relevant humans. (This work was sponsored by the Silicones Environmental, Health and Safety Council of North America)

TRANSPLACENTAL AND POSTNATAL EXPOSURE OF AIDS DRUGS ZIDOVUDINE (AZT) AND LAMIVUDINE (3TC) IN C3B6F<sub>1</sub> TRP53(+/−) TRANSGENIC MICE.

F. W. Lee, S. M. Lewis, C. Crawford, W. T. Allaben and J. E. Leakey. *USFDA, NCTR, Jefferson, AR*.

AZT/3TC antiviral drug combinations are given during pregnancy to reduce maternal-fetal HIV transmission. AZT is genotoxic in fetal mice and monkeys and carcinogenic in mice. We assessed a new C3B6F<sub>1</sub> trp53(+/−) p53 haplodeficient transgenic mouse model to be used for cancer bioassays. These mice, produced by

mating *Taconic C57BL6(N12)trp53(−/−)* males and C3H females, possibly have similar tumor profiles to B6C3F<sub>1</sub> mice. Haplodeficient C3B6F<sub>1</sub> trp53(+/−) and wild-type C3B6F<sub>1</sub> trp53(+/+) mice were dosed with 0, 40, 80, 160 mg/kg AZT or 160 mg/kg AZT combined with 100 mg/kg 3TC, by gavage in aqueous methylcelulose/polysorbate 80 (2/0.1%), transplacentally from GD12 to GD18 then postnatally from PND 1 to PND 28. P53 deficient mice are susceptible to fetal and neonatal mortality particularly when exposed to genotoxic compounds *in utero*. In a previous study using perinatal C57BL6(N5)trp53(+/−) mice dosed with 200 mg/kg AZT, we obtained relatively low pup survival in both control and treated groups (75 & 17% respectively at PND-28). In contrast, C3B6F<sub>1</sub> trp53(+/−) were more robust. Survival in these pups was >95% and >85% for the control and dosed groups respectively and was greater for haplodeficient than for wild type mice. The AZT and AZT/3TC treatment produced only small (<10%) reductions in body weight gain, but mice from the AZT/3TC dose groups showed increased *hprt* mutation frequency when evaluated at PND 28. In adult humans hepatic AZT glucuronidation by UDP-glucuronosyltransferase (UGT) is a major detoxification pathway. In contrast, liver from C3B6F<sub>1</sub> trp53(+/−) and C3H mice expressed very low levels UGT activity towards AZT (0.2–1.5 pmol/min/mg microsomal protein; human and rhesus monkey liver activities ranged between 1.5–2.5 nmol/min/mg microsomal protein), and only low levels of AZT-glucuronide were detected in serum from AZT treated mice. Since human neonates also express low levels of hepatic UGT activity, the C3B6F<sub>1</sub> trp53(+/−) mouse may be a good model for evaluating risk of perinatal AZT exposure.

EFFECT OF A COMPLEX MIXTURE FROM COAL TAR - SRM 1597 ON THE METABOLIC ACTIVATION OF CARCINOGENIC POLYCYCLIC AROMATIC HYDROCARBONS IN CHINESE HAMSTER V79 CELLS.

B. Mahadevan<sup>1</sup>, C. P. Marston<sup>1</sup>, W. Dashwood<sup>1</sup>, E. Brooks<sup>1</sup>, Y. Li<sup>2</sup>, C. Pereira<sup>2</sup>, J. Doehmer<sup>3</sup> and W. M. Baird<sup>1</sup>. <sup>1</sup>*Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR*, <sup>2</sup>*Department of Statistics, Oregon State University, Corvallis, OR* and <sup>3</sup>*GenPharm Toxicology BioTechAG, Martinsried, Germany*.

A complex mixture of polycyclic aromatic hydrocarbons (PAH) extracted from coal tar, Standard Reference Material (SRM) 1597, has been shown to initiate tumor formation in mouse initiation-promotion assays in our laboratory (*Carcinogenesis*, 2001, 22(7) 1077-1086). To understand the role of SRM 1597 on PAH activation and DNA adduct formation, we examined the effects of SRM 1597 on the metabolic activation to DNA-binding derivatives of two carcinogenic PAH, benzo[*a*]pyrene (BP) and dibenzo[*a, h*]pyrene (DBP). Chinese hamster V79 cells expressing either human cytochrome P450 (CYP) 1A1 or CYP1B1 were used to determine the PAH-DNA adduct levels on exposure to SRM 1597, BP, DBP or co-treatments of SRM 1597 and BP or DBP. SRM 1597 inhibited BP-DNA adduct formation through the entire exposure time in the human CYP1A1 expressing cells. On the contrary, V79 cells expressing human CYP1B1 were unable to metabolize SRM 1597 or co-treatments of SRM 1597 and BP or DBP to DNA-binding metabolites. However, both CYP1A1 and CYP1B1 expressing cells metabolized BP and DBP to their respective DNA-binding metabolites. In order to assess the ability of SRM 1597 to inhibit the activity of CYP enzymes, ethoxresorufin *O*-deethylase assay was performed using microsomes isolated from V79 cells expressing CYP1A1 and CYP1B1. Competitive inhibition of resorufin product formation on exposure to SRM 1597 was observed in microsomes from V79 cells expressing both human CYP1A1 and CYP1B1. The results from this study suggests that the relative risk that PAH mixtures pose to humans may be dependent on the ability of the complex mixture to competitively inhibit the metabolic activation of carcinogenic PAH by the induced CYP enzymes and decrease DNA binding metabolites. Supported by NIH grant CA28825.

COMPETING ROLES OF ALDO-KETO REDUCTASE 1A1 AND CYP1A1/CYP1B1 IN THE METABOLIC ACTIVATION OF (+/-)-BENZO(A)PYRENE-7, 8-DIOL IN HUMAN BRONCHOALVEOLAR CELLS: INFLUENCE OF CYP INDUCTION.

H. Jiang, D. Vudathala, I. A. Blair and T. M. Penning. *Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA*. Sponsor: S. Burchiel.

Human aldo-keto reductases (AKR1A1, AKR1C1-AKR1C4) catalyze a novel pathway of (+/-)-Benzo[*a*]pyrene-7, 8-diol (BP-7, 8-diol) activation which leads to BP-7, 8-dione that differs from the cytochrome P450 (CYP1A1/CYP1B1) pathway which leads to anti-benzo[*a*]pyrene-diol epoxide (anti-BPDE). The roles of AKR1A1 vs. CYP1A1/CYP1B1 in the activation of BP-7, 8-diol were equivalent in bronchoalveolar cell extracts containing 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD)-induced CYP1A1/CYP1B1 and stably expressed AKR1A1, and were dependent on the redox-state (NAD<sup>+</sup> : NADPH). This study compares the roles of

AKR1A1 and CYP1A1/CYP1B1 in the activation of BP-7, 8-diol in intact human bronchoalveolar H358 cells manipulated to express both pathways. The proposed metabolites formed in cell cultures via AKR1A1 and CYP1A1/CYP1B1 were identified by LC/MS and quantitatively measured by HPLC coupled to in-line radioactive detection using [<sup>3</sup>H]-(+/-)-BP-7, 8-diol. In TCDD-treated H358 cells (CYP1A1/CYP1B1 expression), BP-tetrols derived from anti-BPDE increased over 3-12 h to a constant level. In H358 AKR1A1-transfected, formation of BP-7, 8-diol was elevated for 3-12 h and significantly decreased after 24 h indicating that subsequent events consumed BP-7, 8-diol (e.g., metabolism or covalent modification of macromolecules). Unexpectedly, BP-tetrols were detected in AKR1A1 transfecteds even though they do not constitutively express CYP1A1/CYP1B1. The AKR1A1 product BP-7, 8-diol can trans-activate the aryl hydrocarbon receptor which could account for the CYP1A1/CYP1B1 metabolites. In H358 AKR1A1 transfecteds treated with TCDD, the formation of BP-tetrols was further elevated while levels of BP-7, 8-diol decreased due to the competing role of TCDD-induced CYPs. AKR1A1 thus plays an important role in PAH carcinogenesis due to the formation of the reactive and redox-active BP-7, 8-diol which induces the CYP pathway [Supported by PO1-CA92537 awarded to TMP].

sum of As species) in all samples, except maternal livers. In maternal livers, iAs represented 26 to 28% of sum of As species. Notably, iAs concentrations were lowest in fetal tissues. Highest concentrations of MAs were found in maternal liver, lung, and blood. No TMA<sub>3</sub>O was detected. These data suggest that in utero exposures to iAs result in accumulation of DMAs in fetal tissues. High levels of DMAs in fetal tissues may contribute to the aberrant patterns of gene expression that underlie the carcinogenic effects of in utero exposure to iAs. Arsenic is widespread in the environment and a human carcinogen. A major metabolite of inorganic arsenic (iAs) in most species, including humans, is dimethylarsinic acid (DMA). Arsenic in the form of DMA is also used as a pesticide. Unlike iAs, DMA induces urinary bladder tumors in rats. DMA is believed to induce bladder cancer through a combination of target cell cytotoxicity, oxidative stress, and DNA damage. We propose that these effects are specific to the cancer target cell and not a general feature of DMA exposure. The present study compares the gene expression associated with DMA exposure in kidney to a previous examination of the rat transitional epithelium lining the urinary bladder. Female F344 rats were treated with 1, 4, 40, or 100 ppm DMA in the drinking water for 4 weeks. The rats were euthanized and kidneys were taken for histology and RNA extraction for 2-dye custom spotted microarray analysis with 4.5K known rat genes. The array signal intensity were subtracted from background, normalized, and analyzed using a one-way ANOVA model with a p value of 0.01 in GeneSpring. There was no significant renal histopathology whereas the urinary bladder had dose-dependent cytotoxicity. Microarray analysis of the transitional epithelia showed that DMA treatment altered the expression of apoptosis, cell cycle regulation, proliferation, signal transduction and oxidative stress response genes. The major functional categories affected in the kidney were genes that control metabolism, particularly lipid metabolism. Differential gene expression profiles between cancer target and non-target tissues can be used to suggest events in target tissues associated with DMA-induced carcinogenesis. [This abstract does not necessarily reflect EPA policy.]

Earlier work found that *in utero* exposure of mice to inorganic arsenic (iAs) produces tumors during adulthood. To help define the biokinetics of arsenic (As) after *in utero* exposure, pregnant C3H mice were given carcinogenic doses of 42.5 or 85 ppm As (as sodium arsenite) in the drinking water from day 8 to 18 of gestation. Total As (TAs) and As species were analyzed in the blood, liver, lung, and placenta collected from dams and in the blood, liver, and lung collected from fetuses at day 18 of gestation. TAs was determined by hydride generation-atomic fluorescence spectrometry. Speciation analysis was carried out by hydride generation-atomic absorption spectrometry, using a liquid nitrogen cold trap for separation of arsines. The latter method simultaneously determined iAs, methyl-As (MAs), dimethyl-As (DMAs), and trimethylarsine oxide (TMA<sub>3</sub>O). TAs levels were generally higher in the maternal tissues than in fetal tissues at either exposure level. For both dams and fetuses, the highest concentrations of TAs were found in the liver and lung. DMAs was the predominant species in maternal and fetal blood and tissues. DMAs represented 46 to 78 % and 85 to 97% of sum of As species in tissues of dams and fetuses, respectively. In contrast, iAs was a minor species (0 to 12% of

### UPTAKE OF INORGANIC AND ORGANIC DERIVATIVES OF ARSENIC AND ASSOCIATION WITH GENOTOXIC EFFECTS IN MAMMALIAN CELLS *IN VITRO*.

E. Dopp<sup>1</sup>, L. M. Hartmann<sup>2</sup>, A. M. Florea<sup>1</sup>, U. V. von Recklinghausen<sup>1</sup>, U. Rauen<sup>3</sup>, A. W. Rettenmeier<sup>1</sup> and A. V. Hirner<sup>2</sup>. <sup>1</sup>Institute of Hygiene and Occupational Medicine, University of Duisburg-Essen, Essen, NRW, Germany,

<sup>2</sup>Institute of Environmental Chemistry, University of Duisburg-Essen, Essen, Germany and <sup>3</sup>Institute of Physiological Chemistry, University of Duisburg-Essen, Essen, Germany. Sponsor: E. Nelson.

The aim of our study was the elucidation of the uptake capabilities of different cell types in relation to the toxic effects of inorganic arsenic and its methylated metabolites. Chinese hamster ovary cells (CHO-9), human hepatoma cells (Hep G2) and primary rat hepatocytes (pRH) were exposed to arsenate [i-As(V)], arsenite [i-As(III)], monomethylarsinic acid [MMA(V)], monomethylarsonous acid [MMA(III)], dimethylarsinic acid [DMA(V)], dimethylarsinous acid [DMA(III)], trimethylarsen oxide [TMAO(V)] for 1 h. The chemicals were applied at different concentrations (0.1 microM to 10 mM) and cellular uptake was measured by ICP-MS. Genotoxic effects were assessed in CHO-9 cells by micronucleus (MN) assay, chromosome aberrations (CA) and sister chromatid exchanges (SCE). Thiobarbituric acid-reactive substances (TBARS) were determined as indication for the formation of reactive oxygen species. Our results show that pRH are most active in cellular uptake of metal(lloid)s followed by Hep G2 and CHO cells. Also, the highest generation of products of lipid peroxidation was found in pRH compared to Hep G2 and CHO-9. MMA(III) and DMA(III) induced genotoxic effects even more pronounced than i-As(V) or i-As(III). A significant increase in the number of MN, CA and SCE was found in CHO cells for DMA(III), MMA(III), i-As(III) and i-As(V). Altogether, we have shown that arsenic compounds in the trivalent oxidation state are better membrane permeable than the pentavalent species. The release of free radicals caused by organo-arsenicals might contribute to the damage of liver cells. This cell damage is dependent upon the uptake capabilities and the cellular extrusion mechanism.

### GENE EXPRESSION ANALYSIS TO IDENTIFY INTERSPECIES CONCORDANCE OF THE MECHANISMS OF ARSENIC-INDUCED BLADDER CANCER.

B. Sen<sup>1</sup>, R. Grindstaff<sup>1</sup>, Y. Turpaz<sup>2</sup>, J. Retief<sup>2</sup> and D. C. Wolf<sup>1</sup>. <sup>1</sup>Environmental Carcinogenesis Division, USEPA, Research Triangle Park, NC and <sup>2</sup>Affymetrix, Santa Clara, CA.

Arsenic is a human carcinogen that induces urinary bladder cancer. Several mechanisms have been proposed for arsenic-induced cancer. Although inorganic arsenic (iAs) does not induce tumors in adult rodents, dimethylarsinic acid (DMA), a major metabolite of iAs, is a rat bladder carcinogen. DMA causes a dose-dependent increase in toxicity and induces modulation of genes that control apoptosis, cell proliferation, and the response to oxidative stress in transitional epithelium of the rat urinary bladder. For extrapolation of rat data to human, normal human transitional epithelial cells (Urotsa) were exposed to DMA at 2µM, 20µM, 200µM or 8000µM. Total RNA was isolated and microarray analysis was conducted using the Affymetrix Human U133 Plus 2.0 chips. One way ANOVA identified 1728 genes (p<0.05) out of the 36, 967 known genes on the chip. Global expression changes were further characterized using Expression Analysis Systematic Explorer (EASE). In addition to confirming previously described processes, EASE identified additional pathways including phosphorylation, ion transport, protein synthesis and catabolism that were modulated after DMA exposure. Further analysis using Ingenuity Pathway Analysis suggest that altered ERK/MAPK signaling (ERK1/2, CMYC), apoptosis (CASP3, PARP), Wnt-β signaling (WNT, AKT), cell cycle regulation (CYCLIN D, CDKN2A), and PI3K/AKT signaling (FRAP1, HSP90) all play a role in DMA induced cellular toxicity. These pathways are consistent with our previous *in vivo* studies. This study demonstrated that an *in vitro* human cell system predicted the same key pathways involved in DMA-induced toxicity as was identified after *in vivo* exposure in rats. [This abstract does not necessarily reflect EPA policy.]

PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR  $\beta$  (PPAR $\beta$ ) SUPPRESSES ANGIOGENESIS.

**A. D. Burdick**<sup>1</sup>, A. N. Billin<sup>2</sup>, T. M. Willson<sup>2</sup> and **J. M. Peters**<sup>1</sup>. <sup>1</sup>Department of Veterinary Science, Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA and <sup>2</sup>Discovery Research, GlaxoSmithKline, Research Triangle Park, NC.

This laboratory has demonstrated that peroxisome proliferator-activated receptor- $\beta$  (PPAR $\beta$ ) functions to attenuate cell proliferation and skin carcinogenesis as PPAR $\beta$ -null mice exhibit increased epidermal hyperplasia and skin tumor formation compared to wild-type mice. Further, preliminary analysis suggests that the activation of PPAR $\beta$  with GW0742, a specific PPAR $\beta$  ligand, can significantly inhibit skin carcinogenesis and keratinocyte cell proliferation in wild-type mice. An additional carcinogenic process that may be regulated by PPAR $\beta$  is tumor angiogenesis, since preliminary data demonstrates dysregulated angiogenic signaling in the absence of PPAR $\beta$  expression. We hypothesized that PPAR $\beta$ -null mice would display higher levels of angiogenesis due to increased hypoxia-inducible factor-1 (HIF-1) activity leading to increased expression of vascular endothelial growth factor (VEGF). Here we demonstrate with an *ex vivo* angiogenesis assay that PPAR $\beta$ -null mice exhibit increased microvessel formation compared to wild-type mice, indicating that PPAR $\beta$ -null are more sensitive to angiogenic stimuli. The activation of PPAR $\beta$  with GW0742 appears to limit the angiogenic response in wild-type mouse aortic cultures but not in similarly treated aortic cultures from PPAR $\beta$ -null mice. Further, we show that VEGF mRNA is more highly expressed in PPAR $\beta$ -null mice, and the expression of VEGF can be suppressed in wild-type mice upon treatment with GW0742. These data suggest that PPAR $\beta$  may function to suppress tumor angiogenesis through a mechanism that involves HIF-1, and that PPAR $\beta$  may represent a useful molecular target to inhibit tumor angiogenesis. Supported by the National Cancer Institute (CA89607).

IMMUNOHISTOCHEMICAL ANALYSIS OF EXOCRINE PANCREATIC TOXICITY INDUCED BY 2, 3, 7, 8-TETRACHLORODIBENZO-*P*-DIOXIN IN FEMALE HARLAN SPRAGUE-DAWLEY RATS.

**T. Marsh, J. F. Foley, A. Nyska, B. Cai, S. Peddada, N. J. Walker** and K. Yoshizawa. *NIEHS, Research Triangle Park, NC.*

In previous studies of dioxin and dioxin-like compounds conducted for 2 years by the National Toxicology Program using female Harlan Sprague-Dawley rats, a rare occurrence of acinar cell adenomas and carcinomas in the pancreas was noted. Acinar cytoplasmic vacuolation, atrophy, inflammation, and arteritis developed at high incidence. In this investigation, we sought to identify the mechanism involved in the early stages of acinar cell lesions. The pancreas was examined immunohistochemically and/or morphometrically from animals treated for 14 and 31 weeks with 100 ng TCDD/kg or corn oil vehicle. Cytochrome P450 (CYP) 1A1 and aryl hydrocarbon receptor (AhR) were evaluated to assess a direct effect of TCDD on the pancreas. Pancreatic CCK-A receptor (CCKAR) and cholecystokinin 8 (CCK) in the duodenum were evaluated, since CCKAR null mice exhibit increased pancreatic atrophy. Amylase expression was examined to visualize acinar structural changes that could affect enzymatic production. Proliferative activity was measured using PCNA staining. Overexpression of CYP1A1 was found in 31-week-treated animals in vacuolated acinar cells that showed decreases in AhR, CCKAR, and amylase expressions with statistical significance. CCKAR expression was increased significantly in non-vacuolated acinar cells. No significant change in CCK expression was noted in the duodenum. H&E analysis revealed that apoptotic activity in acinar cells was increased in 14- and 31-week-treated animals. An increase in proliferation occurred in acinar cells of the 31-week-treated animals only. Our findings indicate that pancreatic acinar cells are responsive to TCDD and that dioxin-induced acinar cell lesions might be related to a direct effect of TCDD on the pancreas. The decrease in CCKAR expression and the increase in CYP1A1 in vacuolated acinar cells may be involved in the pathogenesis of pancreatic acinar lesions.

## INCREASED MITOCHONDRIAL GLUTATHIONE CONTENT ENHANCES APOPTOSIS IN NRK-52E CELLS INDUCED BY THE DNA ALKYLATING AGENT CISPLATIN.

**L. H. Lash**<sup>1</sup>, F. Xu<sup>1</sup> and L. H. Matherly<sup>2,1</sup>. <sup>1</sup>*Pharmacology, Wayne State University Sch. Med., Detroit, MI* and <sup>2</sup>*Karmanos Cancer Institute, Wayne State University Sch. Med., Detroit, MI.*

Previous work showed that increases in mitochondrial glutathione (GSH) content in NRK-52E cells by stable transfection with the cDNA for either of two GSH transporters from rat kidney mitochondria, the dicarboxylate carrier (DCC) or the 2-oxoglutarate carrier (OGC), protected the cells from apoptosis induced by either an oxidant (tert-butyl hydroperoxide) or a mitochondrial toxicant that is both an

oxidant and an alkylating agent (S-(1, 2-dichlorovinyl)-L-cysteine). To determine whether increases in mitochondrial GSH content can also protect NRK-52E cells from DNA alkylating agents, changes in cellular morphology and apoptosis induced by exposure to cisplatin were assessed in both wild-type NRK-52E cells (NRK-52E-WT) and NRK-52E cells stably transfected with the cDNA for the OGC (NRK-52E-OGC). NRK-52E-WT cells incubated for up to 24 hr with 0, 10, 50, 100, or 200  $\mu$ M cisplatin exhibited time- and concentration-dependent changes in cellular morphology consistent with progressive cell death. Photomicrographs showed progressive vacuolization and detachment of cells from the culture surface, indicating cell injury and death. Analysis of cell cycle by propidium iodide staining and flow cytometry showed time- and concentration-dependent increases in apoptosis, with maximal apoptosis (33-58%) occurring with 50-100  $\mu$ M cisplatin at 24-hr incubation times. Contrary to expectations, NRK-52E-OGC cells exhibited increased sensitivity to cisplatin as compared to wild-type cells, as judged by apoptosis and morphology. The fraction of NRK-52E-OGC cells exposed to cisplatin undergoing apoptosis was markedly increased (>90% in cells incubated for 8 hr with 50  $\mu$ M cisplatin). These results suggest that rather than protect the cells from injury induced by cisplatin, increased levels of mitochondrial GSH either increases delivery of cisplatin to cellular alkylation targets or enhances metabolism of cisplatin to a reactive species that induces cell injury. (Supported by NIH Grant DK40725.)

## CISPLATIN REDUCES VIABILITY, BUT NOT HEAT SHOCK PROTEIN LEVELS IN RAT KIDNEY CELLS.

**J. A. Flaws**<sup>1</sup>, J. K. Babus<sup>1</sup>, M. Lipsky<sup>2</sup> and **B. Fowler**<sup>3</sup>. <sup>1</sup>*Department of Epidemiology, University of Maryland, Baltimore, MD*, <sup>2</sup>*Department of Pathology, University of Maryland, Baltimore, MD* and <sup>3</sup>*Division of Toxicology, ATSDR, Atlanta, GA.*

Kidney toxicity is a major treatment-limiting side effect of a number of anti-cancer agents, including cisplatin. Unfortunately, cisplatin-induced kidney damage is often detected only when patients are in the early stages of renal failure, and intervention is unable to stop the progression to failure. In part, the inability to detect cisplatin-induced kidney damage stems from a lack of biomarkers of early kidney toxicity. Thus, this work tested the hypothesis that changes in the levels of selected heat shock proteins (HSP60 and HSP70) could serve as early indicators of cisplatin-induced kidney toxicity. To test this hypothesis, normal rat kidney (NRK) cells (20,000 cells/well) were cultured in media containing cisplatin ( $10^{-7}$  to  $10^{-3}$  M). After culture, cells were subjected to alamar blue assays to measure viability and they were subjected to western blot analyses for HSP60 and HSP70. The results indicate that cisplatin reduces the viability of NRK cells in a dose-dependent manner. The viability of cells treated with low doses of cisplatin ( $10^{-7}$  to  $10^{-5}$ ) was similar to controls (n = 5). In contrast, the viability of cells treated with high doses of cisplatin ( $5 \times 10^{-5}$  to  $10^{-3}$ ) was significantly reduced compared to controls (viability for  $5 \times 10^{-5}$  =  $68.6 \pm 9.9$ ;  $10^{-4}$  =  $45.6 \pm 4.3$ ;  $5 \times 10^{-4}$  =  $28.4 \pm 4.0$ ; and  $10^{-3}$  =  $1.2 \pm 0.7$  % control; n = 5; p < 0.0001). Despite the ability of cisplatin to reduce cell viability, cisplatin did not affect the levels of HSP60 or HSP70. Western blot analysis indicated that control and cisplatin-treated cells had similar levels of HSP60 (control =  $0.6 \pm 0.1$ ;  $10^{-5}$  =  $0.5 \pm 0.1$ ; and  $5 \times 10^{-5}$  =  $0.5 \pm 0.1$  densitometric units; n = 3; p = 0.8). Collectively, these data indicate that cisplatin reduces the viability of NRK cells in a dose-dependent manner, but it does not affect the levels of selected HSPs. These data suggest that selected HSPs may not be good candidate biomarkers for cisplatin-induced kidney damage. Supported by NIH CA097421.

## TCDD-INDUCED GENE EXPRESSION CHANGES IN DEVELOPING ZEBRAFISH HEARTS.

**S. A. Carney**<sup>1</sup>, C. Burns<sup>2,3</sup>, **R. E. Peterson**<sup>1</sup> and **W. Heideman**<sup>1</sup>. <sup>1</sup>*University of Wisconsin, Madison, WI*, <sup>2</sup>*Massachusetts General Hospital, Charlestown, MA* and <sup>3</sup>*Harvard Medical School, Boston, MA.*

Exposure to 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) causes developmental cardiovascular toxicity in various animal models, including zebrafish embryos, by activating the aryl hydrocarbon receptor (AHR) transcription factor. This results in altered gene expression patterns in tissues that likely mediate toxicity. Exposure of zebrafish embryos to TCDD results in smaller heart size, reduced peripheral blood flow, pericardial edema, abnormal heart morphology, and cardiac dysfunction. To identify changes in gene expression in the hearts of embryos that are direct responses to TCDD exposure microarray analysis was performed on heart tissue extracted from zebrafish embryos exposed to 1 ng/ml TCDD or DMSO at 72 hpf (hours post fertilization) for 1 h. Total RNA was extracted from hearts mechanically removed from treated embryos at 74 hpf (2 h post dosing) and 76 hpf (4 h post dosing) for analysis on Affymetrix zebrafish arrays. The TCDD-induced upregulation of P4501A indicates that the AHR pathway is activated in the heart and

demonstrates that such gene expression changes can be detected as early as 2-4 h post dosing. We also identified altered expression of genes involved in cell cycle regulation, proliferation, differentiation, cell signaling, cell adhesion, and cell communication. These changes are consistent with the effects on cardiac morphology and function observed later than 76 hpf. At 4 h post dosing, TCDD-treated embryos show no signs of reduced peripheral blood flow or pericardial edema indicating that the observed changes in heart gene expression precede these later occurring effects. This suggests that TCDD-induced cardiovascular toxicity, at least in part, is due to TCDD activation of AHR in the heart. Identification of AHR regulated genes in the heart is the first step in elucidating the mechanism of TCDD-induced cardiac toxicity in zebrafish embryos. (UW Sea Grant).

## 1825 CHARACTERIZATION OF TCDD CARDIOTOXICITY IN EMBRYONIC ZEBRAFISH.

D. S. Antkiewicz, R. E. Peterson and W. Heideman. *University of Wisconsin, Madison, WI.*

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) has been shown to act as an aryl hydrocarbon receptor (AHR) agonist, and the activation of the AHR pathway has been demonstrated to mediate the toxic effects of TCDD. In the zebrafish model of developmental toxicity, the following endpoints of dioxin toxicity have been reported: reduction in blood flow, edema, craniofacial malformations, growth retardation, reduced heart rate, anemia, impaired bladder inflation and mortality. In this study we characterize the effects of TCDD on the developing zebrafish heart and assess the role of the AHR pathway in mediating the TCDD cardiotoxicity using the morpholino knockdown technology. Zebrafish embryos exposed to TCDD shortly after fertilization exhibit altered cardiac looping at 72 hours post fertilization (hpf), with the atrium positioned posterior to the ventricle in a stretched, thinned heart tube. In contrast, the looped control heart is S-shaped, with the two chambers largely overlapping, when observed laterally. In addition, the TCDD-treated hearts become smaller, as their total tissue volume assessed using stereological software on serial heart sections is significantly reduced at 72 and 96 hpf in comparison to control. To further investigate this effect, a strain of transgenic zebrafish, which expresses red fluorescent protein specifically in the nuclei of cardiac myocytes has been used to count individual myocytes in control and treated hearts. The TCDD-exposed hearts contain a significantly lower number of cardiomyocytes at all inspected time points: 48, 72 and 96 hpf. The detection of this toxic effect on myocardium at 48 hpf indicates that the heart, and specifically the myocardium can be one of the earliest targets of TCDD toxicity in zebrafish. In addition to the effects on heart morphology and size, we found that dioxin had a striking effect on heart function, affecting cardiac contractility. Specifically, it leads to a complete lack of ventricular contraction observable as early as 96 hpf. The described cardiotoxic effects of TCDD were found to be mediated by the AHR pathway. (UW Sea Grant).

## 1826 STUDIES TO IDENTIFY GENE CHANGES IN THE HEART DURING RECOVERY FROM HEART TOXICITY INDUCED BY BIS(2-CHLOROETHOXY)METHANE.

J. Dunnick<sup>1</sup>, J. Parker<sup>2</sup>, P. Blackshear<sup>3</sup> and A. Nyska<sup>1</sup>. <sup>1</sup>*Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC*, <sup>2</sup>*Constella Group, Inc., Research Triangle Park, NC* and <sup>3</sup>*Integrated Laboratory System, Inc., Research Triangle Park, NC.*

Cardiotoxicity is induced in F344/N rats after dermal administration of bis(2-chloroethoxy)methane (BCEM) ((Dunnick et al. 2004a; Dunnick et al. 2004b)). BCEM heart damage occurs by day 2 in all three regions of the heart (atrium, ventricle, interventricular septum) and is characterized by myofiber vacuolation, necrosis, mononuclear-cell infiltration, and atrial thrombosis. Ultrastructural analysis reveals that the primary site of damage occurs in the mitochondrion. Damaged mitochondria have disrupted cristae and loss of membrane structure. Ultrastructural analysis also reveals distention of the myocardial sarcoplasmic reticulum. By day 5, even though dosing is continued, the heart toxic lesions began to resolve, and by study-day 16 the heart appeared normal. Microarray gene analysis was used to test the hypothesis that genes changes at onset of toxicity (day 2) would differ from genes changes during recovery (day 5). RNA was extracted from the whole male rat hearts at day 2 and day 5, and analyzed using Agilent rat oligonucleotide microarray. The significant gene changes (vs. control) at day 2 included: 240 up regulated genes; 101 down regulated genes. The significant gene changes at day 5 included: 113 up regulated genes; 102 down regulated genes. Gene changes at day 2 were different from those at day 5, with the exception of 27 down regulated genes that were common on day 2 and 5. We hypothesize that specific gene changes enable the heart to recover from chemical-induced toxicity.

## 1827

### INCREASED GENE EXPRESSION AND LEVELS OF ANTIOXIDANTS AND PHASE 2 ENZYMES IN CARDIAC CELLS TREATED WITH 3H-1, 2-DITHIOLE-3-THIONE: PROTECTION AGAINST OXIDANT AND ELECTROPHILE-INDUCED CELL INJURY.

Z. Cao<sup>1,2</sup>, H. Zhu<sup>1</sup>, D. Hardej<sup>1</sup>, L. D. Trombetta<sup>1</sup> and Y. Li<sup>1</sup>. <sup>1</sup>*Pharmaceutical Sciences, St. John's University, Jamaica, NY* and <sup>2</sup>*Harvard Medical School, Boston, MA.*

Oxidative and electrophilic species are critically involved in various cardiac disorders. Accordingly, administration of exogenous antioxidants has been shown to be protective against oxidative cardiac injury. However, whether induction of endogenous antioxidative and phase 2 defenses by chemical inducers in cardiomyocytes also affords protection against oxidative and electrophilic injury has not been carefully investigated. Using cultured rat cardiomyocytes, we have studied the induction of the above cellular defenses by 3H-1, 2-dithiole-3-thione (D3T), and the protective effects of the D3T-upregulated cellular defenses on oxidant and electrophile-induced cell injury. Incubation of cardiomyocytes with D3T resulted in a marked induction of a scope of key cellular antioxidants and phase 2 enzymes. These included catalase, glutathione (GSH), GSH peroxidase, GSSG reductase, GSH S-transferase, NAD(P)H:quinone oxidoreductase-1, aldoe reductase, and heme oxygenase-1. D3T treatment also resulted in increased mRNA expression of the above antioxidative and phase 2 genes. Notably, all of the three major isoforms of GST genes (A1, P1 and M1) in cardiomyocytes were upregulated by D3T. D3T pretreatment of cardiomyocytes led to a marked protection against the toxicity induced by H<sub>2</sub>O<sub>2</sub>, xanthine oxidase (XO)/xanthine, and 4-hydroxyxynonenal (HNE), as determined by MTT reduction assay and electron microscopic studies. D3T pretreatment also caused a great reduction in intracellular accumulation of ROS, and HNE-protein adduct formation in cardiomyocytes following incubation with H<sub>2</sub>O<sub>2</sub>, XO/xanthine, and HNE, respectively. Taken together, this study demonstrates that a battery of endogenous antioxidants and phase 2 proteins in cardiomyocytes can be upregulated by D3T via increased gene expression, and that the chemically-upregulated cellular defenses are accompanied by increased resistance to oxidative and electrophilic cell injury (supported by HL71190).

Vascular toxicity observed in pre-clinical toxicology species presents a hurdle for drug development. Assessing clinical relevance of these findings has been hampered by a limited understanding of the molecular and biochemical mechanisms leading to development of drug-induced vascular injury. To investigate early events in the pathogenesis of drug-induced vascular injury, Fenoldopam, a vasoactive DA1 agonist, was given to rats at a dose known to induce mesenteric arterial damage 12 hours following treatment. GeneChip expression analysis of selectively enriched regions of mesenteric arteries [endothelium (E) or smooth muscle (SM)], isolated from OCT-embedded frozen sections of mesentery using laser capture microdissection, were used to evaluate differential gene expression in vehicle control rats and rats killed 1 hour after being given 100mg/kg Fenoldopam. Comparative analysis of E or SM enriched samples between control and treated rats revealed a number of regulated transcripts. Real-Time RT-PCR and/or in situ hybridization and immunohistochemistry were used to confirm select subsets of these transcripts. Bioinformatic analysis identified multiple signaling pathways involved in vasoregulation (dilation/resistance), hemorrhage, extracellular matrix remodeling, cell adhesion, cell growth, metabolism, stress response and inflammation/ immunoregulation. Alterations in gene expression patterns of transcripts in these pathways has provided useful insight into the potential pathogenic mechanism involved in the early evolution of morphologic lesions that eventually lead to intramural hemorrhage and medial damage seen in the mesenteric vasculature 12 hours following administration of Fenoldopam.

## 1829

### GENOMIC ANALYSIS OF THE MECHANISM OF CYCLOPHOSPHAMIDE-INDUCED CARDIOTOXICITY IN RATS: COMPARISON WITH HUMAN CASES OF MYOCARDITIS.

K. K. Daniels, M. S. Orr and W. B. Mattes. *Toxicogenomics, Gene Logic Inc., Gaithersburg, MD.*

Myocarditis, defined as an inflammation of the heart muscle, is caused by various infections, but may also result from exposure to chemotherapeutics like cyclophosphamide. Clinical prediction of myocarditis is difficult and detection can occur too

late to prevent the development of cardiomyopathy. Therefore, an understanding of the mechanism of cardiotoxicity of agents such as cyclophosphamide would provide a basis upon which to drive development of enhanced detection with the ultimate goal of prophylaxis. The present study assessed alterations in gene expression using Affymetrix RG\_U34A GeneChip® arrays in the left ventricle of rats following treatment with cyclophosphamide and compared them with those findings observed in the left ventricle of histopathologically-confirmed cases of human myocarditis samples from Gene Logic's BioExpress® database using Affymetrix HG\_U133A GeneChip® arrays. Rats were dosed once via IP injection with either 20mg/kg or 200mg/kg cyclophosphamide and sacrificed 6, 24, 48 or 192 hours post-dosing. Induction in the expression of complement pathway components, cytokines and apoptosis-associated genes occurred in both rat (200mg/kg dose, 192 hours-post-treatment) and human samples. A significant difference between the rat study and human samples was noted, however, in that the rat cyclophosphamide study exhibited significant induction in the expression of antioxidant defense genes at the 200mg/kg dose, 192 hour- timepoint, while there was a significant repression in the human myocarditis samples in genes such as heme oxygenase and glutaredoxin 2. This suggests a reduction or reduced protective capacity of this mechanism in the human condition but not in the rat. In conclusion, these results provide preliminary mechanistic data of the initiation of inflammatory and apoptotic events in rats following cyclophosphamide treatment and in human myocarditis samples with noted differences in the regulation of antioxidant responsive genes.

A RAT HEART GENE-EXPRESSION SIGNATURE PREDICTIVE OF HERG POTASSIUM CHANNEL BINDING.

X. Xu, R. J. Brennan, G. Napolitano and K. Kolaja. *Chemogenomics and Toxicology, Iconix Pharmaceuticals Inc., Mountain View, CA.*

Life-threatening *torsade de pointes* arrhythmias, linked to HERG (human ether-a-go-go-related gene) potassium channel inhibition, have resulted in the withdrawal of several drugs, including terfenadine, astemizole, and cisapride, from the US market in recent years. Cardiac safety related to  $I_{Kr}$   $K^+$  channels is a major concern for pharmaceutical companies as regulatory agencies have a heightened awareness of cardiac safety pharmacology for new molecular entities. Early identification of off-target HERG channel inhibitory effects has therefore become a high priority in drug development programs. We used a commercially available *in vitro* HERG channel binding assay (MDS Pharmacology), which measures competitive binding affinity relative to the radioligand [ $^3$ H]-astemizole, to classify 167 compounds by their potency into low and high-potential HERG channel inhibitors. Based on their affinity for HERG binding in the *in vitro* assay, the compounds were subsequently segregated into positive and negative classes to form a training set for use in a robust and sparse support vector machine (SVM) algorithm. High-affinity HERG channel binding compounds ( $IC_{50} < 0.5 \mu M$ ) were used as the positive class for the training set and low affinity binding (% inhibition at  $10 \mu M < 10$ ) as the negative class. The SVM generates a Drug Signature™ predictive of HERG channel binding using gene expression in left ventricles isolated from male Sprague-Dawley rats treated for up to 5 days with compounds at a maximum tolerated dose. Based on 60:40 split-sample cross validation on the training set, the signature performance was estimated to have a true positive rate of 76% and true negative rate of 98%. The use of biomarkers predictive of cardiac pathological endpoints from short-term exposure animal models will help to reduce time and cost and improve the success rate of drug development.

AHR AND ARNT SPECIFICALLY BIND PUTATIVE DIOXIN RESPONSE ELEMENTS (DREs) UPSTREAM OF BETA-ADRENERGIC RECEPTOR GENES.

J. M. Ciak and R. J. Sommer. *Biology Department, Bates College, Lewiston, ME.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD) causes cardiovascular toxicity in laboratory animals, including decreased ventricular contractility, decreased myocyte proliferation, increased cardiac apoptosis and inhibition of coronary vasculogenesis. Beta-adrenergic receptor ( $\beta$ -AR) signaling plays an important role in each of these processes. We hypothesize that TCDD exposure directly increases  $\beta_1$ -AR gene expression followed by a maladaptive decrease in  $\beta$ -AR signaling. We have detected a 30% increase in cardiac  $\beta_1$ -AR mRNA in embryonic day 10 (D10) chicks exposed to 0.3 pmol TCDD/g egg prior to incubation (D0) and have observed a reduction in the ability of TCDD-exposed embryonic chicks to increase heart rate in response to isoproterenol, a  $\beta$ -AR agonist. TCDD exposure, however, does not decrease the ability of the chick heart to respond to pharmacological agents effecting downstream events of the  $\beta$ -AR. This suggests that TCDD is mediating its effects at the level of the receptor. The existence of 5, 3 and 2 putative dioxin response elements (DREs) in the 5' enhancer region of the human, rat and mouse  $\beta_1$ -AR genes, respectively, raises the possibility that transcription of the  $\beta_1$ -AR gene is directly regulated by the aryl hydrocarbon receptor (AhR) and its dimerization partner the

AhR nuclear translocator (ARNT). In support of this hypothesis, we detect specific binding of  $\beta_1$ -AR DREs to AhR and ARNT in HeLa cell and cardiac tissue extracts by electrophoretic mobility shift analysis (EMSA). However, this binding is not dependent on the presence of AhR ligand. Current EMSA studies in our laboratory are determining the ability of *in vitro* expressed human and mouse AhR and ARNT to bind  $\beta_1$ -AR DREs in the presence and absence of exogenously applied AhR ligand. Transient transfection experiments using a luciferase reporter gene under the control of  $\beta_1$ -AR promoter will determine whether DRE binding is sufficient to transactivate gene expression, indicating the functionality of  $\beta_1$ -AR DREs. Supported by NIH R15 ES011806.

GLUTATHIONE-S-TRANSFERASE A4-4 MODULATES iNOS EXPRESSION THROUGH NF- $\kappa$ B TRANSLOCATION.

Y. Yang<sup>1</sup>, Y. Yang<sup>2</sup>, Y.C. Awasthi<sup>2</sup> and P.J. Boor<sup>1</sup>. <sup>1</sup>*Pathology, UTMB, Galveston, TX* and <sup>2</sup>*Human Biological Chemistry and Genetics, University of Texas Medical Branch, Galveston, TX.*

4-Hydroxy-2-nonenal (4-HNE) is known to induce cell apoptosis through activation of c-Jun N-terminal kinases and the caspase cascade pathway. Our recent work in endothelium showed that overexpression of glutathione S-transferases (GSTs) in endothelium protects against oxidative damage from aldehydes such as 4-HNE. But the role of GSTs for NF- $\kappa$ B activation and related inducible nitric oxide synthesis (iNOS) remain unknown. In this study, we tested the effect of 4-HNE on iNOS expression and the NF- $\kappa$ B pathway to further elucidate the protective effect of GSTs. A stable transfection of mouse pancreatic islet endothelial cells (MS1) with cDNA of mGSTA4-4, an  $\alpha$ -class GST with highest activity toward 4-HNE, was established. Transfected cells demonstrated significantly higher GSTs enzyme activity and expressed significantly increased resistance to the cytotoxicity of 4-hydroxy-2-nonenal (4-HNE) ( $p < 0.05$ ). mGSTA4-transfected cells showed significant upregulation of iNOS in comparison with vector-transfected cells when treated with 4-HNE. The inhibition of I $\kappa$ B kinase (IKK) by 4-HNE was reversed by mGSTA4 transfection. These studies indicate an important role for GSTs in phosphorylation of I $\kappa$ B $\alpha$  causing the translocation of NF- $\kappa$ B into nucleus. Over expression of mGSTA4-4 in endothelial cells may play a key role in modulating blood vessel tone by upregulation of iNOS, NF- $\kappa$ B. Thus, GSTA4-4 is likely to be an important defensive mechanism against oxidants that act as atherogens. (Supported by NIH grant HL65416.)

CHEMICAL INDUCTION OF ANTIOXIDATIVE AND PHASE 2 DEFENSES IN CARDIOVASCULAR TISSUES *IN VIVO*: INVOLVEMENT OF NRF2 SIGNALING AND IMPLICATIONS FOR CARDIOVASCULAR PROTECTION.

Y. Li<sup>1</sup>, Z. Cao<sup>1</sup>, H. Zhu<sup>1</sup>, E. Hussey<sup>1</sup>, H. Scaramell<sup>1</sup>, K. Itoh<sup>2</sup>, M. Yamamoto<sup>2</sup>, J. M. Cerreta<sup>1</sup> and L. D. Trombetta<sup>1</sup>. <sup>1</sup>*St. John's University, Jamaica, NY* and <sup>2</sup>*University of Tsukuba, Tsukuba, Japan.*

Accumulating evidence supports a causal role for oxidative and electrophilic stress in cardiovascular diseases. In this context, chemical induction of endogenous antioxidative and phase 2 defenses in cardiovascular tissues may represent a novel strategy for protecting against oxidative cardiovascular injury. However, our understanding of the chemical inducibility of antioxidative and phase 2 enzymes, and the underlying signaling mechanisms in cardiovascular tissues *in vivo* is limited. This study was undertaken to investigate the inducibility of cardiovascular antioxidants and phase 2 enzymes by 3H-1, 2-dithiole-3-thione (D3T), and the signaling role of Nrf2 in the regulation of the above cellular defenses in animals. A number of endogenous antioxidants and phase 2 proteins were induced in both cardiac tissue and vasculature in mice and rats after oral administration of D3T. These include superoxide dismutase, catalase, glutathione, glutathione reductase, glutathione S-transferase, and/or NAD(P)H:quinone oxidoreductase-1. The basal expression and chemical inducibility of the above cellular defenses varied between myocardium and vasculature. Nrf2-knock out mice were used to explore the signaling pathways involved in the regulation of the above cardiovascular enzymes. We observed that both the constitutive expression and the chemical inducibility of the cardiovascular antioxidants and phase 2 enzymes were reduced in Nrf2-null mice as compared with those in Nrf2(+/-) mice, indicating a critical role for Nrf2 signaling in the regulation of cardiovascular antioxidant and phase 2 gene expression *in vivo*. Studies are currently under way to determine the protective role of endogenous antioxidants and phase 2 enzymes in animal models of oxidative cardiovascular disorders, including doxorubicin-induced cardiomyopathy and myocardial ischemia-reperfusion injury (supported by HL71190).

UPREGULATION OF ENDOGENOUS ANTIOXIDANTS AND PHASE 2 PROTEINS BY RESVERATROL IN CULTURED AORTIC SMOOTH MUSCLE CELLS LEADS TO CYTOPROTECTION AGAINST OXIDATIVE AND ELECTROPHILIC STRESS.

H. Zhu, Z. Cao and Y. Li. *Pharmaceutical Sciences, St. John's University, Jamaica, NY*.

Resveratrol is known to be protective against oxidative cardiovascular disorders. However, the underlying mechanisms remain unclear. This study was undertaken to determine if resveratrol could upregulate endogenous antioxidants and phase 2 enzymes in cultured aortic smooth muscle cells (ASMCs), and if such increased cellular defenses could provide protection against oxidative and electrophilic vascular cell injury. Incubation of rat ASMCs with resveratrol at low micromolar concentrations resulted in a significant induction of a scope of cellular antioxidants and phase 2 proteins in a concentration- and time-dependent fashion. These cellular defenses include superoxide dismutase, catalase, glutathione (GSH), glutathione reductase, GSH S-transferase (GST), NAD(P)H:quinone oxidoreductase-1 (NOQ1), and heme oxygenase-1 (HO1). Notably, induction of catalase, GST, NOQ1, and HO-1 was most remarkable among the above resveratrol-inducible antioxidants and phase 2 enzymes. Moreover, resveratrol treatment also dramatically increased the mRNA expression of the above cellular antioxidative and phase 2 genes. Pretreatment of ASMCs with resveratrol afforded a significant protection against xanthine oxidase (XO)/xanthine- or 4-hydroxy-2-nonenal-induced cytotoxicity, as assessed by MTT reduction assay and morphological changes. Resveratrol pretreatment also led to a marked reduction in intracellular accumulation of ROS in ASMCs after incubation with XO/xanthine. Taken together, this study demonstrates for the first time that a scope of endogenous antioxidants and phase 2 enzymes in cultured ASMCs can be potently induced by resveratrol at low micromolar concentrations, and that such elevated cellular defenses are accompanied by a markedly increased resistance to oxidant- or electrophile-mediated vascular cell injury. The results of this study have revealed a new mechanism, which may contribute to the cardiovascular protective effects of resveratrol (supported by HL71190).

DEXRAZOXAN INHIBITS ALTERATIONS IN GLYCOLYTIC AND OXIDATIVE CARDIAC METABOLISM INDUCED BY DOXORUBICIN.

R. A. Carvalho<sup>1</sup>, R. B. Sousa<sup>1</sup>, C. M. Palmeira<sup>1</sup> and K. B. Wallace<sup>2</sup>. <sup>1</sup>*Biochemistry, University of Coimbra, Coimbra, Portugal* and <sup>2</sup>*Biochemistry & Molecular Biology, University of Minnesota School of Medicine, Duluth, MN*.

Doxorubicin (DOX) is widely prescribed for the treatment of assorted cancers. However, its success is limited by the development of a cumulative and irreversible mitochondrial cardiomyopathy. The mechanism is believed to involve generation of reactive oxygen species (ROS) leading to oxidative tissue injury which in some cases can be avoided by co-administering selected antioxidant agents, the most promising of which is dextrazoxan. In this investigation, we explored the cardioprotective potential of dextrazoxan by monitoring its effects on metabolic flux through glycolytic and oxidative pathways using <sup>13</sup>C NMR isotopomer analysis. Rats were treated with 6 weekly injections of either: I) saline (control group); II) DOX (2 mg/Kg, s.c.); iii) dextrazoxan (DEX) (25 mg/Kg, i.p.); or iv) DOX + DEX. Hearts were subsequently excised and perfused by the Langendorff method with Krebs-Hensleit bicarbonate buffer supplemented with 5.5 mM glucose, 1.2 mM [3-<sup>13</sup>C]lactate, 0.09 mM [3-<sup>13</sup>C]pyruvate, 0.12 mM [1, 3-<sup>13</sup>C]acetooacetate, 0.05 mM [1, 3-<sup>13</sup>C]13<sup>13</sup>C long-chain fatty-acids. <sup>1</sup>H NMR spectra of lactate in the perfusate provides an estimate of glycolytic flux. DOX caused a 40% increase in glycolytic flux, which was prevented by co-administering DEX, which by itself had no effect on glycolytic rates relative to controls. A <sup>13</sup>C NMR isotopomer analysis of glutamate revealed that DOX treatment caused a 30% reduction in long-chain fatty-acid oxidation and a concomitant increase in glucose oxidation. Long-chain fatty acid oxidation capacity was restored by DEX co-administration. In summary, long-term treatment with DOX alters the metabolic status of cardiac tissue in favor of glycolysis over fatty acid oxidation. Reversal by DEX implies an important role for ROS in modulating this shift in metabolic regulation caused by DOX. (Supported by NIH HL58016 and POCTI/CBO/38611/01).

**1836**

METALLOTHIONEIN PROTECTION FROM PROTEIN NITRATION CAUSED BY LPS/TNF-ALPHA-DERIVED INTRACELLULAR PEROXYNITRITE.

J. Wang, Y. Kang and L. Cai. *Medicine, University of Louisville, Louisville, KY*.

Our previous study showed that metallothionein (MT) prevented the damage of protein and DNA caused by peroxynitrite in an *in vitro* cell-free system. In STZ-induced diabetic mouse hearts, protein nitration, shown by 3-nitrotyrosine (3-NT), significantly increased as compared to control, which was significantly inhibited in MT transgenic (MT-TG) mouse. In order to test whether MT can also prevent protein nitration caused by intracellular peroxynitrite, a primary culture of neonatal mouse cardiomyocytes was exposed to LPS (100 $\mu$ g/ml) and TNF- $\alpha$  (50 $\mu$ g/ml). 3-NT significantly increased along with a significant increase in cell death in wild-type (WT) cardiomyocytes, detected by lactate dehydrogenase (LDH) release.

However, both 3-NT and LDH release were significantly prevented in LPS/TNF- $\alpha$ -treated MT-TG cardiomyocytes. Furthermore, the 3-NT and LDH release were also prevented by incubation of superoxide mimic (MnTTPyP) or peroxynitrite scavenger (urate) for 24 hours in the LPS/TNF- $\alpha$ -treated WT cardiomyocytes. These results indicate that MT can intracellularly prevent peroxynitrite-caused protein nitration, as it did *in vitro* cell-free system, and protein nitration caused by peroxynitrite is a direct cause of the cytotoxicity. (supported, in part, by ADA, Philip Morris USA Inc. and NIH)

THE ROLE OF ENDOTHELIN-1 AND REACTIVE OXYGEN SPECIES IN CARDIAC HYPERTROPHY OBSERVED IN ARYL HYDROCARBON (AHR) NULL MICE.

A. K. Lund<sup>1</sup> and M. K. Walker<sup>1,2</sup>. <sup>1</sup>*College of Pharmacy, University of New Mexico, Albuquerque, NM* and <sup>2</sup>*Department of Cell Biology and Physiology, University of New Mexico, Albuquerque, NM*.

AhR is a ligand-activated transcription factor that mediates the toxicity of environmental pollutants, however the regulation and function of AhR are still largely unknown. Functional inactivation of AhR (AhR null mice) results in profound effects on the cardiovascular system. Previously, we reported AhR null mice exhibit cardiac hypertrophy associated with increased plasma endothelin-1 (ET-1) levels. Increases in both heart-to-body weight (HW/BW) ratios and ET-1 (plasma and tissue) were found to be age-progressive. Therefore, we tested the hypothesis that the observed hypertrophy results from an increase in ET-1 expression and downstream pathways regulated through the ETA receptor. Furthermore, we investigated whether reactive oxygen species (ROS) were associated with cardiac hypertrophy observed in AhR null mice. To determine if the age-progressive increase in ET-1 was associated with cardiac effects, we measured mRNA expression of -myosin heavy chain (MHC) and atrial natriuretic factor (ANF). Results revealed the hypertrophy marker genes are significantly increased in 2 mo AhR null mice (5.4- and 3.9-fold, respectively), compared to C57Bl6, with further elevations seen at age 5 mo. To examine the role of ET-1 in cardiac hypertrophy, 2 mo AhR null and C57Bl6 mice were treated with ETA receptor antagonist BQ-123, delivered via osmotic minipumps (60 days). BQ-123-treated AhR null mice showed reduced HW/BW ratios, compared to untreated AhR null mice (treated: 0.492; untreated: 0.552; C57Bl6 controls: 0.478 grams) and decreased LV posterior wall thickness. BQ-123 treatment also resulted in a significant decrease in expression of cardiac hypertrophy marker genes -MHC and ANF, and also cardiac fibrosis in AhR null mice. Furthermore, TBARS analysis showed decreased levels of cardiac ROS in BQ-123- treated AhR null mice. Such findings indicate that cardiac hypertrophy in AhR null mice is mediated by ET-1 and ROS. Supported by ES10433 and ES12072 to MKW, USEPA U91621501 to AKL.

PCB-INDUCED INFLAMMATORY RESPONSE IN CAVEOLIN-1 DEFICIENT MICE.

Z. Majkova, E. Smart, A. Daugherty, M. Toborek and B. Hennig. *University of Kentucky, Lexington, KY*.

Caveolae are membrane microdomains enriched in cholesterol, sphingomyelin and numerous proteins involved in cellular signaling. They are especially abundant in endothelial cells, and the presence of caveolin-1 protein, a marker and major functional component of caveolae, has been shown to be a protective factor in the development of atherosclerosis. Polychlorinated biphenyls (PCBs) are persistent lipophilic environmental contaminants, that can contribute to the development of atherosclerosis by inducing inflammatory reactions and subsequent endothelial cell dysfunction. We evaluated the potential role of caveolae in preventing PCB-mediated pro-atherogenic events. Caveolin-1 (Cav-1) deficient mice were treated with PCB 77 (ip injection, 170  $\mu$ M/kg) for 24 hours. Total plasma cholesterol was higher in Cav-1-/- mice compared to wild type animals. PCB treatment significantly decreased plasma cholesterol in Cav-1 deficient mice. The expression of selected genes was quantified by real time PCR. With or without PCB treatment, aortas of Cav-1-/- mice had lower mRNA levels of vascular adhesion molecule-1 (VCAM-1), compared with wild type mice. On the other hand, gene expression of CYP 1A1 in liver was comparable in both Cav-1 deficient and wild type mice upon PCB 77 treatment. Peroxisome proliferator activated receptor  $\gamma$  (PPAR- $\gamma$ ) is partially located in caveolae and has been reported to modulate caveolin-1 protein expression. Pretreatment with the PPAR- $\gamma$  agonist thiazolidinedione (25  $\mu$ M) for 6 hours resulted in protection of endothelial cells against PCB 77 (3.4  $\mu$ M) toxicity, in terms of decreased DNA-binding activity of both NF- $\kappa$ B and STAT-3. Our data provide evidence that the endothelial inflammatory response induced by coplanar PCBs may be mediated in part through signaling pathways associated with caveolin-1. PREVENTION OF DIABETES-ENHANCED LPS CARDIOTOXICITY IN CARDIAC-SPECIFIC METALLOTHIONEIN-OVEREXPRESSING TRANSGENIC MICE.

L. Cai and Y. Kang, *Medicine, Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

Previous studies have shown that diabetes significantly enhances LPS-induced cardio-toxicity along with a significant increase in inflammatory cytokines and oxidative damage. Metallothionein (MT) functions as a potent antioxidant in the heart to protect against oxidative injury induced by various stresses including diabetes. In the present study, we examined whether MT can prevent diabetes-sensitized LPS cardiotoxicity using a cardiac-specific MT-overexpressing (MT-TG) mouse model. Type 1 diabetes was induced by streptozotocin (STZ) in the MT-TG and the wild-type (WT) control mice. Two months after STZ treatment, diabetic mice and non-diabetic mice were administrated with a single dose of LPS (2mg/kg) and sacrificed 1, 4.5 and 24 h after the treatment for examination of cardiac toxicity using serum markers creatinine kinase (CPK) and troponin T along with measurements of serum and cardiac pro- or anti-inflammation cytokines including tumor necrosis factor-alpha (TNF- $\alpha$ ), IL-6 and IL-10, by an ELISA method. Results showed that in the WT mice, diabetes significantly enhanced LPS-induced cardiotoxicity, as shown by significant increases in serum CPK and troponin T, and also enhanced the serum and cardiac IL-6 production. However, the diabetes-sensitized LPS cardiotoxicity was significantly prevented in the MT-TG diabetic mice although the IL-6 remained up-regulated in the MT-TG diabetic mice. These results suggest that the enhanced LPS cardiotoxicity in the WT diabetic mice may be associated with the oxidative damage derived from the enhanced production of IL-6 and MT prevents oxidative damage leading to the prevention of cardiac toxicity without affecting IL-6 production. (Supported in part by grants from ADA, Philip Morris USA, Inc. and NIH)

GENETIC BACKGROUND-DEPENDANT VARIATION IN EGFR-RELATED CARDIAC DYSFUNCTION.

D. J. Barrick<sup>1</sup>, M. La Merrill<sup>1</sup>, M. Rojas<sup>3</sup>, S. Smyth<sup>3</sup> and D. W. Threadgill<sup>2,1</sup>.

<sup>1</sup>*Curriculum in Toxicology, UNC-CH, Chapel Hill, NC*, <sup>2</sup>*Genetics, UNC-CH, Chapel Hill, NC* and <sup>3</sup>*Carolina Cardiovascular Biology Center, UNC-CH, Chapel Hill, NC*.

The epidermal growth factor receptor (EGFR/ErbB) family regulates diverse cellular functions such as growth, differentiation, cell motility and survival. Overexpression and/or aberrant signaling by ERBB receptors, especially EGFR and ERBB2, occurs frequently in human cancer, thus targeted therapies have been developed to inhibit ERBB signaling. Clinical trials have revealed major similarities between patient toxicity and phenotypes in mice with reduced ERBB receptor function. Some patients receiving the anti-ERBB2 drug Herceptin/Tarceva develop life-threatening dilated cardiomyopathies; this cardiotoxicity is recapitulated in mice with cardiac-specific ERBB2 ablation. As over-expression of the closely related EGFR occurs in 30 % of human primary tumors, EGFR inhibitors are being tested in ongoing clinical trials. To date there have been no reports of cardiotoxicity, but recent pre-clinical data suggests a subset of patients may also experience cardiotoxicity. Recently, aortic valve hyperplasia and stenosis was described in mice homozygous for the Egfr wa2 hypomorphic mutation. We have detected additional heart defects arising from reduced EGFR activity that vary with genetic background. Histological examination of the hearts of adult C57Bl/6J(B6) Egfr wa2/wa2 mice reveals severely enlarged, fibrotic hearts with hypertrophied cardiomyocytes. Echocardiography describes a dilated left ventricular chamber, impaired systolic function and thickened chamber walls. In addition, hearts of B6 Egfr wa2/wa2 mice show significant expression changes in classic markers for cardiac hypertrophy. By contrast, inbred 129S1 and hybrid B6.129 Egfr wa2/wa2 mice display none of these defects, despite having enlarged aortic valves. Moreover, wild-type B6 mice chronically exposed to the EGFR inhibitor EKB-569 have altered cardiac function and enlarged cardiomyocytes. These results imply that a subset of patients on anti-EGFR therapy may be at risk for cardiotoxicity. Identification of 129S1 modifiers may reveal new targets for the treatment of cardiac hypertrophy.

EFFECTS OF ARSENIC ON ENDOTHELIAL CELL ACTIVATION AND ACETYLATED-LDL UPTAKE BY MACROPHAGES.

E. E. Pereira, M. Bunderson, J. C. Schneider, M. C. Schneider, D. D. Coffin and H. D. Beall. *Center for Environmental Health Sciences, University of Montana, Missoula, MT.*

Cardiovascular disease (CVD) is an important cause of morbidity and mortality in the developed world. Arsenic is widely dispersed in the environment, and epidemiological studies have linked chronic arsenic exposure to a range of CVDs including

atherosclerosis, ischemic heart disease, peripheral vascular disease and hypertension. Atherosclerosis is an inflammatory disease, characterized by release of cytokines and chemokines and activation of endothelial cells. We used a combination of ELISA, flow cytometry and Western blot analysis to study endothelial cell activation in human aortic endothelial cells (HAECS). Our results showed that arsenic decreased expression of VE-cadherin, a protein that is responsible for maintaining tight junctions between the endothelial cells. This could lead to increased permeability of the endothelial barrier. We also found that arsenic modulated the expression of vascular cell adhesion molecule (VCAM-1) and interleukin-6 (IL-6) at concentrations as low as 1 uM at various time points up to 48 h. These events could lead to an increase in transmigration of monocytes across the endothelium. The monocytes are differentiated into macrophages within the intima of the blood vessel and play a key role in formation of foam cells. Using flow cytometry, we assessed the effects of arsenic exposure on uptake of acetylated LDL (Ac-LDL) by macrophages. Differentiated THP-1 cells were treated with arsenic-conditioned medium from HAECS and mouse macrophage cells (RAW264.7) were treated with serum from atherosclerotic apoE-/-LDLR-/- mice that had been exposed to arsenic in drinking water for 18 weeks. Arsenic treatment led to increased Ac-LDL uptake in both cases suggesting that endothelial activation by arsenic could facilitate foam cell formation. (Supported by NIH grant P20 RR17670).

EXAMINATION OF THE VASCULAR INJURY IN SPRAGUE-DAWLEY (SD) RATS INDUCED BY THE PHOSPHODIESTERASE (PDE) IV INHIBITOR SCH 534385: A COMPARISON WITH SCH 351591.

Our previous study showed that the PDE IV inhibitor SCH 351591 induced vascular injury in SD rats and suggested that a panel of serum proteins could potentially serve as biomarkers for detecting and monitoring vascular lesions (Toxicologist 78: 375, 2004). The present study was begun to determine whether the structurally distinct PDE IV inhibitor SCH 534385 would induce similar vascular injury and, if so, whether these same biomarkers would again be observed. SD rats were given SCH 534385 (20 or 40 mg/kg/day for 3 days) by gavage. Microscopic evaluation of tissues obtained 24 h after the final dose revealed dose-dependent vascular injury. Arterial hemorrhage and necrosis, periarterial inflammation, and microvascular injury (fibrin insudation and fibrin exudation) were found in the mesentery, pancreas, kidney, liver and small intestine. Activation of immune system cells (endothelial cells, mast cells, and macrophages) and proliferation of fibroblasts were also noted at sites of inflammation. Lymphocyte numbers were markedly decreased in splenic and thymic cortex. In peripheral blood, granulocytes were elevated and lymphocytes decreased. SCH 534385 induced increases in the serum proteins alpha-1-acid glycoprotein, haptoglobin, GRO/CINC-1 (homolog of human interleukin-8), vascular endothelial growth factor, and tissue inhibitor of metalloproteinase-1. No significant changes were found in C-reactive protein. The pathological changes in the splanchnic vasculature, elevations in serum proteins, and alterations in leukocyte numbers in rats treated with this compound were similar to those seen in rats given SCH 351591. The data show that two structurally different PDE IV inhibitors, SCH 351591 and SCH 534385, induced similar vascular injury and comparable changes in biomarkers. Studies are underway to further characterize the etiology of vascular damage induced by PDE IV inhibitors and the clinical utility of serum biomarkers.

SMOOTH MUSCLE CELL MARKERS OF FENOLDOPAM INDUCED VASCULAR INJURY.

Louden<sup>1,2</sup>, <sup>1</sup>*Global Safety Assessment, AstraZeneca Pharmaceuticals, Wilmington, DE*, <sup>2</sup>*Toxicology Program, EHS, The University of Michigan, Ann Arbor, MI* and <sup>3</sup>*Global Safety Assessment, AstraZeneca Pharmaceuticals, Alderley, United Kingdom.*

Vascular lesions in the rat occur as a result of toxic insult or spontaneous disease. The mechanism (s) is unknown. Vascular smooth muscle cells (SMC) appear to be the primary target because damage to endothelial cells (EC) is not apparent. Research activities have focused on characterization of changes in protein expression and/or enzymes specific to SMC as lesions develop. Fenoldopam (FP, 6-chloro-7-8-dihydroxy-1-[ $\rho$ -hydroxyphenyl]-2, 3, 4, 5-tetrahydro- [H]-3-benzazepine) consistently induces vascular lesions in mesenteric arteries of the rat and is therefore a useful tool to study these events. In an investigative study, immunohistochemistry (IHC) was utilized as one endpoint to identify and characterize some of these proteins and/or enzymes. Proteins evaluated include von Willebrand factor (vWF), Smooth muscle  $\alpha$  actin (SMA), caveolin-1, (Cav-1) and the enzyme extracellular superoxide dismutase (ecSOD). Normal rat mesenteric artery SMC express Cav-1, SMA and ecSOD, while EC express vWF and Cav-1. Administration of

fenoldopam caused segmental arterial damage characterized by medial necrosis, hemorrhage and edema. The SMC layer of damaged arteries had a marked increase in vWF expression, and a significant loss of Cav-1, SMA and ecSOD. EC of damaged arteries expressed vWF comparable to controls and uninjured arteries while immunoreactivity for Cav-1 was lacking in these cells. These findings support previous observations that SMC are the likely primary targets of fenoldopam induced vascular injury and evaluation of serum analytes for Cav-1 and SMA should be further investigated as potential diagnostic markers. Additionally, serum vWF may not be useful as a reporter of progressive injury because of increased vascular permeability and leakage into the surrounding tissues. Furthermore, the reduction in SMC ecSOD suggests a role for free radicals in the mechanism of fenoldopam induced vascular injury.
