Acrolein is a highly reactive, ubiquitous aldehyde pollutant of industrial and automobile exhausts, tobacco smoke, and foods. Acrolein inhalation adversely affects the cardiovascular system while the effects of oral acrolein exposure on cardiovascular risk factors are less studied. Using C57Bl/6 and ApoE-null male mice (7-16 wks old) as models of normal and at-risk human populations, we determined the effects of acute oral acrolein exposure on plasma lipoprotein levels and endothelial function. Acrolein exposure in mice (0.1-5 mg/kg) within the range of expected daily human intake induced significant dose- and time-dependent alterations of plasma lipoprotein levels and electrophoretic mobility (EPM) on agarose gels. Oral acrolein (5 mg/kg) significantly increased total plasma cholesterol (mg/dl, control=64.4; treated=115.3, n=10, 9), phospholipids (mg/dl, control=132.5; treated=230.7, n=10, 7), and triglycerides (mg/dl, control=67.5; treated=382.1, n=10, 9) at 24h, which were positively correlated with plasma lipoprotein EPM changes and unaltered by pretreatment with the glucocorticoid receptor antagonist RU486 (25 mg/kg). Plasma ultracentrifugation and FPLC fractionation revealed significant alterations in VLDL and HDL EPM and VLDL lipid levels of acrolein-treated mice compared to controls. Plasma EPM changes were significantly altered at 12h and 24h but not at 1h, 4h, or 48h post-acrolein exposure and preceded plasma lipid level changes. Acrolein exposure significantly increased liver weight/body weight ratio, decreased plasma albumin and glucose, but did not alter plasma liver enzyme activity levels. Additionally oral acrolein significantly decreased acetylcholine-induced relaxation in isolated aorta. Oral acrolein caused dramatic VLDL-associated dyslipidemia and decreased endothelial function perhaps due to direct lipoprotein modification(s) and hyperlipidemia, and thus, may contribute to increased cardiovascular disease risk. #### ATTENUATION OF HYPEROXIA-INDUCED RETINOPATHIES IN NEONATAL RATS BY RETINOIC ACID.

X. I. Couroucli, L. Kong, Y. Wei, W. Jiang and B. Moorthy. *Pediatrics, Baylor College of Medicine, Houston, TX*.

Supplemental oxygen administration, which is routinely encountered in the treatment of premature infants having respiratory distress, contributes to the development of retinopathy of prematurity (ROP). Retinal capillary damage, caused by hyperoxic exposures, often leads to retinal vascularization and proliferative retinopathy. Several studies suggest that vascular endothelial growth factor (VEGF) plays an important role in abnormal vessel proliferation in ROP patients. In this study, we tested the hypothesis that neonatal exposure of rats to a combination of all-trans retinoic acid (RA) and hyperoxia would alleviate oxygen-mediated retinopathy, and that modulation of VEGF expression contributes to the retinoprotective effects of RA. Newborn Fisher rats were maintained in room air or exposed to hyperoxia ([gt] than 95% O<sub>2</sub>) for 7 days. Some animals were treated i.p. with RA (0.5 mg/kg) or vehicle (saline), once daily for 5 days. Animals were sacrificed 1 or 30 days after termination of hyperoxia, and retinopathy was assessed by histological analysis of the retina. VEGF mRNA expression was studied by *in situ* hybridization and RT-PCR, and protein expression by Western blotting. Exposure of animals to hyperoxia alone for 7 days showed reduced number of retinal vessels, many of which were constricted, at 1 day compared to those breathing room air, and there were no significant differences in the retinal pathology of animals that were given RA + hyperoxia. At the 30 day time point, the oxygen-exposed animals displayed formation of new retinal vessels, whereas animals given RA + hyperoxia showed significantly lesser extent of neovascularization. At the 1 day as well as the 30 d time points, hyperoxia significantly upregulated retinal VEGF mRNA and protein expression, compared to those given RA + hyperoxia. In conclusion, the results of our study

support the hypothesis that RA protects animals from oxygen-induced retinopathy, and that downregulation of VEGF expression contributes to the retinoprotective effects of RA. (Supported in part by NIH grant KO8 HL04333 to XC.)

#### 1846

#### THE SUSCEPTIBILITY OF INBRED MOUSE STRAINS TO HYPEROXIA-INDUCED LUNG INJURY.

G. S. Whitehead, K. G. Berman, L. H. Burch, W. Foster and D. A. Schwartz. *Medicine, Duke University, Durham, NC*.

To evaluate the effect of genetic background on susceptibility to hyperoxia-induced lung injury, male mice (6-8 wks) from nine genetically diverse strains (129/SvImJ, A/J, BALB/cJ, BTBR T+/-tf/tf, C3H/HeJ, C57BL/6J, Cast/Ei, DBA/2J, and FVB/NJ) were exposed to >99% O<sub>2</sub> or room air for 72 hours. Inflammation in the airways and alterations of lung permeability, total bronchoalveolar lavage protein concentrations and lung wet-to-dry ratios, determined that there was a range of susceptibility among the mouse strains. The susceptible strains, BALB/cJ and CAST/Ei, were the only strains to have infiltration of neutrophils in the airways and were of six strains, including A/J, BTBR T+/-tf/tf, C3H/HeJ, and DBA/2J, to have significantly increased IL-6 levels in the airways. In addition, the BALB/cJ and CAST/Ei strains were among five strains, including BTBR T+/-tf/tf, C57BL/6J and 129/SvIm strains, which had the greatest alterations of lung permeability. In contrast, of the resistant strains, DBA/2J, FVB/NJ, A/J and C3H/HeJ, the DBA/2J strain was the only strain not to have significant alterations of lung permeability compared to air-exposed controls. Furthermore, total superoxide dismutase (SOD) and manganese-SOD (Mn-SOD) activity was measured and correlated to the amount of injury for each strain. The BALB/cJ strain was the only strain that had significantly increased total SOD activity. No strains had significantly increased Mn-SOD activity compared to the air-exposed controls; however, the amount of activity correlated to the permeability of the lungs following the hyperoxic exposure. The differences of lung injuries among the inbred mouse strains after hyperoxia challenge suggest a genetic basis for the lung response to oxygen stress. #### OXIDATION OF PURINE NUCLEOSIDES AND NUCLEOTIDES WITH DIMETHYLDIOXIRANE: STRUCTURAL CHARACTERIZATION OF REACTION PRODUCTS.

L. M. Ball, D. E. Degen, W. Ye, Y. Li, R. Sangaiah and A. Gold.

*Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC*.

Oxidative damage to DNA bases has been linked to adverse outcomes including genotoxicity and ageing. Reactive oxygen species such as hydroxyl radicals, superoxide anion and singlet oxygen have been implicated as causative agents of oxidative damage. We investigated the spectrum of products generated from oxidation of purine nucleosides and nucleotides with the powerful chemical oxidant dimethyldioxirane (DMDO). DMDO acts by epoxidation rather than by radical chemistry, and we wished to determine whether both these routes yielded similar oxidation products. DMDO was generated from the action of ozone on acetone; oxidation reactions were carried out at 0 °C. Products were characterized by HPLC, by proton and multidimensional heteronuclear NMR, and by electrospray MS in the positive ion mode. Epoxidation at the C4-C5 double bond followed by solvolysis represented the major product fraction. Thus in aqueous solution 2'-deoxy-4, 5-dihydroxyguanosine was formed from 2'-deoxyguanosine, at molar ratios of DMDO-to-nucleoside ranging from 1:1 to 5:1. With the nucleoside in excess over DMDO little oxidation was observed. 2'-Deoxy-8-oxoguanosine was similarly oxidised to 2'-deoxy-4, 5-dihydroxy-8-oxoguanosine. In methanolic solution the analogous product 2'-deoxy-4-hydroxy-5-methoxy-8-oxoguanosine was formed, confirming the involvement of solvent. The latter was further verified by conducting oxidations in perdeuterated methanol. Oxidation of 2'-deoxyguanosine-5'-phosphate yielded 2'-deoxy-4, 5-dihydroxyguanosine-5'-phosphate. Thus oxidation by a mechanism analogous to the mixed-function oxidases generates products distinct from those arising from radical chemistry. The oxidized nucleotide was more susceptible to deglycosylation than was the nucleoside, raising questions about the stability of such a lesion in DNA and its role in generation of abasic sites.

#### PI3-KINASE MEDIATED INDUCTION OF NRF-2 PROTEIN BY OXIDANTS IN CARDIOMYOCYTES.

S. E. Purdom<sup>1</sup> and Q. M. Chen<sup>2,1</sup>. <sup>1</sup>*Interdisciplinary Graduate Program in Genetics and Genomics, University of Arizona, Tucson, AZ* and <sup>2</sup>*Department of Pharmacology, University of Arizona, Tucson, AZ*.

Oxidative stress plays an important role in many diseases including heart disease. The levels of antioxidant and detoxification enzymes in the cell can be critical in determining how cells respond to oxidative insult. Previous studies from our lab

found that sublethal doses of  $H_2O_2$  induce the expression of a battery of antioxidant and detoxification enzymes in primary cultured neonatal rat cardiomyocytes (CMCs). Using a promoter-reporter chimerical construct transfected into CMCs, we found that  $H_2O_2$  activates the Antioxidant Response Element (ARE), a cis-element present in the promoters of many antioxidant and detoxification-related genes. Activation of the ARE is regulated by the transcription factor NF-E2-related factor 2 (Nrf-2), which also contains an ARE in its promoter and may undergo positive feedback when the ARE is activated.  $H_2O_2$  induces the expression of Nrf-2 mRNA and protein in CMCs. Nrf-2 protein induction is detectable within 1-2 hrs after  $H_2O_2$  treatment, a time frame that precedes the activation of the ARE promoter (4 hrs). Using pharmacological inhibitors and dominant negative forms of signaling molecules, we found that the Phosphoinositol-3 Kinase (PI3K) pathway regulates the induction of Nrf-2 without affecting its nuclear translocation. Chemical inhibitors of PI3K, LY294002 and Wortmannin, blocked Nrf-2 elevation at the protein level and prevented  $H_2O_2$  from activating the ARE. Dominant negative Nrf-2 failed to inhibit the induction of Nrf-2, arguing against Nrf-2/ARE mediated positive feedback after oxidative stress. Taken together,  $H_2O_2$  induces Nrf2 protein elevation via a PI3K mediated mechanism in CMCs and such induction does not involve Nrf2-mediated positive feedback.

**HYPERGLYCEMIA-INDUCED OXIDATIVE STRESS ACTIVATES THE HEXOSAMINE PATHWAY AND INHIBITS MITOCHONDRIAL BIOGENESIS.**

C. M. Palmeira<sup>1</sup>, J. Berthiaume<sup>2</sup>, J. A. Bjork<sup>2</sup>, A. P. Rolo<sup>1</sup> and K. B. Wallace<sup>2</sup>.

<sup>1</sup>Department of Zoology, University of Coimbra, Center for Neurosciences and Cell Biology, Coimbra, Portugal and <sup>2</sup>Department of Biochemistry & Molecular Biology, University of Minnesota, Medical School, Duluth, MN.

High glucose conditions routinely observed in diabetes have been shown to cause a variety of pathological changes. Hyperglycemia is known to induce the generation of ROS, and is implicated in the cellular oxidative stress that is believed to be responsible for the observed "glucose toxicity". However, little is known about the action of this nutrient on the expression of transcription factors in different cell types, especially those involved in mtDNA replication and transcription. We hypothesized that high glucose concentrations stimulate the generation of ROS, decreasing NRF-1 and Tfam transcription and, as a consequence, lead to a decrease in mtDNA copy number. Furthermore, the associated decrease in mitochondrial oxidative phosphorylation may cause a compensatory stimulation of the hexosamine pathway. HepG2/C3A cells were cultured in the presence of 30 mM glucose for 7 days, while cells cultured in the presence of 5 mM glucose served as controls. After 7 days exposure to high glucose, HepG2C3A cells showed a 3.6-fold increase in ROS generation and a 25% decrease in mtDNA, which was accompanied by a 16% decrease in both Tfam and NRF-1 transcripts, which regulate mtDNA replication and transcription. The expression of plasminogen activator inhibitor-1 (PAI-1), which plays a pivotal modulatory role in regulating the activity of the hexosamine pathway, was increased 60% in hyperglycemic conditions. These results indicate that high glucose concentrations regulate mtDNA copy number by modulating the expression and perhaps transcriptional activity of Tfam and NRK-1, suggesting that the decrease of mtDNA content and inhibition of mitochondrial metabolism may be pathogenic hallmarks in the altered metabolic status associated with diabetes. (Supported in-part by HL58016 and HL 72175).

**HYDROQINONE, p-BENZOQUINONE, BUT NOT BENZENE OR PHENOL CAUSE AN INCREASE IN REACTIVE OXYGEN SPECIES IN HD3 CELLS.**

J. Wan<sup>1</sup> and L. M. Winn<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada and <sup>2</sup>School of Environmental Studies, Queen's University, Kingston, ON, Canada.

Exposure to the environmental toxicant benzene, a cyclic organic compound, has been proposed to lead to carcinogenesis. While the mechanism behind benzene mediated leukemogenesis remains unknown, it is generally accepted that benzene exerts its toxicity after being metabolized by cytochrome P450s. The c-Myb oncoprotein is important in blood cell production, as mice deficient in this protein die on the 15th day of gestation. This gene has been found to be overexpressed in a number of leukemic cell lines and other cancers. We hypothesize that benzene may act upon c-Myb as a potential mechanism of leukemogenesis and that oxidative stress from benzene's metabolites regulate c-Myb activity. Previously, we have shown that the benzene metabolites catechol, hydroquinone, and benzoquinone cause increases in c-Myb activity and in phosphorylated c-Myb protein expression in chicken erythroblast HD3 cells after 24 hours of exposure. However, these changes were not observed in cells exposed to benzene or phenol. Our objective was to evaluate the role of reactive oxygen species (ROS) by exposing HD3 cells to 300  $\mu$ M benzene, 300  $\mu$ M phenol, 30 or 300  $\mu$ M catechol, 50  $\mu$ M hydroquinone and 50  $\mu$ M p-benzoquinone for up to 24 hours. Exposure to 50  $\mu$ M hydroquinone or p-benzo-

quinone resulted in a significant increase in cells with higher ROS at 24 hours as detected by 5-(and-6)-chloromethyl-2', 7'- dichlorodihydrofluorescein diacetate and flow cytometry. Furthermore, addition of 10  $\mu$ M phenol did not further increase the presence of ROS in cells exposed to 50  $\mu$ M of hydroquinone. These results support our hypothesis that benzene mediates aberrant c-Myb activity through ROS.

**MEASUREMENT OF OXIDATIVE STRESS USING KINETIC HIGH CONTENT CELL-BASED ASSAYS.**

V. Abraham and J. R. Haskins. *Cellomics, Pittsburgh, PA.* Sponsor: E. McGuire.

We have developed a high content bioassay that enables fully automated measurement of oxidative stress in individual cells in microplate format. The bioassay involves measurement of individual cell responses that are automatically extracted from high-resolution digital images captured using automated kinetic fluorescence imaging microscopy. The bioassay is based on detecting the conversion of non-fluorescent dihydroethidium (DHE) to fluorescent ethidium by reactive oxygen species (ROS). The assay involves simultaneous addition of DHE and test compounds to cells followed by acquisition of image data at regular intervals. The formation of ethidium is quantified as the accumulation of fluorescence of the ethidium:DNA complex in individual cell nuclei. Nuclear morphology was simultaneously monitored to determine when compound treatment causes irreversible cellular damage. Multiple concentrations of known oxidative stress inducers, such as tacrine and rotenone, were tested in the same experiment. Cumulative ROS production and nuclear condensation were automatically quantified at each time point using the Target Activation BioApplication on the Cellomics KineticScan® HCS Reader. Rates of ROS generation were also derived from the first 30 min. for each experimental condition tested to (a) enable measurement of the initial linear rate of ROS production and (b) eliminate effects of any eventual degradation of cellular metabolism/viability. Dose-dependent oxidative stress was observed for tacrine and rotenone. In addition, analysis of individual cell responses showed varying patterns of ROS generation and nuclear condensation. The assay was found to perform well using multiple relevant cell types, including HepG2 cells (human liver carcinoma) and primary rat hepatocytes. In conclusion, this bioassay is a valuable screening tool for conducting rapid quantitative assessment of oxidative stress on a large scale, involving testing of several experimental variables, including drug concentrations, cell types and time course.

**ANALYSIS OF THE ROLE OF THE ANTIOXIDANT RESPONSE ELEMENT IN THE PROGRESSION OF AMYOTROPHIC LATERAL SCLEROSIS.**

C. B. Rideaux, J. C. Kern, D. A. Johnson and J. A. Johnson. *University of Wisconsin-Madison, Madison, WI.*

Oxidative stress plays a prominent role in a number of neurodegenerative diseases including amyotrophic lateral sclerosis (ALS). ALS is characterized by the progressive loss of motor neurons in the brainstem and spinal cord. The antioxidant response element (ARE) and its transcription factor, NF-E2 related factor 2 (Nrf2), play a pivotal role in the activation of detoxification pathways in multiple cellular systems. Interestingly, the development of ALS pathogenesis in the prototypical mouse model, superoxide dismutase with a G93A mutation (SOD<sup>G93A</sup>), revealed a time-dependent activation of the ARE using an hPAP reporter mouse (ARE-hPAP mice) in the spinal cord, as well as some key areas of the brain, brainstem, and cortex. SOD<sup>G93A</sup> transgenic mice exhibit ALS symptoms including muscle atrophy, motor neuron loss and eventual hindlimb paralysis at 120 days. SOD<sup>G93A</sup>/ARE-hPAP mice displayed increased ARE activation, as measured by defined hPAP enzymatic activity, temporally with disease progression. We have used explant spinal cord cultures to further investigate this mechanism of ARE activation *in vitro*. Spinal cord slices are cultured from postnatal day eight ARE-hPAP reporter mice and treated with known ARE activators following eight days *in vitro*. Spinal cord cultures from ARE-hPAP mice were treated with adenovirus (Ad-Nrf2) to detect if viral infection of Ad-Nrf2 would stimulate the ARE. Ad-Nrf2 infection has previously been shown to activate the ARE and is neuroprotective both *in vitro* and *in vivo*. Preliminary data shows significantly increased histological staining for hPAP activity in Ad-Nrf2 vs. GFP or PBS treated cultures. Ex-vivo spinal cord cultures represent a novel approach to exploring the mechanisms of ALS-related ARE activation and the resultant protective mechanisms.

**ORAL GLUTATHIONE RAPIDLY ELEVATES GLUTATHIONE LEVELS IN LUNG EPITHELIAL LINING FLUID AND LAVAGED CELLS.**

C. T. kariya<sup>1</sup>, H. Leitner<sup>1</sup>, E. Min<sup>3</sup> and B. J. Day<sup>3,1,2</sup>. <sup>1</sup>Molecular Toxicology and Environmental Health Sciences, UCHSC, Denver, CO, <sup>2</sup>Medicine, UCHSC, Denver, CO and <sup>3</sup>Medicine, National Jewish Medical and Research Center, Denver, CO.

The lung adapts to oxidative stress by upregulation of antioxidants such as glutathione (GSH), uric acid and ascorbic acid. GSH plays an important role in protecting the lung from oxidative stress generated by endogenous and exogenous oxi-

dants. Previous studies in our laboratory have shown that following primary lung infection, levels of GSH in the epithelial lining fluid (ELF) are elevated. The levels of GSH in the ELF are low in a number of lung diseases including cystic fibrosis, acute respiratory distress syndrome, HIV infection and lung transplantation. These low ELF GSH levels have been proposed to play a role in the lung pathophysiology associated with these conditions and may sensitize this population to environmental air pollutants. The purpose of this study was to determine whether oral GSH treatment could increase ELF GSH levels in mice. Mice were given a bolus oral dose of GSH (300mg/kg). Mice were sacrificed at various time points and blood and bronchoalveolar lavage fluid was collected. Serum and lavage fluid as well as cells obtained from lavage fluid were measured for GSH levels by HPLC with electrochemical detection at 15, 30, 60, 100 and 240 min post dose. The concentration of GSH in the ELF was estimated by using the urea dilution method. GSH levels steadily increased and peaked at 60 minutes in the ELF. The GSH peak level was three-fold higher as compared to the control animals. GSH levels within lavaged cells peaked at 60 min and decreased at 100 and 240 min, but remained elevated as compared to controls. This data suggests that oral GSH treatment can increase ELF GSH level and could be used as therapeutic approach to protect the lung from toxic effect of oxidants generated by various lung disease processes and environmental exposures. (Supported by: Cystic Fibrosis Foundation grant and NIH grant HL075523).

## 1854

### SELECTIVE ENHANCEMENT OF HYPEROXIC LUNG INJURY BY AUROTHIOPROGLUCOSE IN GLUTATHIONE-DEFICIENT MICE SUGGESTS CROSS-TALK BETWEEN THIOREDOXIN AND GLUTATHIONE SYSTEMS.

S. E. Welty, L. K. Rogers, T. E. Tipple, T. N. Hansen and C. V. Smith. *Center for Developmental Pharmacology and Toxicology, Columbus Children's Research Institute, Columbus, OH.*

Reduction of glutathione disulfide (GSSG) to glutathione (GSH) by glutathione reductase (GR) is an essential function of GSH-dependent antioxidant defense mechanisms, but GR-deficient (Neu) mice are not markedly more susceptible to hyperoxic lung injury. Greater thioredoxin (Trx) and thioredoxin-2 (trx-2) levels in the livers of Neu mice suggest compensation by Trx-dependent mechanisms. To test the hypothesis that the Neu mice are dependent on Trx/thioredoxin reductase (TrxR) mechanisms for protection against hyperoxic lung injury, 0 or 25 mg/kg aurothioglucose (ATG) were administered IP to six week-old Neu and C3H/HeJ mice, which were exposed to >95% O<sub>2</sub> for 96 h or maintained in room air. Lung injury was assessed by right lung weight to body weight ratios. Data were log transformed and analyzed by three-way ANOVA, with differences noted at p<0.05. In Neu, but not in C3H/HeJ mice, mortality was observed at ATG doses greater than 25 mg/kg. Exposure of Neu and C3H/HeJ mice to >95% O<sub>2</sub> for 96 h caused lung injury. Pretreatment with ATG exacerbated hyperoxic lung injury in Neu mice (11.9±2.5 vs 6.8±1.3 g right lung/kg body, n=3, p<0.01; saline/room air 3.8±0.3), whereas ATG pretreatment did not enhance lung injury in C3H/HeJ mice. Enhanced hyperoxic lung injury in Neu mice by administration of ATG suggests functionally important cross-talk between the GSH and Trx systems in the GR-deficient animals. Whether direct increases or decreases in expression of Trx/TrxR-dependent mechanisms can be employed to increase or decrease resistance to oxidant stresses or problems arising from diseases or environmental exposures remains to be determined.

### PHENOTYPIC ANCHORING OF ACETAMINOPHEN-INDUCED OXIDATIVE STRESS AND GENE EXPRESSION PROFILES IN RAT LIVER.

C. L. Powell<sup>1,2</sup>, P. Ross<sup>2</sup>, A. Heinloth<sup>3</sup>, G. Boorman<sup>4</sup>, M. Cunningham<sup>4</sup>, R. Paules<sup>3</sup> and I. Rusyn<sup>1,2</sup>. <sup>1</sup>*Curriculum in Toxicology, UNC, Chapel Hill, NC*, <sup>2</sup>*Department Env Science & Engr, UNC, Chapel Hill, NC*, <sup>3</sup>*NIEHS, National Center for Toxicogenomics, Research Triangle Park, NC* and <sup>4</sup>*NIEHS, Env Toxicology Program, Research Triangle Park, NC*. Sponsor: I. Rusyn.

Toxicogenomics is an emerging field providing the ability to define in greater detail the underlying molecular events preceding and accompanying toxicity. The incorporation of this new technology requires careful validation and altered gene expression patterns should be corroborated with conventional indices of toxicity in a dose and time dependent manner. Acetaminophen (APAP) is a therapeutic drug with documented liver toxicity that causes similar metabolic and toxic responses in rodents and humans. APAP overdose-associated toxicity in liver is an important clinical problem and a significant contributor to acute liver failure. Recent gene expression profiles for APAP have demonstrated an oxidative stress signature beginning at sub-toxic doses that we hypothesized can be phenotypically anchored to conventional biomarkers of oxidative stress. Liver tissue was obtained from same experimental animals used to generate micro-array data and histopathology where male rats were given a single dose of APAP at sub-toxic (50 and 150) and toxic (1, 500 and 2, 000 mg/kg) doses and sacrificed at 6, 24, and 48 hrs. Oxidative stress was as-

sessed by measuring expression of base excision repair genes (BER), quantifying oxidative lesions in genomic DNA, and evaluating lipid peroxidation in liver. Toxic doses of APAP significantly induced gene expression levels of several BER genes including PCNA, PARP, APE, and Ogg1. Although induction of BER genes occurred with toxic doses of APAP, significant increases in abasic sites over controls was not observed for any doses examined. In summary, the increased expression of BER genes was found to correlate with toxic doses of APAP, the onset of hepatic necrosis, and an increase in activity of alanine aminotransferase. Conversely, the presence of an oxidative stress signature at sub-toxic doses must be interpreted carefully without further experimental corroboration.

### NEAR-INFRARED LIGHT TREATMENT IN A CELLULAR MODEL OF MITOCHONDRIAL DYSFUNCTION.

K. DeSmert<sup>1</sup>, M. M. Henry<sup>2</sup>, E. Buchmann<sup>3</sup>, M. Connelly<sup>3</sup>, H. T. Whelan<sup>3,1</sup> and J. T. Eells<sup>1,3,2</sup>. <sup>1</sup>*Health Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI*, <sup>2</sup>*Ophthalmology, Medical College of Wisconsin, Milwaukee, WI* and <sup>3</sup>*Neurology, Medical College of Wisconsin, Milwaukee, WI*.

Mitochondrial dysfunction and oxidative damage to biological molecules in the retina and optic nerve is known to contribute to the pathogenesis of Lebers hereditary optic neuropathy (complex I dysfunction) and has been postulated to contribute to retinal aging and age related retinal diseases. Photobiomodulation by red to near-infrared (630 to 1000 nm) light has been shown to stimulate mitochondrial energy production, accelerate wound healing and promote and cellular survival following a mitochondrial insult. The present studies were undertaken to test the hypothesis that: near-infrared (NIR) light emitting diode (LED) photobiomodulation will stimulate mitochondrial function, attenuate oxidative stress and improve cell survival in a cellular model of complex I dysfunction. 661W cells, a photoreceptor-derived cell line, were plated at a density of 150, 000 cells/cm<sup>2</sup> in 96 well plates and incubated at 37 °C in DMEM supplemented with 5% FBS. At 72 h, cultures were treated with the complex I inhibitor, rotenone, (1-250 micromolar) for 24 hr. Duplicate cultures were pretreated with (24 and 48 h after plating) with 670nm LED light (power intensity of 28 mW/cm<sup>2</sup> and fluence of 4 joules/cm<sup>2</sup>) exposed to rotenone (72 h) and given one post-670 nm LED treatment, one h after the addition of rotenone. Rotenone produced a concentration-dependent increase in reactive oxygen species (ROS) generation and cell death. 670 nm LED treatment produced a significant attenuation in ROS production with little observable change in cell death. These studies support the hypothesis NIR photobiomodulation decreases ROS production in an *in vitro* model of an important clinical disease. This may lead to the development of NIR-LED as a innovative, non-invasive, therapeutic approach for the treatment of retinal diseases. (Supported by Fight for Sight Student Fellowship SF04041 and DARPA N66001-04-1-8923)

## 1857

### TOLL-LIKE RECEPTOR 4 (TLR4) CONTRIBUTES TO OZONE-INDUCED INCREASES IN COSTIMULATORY MOLECULE (CD86) EXPRESSION IN MICE.

G. Backus<sup>1,2</sup>, A. K. Bauer<sup>2</sup>, H. Cho<sup>2</sup> and S. R. Klebeberger<sup>2</sup>. <sup>1</sup>*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC* and <sup>2</sup>*NIH/NIEHS, Research Triangle Park, NC*.

Rationale: Ambient ground level ozone (O<sub>3</sub>) induces airway inflammation and may modulate adaptive immune responses in the lung. T-cell activation is at least partially dependent on macrophage-induced upregulation of co-stimulatory molecules such as CD86. Previous work demonstrated that the innate immune receptor TLR4 modulates pulmonary inflammatory responses to O<sub>3</sub>. We hypothesized that CD86 expression is upregulated in response to O<sub>3</sub> and depends on TLR signaling. Methods: We exposed O<sub>3</sub> resistant, TLR4 dysfunctional C3H/HeJ (HeJ) mice and O<sub>3</sub> susceptible, TLR4 sufficient C3H/HeOuJ (OuJ) mice to 0.3 ppm O<sub>3</sub> or air for up to 72 hrs. Mean total protein concentration (a marker of lung hyperpermeability) and numbers of polymorphonuclear leukocytes (PMNs) were determined in bronchoalveolar lavage fluid (BALF). Surface CD86 expression was assessed via flow cytometry on macrophages recovered from BALF and confirmed in whole lung homogenates using Western blot analysis. Results: Mean total protein concentration, numbers of PMNs, and total cells increased significantly in HeJ and OuJ mice after 48 and 72 hr O<sub>3</sub>, and were significantly greater in OuJ compared to HeJ mice. CD86 expression was significantly elevated in OuJ compared to HeJ mice at baseline and after O<sub>3</sub>. Conclusion: This study demonstrates that macrophage-specific CD86 expression increases in response to 0.3 ppm O<sub>3</sub>. TLR4 may partially mediate O<sub>3</sub>-induced adaptive immune responses through upregulation of CD86.

## 1858

### ARSENIC TRIOXIDE INDUCED OXIDATIVE STRESS IN SPRAGUE-DAWLEY RATS.

A. K. patlolla and P. B. Tchounwou. *Biology, Jackson State University, Jackson, MS*.

Arsenic is a known human carcinogen and induces a variety of human diseases in addition to cancers of the lung, skin, bladder, kidneys and liver. The mechanism(s) by which arsenic induces cancer, however remains poorly understood. Recent studies have pointed out that arsenic toxicity is associated with the formation of reactive

oxygen species, which has a role in the pathogenesis of arsenic-induced diseases. The aim of the present study was to investigate the effect of arsenic trioxide on the lipid peroxidation changes in the plasma samples of Sprague-Dawley rats. Four groups of six male rats each weighing approximately  $50 \pm 2$  g, were injected intraperitoneally, once a day for five days with doses of 5, 10, 15, 20 mg/kg body weight (BW) of arsenic trioxide dissolved in distilled water. A control group was also made of six animals injected with distilled water without chemical. Following anaesthetization, blood specimens were immediately collected in tubes containing EDTA as an anticoagulant, and the concentration of malondialdehyde (MDA), a convenient index of lipid peroxidation in plasma samples was determined using colorimetric assay from Calbiochem. Concentration of MDA was significantly ( $p < 0.05$ ) higher in the treated groups when compared with the control group, indicating a gradual increase in lipid peroxidation with increasing doses of arsenic. Our results demonstrate that arsenic trioxide has a potential of causing oxidative stress, a biomarker of cellular injury, in the plasma samples of Sprague-Dawley rats. Keywords: arsenic, reactive oxygen species, oxidative stress, malondialdehyde (MDA), lipid peroxidation, Sprague-Dawley rats.

1859

EFFECT OF ACETAMINOPHEN ON CYTOSOLIC AND MITOCHONDRIAL GLUTATHIONE IN THE LIVERS OF WILD-TYPE, GCLM-HETEROZYGOUS, AND GCLM-NULL MICE.

I. Mohar, L. A. McConnachie, C. Fernandez and T. J. Kavanagh. Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.

Acetaminophen (APAP) is metabolized by CYP450s to N-acetyl-p-benzoquinoneimine, a reactive molecule, which is detoxified via glutathione (GSH) conjugation. APAP overdose can cause GSH depletion, which is correlated with the degree of observed APAP-induced liver injury. Mitochondrial GSH (mtGSH) status is hypothesized to play a pivotal role in this process. GSH synthesis is in part controlled by glutamate cysteine ligase (GCL), a heterodimer of catalytic (GCLC) and modulatory (GCLM) subunits. In order to investigate the hypothesis that mtGSH is preferentially maintained under conditions of chronic GSH depletion and acute oxidative stress, we utilized our GCLM-null mouse model. GCLM  $+/+$ ,  $+/$ -, and  $-/-$  mice ( $n=7$  ea.) were fasted for 12-hours followed by i.p. injection of saline or APAP (300 mg/kg). Mice were euthanized 6 hours post-treatment and hepatic mitochondria isolated. Analysis of mean cytosolic GSH (ctGSH) (nmol GSH/mg wet liver) in control mice demonstrated  $-/-$  mice to contain 18% of  $+/+$  mice. Mean ctGSH was observed to decrease by 52 and 60% upon APAP treatment of  $+/+$  and  $-/-$  mice, respectively. Mean mtGSH in control  $-/-$  mice was not statistically different from  $+/+$  mice. A decrease in mean mtGSH upon APAP treatment was only observed in  $-/-$  mice (68% decrease). However, as a percent of combined (ct+mt) GSH, mtGSH of  $-/-$  mice was observed to be 67 and 200% greater than mtGSH of APAP-treated and control  $+/+$  mice, respectively. APAP treatment increased the mean percentage of GSH in mitochondria of  $+/+$  mice by 55%. Measures of  $-/-$  mice were not statistically different from  $+/+$  mice. These results demonstrate that under conditions of chronic GSH depletion, as occurs in  $-/-$  mice, or acute oxidative stress, as induced by APAP, mtGSH is not depleted to the same degree as ctGSH. These results support the hypothesis that mtGSH is preferentially maintained even as ctGSH is being depleted. Supported by NIH grants 1P42ES04696, 1R01ES10849, 1T32ES07032, and 1P30ES07033.

ANTIOXIDANT GENE EXPRESSION LEVELS IN BRAIN AREAS THAT ARE TARGETS OF 1, 3-DNB MEDIATED NEUROTOXICITY.

T. R. Miller<sup>1</sup> and P. Venkatakrishnan<sup>1</sup>. <sup>1</sup>Graduate Center for Toxicology, University of Kentucky, Lexington, KY and <sup>2</sup>Graduate Center for Toxicology, University of Kentucky, Lexington, KY.

1, 3 Dinitrobenzene(1, 3-DNB), a chemical entity used in the production of dyes, plastics and explosives, is a neurotoxicant in rats affecting cerebellar function and targeting distinct brain-stem nuclei. Our lab has established that in the presence of the dinitrobenzene isomers, electron transfer through Nitric Oxide Synthase (NOS) may result in the simultaneous production of both nitric oxide and superoxide anion radical to produce peroxynitrite. It is postulated that 1, 3 DNB mediated free radical formation and the oxidative stress results in increased energy metabolism and cellular changes in redox and antioxidant status. We are investigating the possible changes in gene expression levels of important antioxidant enzymes, Cu/Zn superoxide dismutase (SOD1) and glutathione peroxidase (GSH-Px) in neuronal NOS localized areas of brain. In preliminary experiments, rats were dosed with 1, 3-DNB (10 mg/kg in corn oil i.p. every 12h \* 3). The experimental design consisted of 5 groups of rats which differed by 1) receiving 1, 3-DNB in corn oil or only corn oil and, 2) the time of brain removal after final dose of 1, 3-DNB (0, 6, 12, and 24 hr). Brain samples consisting of the lower half of the cerebellum plus the

pons and medulla were removed and RNA was isolated and standardized spectrophotometrically as a function of protein concentration. RTPCR was performed wherein 2.5 mg of total RNA was reverse-transcribed into cDNA and PCR reaction was performed followed by separation, visualization and densitometric analysis. They showed that following 1, 3-DNB, GSH-Px was increased by around 35% at both 12 hr and 24 hr but SOD1 levels showed little to no increase (10%) at 24 hrs. These data show that there are specific differences in the regulation of at least these two antioxidant genes by 1, 3-DNB. Experiments are now underway to define the detailed time-course of gene expression following 1, 3-DNB as well as the expression and regulation of other genes involved in oxidative stress like MnSOD and P53

ENHANCED RENAL TOXICITY OF FERRIC NITRILOTRIACETATE IN NRF2 DEFICIENT MICE.

K. KANKI<sup>1</sup>, T. Umemura<sup>1</sup>, Y. Kitamura<sup>1</sup>, Y. Ishii<sup>1</sup>, Y. Kodama<sup>2</sup>, K. Itoh<sup>3</sup>, M. Yamamoto<sup>3</sup>, A. Nishikawa<sup>1</sup> and M. Hirose<sup>1</sup>. <sup>1</sup>Division of Pathology, National Institute of Health Sciences, Tokyo, Japan, <sup>2</sup>Division of Toxicology, National Institute of Health Sciences, Tokyo, Japan and <sup>3</sup>Graduate school of Comprehensive Human Sciences, Tsukuba University, Tsukuba, Japan.

Intracellular defense systems against oxidative stress play a key role in the prevention of diseases related with aging and carcinogenesis. Knock-out mice for Nrf2, a transcriptional factor to antioxidant-response genes, including phase2 metabolizing enzymes, show high sensitivity to oxidative stress, offering an useful animal model for understanding such cellular responses. In order to clarify a possible role of Nrf2 in oxidative stress occurring in the kidney, expression of renal toxicity induced by ferric nitrilotriacetate (Fe-NTA), a known renal carcinogen for rodents involving oxidative stress in the carcinogenesis, was investigated using three genotypes. Male Nrf2 (+/+, +/- or -/-) mice received single injection of 3 or 6 mg iron/kg of Fe-NTA, and killed at 1, 2, 4 and 24 hours after the treatment for collecting kidney samples. Histopathological examination revealed that renal lesions such as pyknosis or fragmentation of nuclei, and degeneration or desquamation of proximal convoluted tubular cells were expressed earlier in the -/- mice than +/+. Lipid peroxidation (TBARS) and DNA oxidation (8-oxodeoxyguanosine), major parameters of oxidative stress, were significantly and dose-dependently increased in the kidney of Fe-NTA-treated groups and showed some tendency to be more severe in the -/- mice. Total glutathione (GSH) and  $\gamma$ -glutamylcysteine synthetase activity were both reduced constitutionally in the -/- mice. Moreover, the Fe-NTA treatment depleted GSH more severe in the -/- mice than the +/+. Thus, it is suggested that Nrf2-mediated GSH-regulation system plays an important role in the cellular defense against iron-induced oxidative stress in the kidney.

THE BIO-NANO INTERFACE: EXAMINING THE INTERACTIONS BETWEEN WATER SOLUBLE FULLERENES AND BIOLOGICAL MEMBRANES.

C. M. Sayes<sup>1</sup>, J. Mendez<sup>1</sup>, K. D. Ausman<sup>4</sup>, J. L. West<sup>2, 4</sup>, J. H. Hafner<sup>3, 4</sup> and V. L. Colvin<sup>1, 4</sup>. <sup>1</sup>Chemistry, Rice University, Houston, TX, <sup>2</sup>Bioengineering, Rice University, Houston, TX, <sup>3</sup>Physics and Astronomy, Rice University, Houston, TX and <sup>4</sup>Center for Biological and Environmental Nanotechnology, Rice University, Houston, TX.

The cytotoxicity of water-soluble fullerene species is a sensitive function of their surface derivatization. In three different human cell lines, dermal, liver, and brain, the lethal dose of fullerene changed over 7 orders of magnitude with relatively minor alterations in fullerene structure. An aggregated form of C<sub>60</sub>, the least derivatized of the four materials, was substantially more toxic than highly soluble derivatives such as C<sub>3</sub>, Na<sup>+2-3</sup>[C<sub>60</sub>O<sub>7.9</sub>(OH)<sub>12-15</sub>]<sup>(2-3)</sup>, and C<sub>60</sub>(OH)<sub>24</sub>. Oxidative damage to the cell membranes was observed in all cases where fullerene exposure led to cell death. We show that under ambient conditions in water fullerenes can generate superoxide anions, and postulate these oxygen radicals are responsible for membrane damage. We have also utilized Atomic Force Microscopy (AFM) to examine the interaction of the aggregated form of C<sub>60</sub> with artificial membranes. The AFM images show that the C<sub>60</sub> aggregate selectively binds only to the membrane. This work demonstrates both a strategy for enhancing the toxicity of fullerenes for certain applications such as cancer therapeutics or bactericides, as well as a remediation for the possible unwarranted biological effects of pristine fullerenes.

INVOLVEMENT OF REACTIVE OXYGEN FORMATION IN THE 3-HYDROXY-3-METHYLGLUTARYL-COA REDUCTASE INHIBITOR-INDUCED SKELETAL MUSCLE CELL DEATH.

A. Wolf<sup>1</sup>, L. Ndountse-Tchapda<sup>1</sup>, U. Schramm<sup>1</sup> and W. E. Trommer<sup>2</sup>. <sup>1</sup>Biomarker Development, Novartis Pharmacology AG, Basel, Switzerland and <sup>2</sup>Department of Chemistry, University of Kaiserslautern, Kaiserslautern, Germany.

Statins (3-hydroxy-3-methylglutaryl-coenzyme A reductase inhibitors) are potent cholesterol lowering agents, which may cause myopathy and in rare cases even rhabdomyolysis in man. The mechanisms leading to rhabdomyolysis are not yet

known. There is indirect evidence that reactive oxygen species (ROS) might play a role in muscle cell necrosis. The purpose of this study was to determine whether ROS is formed and contributes to cell death in human skeletal muscle primary culture (hSkMCs) in response to statin treatment. Thus, hSkMCs were incubated with atorvastatin (ATV), simvastatin (SIM) or pravastatin (PRA) at different concentrations and for varying time. ROS formation, caspase-3 activation (apoptosis), cellular ATP contents and LDH-leakage (surrogate for necrotic cell damage) were measured. All statins, except PRA caused: 1) increased ROS formation (after 30 min of incubation), 2) caspase-3 activation (after 2 hours), 3) increased LDH-leakage (after incubation times of 4, 24 or 48 hours) and 4) increased cellular ATP contents after 1 and 2 hours, which dropped below control levels after 24 or 48 hours of incubation. In general SIM was more potent than ATV, having effects at lower concentration and after shorter incubation times. In the presence of the antioxidants N-acetyl cystein (NAC), dithiothreitol (DTT) and DL- $\alpha$ -tocopherol-polyethylene-glycol-1000-succinate (TPGS), statin-induced caspase-3 activity as well as increased LDH-leakages were inhibited. Inhibition of LDH-leakage was also achieved by co-incubation with the caspase-3 inhibitor AC-DEVD-CHO. The present data confirm that oxidative stress is an early event following the treatment of hSkMCs with statins. The statin-induced ROS formation might contribute to the apoptotic and necrotic cell death in hSkMCs.

SURFACE ACTIVITY OF ERIONITE SAMPLES FROM DIFFERENT LOCALITIES.

M. Gulumian<sup>1,2</sup>, M. Semano<sup>1</sup> and G. Hearne<sup>3</sup>. <sup>1</sup>*Toxicology, NIOH, Johannesburg, Gauteng, South Africa*, <sup>2</sup>*Department of Haematology and Molecular Medicine, University of the Witwatersrand, Johannesburg, Gauteng, South Africa* and <sup>3</sup>*Department of Physics, University of the Witwatersrand, Johannesburg, Gauteng, South Africa*. Sponsor: M. Karol.

Erionite is an aluminosilicate with a structure that consists of silicon (Si) tetrahedrally coordinated to oxygen atoms. The tetrahedra are arranged into six-membered rings which in turn form channels or cages through which cation migration takes place. The Si atoms are occasionally replaced by the Al atoms in the framework, giving rise to a negative charge on the mineral, which is balanced by positive counter-ions contained in the cages. Counter-ions normally associated with erionite are Na<sup>+</sup>, K<sup>+</sup>, Ca<sup>2+</sup> and Mg<sup>2+</sup>, but other cations such as iron also exist naturally in trace amounts. Iron has been reported to act as a source of radicals in erionite fibers, but the nature and the mechanism of the generating iron surface sites are still not clear and most reports present only limited mineral characterization of samples. Erionite is more carcinogenic than crocidolite and amosite asbestos fibers, in both laboratory animals and humans. Six erionite fiber samples obtained from different localities were studied. Mossbauer Spectroscopy (MS) analysis has shown that these samples contained different proportions of iron in either ferric or ferrous oxidation states, or both. Photoelectron Spectroscopy (XPS) confirmed these observations. Scanning Electron Microscopy (SEM) has indicated that not all fibers in a particular sample contained iron. The ability of these erionite samples to peroxidise lipids was also tested and it was found that these samples could initiate the peroxidation of lipids to various extents. Treatment of these samples with desferrioxamine could decrease but not completely abolish this peroxidation ability. These results elucidate the bioavailability of iron in these erionite samples which in turn may determine their toxicity and carcinogenicity.

IDENTIFICATION OF NF- $\kappa$ B MODIFICATIONS GENERATED BY CIGARETTE SMOKE ALDEHYDES.

C. Lambert, J. Li, M. Portas, S. Lazis, M. Quintana, J. McCue and B. M. Freed. *Allergy and Clinical Immunology, School of Medicine, University of Colorado Health Sciences Center, Denver, CO*.

Cigarette smoke is associated with an increased incidence and severity of respiratory tract infections, which appears to be due to profound suppression of T cell responses in smokers' lungs. Our lab has identified several immunosuppressive compounds in the vapor phase of cigarette smoke that block T cell cytokine production. Acrolein and crotonaldehyde are  $\alpha$ ,  $\beta$ -unsaturated aldehydes that inhibit cytokine production by covalently binding to and inactivating the p50 subunit of NF- $\kappa$ B. Pretreatment of purified p50 with 1  $\mu$ M acrolein blocked its ability to bind an NF- $\kappa$ B target sequence. The saturated aldehydes (acetaldehyde, butyraldehyde, and propionaldehyde) had no effect. Crotonaldehyde also inhibited binding, but at much higher doses (1 mM). Mass spectrometry analysis of purified p50 treated with acrolein, crotonaldehyde or the saturated aldehydes revealed that several amino acids were covalently modified. Acrolein bound to Cys61, Lys146 and Lys274, amino acids critical for DNA binding. Additionally, acrolein was found conjugated to Cys272 and His306, which are involved in p50/p65 heterodimer formation. Crotonaldehyde also reacted with Cys61, but did not bind any other

amino acid in the DNA-binding domain of p50. No modification of p50 by the saturated aldehydes was detected even though present in high levels in cigarette smoke. These observations suggest that acrolein inhibits NF- $\kappa$ B activity by reacting with cysteines, lysines and histidines which prevents DNA binding and heterodimer formation.

2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) INDUCES THE EXPRESSION OF FAS AND FAS LIGAND THROUGH DISTINCT PATHWAYS INVOLVING DRE AND NF-KAPPAB MOTIFS ON THE PROMOTERS.

N. P. Singh<sup>1</sup>, <sup>1</sup>*Pharmacology & Toxicology, Virginia Commonwealth University, Richmond, VA* and <sup>2</sup>*Microbiology & Immunology, Medical College of Virginia Campus, Virginia Commonwealth University, Richmond, VA*. Sponsor: P. Nagarkatti.

We have shown previously that TCDD induces apoptosis in immune cells through upregulation and recruitment of Fas and Fas ligand (FasL). In the present study, we examined the regulation of Fas and FasL promoters following TCDD exposure. To this end, we cloned murine Fas and FasL promoters into pGL3 vector that contained luciferase gene. EL4 cells transiently expressing Fas or FasL promoter were treated with 100nM TCDD and luciferase assays were performed 18 hrs post treatment. We observed 15-20 and 6-10 fold induction of promoter activity for Fas and FasL respectively following TCDD exposure. However, the induction of luciferase was significantly reduced (1-2 folds) when alpha-naphthoflavone, an AhR antagonist was used in the culture together with TCDD, demonstrating that the regulation of Fas and FasL promoters by TCDD may be mediated by TCDD-AhR interaction. To further understand the regulation of Fas and FasL promoters by TCDD and participation of AhR, we generated various clones of Fas promoter containing either dioxin response elements (DRE) or nuclear factor kappaB (NF- $\kappa$ B) binding motifs as well as clones that contained NF- $\kappa$ B sites of FasL promoter and used them for transfection. We also generated mutations in DRE and NF- $\kappa$ B regions present in Fas and FasL promoters. TCDD treatment of EL4 cells transiently expressing DRE or NF- $\kappa$ B regions of Fas promoter demonstrated varying levels of luciferase expression (5-7 folds). We observed 2-3 fold luciferase induction when NF- $\kappa$ B1 or NF- $\kappa$ B2 of FasL promoter was used for transfection. Use of DRE or NF- $\kappa$ B mutants demonstrated similar results. Together, our data demonstrate that TCDD-AhR interactions may regulate Fas promoter through DRE and NF- $\kappa$ B binding sites and FasL promoter, only through NF- $\kappa$ B motifs. (This work was supported in part by NIH grants R01AI053703, R01ES09098, R01 AI058300, R01DA016545 and R01HL058641).

2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) DISRUPTS THE NORMAL DAILY RHYTHMS OF HEMATOPOIETIC PRECURSORS.

R. Garrett and T. A. Gasiewicz. *Environmental Medicine, University of Rochester School of Medicine & Dentistry, Rochester, NY*.

Hematopoietic stem cells (HSC) and progenitor cells are responsible for the daily production of all blood cells through an ordered process of proliferation and differentiation. These processes are controlled by both extrinsic and intrinsic factors including a myriad of transcription factors. One possible member of this network is the aryl hydrocarbon receptor (AhR), a member of the bHLH-PAS transcription factor family and the mediator of TCDD toxicity. Previous studies indicated that *in vivo* exposure to TCDD decreased the ability of HSC to rescue irradiated mice. Interestingly, the numbers and function of these hematopoietic precursors are regulated in a circadian manner. Because many of the bHLH-PAS transcription factors are involved in the regulation of circadian physiology, we investigated whether disruption of normal AhR signaling following exposure to TCDD could alter the circadian rhythm of these cells. Six week old female C57BL/6 mice were given a single oral exposure to TCDD, and bone marrow was isolated and immunolabeled five days later. Flow cytometry revealed shifts in both the phase and magnitude of the daily cycle of HSCs, common myeloid progenitors, granulocyte-macrophage progenitors, and megakaryocyte-erythrocyte progenitors. In addition, the daily rhythm of functionally defined high proliferative potential-colony forming cells (HPP-CFC) was also shifted. Dual staining with 7-AAD and Pyronin Y revealed an alteration of the ratio of quiescent to cycling HSC following TCDD treatment. When HPP-CFC were exposed to TCDD *in vitro*, their ability to respond to assay conditions was either inhibited or enhanced in a maturation phase- and dose-dependent manner. It therefore appears that while TCDD may directly impact the proliferative capacity of hematopoietic precursors *in vitro*, the net effect following an *in vivo* exposure is more complex due to additional levels of regulation. This research was supported by NIH Grant ES04862, Training Grant ES07026, and Center Grant ES01247.

INTERFERON-GAMMA REVERSES TCDD-MEDIATED SUPPRESSION OF THE IGM ANTIBODY RESPONSE AND ATTENUATES CYP1A1 INDUCTION.

**N. Kaminski**<sup>2,3</sup>, B. Kim<sup>1</sup>, R. Crawford<sup>2</sup> and M. Holsapple<sup>2</sup>. <sup>1</sup>*Biological Sciences and Immunomodulation Research Center, University of Ulsan, Ulsan, South Korea*, <sup>2</sup>*Pharmacology and Toxicology, Michigan State University, East Lansing, MI* and <sup>3</sup>*Center for Integrative Toxicology, Michigan State University, East Lansing, MI*.

2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) is a potent suppressor of the primary immunoglobulin(M) response. The molecular mechanism is dependent on the aryl hydrocarbon receptor and involves a disruption of B cell differentiation into plasma cells. We have previously reported that direct addition of interferon (IFN) $\gamma$  to splenocyte cultures attenuated TCDD-mediated suppression of the anti-sRBC IgM antibody forming cells response (AFC). The objective of the present study was to further characterize the effect of IFN $\gamma$  on mRNA levels for the Ig  $\mu$  heavy chain (IgH), kappa light chain (Igk) and J chain (Igl) as well as determine whether the ability to antagonize suppression by TCDD of the anti-sRBC IgM AFC response was shared by other forms of IFN. Direct addition of TCDD (30 nM) to spleen cell cultures produced a significant suppression (58%) in the anti-sRBC IgM response and a decrease in mRNA levels for IgH (37%), Igk (36%) and IgI (68%), when compared to vehicle control. However, in splenocytes co-treated with TCDD (30 nM) and IFN $\gamma$  (100 Units/ml), complete reversal of both the TCDD-mediated suppression on the anti-sRBC IgM AFC response and inhibition of mRNA levels for IgH, Igk and IgI was observed. Likewise, TCDD-mediated induction of CYP1A1 mRNA levels was diminished (50%) by IFN $\gamma$ . Time of addition studies revealed that IFN $\gamma$  had to be present in culture within the first 24 h after antigen sensitization to attenuate the TCDD-mediated suppression of the AFC response. No attenuation of the TCDD-mediated suppression of the anti-sRBC IgM AFC response was observed with IFN $\alpha$  or IFN $\beta$ . These results suggest that signaling induced through the IFN $\gamma$  receptor interfere with the AhR signaling cascade. (Supported in part by NIH ES02520, P42 ES04911, and University of Ulsan, Korea).

MAP KINASES, BUT NOT CALCIUM OR REACTIVE OXYGEN SPECIES, ARE INVOLVED IN PPAR $\gamma$  AGONIST-INDUCED PRO/PRE-B CELL APOPTOSIS.

D. Liu, J. Emberley, D. Sherr and J. Schlezinger. *Environmental Health, Boston University School of Public Health, Boston, MA*.

Peroxisome proliferator-activated receptor  $\gamma$  (PPAR $\gamma$ ) is expressed highly in the immune system and influences multiple aspects of immune function. We have shown that the high-affinity PPAR $\gamma$  ligand GW7845 activates the stress kinase (p38 MAPK and JNK) pathway and that this pathway contributes to GW7845-induced apoptosis in pro/pre-B cells. Here, we have extended our studies to investigate kinase activation by other PPAR $\gamma$  agonists, to examine the mechanism of p38 MAPK activation, and to determine how p38 MAPK interfaces with the caspase cascade. Treatment of a non-transformed murine pro/pre-B cell line (BU-11) with the synthetic PPAR $\gamma$  agonist GW7845 (40  $\mu$ M) or the endogenous PPAR $\gamma$  agonist 15-deoxy- $\Delta^{12,14}$ -prostaglandin J<sub>2</sub> (15d-PGJ<sub>2</sub>) (10  $\mu$ M), strongly induce p38 MAPK phosphorylation and p38 MAPK kinase activity. Pre-treatment with the p38 MAPK inhibitor PD169316 (5  $\mu$ M) prevented PPAR $\gamma$  agonist-induced apoptosis and reduced p38 MAPK phosphorylation, JNK phosphorylation, NF- $\kappa$ B-DNA binding, cytochrome c release and caspase-3 activation. However, the calcium chelator BAPTA and the antioxidant ebselen had minimal effects on kinase activation or caspase activation. These data support the conclusion that PPAR $\gamma$  agonists induce early B cell apoptosis through a PPAR $\gamma$ - and p38 MAPK-dependent signaling cascade. This research was supported by: RO1-ES06086, P01-ES11624

CASPASE-8 IS NOT THE MOST PROXIMAL CASPASE INVOLVED IN DMBA-INDUCED BONE MARROW B CELL APOPTOSIS.

D. H. Sherr, H. Ryu, J. K. Emberley, L. L. Allan and J. J. Schlezinger. *Environmental Health, Boston University, Boston, MA*.

Environmental PAHs are both carcinogenic and immunosuppressive. We have shown that 7, 12-dimethylbenz[a]anthracene (DMBA) induces a loss of bone marrow cellularity *in vivo* and bone marrow B cell apoptosis *in vitro*. Here we examine the caspase pathway activated during DMBA-induced apoptosis in primary bone marrow pro-B cells and in a non-transformed pro/pre-B cell line (BU-11). Significant apoptosis was induced within 10 hours in both primary pro-B cells and in the BU-11 cell line when cultured with bone marrow stromal cells and exposed to 1  $\mu$ M DMBA. Apoptosis was accompanied by the activation of caspase-3 and was suppressed by a caspase-3 inhibitor. DMBA treatment also activated caspase-8, although several results indicated that caspase-8 was neither the most proximal caspase activated nor was its activation dependent on TNF receptors or on Fas: 1)

DMBA did not induce TNF- $\alpha$ , TNF- $\beta$ , or LT- $\beta$  mRNA and/or protein expression in bone marrow stromal cells, 2) DMBA-induced apoptosis was not mitigated in BU-11 cells cultured with TNF- $\alpha^{-/-}$  bone marrow stromal cells, 3) the level of primary pro-B cell apoptosis was not affected by deletion of TNF- $\alpha$ , TNFR1/R2, or Fas in the B cells. In contrast, caspase-8 activation appeared to be caspase-3-dependent since it occurred only after caspase-3 activation and was suppressed by a caspase-3-specific inhibitor. Results presented here demonstrate that the BU-11 system is an accurate model of DMBA-induced primary pro-B cell apoptosis and that caspase-8 is likely activated by a more proximal caspase (e.g. caspase-3) and not by a TNFR family member. This work was supported by RO1-ES06086 and P01-ES11624.

THE ROLE OF PAH METABOLISM IN AHR-DEPENDENT INHIBITION OF HUMAN B CELL PROLIFERATION.

L. L. Allan<sup>1,2</sup>, J. J. Schlezinger<sup>2</sup>, M. Shansab<sup>2</sup> and D. H. Sherr<sup>2</sup>. <sup>1</sup>*Microbiology, Boston University School of Medicine, Boston, MA* and <sup>2</sup>*Environmental Health, Boston University School of Medicine, Boston, MA*.

Polycyclic aromatic hydrocarbons (PAHs), ubiquitous environmental hydrocarbons, are immunosuppressive and carcinogenic AhR ligands. Previous studies indicated that activation of human B cells with surrogate T cell signals, CD40 ligand (CD40L) and IL-4, profoundly up-regulates AhR expression and activity. This led to the hypothesis that such activated B cells would be more sensitive to environmental AhR agonists, potentially through increased activity of the AhR-dependent CYP1A1 enzyme and agonist metabolism. To test this directly, CD40L / IL-4-activated human B cells were treated with AhR ligands that are either readily metabolizable (B[a]P) or relatively non-metabolizable (TCDD), and then evaluated for CYP1A1 induction and changes in cell function. Treatment with either AhR ligand significantly increased CYP1A1 expression. However, we found that only B[a]P significantly reduced the proliferation of activated B cells, whereas TCDD did not. Thus, AhR activation per se is not entirely sufficient for the suppression of B cell growth, instead, AhR-induced CYP1A1-mediated metabolism of the agonist B[a]P is also responsible for growth suppression. This hypothesis was supported by subsequent observations: 1) 1-PP, a CYP1A1 inhibitor, completely protected CD40L IL-4-activated B cells from B[a]P-induced growth suppression; 2) direct application of the B[a]P metabolites B[a]P-7, 8-dihydrodiol or BPDE potently inhibited B cell proliferation; 3) growth inhibition induced by the B[a]P-7, 8-dihydrodiol, which is metabolized into BPDE by CYP1A1, was inhibited by 1-PP while 1-PP had no effect on BPDE-induced growth inhibition. These data suggest that expansion of activated B cell clones are particularly sensitive to metabolizable AhR ligands, such as B[a]P, and that this sensitivity is mediated by the AhR-induced CYP1A1-mediated generation of reactive end products, such as BPDE, that are both carcinogenic and immunosuppressive. (Supported by RO1-ES06086 and P01-ES11624.)

DISTINCT EFFECTS OF TGF-B1 ON THE SURVIVAL AND DIVISION OF CD4+ AND CD8+ T CELLS: A ROLE FOR T CELL INTRINSIC SMAD3.

S. C. McKarns and R. H. Schwartz. *Laboratory of Cellular and Molecular Immunology, National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD*.

TGF-b1 is critical for maintaining T cell immune homeostasis as illustrated by multi-organ inflammation in mice deficient in TGF-b1 signaling, yet the cellular targets and molecular details remain poorly understood. TGF-b1 signals through transmembrane receptor serine/threonine kinases to activate multiple intracellular effector molecules, including the cytosolic signaling transducers of the Smad protein family. Using a loss-of-function model to define the role of TGF-b1-induced Smad3 signaling in the regulation of CD4+ and CD8+ T cell expansion, we show found that TGF-b1 inhibits the entry of CD4+ and CD8+ T cells into the cell cycle as well as their progression through subsequent rounds of divisions. However, Smad3 was essential for TGF-b1 to inhibit TCR-induced division of CD4+ but not CD8+ T cells. Not all CD8+ T cell responses to TGF-b1 are Smad3-independent as demonstrated by an inability of TGF-b1 to suppress IL-2 production in both Smad3-/- CD4+ and CD8+ T cells. Neutralization of IL-2 signaling did not alter the nonresponsiveness of Smad3-/- CD4+ T cells to TGF-b1-induced growth arrest. The Smad3-dependent effects of TGF-b1 were all T cell intrinsic as they were reproduced in purified CD4+ and CD8+ T cells stimulated with plate-bound anti-CD3 + anti-CD28. We also found that Smad3-/- CD8+ T cells were more susceptible to TCR-induced apoptosis and exogenous TGF-b1 partially rescued this CD8+ selective death through a Smad3-independent pathway. Collectively, these findings establish for the first time that TGF-b1 discriminatory regulates CD4+ and CD8+ T cell expansion by signaling through distinct intracellular pathways.

EXPOSURE TO TCDD AUGMENTS CD25 EXPRESSION ON RECENTLY ACTIVATED T CELLS.

C. J. Funatake, L. B. Stepan and N. I. Kerkvliet. *Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR.*

TCDD is a potent immunosuppressive chemical that mediates its immunotoxic effects through binding to the AhR, a ligand-activated transcription factor that is expressed in both CD4<sup>+</sup> and CD8<sup>+</sup> T cells. Previous studies have shown that the distal promoter of the *interleukin (IL)-2* gene has three AhR-response elements (ARE) and that IL-2 production may be enhanced by TCDD in activated T cells. Because IL-2 mediates both survival and death signals in activated T cells, changes in the IL-2 signaling pathway by TCDD may play an important role in its immunotoxicity. IL-2 signaling in T cells is regulated by the expression of the high-affinity IL-2 receptor, CD25. CD25 itself is dose-dependently upregulated by IL-2. To determine if TCDD exposure alters expression of CD25, we used flow cytometry to measure CD25 on CD4<sup>+</sup> and CD8<sup>+</sup> donor T cells during the first five days of an acute graft-versus-host response. F1 host mice were treated with vehicle or TCDD one day prior to donor T cell injection. TCDD exposure significantly increased the percentage of CD4<sup>+</sup> and CD8<sup>+</sup> donor T cells that expressed CD25, with a maximum increase observed on day 2. Using CFSE to track cell division, the increased percentage of CD25<sup>+</sup> T cells was apparent by the second cell division and was maintained through four divisions. The median expression level of CD25 also increased with each round of cell division in TCDD-treated mice. When donor T cells were obtained from AhR<sup>-/-</sup> mice, TCDD did not alter CD25 expression on CD4<sup>+</sup> T cells whereas a small increase was still observed in CD8<sup>+</sup> T cells. When CD4<sup>+</sup> and CD8<sup>+</sup> donor cells from AhR<sup>+/+</sup> and AhR<sup>-/-</sup> mice were purified and recombined, the induction of CD25 expression on CD4<sup>+</sup> T cells was driven by the AhR in CD4<sup>+</sup> T cells. These results are consistent with an ARE-mediated increase in IL-2 production in CD4<sup>+</sup> T cells acting in an autocrine or paracrine fashion to enhance CD25 expression on CD4<sup>+</sup> T cells. AhR-mediated regulation of CD25 expression on the CD8<sup>+</sup> T cells was not clearly delineated. This work was supported by NIH grant P01ES00040.

Δ<sup>9</sup>-TETRAHYDROCANNABINOL (Δ<sup>9</sup>-THC) ELICITS A CALCIUM ELEVATION IN T CELLS THROUGH THE TRPC CHANNELS.

G. Rao<sup>1,2</sup> and N. E. Kamienski<sup>1,2</sup>. <sup>1</sup>*Pharmacology and Toxicology, Michigan State University, East Lansing, MI* and <sup>2</sup>*Center for Integrative Toxicology, Michigan State University, East Lansing, MI.*

Cannabinoid compounds have been widely reported to alter immune function. Previous studies from this laboratory have shown T cells to be a sensitive target to cannabinoid treatment. The objective of the present studies was to examine the effect of Δ<sup>9</sup>-THC, the primary psychoactive constituent in *Cannabis sativa*, on the regulation of intracellular calcium ([Ca<sup>2+</sup>]<sub>i</sub>) in HPB-ALL cells, a human CB2 expressing T cell line. Δ<sup>9</sup>-THC (10-12.5 μM) induced a robust rise in [Ca<sup>2+</sup>]<sub>i</sub> in resting HPB-ALL cells, which was antagonized upon pretreatment with the CB2 receptor antagonist, SR144528. Studies performed in the absence of extracellular calcium revealed that the Δ<sup>9</sup>-THC-mediated elevation in [Ca<sup>2+</sup>]<sub>i</sub> was due to influx of extracellular calcium. Furthermore, pretreatment with thapsigargin to deplete intracellular calcium pools did not abrogate the Δ<sup>9</sup>-THC-mediated elevation in [Ca<sup>2+</sup>]<sub>i</sub>, indicating that Δ<sup>9</sup>-THC-mediated rise in [Ca<sup>2+</sup>]<sub>i</sub> was independent of calcium stores. Pretreatment of cells with inhibitors of calcium channels revealed that the Δ<sup>9</sup>-THC-mediated elevation in [Ca<sup>2+</sup>]<sub>i</sub> was more sensitive to the receptor-operated calcium channel blocker, SKF96365, than to the store-operated calcium channel blocker, LaCl<sub>3</sub>. Recently, several members of the TRPC (transient receptor potential canonical) subfamily of cation channels have been implicated in the formation of store- and/or receptor-operated calcium channels. RT-PCR analysis for the TRPC channel subfamily demonstrated that HPB-ALL cells express TRPC1, a channel gated by diacylglycerol (DAG). Treatment of HPB-ALL cells with OAG, a DAG analog, led to a rise in [Ca<sup>2+</sup>]<sub>i</sub>. Moreover, when cells were sequentially treated with OAG followed by Δ<sup>9</sup>-THC, Δ<sup>9</sup>-THC failed to elicit a further rise in [Ca<sup>2+</sup>]<sub>i</sub>. Together these data suggest that Δ<sup>9</sup>-THC elicits a cannabinoid receptor-dependent elevation in [Ca<sup>2+</sup>]<sub>i</sub> in resting T cells independently of calcium store depletion, putatively through the OAG-gated TRPC1 channels. (Supported by NIH grants DA07908 and DA016828)

SODIUM ARSENITE DECREASES PROLIFERATION IN PHA-STIMULATED LYMPHOCYTES, BY INHIBITING INTERLEUKIN-2 EXPRESSION AND SECRETION.

P. C. Conde-Moo, L. C. Acosta-Saavedra, M. E. Cebrian and E. S. Calderon-Aranda. *Toxicologia, Cinvestav, Mexico, DF, Mexico.*

Evidence from human and animal models have shown that arsenic (As) induces suppression of T lymphocytes. We have previously shown that sodium arsenite inhibited phytohemagglutinin (PHA)-induced proliferation in murine T lympho-

cytes (Goytia-Acevedo et al., 2003) probably by a mechanism mediated by high intracellular Ca<sup>2+</sup> [Ca<sup>2+</sup>]<sub>i</sub> level. On the other hand, it has been shown that sodium arsenite reduces secretion of IL-2 in human lymphocytes and the expression of its receptor (Yu et al., 1998); however the effect of arsenite on IL-2 gene transcription has not been evaluated. Thus, we evaluated, the effect of sodium arsenite on IL-2 mRNA expression by RT-PCR, and IL-2 secretion by ELISA in PHA-stimulated spleen T lymphocytes obtained from female C57BL/6 mice. T lymphocyte activation was measured through CD69 expression by cytofluorometry, and ERK1/2 phosphorylation was determined by immunoblotting. Sodium arsenite (1 and 10 μM) significantly inhibited IL-2 mRNA expression and IL-2 secretion in a concentration-dependent manner in PHA-stimulated lymphocytes (24 h). Interestingly, in PHA-stimulated lymphocytes (4 h), sodium arsenite (1 and 10 μM) significantly inhibited (75%) CD69 expression. These results were in agreement with our previous data showing that sodium arsenite (1 and 10 μM) inhibited PHA-induced ERK1/2 phosphorylation in a concentration dependent manner (Conde-Moo et al., 2003). Our results suggest that sodium arsenite modulate IL-2 gene expression probably by interfering with ERK1/2 signaling, and this may be related, at least partially, to the inhibition of PHA-induced proliferation of T lymphocytes. Further research on the relationships between As-induced [Ca<sup>2+</sup>]<sub>i</sub> imbalance and the ability of As to modulate IL-2 gene expression is needed. This work was partially supported by the Mexican Council for Science and Technology (Conacyt 34508-M).

MECHANISMS OF 4-HYDROXYNONENAL-HNE (LIPID HYDROPEROXIDE) INDUCED APOPTOTIC DEATH IN CD4<sup>+</sup> T LYMPHOCYTES: RELEVANCE TO HIV AND HCV PATHOGENESIS.

W. Chang<sup>1</sup>, R. Sahoo<sup>2</sup>, S. Srivastava<sup>2</sup>, C. J. McClain<sup>2,1</sup>, T. S. Chen<sup>1</sup> and S. S. Barve<sup>2,1</sup>. <sup>1</sup>*Pharmacology & Toxicology, University of Louisville, Louisville, KY* and <sup>2</sup>*Medicine, University of Louisville, Louisville, KY.*

During the process of lipid peroxidation, several reactive low-molecular weight products are formed, including reactive aldehydes as 4-hydroxynonenal (HNE). 4-HNE, one of the major aldehydic products of the peroxidation of membrane ω-6 polyunsaturated fatty acids, has been suggested to contribute to oxidant stress mediated cell injury. 4-HNE is associated with multiple pathophysiological conditions causing immune dysfunction, such as HIV and HCV infection. CD4<sup>+</sup> T lymphocytes are the central regulators of both cell-mediated and humoral immune responses and loss of their survival can affect multiple immune functions. Since both lipid peroxidation and loss of CD4<sup>+</sup> T lymphocytes are observed during the clinical progression of HIV and HCV infection, the present work was undertaken to examine the effects of 4-HNE on CD4<sup>+</sup> T cell survival. The data obtained showed that exposure of Jurkat CD4<sup>+</sup> T cells to 4-HNE induces significant loss of survival due to the induction of apoptotic cell death. Further investigation showed that 4-HNE down-regulates Akt kinase activation, and results in enhanced FasL expression (mRNA and protein). In turn enhanced FasL expression led to the induction of the death initiating signaling complex (DISC) as documented by the correspondent decrease in c-FLIPs protein and caspase-8 activation. These data identify the pathogenic molecular mechanism(s) induced by 4-HNE in CD4<sup>+</sup> T cells and are consistent with a potential role of lipid peroxidation-derived products in programmed cell death. Importantly, this work has begun to elucidate the potential role of lipid peroxidation (4-HNE) in the pathogenesis of immunosuppressive disorders involving CD4<sup>+</sup> T cell depletion such as HIV and HCV infection and can lead to the development of the much needed anti-oxidant therapies.

**1877**

MECHANISMS OF LEAD-INDUCED IMMUNOTOXICITY: THE ROLE OF IL-2 IN ALLO-ENHANCEMENT.

S. M. Hueber, D. G. Farrer and M. J. McCabe. *Environmental Medicine, School of Medicine and Dentistry, University of Rochester, Rochester, NY.*

Despite great efforts to remove lead (Pb) from the environment it continues to be implicated in various adverse health effects. Pb is a documented immunotoxicant and, T cell-mediated processes are believed to be particularly sensitive to it. Using an allogeneic mixed lymphocyte culture system, which measures T cell proliferation in response to peptide/MHC complexes, we have observed marked enhancement (approximately 3 fold) of T cell proliferation in the presence of Pb. Since interleukin 2 (IL-2) is an autocrine growth factor that drives T cell proliferation, we sought to determine whether an increase in IL-2 production was responsible for this allo-enhancement. The kinetics (days 1-6) of IL-2 production in control versus Pb-treated allo-MLC were measured by bioassay. These experiments revealed that the initial production of IL-2 was not affected by Pb; however, IL-2 levels declined more rapidly in the Pb-exposed splenocyte cultures compared to control. This more rapid decline in IL-2 levels raised the issue of whether subpopulations of cells were utilizing IL-2 and if this utilization of IL-2 served as the basis of increased proliferation. To address this issue, splenocytes and CD4<sup>+</sup> T cells set up in allo-MLCs were cultured in the presence and absence of Pb as well as with neutralizing levels of anti-IL-2. Anti-IL-2 added on day 0 markedly suppressed T cell proliferation in both

control and Pb-treated allo-MLC. Anti-IL-2 added on day 3 partially attenuated, but did not ablate, the Pb-induced enhancement of allo-reactive T cell proliferation; suggesting that allo-enhancement is both IL-2 dependent and independent. Due to the fact that Pb did not cause an increase in IL-2 levels and that IL-2 dependent proliferation is not the major basis of allo-enhancement, another cytokine IL-4, was considered. Pb allo-enhancement was not affected by anti-IL-4. Thus, allo-enhancement due to Pb exposure is not a result of increased IL-2 production or the work of a common Th2 cytokine.

**1878 ENFUVIRTIDE: *IN VITRO* STUDIES OF PUTATIVE IMMUNOTOXIC EFFECTS RELATED TO ACTIVATION OF N-FORMYL PEPTIDE RECEPTORS.**

F. Regenass<sup>1</sup>, M. Adibzadeh<sup>1</sup>, T. D. Steele<sup>2</sup> and H. Kropshofer<sup>1</sup>. <sup>1</sup>Nonclinical Drug Safety, Hoffmann-LaRoche, Inc., Basel, Switzerland and <sup>2</sup>Nonclinical Drug Safety, Hoffmann-LaRoche, Inc., Nutley, NJ. Sponsor: A. Braen.

*In vitro* studies suggest enfuvirtide (ENF) may suppress monocyte IL-12 secretion by activating N-formyl-peptide receptors (FPRs). If seen *in vivo*, this effect could increase the susceptibility of ENF-treated HIV patients to opportunistic infections. This series of studies examined potential FPR-related immunomodulatory effects of ENF *in vitro*. Methods: To assess the effect of ENF on cytokine secretion by human monocytes and dendritic cells (DCs), purified cell fractions were incubated with varying concentrations of ENF, N-formyl-methionyl-leucyl-phenylalanine (fMLP; + control) or TPI (neg. control). Cells were stimulated with IFN- $\gamma$  + fixed *S. aureus* or LPS. After 24 hrs, culture supernatants were assessed for IL-12 p70 and IL-10 levels. Human neutrophils were pre-treated with ENF, TPI or GM-CSF (+ control), or untreated, before activation with LPS or LPS + IFNg. Levels of IL-6, IL-8, IL-10 & TNF $\alpha$  in the supernatant were measured using a human inflammation CBA assay. Similar or analogous cytokine assessments were performed on mice and rat neutrophils. To assess DC maturation, immature DCs were cultured with fMLP or ENF then stimulated into maturation with LPS or TNF $\alpha$ . The expression of FPRs and surface markers characteristic of mature DCs was quantified using flow cytometry. Results: ENF did not significantly affect secretion of IL-12 p70 or IL-10 by FPR-positive human monocytes. Similar results were obtained for mature, FPR-negative DCs. However, monocyte IL-12 secretion declined when an artificial pH drop was induced in the with acetic acid, a solvent for ENF. ENF did not appreciably affect secretion of IL-8, IL-6 or TNF $\alpha$  by human neutrophils, or cytokines from mouse or rat neutrophils. ENF did not induce up-regulation of DC surface markers, CD83 or co-stimulatory molecules, suggesting that ENF does not interfere with DC maturation. Conclusion: This study suggests that ENF is unlikely to exert an immunosuppressive effect on the key cells of the innate or adaptive immune system.

**1879 INFLAMMATORY RESPONSES IN MOUSE RAW264.7 MACROPHAGES CAN BE ALTERED BY INTERACTIONS BETWEEN INDOOR AIR MICROBES IN SIMULTANEOUS EXPOSURE.**

P. Penttinen<sup>1,2</sup>, K. Huttunen<sup>1</sup>, J. Pelkonen<sup>2,3</sup> and M. Hirvonen<sup>1</sup>. <sup>1</sup>Department of Environmental Health, National Public Health Institute, Kuopio, Finland, <sup>2</sup>University of Kuopio, Kuopio, Finland and <sup>3</sup>Kuopio University Hospital, Kuopio, Finland. Sponsor: M. Viluksela.

Indoor air exposure in moisture-damaged buildings consists of a complex mixture of fluctuating concentrations of various microbial species and other indoor air pollutants. Adverse health effects in such environments are usually associated with inflammatory response. To elucidate the influence of microbial interactions on inflammatory responses, the effects of simultaneous exposure with modified proportions of actinomycete *Streptomyces californicus* and fungus *Stachybotrys chartarum* were studied in mouse RAW264.7 macrophages. Cells were co-exposed for 24 hours to the total dose of  $3 \times 10^5$  spores/ml in five different proportions (*Str. californicus*:*S. chartarum* 10:1; 5:1; 1:1; 1:5; 1:10). In addition, the macrophages were exposed to the spores of these microbes separately at the respective doses. The production of cytokines (MIP2, IL-6 and TNF $\alpha$ ) was measured immunochemically, and nitric oxide (NO) was assayed by the Griess method. When the co-exposure contained more of the fungal (*S. chartarum*) than the bacterial (*Str. californicus*) spores, even more than 3-fold synergistic increase in all the measured cytokine concentrations was detected compared to the sum response caused by these microbial spores separately. When the co-exposure contained an equal number (1:1) or more (10:1) of bacterial than fungal spores, synergistic increase was only seen in the MIP2 concentrations (60 % and 30 % increase respectively). Instead, the antagonistic NO production was detected when co-exposure contained more bacterial than fungal spores (5:1) compared to the sum response induced by the microbial spores separately (40 % decrease). The present results revealed that mutual proportion of fungal and bacterial spores in simultaneous exposure affect the nature of their interactions leading to increased or suppressed production of inflammatory mediators in RAW264.7 macrophages.

**SIMULTANEOUS EXPOSURE TO MOLDY HOUSE MICROBES *STREPTOMYCES CALIFORNICUS* AND *STACHYBOTrys CHARTARUM* CAUSE SYNERGISTIC INFLAMMATORY RESPONSES IN HUMAN WHOLE BLOOD CELL CULTURE.**

M. Roponen, K. Huttunen, M. Lappalainen and M. Hirvonen. Department of Environmental Health, National Public Health Institute, Kuopio, Finland. Sponsor: M. Viluksela.

Microbial exposure in moisture damaged building consists of a complex mixture of compounds, including bacteria, fungi and their metabolites. Synergistic interactions between moldy house microbes *Streptomyces californicus* and *Stachybotrys chartarum* have been recently shown in mouse macrophages *in vitro*. In this study, we measured production of tumor necrosis factor alpha (TNF- $\alpha$ ), interferon-gamma (IFN- $\gamma$ ) and interleukin-6 (IL-6) in human whole blood cell culture after 24 hour exposure to spores of *S. chartarum* and two microbial toxins (vomitoxin and valinomycin) alone and together with spores of *Str. californicus*. Lipopolysaccharide (LPS) was used as a positive control. Data are reported as mean $\pm$ SD pg/10<sup>6</sup> leukocytes. Spores of *Str. californicus* ( $5 \times 10^4$  spores/ml) were alone capable of inducing production of IFN- $\gamma$  ( $160 \pm 100$ ), TNF- $\alpha$  ( $500 \pm 250$ ) and IL-6 ( $2100 \pm 600$ ). Co-exposure to *Str. californicus* ( $5 \times 10^4$  spores/ml) together with *S. chartarum* ( $10^5$  spores/ml) caused a synergistic (1.7-fold) increase in the production of IL-6. Also LPS (0.1 mg/ml) alone triggered TNF- $\alpha$  and IL-6 responses in whole blood cell culture ( $1400 \pm 400$  and  $6100 \pm 1200$ , respectively) and simultaneous exposure with valinomycin (10 ng/ml and 50 ng/ml) caused a slight increase in the production of these cytokines. In conclusion, moldy house microbe *Str. californicus* evoked inflammatory responses in human blood cells *ex vivo* and these responses were potentiated by *S. chartarum*. Current results are in line with *in vitro* findings and support the view that the synergistic interactions between different exposure agents may explain the health complaints already at the relatively low microbial concentrations in moisture damaged buildings.

**1881**

**THE BIOLOGICAL ACTIVITY OF GRAM-POSITIVE BACTERIA *STREPTOMYCES CALIFORNICUS* CANNOT BE COMPLETELY INHIBITED WITH LPS -INHIBITOR PMX.**

K. Huttunen, A. Halinen and M. Hirvonen. Department of Environmental Health, National Public Health Institute, Kuopio, Finland. Sponsor: M. Viluksela.

The microbial characteristics of airborne particulate matter (PM) are poorly known. Studies on microbial components have mainly concentrated on the microbial cell wall fragment lipopolysaccharide (LPS). However, components of other microbes in PM such as gram-positive bacteria *Streptomyces californicus* may have equally potent effects. Thus, if the activity of the biological fraction of the PM is evaluated only by using LPS inhibitors such as Polymyxin B (PMX), the remaining effects may be erroneously interpreted to originate from inorganic fraction of the PM while it can actually be the biological fraction other than LPS causing the effects. To test this hypothesis, we studied the effects of LPS inhibitor PMX on the production of inflammatory mediators induced by spores of gram-negative bacteria *Pseudomonas fluorescens* ( $10^5$  microbes/ml) and gram-positive bacteria *Streptomyces californicus* ( $10^6$  microbes/ml). Mouse macrophages (RAW264.7) were exposed to either of these microbes with increasing doses (0, 5-20  $\mu$ g/ml) of PMX. Inflammatory mediators were measured from the cell culture medium; cytokines (TNF $\alpha$  and IL-6) immunochemically and nitric oxide (NO) by Griess-method. Viability of the cells was determined by using the MTT-test. Exposure to the spores of *P. fluorescens* increased markedly the production of all inflammatory mediators in mouse cells. PMX inhibited dose-dependently the production of these markers, e.g. the production of IL-6 decreased  $93 \pm 4$  % from  $2200 \pm 240$  pg/ml. The spores of *S. californicus* increased the production of IL-6, TNF $\alpha$  and NO as well, but PMX was not able to inhibit totally the production of these mediators; the production of IL-6 decreased  $61 \pm 9$  % from  $1400 \pm 270$  pg/ml. Altogether, these data indicate that immunotoxic effect induced by *Streptomyces californicus* in mouse macrophages cannot be completely blocked by PMX. This should be taken into account when considering the role of biologically active components of PM in immunotoxic activity.

**1882**

***IN VITRO* AND *IN VIVO* IMMUNOLOGIC RESPONSES BY POLYACRYLAMIDE NANOPARTICLES TO MH-S CELLS AND RATS.**

R. J. Schneider<sup>1</sup>, R. Reddy<sup>2</sup> and M. A. Philbert<sup>1</sup>. <sup>1</sup>Environmental Health Sciences, University of Michigan, Ann Arbor, MI and <sup>2</sup>Molecular Therapeutics, Inc., Ann Arbor, MI.

Nano-scale technologies are currently being employed by a variety of industries and incorporated into pharmaceuticals, electronics and cosmetics. The development of nanoparticles for enhanced drug delivery offers the potential for increased speci-

ficiency of currently used pharmaceuticals, while decreasing the total dose required. Polyacrylamide (PAA) nanoparticles are being developed for enhanced MR imaging, drug delivery, photodynamic therapy, and real time analysis of intracellular measurements at the level of a single cell. Evaluation of histopathologic changes and clinical chemistry provides strong evidence that PAA nanoparticles are well tolerated by rats at intravenous doses up to 500 mg/kg; while pharmacokinetic data implicates the reticular endothelial systems in the clearance of this material. To further investigate the cellular (macrophage) responses of a nano-scale polymer that has been accumulated by an immune cell, the mouse alveolar macrophage cell line, MH-S, was used to study the effect on cellular responses such as; viability, morphology, and the induction of cytokines and chemokines. Furthermore, tissue recruitment of antigen presenting cells (dendritic) was evaluated in liver and spleen. In culture, data suggests that the PAA nanoparticles are well tolerated by the MH-S cells. Scanning electron micrographs show changes in the morphology of MH-S cells at 24h and 48h with significant rounding and retraction of phagopodia suggesting effects on cellular adherence properties. Measurements of secreted TNF- $\alpha$  and MIP-1- $\alpha$  by MH-S were not detectable at significant levels by ELISA. Finally, fluorescently labeled nanoparticles were detected in hepatic but not splenic lymph nodes and positive staining for the dendritic cell marker, OX-62 was detected in liver but not spleen 14 days after exposure to PAA nanoparticles. These data suggest that PAA nanoparticles are targets for phagocytosis by macrophages and may elicit inflammatory responses *in vivo* and *in vitro*.

### 1883

#### IMPACT OF EXPOSURE TO JET A JET FUEL ON CYTOKINE PRODUCTION IN RAT LUNG MACROPHAGES.

D. L. Courson<sup>1</sup>, E. R. Wilfong<sup>1</sup>, J. R. Cunningham<sup>2</sup>, E. W. Johnson<sup>1</sup> and S. Lohrke<sup>1</sup>. <sup>1</sup>*Naval Health Research Center / Detachment EHE Laboratory, Wright-Patterson AFB, Fairborn, OH* and <sup>2</sup>*Wright State University, Fairborn, OH*.

A variety of adverse health effects have been reported in military and civilian fuel handlers which have been attributed to exposure to jet fuel mixed atmospheres. Many of the reported effects are similar to those produced by endotoxin (LPS). Both commercial and military fuel stores have been shown to be contaminated by LPS in addition to other microbial products. The nature and degree of contamination may be influenced by a variety of factors, including the age of the jet fuel, as lengthy storage conditions may allow for microbial growth to occur with a concomitant increase in LPS levels. In a previous study, we had utilized aged JP-8 jet fuel. Exposure of rat lung macrophages to this aged JP-8 led to a significant increase in production of the pro-inflammatory cytokines IL-6 and TNF- $\alpha$ , compared to the control group. Filtration of the JP-8 prior to exposure resulted in a reduction in the levels of these cytokines, but the reduction was not statistically significant. Since the length of time the JP-8 was allowed to age may not accurately reflect what typically occurs under real world conditions, we carried out another set of exposures, but with fresh jet fuel. In place of JP-8, we utilized Jet A, which differs from JP-8 in that it lacks the additive packages present in JP-8. In this study, we exposed cultured rat lung macrophages to samples of Jet A, samples of Jet A that had been filtered to remove microbial contamination including LPS, and filtered Jet A which had been spiked with a known quantity of LPS. We evaluated the spent media for levels of IL-1 $\beta$ , IL-6 and TNF- $\alpha$  cytokines in the spent media. Our preliminary findings have been similar to what was observed with the JP-8 exposures, with a significant increase in levels of the pro-inflammatory cytokines IL-6 and TNF- $\alpha$ , in all three JP-A groups, as compared to the control group. Filtration of the Jet A appears to have resulted in a small reduction in levels of these cytokines which was not statistically significant.

### 1884

#### MACROPHAGES ARE THE PROXIMAL TARGET CELL IN LEAD-INDUCED IMMUNOTOXICITY.

D. G. Farrer and M. J. McCabe. *Environmental Medicine, School of Medicine and Dentistry, University of Rochester, Rochester, NY*.

Lead (Pb) is a persistent environmental contaminant and a known immunotoxin. Although Pb is immunosuppressive *in vivo*, many indices of immune function *in vitro* are, paradoxically, enhanced by Pb. In particular, CD4 $^{+}$  T cell proliferation in mixed lymphocyte culture (MLC) is markedly enhanced. The goal of this study was to identify Pb's target cell in MLC in which BALB/c-derived CD4 $^{+}$  T cells responded to allo-antigen presenting cells (APC). We found that Pb allo-enhancement was abrogated when APCs were paraformaldehyde-fixed prior to use as stimulators in MLC. Also, CD4 $^{+}$  T cell proliferation in response to the T cell mitogen, concanavalin A, was not enhanced with Pb treatment. These data ruled out a direct effect of Pb on CD4 $^{+}$  T cells. We next sought to identify which APC type mediated Pb allo-enhancement. Using magnetic bead separation and adherence properties of 3 APC types, B cells, macrophages, and dendritic cells (DC) were used, alone, or in combination as stimulators in MLC. Allogeneic B cells, alone, were not able to stimulate enhanced proliferation in alloreactive CD4 $^{+}$  T cells with Pb treatment. Pb allo-enhancement was restored when CD11c-enriched, syngeneic splenocytes were added to these cultures. Of the CD11c-enriched splenocytes, the adherent fraction

appeared to be most critical for Pb allo-enhancement suggesting that DC or macrophages were the proximal target of Pb. Based on differential adherence properties between macrophages and DC, we suspect that the macrophage is more responsible for the allo-enhancing effects of Pb. The results of these experiments suggest a scenario wherein enhanced cross-priming of syngeneic macrophages with allogeneic B cells is the underlying bases of Pb allo-enhancement. These findings implicate the macrophage as a key cellular target in Pb immunotoxicity, and begin to define the mechanism(s) whereby Pb exerts deleterious effects on T cell function. Although speculative, we envision that this scenario may have implications in transplantation immunology.

### 1885

#### WOOD DUST-INDUCED PULMONARY INFLAMMATION IN MICE.

J. Maatta, M. Lehto, M. Leino, S. Tillander, H. Haataja, K. Savolainen and H. Alenius. *Department of Industrial Hygiene and Toxicology, Finnish Institute of Occupational Health, Helsinki, Finland*.

In addition to nasal and sino-nasal adenocarcinomas, wood dust exposure can induce nonmalignant, mainly respiratory diseases such as asthma and chronic bronchitis. In the present study, we have elucidated the mechanisms by which exposure to wood dust induces inflammatory responses in murine lungs. BALB/c mice were exposed to intranasally administered birch or oak dusts twice a week for three weeks. TiO<sub>2</sub> and LPS were used as controls. Inflammatory cell infiltration was characterized from bronchoalveolar lavage (BAL) fluid. Cytokine, chemokine, and chemokine receptor mRNA expression in lung tissue was assessed by real time PCR. Bronchial responsiveness to methacholine was determined by whole body plethysmography. Intranasal installation of birch or oak dusts elicits in mice influx of inflammatory cells to the lungs. Lymphocytes dominated after oak dust exposure, whereas eosinophil infiltration was higher after birch dust exposure. Infiltration of inflammatory cells was associated with an increase in the mRNA levels of several cytokines, chemokines, and chemokine receptors in lung tissue. Oak dust appeared to be a more potent inducer of these inflammatory mediators than birch dust. Methacholine induced bronchial responsiveness was not altered significantly after wood dust installation. Our findings suggest that exposure to wood dust may significantly influence development of inflammatory process in the airways by modulating the expression of proinflammatory cytokines and chemokines. Supported by the EU 5th Framework Programme Grant QLK4-2000-00573.

### 1886

#### ATRAZINE-INDUCED INHIBITION OF NK-CELL MEDIATED CYTOTOXICITY.

A. M. Rowe<sup>1</sup>, K. M. Brundage<sup>1,2</sup>, R. Schafer<sup>2</sup> and J. B. Barnett<sup>1,2</sup>. <sup>1</sup>*Microbiology, Immunology and Cell Biology, West Virginia University, Morgantown, WV* and <sup>2</sup>*Mary Babb Randolph Cancer Center, Morgantown, WV*.

Atrazine (ATR) is a chlorinated triazine compound used extensively as an herbicide in the United States. As a result of this extensive use ATR is the most commonly encountered water contaminant in the United States. ATR exposure models, both *in vivo* and *in vitro*, have demonstrated multiple forms of immune suppression. Our preliminary data, in addition to work published by others, has shown that ATR exposure inhibits lymphocyte mediated cell lysis. An ATR-induced reduction of cytotoxic activity has been observed in both human natural killer cells and mouse CD8 $^{+}$  lymphocytes. Earlier published studies failed to identify a mechanism for ATR toxicity or subcellular target(s) of ATR exposure. Therefore, the goal of our study was to determine the mechanism of ATR-induced inhibition of cell mediated lysis by better characterizing the toxicological phenotype of ATR-exposed lymphocytes. Human peripheral blood lymphocytes were cultured *in vitro* with concentrations of ATR ranging from 30 to 0.03 $\mu$ M. No change in viability at any of the assayed concentrations was measurable. As others have described, a reduction in NK cell specific lysis was observed. However, we have extended these previous studies as described below. a) We noted a reduced T cell IL-2 production as result of allogeneic cell stimulation. IL-2 is potent modulator of NK cell function. b) A reduction in NK cell specific lysis in ATR containing cultures which had not been stimulated to produce IL-2 was apparent. c) The ability of NK cells to stably bind the NK-specific K562 target cells in the absence of *in vitro* IL-2 stimulation was also found to be reduced. This data suggests that ATR directly decreases the lytic potential of human NK cells. We hypothesize that ATR-exposed NK cells have reduced levels of lytic proteins. We plan to further test this hypothesis by assessing expression levels of these proteins. Supported by NIEHS and NIOSH grants.

### 1887

#### ALTERATIONS IN CYTOKINE PRODUCTION IN THE PRESENCE OF THE PESTICIDES, BENTAZON, ISOXAFLUTOLE AND TERBUFUS.

K. M. Brundage<sup>1</sup> and R. S. Ellis<sup>2</sup>. <sup>1</sup>*Microbiology, Immunology and Cell Biology, West Virginia University, Morgantown, WV* and <sup>2</sup>*Bluefield State College, Bluefield, WV*.

Millions of pounds of pesticides are applied annually around the world to protect crops, lawns and gardens from unwanted weeds and insects. As a result of their widespread use pesticides are common contaminants of water supplies. Even

though extensive screening of pesticides for potential health risks are performed prior to their release for use by the general public in many cases the immunotoxic potential has not been fully evaluated. We have chosen to evaluate three pesticides, bentazon, isoxaflutole and terbufus for their immunotoxicity. Bentazon, a post-emergence herbicide, is used to control broadleaf weeds in soybean, corn, peanuts and rice fields and is a common contaminant of water supplies. Isoxaflutole, a pre-emergence herbicide, is usually applied with atrazine to corn and sugarcane fields. Terbufus, an organophosphate insecticide, is used on corn, sugar beets, grain, sorghum, soybean, wheat, rice and cotton fields. Although terbufus is tightly regulated, it too is found in the water supply. Cytokines are important mediators of the immune response. Thus, they can be used to evaluate the immunotoxic potential of chemicals. To determine if these three herbicides have the potential to be immunotoxic, we assayed their effect on interleukin-2 (IL-2) secretion by the human T cell lymphoma Jurkat. All three pesticides inhibited IL-2 secretion by phorbol ester and calcium ionophore stimulated Jurkat cells. Bentazon and isoxaflutole decreased IL-2 secretion by the Jurkat cells at a concentration of 100  $\mu$ M. However, lower doses of bentazon (5  $\mu$ M) actually increased IL-2 secretion by Jurkat cells. When Jurkat cells were exposed to terbufus (5-100  $\mu$ M), a decrease in IL-2 secretion was also observed. Together these data suggest that bentazon, isoxaflutole and terbufus appears to be immunotoxic. Supported by grant P20-RR16477 from the National Center for Research Resources award to WV Biomedical Research Infrastructure Network.

### THE FUNGICIDES

#### ETHYLENEBISDITHIOTOCARBAMATES INHIBIT NF-KB ACTIVATION AND CYTOKINE PRODUCTION IN THE HUMAN PROMYELOCYTIC CELL LINE THP-1.

E. Corsini<sup>1</sup>, S. Birindelli<sup>2</sup>, M. Marinovich<sup>1</sup>, C. L. Galli<sup>1</sup> and C. Colosio<sup>2</sup>.

<sup>1</sup>Pharmacological Sciences, University of Milan, Milan, Italy and <sup>2</sup>ICPS, International Centre for Pesticides and Health Risk Prevention, Busto Garofolo, Italy.

Literature data indicate that ethylenebisdithiocarbamates may have immunomodulatory effects. The purpose of this work was to characterize the molecular mechanism of action of ethylenebisdithiocarbamates underlying their inhibitory effect on lipopolysaccharide (LPS)-induced TNF-alpha and IL-8 release. The human promyelocytic cell line THP-1 was used throughout the study. Cells were treated with increasing concentrations of mancozeb, zineb and ziram different times. TNF-alpha and IL-8 release was evaluated following LPS stimulation by specific sandwich ELISA. Cell viability was assessed by measuring lactate dehydrogenase leakage. All tested fungicides, at non cytotoxic concentrations, induced a dose and time related inhibition of LPS-induced TNF-alpha and IL-8 release. It has been shown that LPS triggers multiple signaling molecules, such as protein-tyrosine kinase, protein kinase C, Ras, Raf-1, I<sub>K</sub>B kinase, MEK, mitogen-activated protein kinases, etc. Subsequently, the signals further transduce to downstream pathway and activate numerous transcription factors, including AP-1, NF-<sub>k</sub>B and ATF-2. This in turn induces a large amount of genes encoded for inflammatory mediators and cytokines. There are several indications that reactive oxygen species may act as a cellular secondary messenger and it has been demonstrated that H<sub>2</sub>O<sub>2</sub> can activate NF-<sub>k</sub>B, which in turn regulates the expression of many immune and inflammatory molecules, including TNF-alpha. In order to define the molecular target of ethylenebisdithiocarbamates, their effect on LPS-induced NF-<sub>k</sub>B activation were evaluated by Western blot analysis. We demonstrated that all three fungicides, interfering with ROS generation, directly inhibit NF-<sub>k</sub>B activation, preventing I-<sub>k</sub>B degradation and NF-<sub>k</sub>B p65 and p50 nuclear translocation, this in turn results in decreased cytokine production in monocytes.

### ANALYSIS OF THE PROTEOMIC CHANGES INDUCED BY PROPANIL ON A MACROPHAGE CELL LINE.

I. V. Ustyugova<sup>1</sup>, C. L. Walton<sup>1</sup>, K. M. Brundage<sup>1,2</sup> and J. B. Barnett<sup>1,2</sup>.

<sup>1</sup>Proteomic Core Facility, Department of Microbiology, Immunology and Cell Biology, West Virginia University, Morgantown, WV and <sup>2</sup>Mary Babb Randolph Cancer Center, West Virginia University, Morgantown, WV.

DCPA (3, 4-dichloropropionaniline) is a post-emergent herbicide used extensively to control weeds in rice. Previous studies have demonstrated that treatment of the IC-21 macrophage cell line with DCPA resulted in changes of critical macrophage functions, including a decrease in cytokine production, and in the ability to phagocytize and kill bacteria. To understand the mechanism involved in the propanil induced changes, a proteomics analysis was undertaken. For this study, IC-21 cells were exposed to 100  $\mu$ M propanil or ethanol (vehicle) and stimulated with lipopolysaccharide. After 30 min of exposure, cytosolic fraction was isolated and analyzed by two-dimensional gel electrophoresis. Differential statistical analysis identified 12 spots that were all decreased in the propanil exposed cells compared to vehicle. Mass spectrometry analysis was used to identify the proteins, which was later confirmed by other methods. One of these proteins, Sorting Nexin 6 (SNX6)

interacts with the TGF-beta family of receptor serine-threonine kinases and associates with early endosomes during intracellular receptor trafficking. Another protein, H<sub>+</sub>-ATPase functions as a cytoplasmic pH-regulator promoting acidification of intracellular compartments in macrophages during the respiratory burst. A third protein, fibroblast growth factor regulated-1 (FR-1) protein induced by FGF-1 stimulation is important for enhancement of phagocytosis and plays a role in promoting inflammation. Confirmation of other significantly changed proteins and linking their identity to the alterations in macrophage function is currently in progress. Together the data from toxicoproteomics analysis provides an additional evidence of the mechanism by which propanil suppresses macrophage functions. Supported by the USPHS-NIEHS and NCI.

### ALTERED ACTIVATION OF T CELLS BY SILICA-EXPOSED ANTIGEN-PRESENTING CELLS.

C. T. Migliaccio and A. Holian. Ctr for Environ Health Sciences/Biomed Pharmacology Sciences, University of Montana, Missoula, MT.

The classic immune response consists of vital cross-talk between an antigen presenting cell (APC) and a T cell (TC). Antigen is incorporated in the MHC class II molecule and expressed on the surface of the APC for TC stimulation. The resulting TC response includes upregulation of cytokine production, surface marker and receptor expression, and cell proliferation. Previous work has shown that crystalline silica appears to increase the APC activity of macrophages, as measured by TC cytokine production, specifically interferon (IFN)-gamma, interleukin (IL)-13. In an effort to determine the nature of this increase, additional elements of the APC-TC interaction were assayed including macrophage cytokines, TC proliferation, TC early activation markers, and intracellular signaling molecules. While TC proliferation experiments correlated with the lymphocyte cytokine production. Macrophage cytokines, including TNF-alpha, IL-6 and IL-12, significantly decreased following silica exposure. In addition, surface expression levels of the early TC activation markers CD25, CD44, CD62L and CD69 were found to lag behind both saline- and TiO<sub>2</sub>-treated controls. These results indicate that activation of the TC by silica-exposed APC is altered such that the normal rules of activation are unable to be applied. Our present observations regarding the effects of crystalline silica and an atypical immune activation could explain the resulting chronic inflammation and fibrosis associated with silicosis. This work is supported by NIH grants ES 04804 and RR-017670

## 1891

### ROLE OF NEUTROPHILS IN 1-NITRONAPHTHALENE-INDUCED PULMONARY INJURY AND REPAIR.

L. Pantle, M. Fanucchi and C. Plopper. University of California, Davis, Davis, CA.

Acute pulmonary injury is often associated with a neutrophilic inflammatory response. Neutrophils can enhance injury through release of oxidative agents and phagocytosis, however neutrophils also promote repair through the clearance of injured and necrotic cells. 1-Nitronaphthalene (1NN), a ubiquitous environmental pollutant, is a pulmonary cytotoxicant that has been directly associated with an inflammatory response in the rat lung. The purpose of this study was to characterize the role of neutrophils in acute injury and repair from 1-nitronaphthalene in the adult rat lung. Rats received an IP injection of an anti-neutrophil serum or serum carrier prior to administration of either 50 or 75 mg/kg 1NN. This anti-neutrophil serum reduced circulating neutrophils from 14% to 0% by 14 hours post treatment. In contrast, rats given the carrier serum had an elevation of neutrophils from 15% to 54%. The anti-neutrophil serum also inhibited neutrophils from epithelial transmigration with only 0.13% found in BAL fluid of neutrophil-deficient rats and 12% found in neutrophil-sufficient rats. Lungs were evaluated at 24 hrs or 4 days post 1NN by high resolution light microscopy. 1NN induced acute injury at 24 hrs was similar between the neutrophil-sufficient and neutrophil-depleted rats and included areas of extensive vacuolated and necrotic cells and denudation of the basement membrane. At 4 days post injury, both neutrophil-sufficient and neutrophil-depleted rats had similar signs of repair including thickened epithelium, proliferation of ciliated and nonciliated cells and very few vacuolated or necrotic cells. There was no difference in epithelial thickness between neutrophil-depleted rats at 24 hrs and 4 days. However, neutrophil sufficient rats had a thicker epithelium at 4 days compared to 24 hrs suggesting repair of the epithelium. We conclude that neutrophils do not play a significant role in acute pulmonary epithelial 1NN injury. However, it does appear that neutrophils promote repair from acute epithelial injury. ## 1892

### PARTICULATE MATTER-INDUCED AIRWAY INFLAMMATION CORRELATES WITH IMMUNE ADJUVANT POTENTIAL.

C. de Haar, I. Hassing, R. Bleumink and R. Pieters. Institute for Risk Assessment Sciences, Utrecht, Netherlands.

Rationale: Epidemiologic studies suggest a causal relationship between particulate air pollution and the increase in allergic airway disease. Animal inhalation toxicity studies showed that ultrafine particles are more potent than fine particles in induc-

ing local airway inflammation and immunotoxicity studies suggest that particles have adjuvant activity. The aim of this study was to investigate to what extend fine and ultrafine particles cause local airway inflammation and if the severity of inflammation correlates to the adjuvant potential. Methods: Balb/c mice were exposed intranasally to ovalbumin (OVA) with or without fine and ultrafine Carbon Black (CB) and Titanium dioxide (TiO<sub>2</sub>) particles. Local airway responses were assessed by studying LDH, total protein, TNF- $\alpha$ , and numbers of inflammatory cells in bronchoalveolar lavage (BAL) fluid. To study the adjuvant activity of the particles, antigen – specific cytokine production by cells of the mediastinal lymph nodes, OVA – specific serum IgE levels and allergic airway inflammation after antigen challenge were studied. Results: Ultrafine CB and TiO<sub>2</sub> particles induced severe airway inflammation and cause allergic sensitization against OVA. Fine particles of both CB and TiO<sub>2</sub> were less toxic and induced only moderate inflammation and allergic sensitization. Conclusions: These data indicate that ultrafine particles are more toxic and induce a stronger inflammatory response than fine particles, and these ultrafine particles have a stronger adjuvant activity. Together data suggest a direct link between airway inflammation and adjuvant activity.

IMMUNE RESPONSE OF HUMAN LYMPHOBLASTOID AND BRONCHIAL EPITHELIAL CELL LINES TO ORGANIC COMPOUNDS FROM FINE PARTICLES (PM2.5) IN PUERTO RICO

E. Fuentes-Mattei<sup>1,3</sup>, I. Rodriguez-Fernandez<sup>2,3</sup>, A. Gioda<sup>3</sup>, W. Delgado-Morales<sup>1</sup> and B. D. Jimenez Velez<sup>1,3</sup>. <sup>1</sup>Biochemistry, UPR Medical Sciences Campus, San Juan, Puerto Rico, <sup>2</sup>Biology, UPR Ponce Campus, Ponce, Puerto Rico and <sup>3</sup>Center of Environmental and Toxicological Research-UPR Medical Science Campus, San Juan, Puerto Rico.

Fine atmospheric particles (PM2.5) were sampled in an urban, industrialized area (Guaynabo) and in a rural reference site (Fajardo) in Puerto Rico. Sampling of fine air particles was performed for periods of 72 hrs from Nov/2000 to Sept/2001 using RAAS 2.5-400 Andersen Instrument air sampler. Composite samples were established by pooling them for each month and performing soxhlet extraction for further analyses. Organic extracts (Hex and Acetone) from composite samples collected during a year (2000-2001) were re-dissolved in DMSO and used to evaluate the effect of organic extracts from stations described above on the immune-response (17 different human cytokines) of two human cell types. After exposure to the various extracts, the release of these cytokines by human lymphoblastoid (CEMss PBMC) and bronchial epithelial (BEAS-2B) cell lines were assessed using Bio-Plex Cytokine Array System (BioRad). Results from these experiments revealed two interesting findings. Both organic extracts from Guaynabo and Fajardo exert a significant increase on the release of GM-CSF by human lymphoblastoid cell line. Relative increase in MCP-1 was also observed for these extracts, which indicates the need for monocytes recruitment. This research provides the tools for studying the effects of specific organic components in air particulate matter and elucidating their role on the development of respiratory diseases such as Asthma in Puerto Rico.

MURINE PULMONARY MACROPHAGE EXPRESSION AND PRODUCTION OF TNF $\alpha$  AND MIP-2 AFTER EXPOSURE TO DIESEL EXHAUST PARTICLES (DEP) AND EXTRACTS.

T. Stevens<sup>1</sup>, M. Daniels<sup>2</sup> and I. Gilmour<sup>2</sup>. <sup>1</sup>UNC, Chapel Hill, NC and <sup>2</sup>EPA, Research Triangle Park, NC.

DEPs constitute an important fraction of particulate air pollution and have been shown to cause inflammation of the airways. The aim of this study was to investigate the inflammatory cytokine response of alveolar macrophages exposed to DEP and DEP-extracts. A murine alveolar macrophage cell line was incubated for 4 hours with varying doses of DEPs or DEP-extract (10, 50, or 150  $\mu$ g/ml) as well as vehicle control and endotoxin (0.2, 1, or 5  $\mu$ g/ml). After exposure, biochemical markers of cytotoxicity (lactate dehydrogenase (LDH), ATP production, and calcein) were measured. Pro-inflammatory cytokine expression and production of TNF $\alpha$  and MIP-2 were measured by real time PCR and ELISA, respectively. Expression and production of TNF $\alpha$  and MIP-2 were greatly increased in LPS-exposed macrophages indicating the ability of the cells to make these cytokines. Overall, DEPs and their extracts showed no cytotoxicity by the ATP and calcein assays although LDH levels were increased in culture supernates. TNF $\alpha$  expression and production was not affected by exposure to any of the DEPs or their extracts. MIP-2 production was greatly reduced after exposure to the highest concentration of any of the DEPs. In contrast, MIP-2 mRNA expression was increased in a dose dependent fashion compared to controls suggesting a disconnect between genetic induction and protein synthesis. These results confirm recent reports that *in vitro* particle exposures increase gene expression of cytokines but reduce the level of protein measured by immunoassay, either via quenching antigenic moieties or by in-

terfering with the assay. This phenomenon should be considered while conducting *in vitro* experiments involving exposure to particulate matter. (Supported by UNC Cooperative Training Agreement CT829472. This abstract does not reflect EPA policy.)

IN-VITRO INFLAMMATORY AND CYTOTOXIC RESPONSES TO URBAN AIR FINE AND ULTRAFINE PARTICULATE SAMPLES COLLECTED DURING CONTRASTING POLLUTION SITUATIONS IN SIX EUROPEAN CITIES (PAMCHAR).

P. Jalava<sup>1,2</sup>, R. O. Salonen<sup>1</sup>, A. I. Halinen<sup>1</sup> and M. Hirvonen<sup>1</sup>. <sup>1</sup>Department of Environmental Health, National Public Health Institute (KTL), Kuopio, Finland and <sup>2</sup>University of Kuopio, Kuopio, Finland. Sponsor: M. Viluksela.

Ambient air particulate (PM) samples collected in six European cities in selected seasons were studied: Duisburg (autumn), Prague (winter), Amsterdam (winter), Helsinki (spring), Barcelona (spring) and Athens (summer). Fine (PM<sub>2.5,0.2</sub>) and ultrafine (PM<sub>0.2</sub>) particles were collected using an optimized high volume cascade impactor (HVCI). The particles were extracted with methanol and dried; the PM<sub>0.2</sub> suspension was also filtered to remove glass fiber filter fragments. Mouse macrophages (RAW 264.7) were exposed in a dose-related manner (15, 50, 150 and 300  $\mu$ g/ml) to the PM samples for 24 h. Thereafter, nitric oxide (NO) production was measured by the Griess method, production of cytokines (TNF $\alpha$ , IL-6, and MIP-2) immunochemically (ELISA) and cytotoxicity by using the MTT test. Both PM<sub>2.5,0.2</sub> and PM<sub>0.2</sub> induced mostly similar, dose-dependent NO production and cytotoxicity. The differences in cytotoxic potency between the PM samples from six cities were large; the cell viability after exposure to the largest mass dose was 32%-61% with PM<sub>2.5,0.2</sub> and 26%-77% with PM<sub>0.2</sub>. Correspondingly, the largest NO production ranged from 2.5 to 5.5  $\mu$ M with PM<sub>0.2</sub> and from 2.5 to 4.1  $\mu$ M with PM<sub>2.5,0.2</sub>. The differences in cytokine production between the two PM size classes were large. PM<sub>0.2</sub> induced only minor TNF $\alpha$  and no IL-6 production and, thereby, there were no differences between the six city samples. In contrast, PM<sub>2.5,0.2</sub> induced in most cases large IL-6 and TNF $\alpha$  productions with remarkable differences between the six city samples. In conclusion, there were clear differences between the six city PM samples with regard to their potency to induce cytotoxicity and production of inflammatory mediators in mouse macrophages. PM size class had a large effect on cytokine production but not on the induced NO production or cytotoxicity. Grants: EC-FP5 contract QLK4-CT-2001-00423 and The Academy of Finland and TEKES.

**1896**

EXPRESSION AND KINETICS OF TOLL-LIKE RECEPTORS AND INFLAMMATORY CYTOKINE SECRETION IN MURINE ALVEOLAR MACROPHAGES.

K. M. Gowdy<sup>2,1</sup>, M. Daniels<sup>1</sup>, E. Boykin<sup>1</sup> and M. Gilmour<sup>1</sup>. <sup>1</sup>Environmental Toxicology Division, USEPA, Research Triangle Park, NC and <sup>2</sup>North Carolina State University, Raleigh, NC.

Toll-like receptors (TLR) play a major role in pathogen recognition of the innate immune response. To date ten TLR family members have been identified, and recognize different pathogen-associated molecular patterns (PAMPs). All of these TLRs stimulate the immune system and can result in the activation of Nfk $\beta$ 1 and upregulation of immunomodulatory cytokines. The purpose of this study was to evaluate the mRNA expression and protein levels of TLR2 and TLR4 following microbial stimulation and relate their signaling effects to pro-inflammatory cytokine production. Murine alveolar macrophages (cell line MH-S) were incubated with either ethanol killed *Streptococci* sp (gram positive) or *Pseudomonas* sp (gram negative) bacteria, or media alone. Cells were harvested at 0, 2, 6, 12, and 24 hours post stimulation and cellular mRNA was assessed by real time PCR analysis for expression of TLR2 and TLR4. Culture supernatants were quantified by ELISA for levels of IL-1 $\beta$ , TNF- $\alpha$ , IL-6, and MIP-2. A significant increase was seen in the mRNA levels of TLR2 and TLR4 with both bacterial species. TLR2 message was upregulated more quickly (2 hours) with the streptococci and this effect persisted for longer (through 24 hours) than the pseudomonas. TLR4 signal was also up-regulated by both bacteria but the initial signal was much higher in cells incubated with streptococci. Cytokine analysis indicated that IL-1 $\beta$  production peaked after 2 hours of incubation while TNF- $\alpha$ , IL-6 and MIP-2 levels were highest after 6 hours of incubation. In contrast to the TLR signaling, the pseudomonas bacteria had increased cytokine output compared to the streptococci at 2, 6, and 12 hours. Taken together the results suggest that the strength of TLR signaling does not coincide with the level of inflammatory cytokine production *in vitro*, and suggests that other PAMPs function through alternative signaling mechanisms. (Funded by EPA CT829470. This abstract does not reflect EPA policy).

## IMPROVED RAT MODELS FOR PREDICTIVE TOXICOLOGY.

S. Nye, N. Cozzi, J. Baye, A. Wittenburg, S. Korb, Y. Evrard, R. Roman and H. Jacob. *Research & Development, PhysioGenix, Inc., Wauwatosa, WI*. Sponsor: [Y. Dragan](#).

The belated discovery of drug toxicity after successful preclinical trials plagues the pharmaceutical industry. We believe that a major reason for this failure is that researchers often neglect the role genetics plays in predicting drug toxicity in model systems. Current rodent models typically lack genetic diversity, have variable phenotypic responses, or cannot be reliably produced. To address this, PharmGenix rat panels (each comprised of six F1 strains) were created using a novel combinatorial breeding strategy. These PharmGenix rats are the first genetically diverse system that can faithfully recapitulate a heterozygous test population in a controlled fashion. PharmGenix panels capture over 80% of the genetic diversity found in the rat genome and enable drug responses to different genome backgrounds to be tested simultaneously. PharmGenix rats were tested for their sensitivity to the toxic effects of gentamicin, methapyrilene, and tacrine. Following drug treatment, biomarkers in the urine and blood were analyzed and organ pathology was assessed. Gentamicin caused elevations in BUN and creatinine in two of the PharmGenix strains. F344 rats also responded to gentamicin, but it was only the differential response exhibited by the PharmGenix panel that revealed that genetic components underlie the toxic response. After methapyrilene treatment, most of the strains exhibited elevations in ALT and AST. However, several of the PharmGenix hybrids were more sensitive than either CD-IGS or F344 in detecting toxicity. Tacrine led to elevated ALT and AST levels in three of the PharmGenix strains but not in the industry-standard CD-IGS or F344 strains. Abnormal clinical chemistries were accompanied by histopathological changes in the kidney (gentamicin) and liver (methapyrilene). These results underscore the need to consider the influence of genetic components when evaluating new drugs in preclinical studies. Researchers who discover a differential toxic response among PharmGenix strains will use this information as a starting point for drug optimization, drug rescue, and mechanistic studies.

## IN VIVO HEPATIC CELL PROLIFERATION IS AN EARLY, SENSITIVE MARKER OF HEPATOTOXICITY.

S. Turner<sup>1</sup>, J. Gardner<sup>1</sup>, J. Stark<sup>1</sup>, D. Buffmum<sup>2</sup> and M. Hellerstein<sup>3, 2, 1</sup>.

<sup>1</sup>Research, Kinemed Inc., Emeryville, CA, <sup>2</sup>Medicine, UC San Francisco, San Francisco, CA and <sup>3</sup>Nutritional Sciences and Toxicology, UC Berkeley, Berkeley, CA. Sponsor: [I. Heyman](#).

Advances in stable isotope/ mass spectroscopic technology now make rapid, high throughput, quantitative determination of cell proliferation possible. We have applied this technology to the evaluation of hepatotoxicity of drugs. The underlying principle of this approach is that liver cells regenerate rapidly, replacing cells lost through apoptosis or necrosis. This regenerative response can be used as a biomarker of cell death *in vivo*. The effects of hepatotoxins (carbon tetrachloride (CCl<sub>4</sub>)) and griseofulvin (gris)) and non-toxic agent (tamoxifen (tam)) on hepatic cell proliferation were measured using the recently described heavy water (<sup>2</sup>H<sub>2</sub>O) labeling technique. A quantitative dose response to CCl<sub>4</sub> at doses from 0.05 to 0.3 ml/kg was seen in mice. Maximal hepatic cell proliferation (8%/day) was achieved at 0.3ml/kg and was not increased by higher doses. Necrosis was histologically evident in only 20% of the livers at doses below 0.3 ml/kg. In contrast there was a significant increase in cell proliferation in 100% of livers > 0.05 ml/kg. BrdU incorporation correlated with <sup>2</sup>H<sub>2</sub>O results (although with higher s.d.). Dose and strain effects on the response to griseofulvin were also evaluated. 5 days of dietary gris produced a linear dose response from 0.1% to 0.5% (w/w diet) (all doses we significantly different from control p<0.1). The reported NOEL for gris is 0.5%. BALB/c mice are reportedly more resistant than C57Bl/6 to gris induced hepatotoxicity. At 14 days of gris treatment cell proliferation was significantly higher in C57Bl/6 mice (67%) compared to BALB/c (53%) (p<0.05). Finally, safe, doses of tam were given to rats. One or three weeks of tam (15 mg/kg/day) showed no increase in hepatic cell proliferation. In conclusion, the measurement of hepatic cell proliferation is a rapid, sensitive and quantitative marker of liver cell death that is scalable to high throughput assessment of hepatotoxicity.

## INVESTIGATIONS OF THE EFFECTS ON PROTEIN EXPRESSION INDUCED BY HEPATOTOXICANTS ON PRIMARY CULTURED RAT HEPATOCYTES.

T. Yamamoto, T. Fukushima, R. Kikkawa, H. Yamada and I. Horii. *Worldwide Safety Sciences, Pfizer Japan Inc., Taketoyo, Aichi, Japan*. Sponsor: [M. Kurata](#).

Hepatotoxicity is one of the major concerns, and we have to observe that carefully on drug development. It would be really valuable to select drug candidates at the stage of screening with regard to hepatotoxicity, without large-scale toxicity studies.

Biomarkers will enable us to detect the potentials for liver damage prior to the appearance of visible changes such as morphology. Therefore, novel biomarkers for hepatotoxicity, which are available at screening stage, are strongly needed. We investigated the effects on protein expressions in the primary rat hepatocytes of well-known liver toxicants, acetaminophen (APAP), amiodarone (AD) and tetracycline (TC), using proteomic approaches. Rat hepatocytes cultures were exposed to APAP (10mM), AD (50uM) and TC (500uM) for 6 and 24 hours. Toxicity was determined by lactate dehydrogenase leakage, mitochondrial respiration ability and morphological observations. Proteins in the rat hepatocytes were precipitated with trichloroacetic acid (TCA), and then analyzed by two-dimensional gel electrophoresis (2DGE). The results of gel-to-gel comparisons between control and treated group revealed that 73, 111 and 70 spots were affected by APAP, AD and TC treatments for 24 hours, respectively. Identifications of differentially expressed protein by means of Q-ToF mass spectrometry indicated that several proteins that were involved in energy metabolism and signal transduction, such as glutathione S-transferase (GSTs), apolipoprotein A-IV and senescence marker protein-30 (SMP-30, Regucalcin) were altered. We concluded that the proteins identified in present study have a potential to be biomarker candidates for hepatotoxicity, and altered protein expression patterns also allow us to consider hepatotoxicity with a mechanism base.

## PROTEOMIC ANALYSIS OF LIVER AND SERUM FROM LIPOSACCHARIDE TREATED RATS DURING ACUTE INFLAMMATION.

J. H. Madenspacher<sup>1</sup>, M. E. Bruno<sup>1</sup>, B. A. Wetmore<sup>1</sup>, R. Pieper<sup>2</sup>, C. L. Gatlin<sup>2</sup>, A. J. Makusky<sup>2</sup>, A. M. McGrath<sup>2</sup>, M. Zhao<sup>2</sup>, J. Zhou<sup>2</sup>, J. Taylor<sup>2</sup>, [S. Steiner](#)<sup>2</sup>, [R. W. Tennant](#)<sup>1</sup>, K. B. Tomer<sup>1</sup> and [B. A. Merrick](#)<sup>1</sup>. <sup>1</sup>National Center for Toxicogenomics, NIEHS, Research Triangle Pk, NC and <sup>2</sup>Proteomics Division, Large Scale Biology Corporation, Research Triangle Pk, NC.

Lipopolysaccharide (LPS), induces an acute systemic endotoxemia and widespread inflammatory response after i.p. exposure with release of cytokines, chemokines and bioactive peptides. The purpose of this proteomic study was to determine changes in liver and serum proteins in male, Sprague-Dawley rats to gain insight into the pathophysiology of acute systemic inflammation after LPS 5 mg/kg, i.p. Proteomic analysis was by two dimensional (2D) gel protein separation, image analysis and mass spectrometry (MS) identification of proteins. The acute inflammatory phase of LPS showed TNF $\alpha$  and IL6 ELISA increases. Liver homogenates were analyzed by 2D gels and mass spectrometry (MS) at 2 and 6 hr in both liver and serum. Proteomic analysis of liver after 2 hr LPS revealed 152 protein features were changed at p<0.005 and at 6 hr there were 192 features altered. A large increase in liver carbamoyl-phosphate expression (20 to 60 fold) was consistent with nitric oxide formation produced by LPS-induced inflammation. Other liver proteins induced were SAM synthetase isozymes (15 to 40 fold), ATP synthase isozymes, Hsp 70 and 90 isoforms and others proteins that supported acute phase protein production. Serum was analyzed after immunoaffinity removal of abundant proteins such as albumin, immunoglobulins and others. Remaining serum proteins were then analyzed by gradient elution into five fractions that were dialyzed and analyzed by 2D-MS. In serum, complement C3 isoforms were consistently reduced by LPS treatment while Apo-A1 precursor was consistently increased and alpha-inhibitor H4 heavy chain (liver protein) increased at 2 hr but fell at 6 hr after LPS treatment. These observations from proteomic analysis suggest an interplay among liver protein and serum proteins changes involved acute inflammation and production of acute phase proteins during acute exposure to LPS.

## EVALUATION OF THE BACKGROUND DATA OBTAINED IN THE TOXICOGENOMICS PROJECT IN JAPAN.

H. Nitta, T. Miyazaki, H. Totsuka, T. Miyagishima, T. Urushidani and T. Nagao. *Toxicogenomics Project, National Institute of Health Sciences, Tokyo, Japan*. Sponsor: [T. Inoue](#).

National Institute of Health Sciences and 17 pharmaceutical companies have started a five-year project, the Toxicogenomics Project in Japan (TGPJ) in 2002. The objective of TGPJ is to construct a large-scale database of over 150 drugs on rats and develop a system which will forecast the toxicity of new chemical in the early stage of drug development. In TGPJ, 0.5 w/v% methylcellulose solution is usually employed as vehicle for oral administration of test drugs to 5 animals. Gene expression profiles in liver (and additionally in kidney for some cases) are evaluated in 3 out of 5 animals for each group by Affymetrix GeneChip. Autopsy is performed 3, 6, 9, 24 hours after single administration, and 3, 7, 14, 28 days after repeated administration. The gene expression data are being accumulated in the database together with the traditional toxicology data. In order to evaluate drug effects using microarray data, we generally employ the fold change of the value compared to the control. Therefore, our investigation has been especially focused on the variation of control data obtained in TGPJ. The treatment of animals has been done in 4 different contract research organizations, and gene expression profiling in liver

was performed by using RAE230A and RAE230 2.0 GeneChip. We evaluated vehicle control data from the first 28 compounds (672 chips). Perchip normalization was applied for data analysis. Within the 3 control data in the same group, scatter plotting of each pair constantly showed a good correlation. It was noteworthy that inter-organization variations of the data were negligible. We also confirmed that many of the circadian genes, such as albumin D site-binding protein, period 1, etc., showed reproducible and typical expression patterns in the single dose study. Moreover, many of the genes, which are reported to be age-dependently up- or down-regulated, showed reproducible changes in the repeated dose study. These results suggest that the data being accumulated in our database are well-qualified and reproducible.

## 1902

### THIOACETAMIDE AND METHAPYRILENE SHOWED A UNIQUE GENE EXPRESSION PROFILE AMONG THE CHEMICALS IN THE TOXICOGENOMICS PROJECT IN JAPAN.

Y. Mizukawa, T. Miyagishima, T. Urushidani and T. Nagao. *Toxicogenomics Project, National Institute of Health Sciences, Tokyo, Japan.* Sponsor: T. Inoue.

National Institute of Health Sciences and 17 pharmaceutical companies have started a five-year project, the Toxicogenomics Project in Japan (TGJP) in 2002. The objective of TGJP is to construct a large-scale database of over 150 drugs on rats and develop a system which will forecast the toxicity of new chemical in the early stage of drug development. In order to characterize the effects of chemicals by gene expression, we employed clustering analyses using multi-dose (3 dose levels), multi time-point data (3, 6, 9, or 24 hr after single dose and 24 hr after repeated dose for 3, 7, 14, or 28 days) by Affymetrix GeneChip. K-means or hierarchical clustering with gene expression in the liver revealed that thioacetamide (TAA) and methapyrilene (MP) were strikingly similar among 25 chemicals during repeated administration. In clinical biochemistry both chemicals caused a similar pattern, e.g., decrease in triglyceride, increase in serum enzymes. Similarity in gene expression was also noticed with several gene subsets categorized by physiological functions. However, the similarity was much less within 24 hrs after single administration. A gene set modulated in common for TAA and MP at 24hr was extracted by K-means clustering. Hierarchical clustering using this gene set showed high similarity between these two chemicals. Of these genes, up-regulated ones were categorized into protein metabolism, biosynthesis, stress response, cell cycle, whereas down-regulated ones were into fatty acid metabolism/transport. Modulated genes common between single and repeated dosing were categorized into response to stress/stimulus, whereas those exclusively modulated in repeated dosing group included genes related to cell cycle/proliferation, protein synthesis or transcription. In conclusion, we could extract a gene set that characterize chronic phenotype from the data of single treatment. This would be a model case of toxicity prediction by gene expression data.

## 1903

### GENE EXPRESSION IN PORPHYRIA INDUCED BY 2, 3, 7, 8-TETRACHLORO-DIBENZO-P-DIOXIN IN SUSCEPTIBLE MICE.

A. G. Smith, B. Clothier and R. Davies. *MRC Toxicology Unit, University of Leicester, Leicester, United Kingdom.*

The mechanism by which TCDD induces hepatic porphyria, a disruption of heme synthesis, is unknown but as with other toxic actions it is mediated through the AH receptor (AHR) and must be associated with a cascade of gene expression changes. C57BL/6J mice (high affinity AHR) are the most susceptible and DBA/2 (low affinity AHR) are a highly resistant strain. Previous studies have implicated iron metabolism and an oxidative mechanism with susceptibility linked to polymorphism in other genes in addition to the *Ahr* gene. Male C57BL/6J and DBA/2 mice were dosed (orally) with TCDD (75  $\mu$ g/kg in corn oil) and hepatic gene expression examined after 3 days, 2 weeks and 5 weeks by which time hepatic porphyria developed in the former strain but not in the latter. Hepatic gene expression changes were analysed primarily with cDNA microarrays constructed from approximately 3000 IMAGE clones of candidate genes. At this dose of TCDD maximum induction of most AH battery genes including those for CYP1A1/CYP1A2 occurred by 3 days in both strains similarly declining slowly over 5 weeks. In contrast, expression of the *Cyp1b1* gene fell much quicker in DBA/2 mice than C57BL/6J. Expressions of some genes of heme metabolism (*Alad* and *Hmbs*) were down-regulated only in C57BL/6J not DBA/2 mice over the experimental period whereas *Alas1* and *Hmox1*, associated with heme regulation, were up-regulated. There was no compensatory up-regulation of the gene for uroporphyrinogen decarboxylase. The iron homeostasis genes cytosolic aconitase (*Aco1*) and transferrin receptor 2 (*Trf2*) were down regulated whereas haemastatin (*Heph*) was up-regulated, again in the susceptible strain. Hepcidin (*Hamp*) a hormonal peptide regulator of iron absorption was unaffected. Some genes associated with oxidative stress showed changes in expression concomitant with porphyria development (*Fab*, *Car3*, *Sod3*, *Cat*) in C57BL/6J but not DBA/2 mice. The results are consistent with an association of TCDD induced-porphyria with disturbances of iron homeostasis and an oxidation mechanism.

### STRESS- AND INFLAMMATORY-RELATED MNRA INDUCTION IN HEPATOCYTES AND NON-PARENCHYMAL CELLS RESPONSE TO OXIDATIVE STIMULI.

T. Yamamoto, H. Utsumi, N. Shimada and N. Tsutsui. *Mitsubishi Pharmacology Corporation, Kisarazu, Chiba, Japan.* Sponsor: J. Sugimoto.

Oxidative stress plays a major role in various hepatic injuries. However, the gene expression in hepatocytes and non-parenchymal cells in response to oxidative stimuli has not been well known. In this study, stress- and inflammatory-related gene expressions were analyzed in hepatocytes and non-parenchymal for two liver injury models, ischemia/reperfusion and acetaminophen (APAP)-administration. Male SD rats were subjected to ischemia for 45 min, followed by 1 or 3hr of reperfusion, and sacrificed under anesthesia. As for APAP-administration, the animals were treated at 1000 mg/kg (po) and sacrificed under anesthesia at 24hr after treatment. After the liver was removed, hepatocytes and non-parenchymal cells were separated out by collagenase perfusion method. The levels of gene expression in the whole liver, hepatocytes and non-parenchymal cells were determined by RT-PCR. In ischemia/reperfusion model, the expressions of HSP70 and IL-6 were increased in whole liver at 1hr-reperfusion. At 3hr- reperfusion, HO-1, HSP70, iNOS and IL-6, were the genes which expression was enhanced. When the liver was separated the two components, HO-1 expression was increased in hepatocytes, the expressions of iNOS and IL-6 were seen in non-parenchymal cells. Furthermore, HSP70 expression was increased to a great extent in hepatocytes and non-parenchymal cells. The increases in expressions of iNOS and inflammatory cytokines were detected from 1hr-reperfusion in non-parenchymal cells, while these changes were seen only at 3hr-reperfusion in whole liver. The gene expressions in hepatocytes and non-parenchymal cells after APAP treatment were similar to those of ischemia/reperfusion model. Thus there were obvious differences in the induction of oxidative stress-related genes between hepatocytes and non-parenchymal cells. These results suggest that the intracellular response in hepatocytes and non-parenchymal cells to oxidative stimuli might be controlled with different mechanisms.

### DEVELOPMENT OF PROTEIN MICROARRAY TECHNOLOGY TO FACILITATE IDENTIFICATION OF PROTEINS ISOLATED BY GEL FILTRATION AND ION-EXCHANGE CHROMATOGRAPHIES.

H. Kim<sup>1,2</sup>, Y. Yuan<sup>1</sup>, D. J. Kaplan<sup>1</sup>, D. A. Putt<sup>1</sup>, Z. Li<sup>1</sup> and K. Fleischmann<sup>1</sup>.  
<sup>1</sup>*Detroit R&D, Inc., Detroit, MI* and <sup>2</sup>*Institute of Environmental Health Sciences, Wayne State University, Detroit, MI.*

Protein microarray technology was developed to facilitate protein purification. This technology can be utilized to produce a reference protein mixture to be used for an antibody microarray analysis with a reference design. Hepatic microsomes and cytosol were obtained by differential centrifugation from male Sprague-Dawley rats treated with phenobarbital (100 mg/kg/day for 3 days). Cytosolic proteins were fractionated by gel filtration chromatography. Seventy two fractions collected from gel filtration chromatography were spotted (spotting volume, 1 nl) in quadruplicate (4 blocks) on a nitrocellulose-based chip using split pin technology. GST-alpha IgG was hybridized with the cytosolic protein fractions spotted on the chip in a hybridization buffer containing blocking proteins and a detergent. Secondary hybridization of the chip was carried out with a Cy5-conjugated anti-rabbit IgG. Scanning of the slide revealed dots with a strong red signal in the middle section of all 4 blocks. The dots corresponded to fractions No. 25 through No. 36. No background signal was detected. Western blot analysis with GST-alpha IgG verified the result obtained by protein microarray analysis. Microsomal proteins were fractionated using anionic exchange chromatography. Every third fraction out of 240 fractions were spotted on a nitrocellulose-based chip and hybridized with cytochrome P450 2C23 antibody followed by a secondary hybridization with a Cy5-conjugated anti-rabbit IgG. Dots with a strong red signal corresponded to fractions No. 183 through No. 195. The results demonstrated that protein array technology facilitated identification of proteins isolated by gel filtration and ion-exchange chromatographies. Supported by NIEHS SBIR Phase I contract ES35506.

### HEPATIC GENE EXPRESSION PROFILES OF RATS EXPOSED TO PERFLUOROOCTANESULFONATE (PFOS) IN UTERO.

J. A. Bjork<sup>1</sup>, J. M. Berthiaume<sup>1</sup>, C. Lau<sup>2</sup>, J. L. Butenhoff<sup>3</sup> and K. B. Wallace<sup>1</sup>.  
<sup>1</sup>*Biochem. & Mol. Biology, Medical School, University of Minnesota, Duluth, MN*,  
<sup>2</sup>*Reproductive Toxicology Division, NHEERL, USEPA, Research Triangle Park, NC* and <sup>3</sup>*3M Company, St. Paul, MN*.

Perfluorooctanesulfonate (PFOS) is a surfactant that occurs primarily as a degradation product of some materials used for oil and water resistance. PFOS is persistent and widely dispersed in the environment. Toxicity testing indicates that PFOS interferes with intermediary metabolism by inducing the proliferation of peroxisomal

bodies via transactivation of PPAR- $\alpha$ , both in adult and neonatal rodent species. The purpose of this investigation was to assess whether the observed modulation of lipid and fatty acid metabolism in liver of exposed neonates is reflected at the transcriptional level. Gravid Sprague-Dawley rats were exposed by gavage to 3 mg/kg PFOS/K $^{+}$  beginning on gestational day (GD) 2. On GD21, liver was harvested from fetuses for RNA extraction and cRNA was generated for hybridization to Affymetrix 230A chips. Raw intensities were adjusted for background and normalized by the robust multichip analysis method. Statistical analysis revealed treatment-related differences in the degree of expression of 153 genes between the control and PFOS exposed animals (91 upregulated and 62 downregulated, p<0.01). The most prominent changes were the increased expression of both lipid synthesis and degradation pathways, as well as mitochondrial and peroxisomal  $\beta$ -oxidation genes, with no change in expression of the mitochondrial electron transport chain genes. On average, there was a two-fold induction of genes related to metabolism. The results of this investigation are in good concordance with previously observed changes in metabolic enzyme activity and intermediate profiles, suggesting that the metabolic effects associated with *in utero* PFOS exposure in rodents are manifested at the transcriptional level and are likely related to PPAR $\alpha$  activation. Supported by the 3M Company. This abstract does not reflect EPA policy.

**1907 LIVER SLICE MODEL SYSTEM FOR BILIARY CELL EFFECTS: CHANGES IN CLINICAL CHEMISTRY PARAMETERS.**

H. P. Behrsing, C. Ip, L. Jimenez and C. A. Tyson. *Toxicology Laboratory, SRI International, Menlo Park, CA.*

Hepatobiliary toxicants induce histological changes in rat liver slice cultures similar to their known effects *in vivo* (Poster No. \_\_\_\_). Demonstrating a relationship between diagnostic biomarkers and histological findings *in vitro* would strengthen confidence in the use of roller slice culture systems for investigations and assays of biliary toxicant effects. In this aspect of the work, concurrently with histological tissue examination, we measured the effects of various hepatobiliary toxicants on clinical chemistry parameters in precision-cut slices from male F-344 and Sprague-Dawley rat livers. Geldanamycin (GEL), 17-allylaminogeldanamycin (17AAG),  $\alpha$ -naphthylisothiocyanate (ANIT), and 4, 4'-methylene dianiline (MDA), compounds known to induce biliary duct necrosis and/or cell hyperplasia in these strains, were examined. GEL and 17AAG induced concentration-dependent alterations in biomarker levels, with the most prominent being (in order of percentage change relative to corresponding control slice levels): ALP $\downarrow$ , LDH $\downarrow$ , GGT $\downarrow$ , ALT $\downarrow$ , Bili $\uparrow$ , AST $\downarrow$  in the effect range. The loss of slice enzyme content was associated with increased levels in the medium. The biomarker changes occurred at physiologically relevant exposures, and GEL was appreciably more toxic than 17AAG over the test concentration range. In contrast, ANIT and MDA appeared to induce increased slice contents of the enzyme biomarkers relative to control slice levels (most notably in ALP and/or LDH and GGT) up to concentrations at which necrosis was evident histologically. The biomarker profiles were similar to those seen in rats *in vivo*. At these latter exposures the increases in slice enzyme parameters were markedly reversed, indicative of a loss in cell viability. The biomarker patterns associated with BEC necrosis and hyperplasia were distinctly different and consistent with the type of injury histologically present in the slice tissues. These results provide further support for the reliability of the model system for studies and assays of biliary cell effects. Supported by NIH grant R21/R33 CA093262.

**1908 LIVER SLICE MODEL SYSTEM FOR BILIARY CELL EFFECTS: HISTOLOGICAL CHANGES.**

K. Amin, C. Ip, H. P. Behrsing and C. A. Tyson. *Toxicology Laboratory, SRI International, Menlo Park, CA.*

Precision-cut slices which maintain intact biliary duct structures are an attractive option for studying biliary cell effects but are limited in value for this application because slice viability in culture deteriorates too rapidly. Advances in preparation and roller culture methods have resulted in better quality tissues and integrity over 10 days of incubation (Behrsing et al., *Biochem. Biophys. Res. Commun.* 312: 209-213, 2003) and more recently up to 21 days. In the studies reported here, we examined histological changes in liver slices from male F-344 and Sprague-Dawley rats incubated with and without hepatobiliary toxicants known to induce biliary epithelial cell (BEC) necrosis and hyperplasia *in vivo*. Control slice preparations in roller organ cultures supplemented with CMH1a medium under a 70-75% O $_2$ -containing atmosphere retained 60-70% hepatocellular and 80-90% BEC viability over the experimental period as assessed by semi-quantitative histological examination. Geldanamycin (GEL) and 17-allylaminogeldanamycin (17AAG) at 0.40-5.0  $\mu$ M caused pronounced injury to BEC; hepatocytes were also affected though generally to a lesser extent. GEL-induced injury was more severe than that due to 17AAG in the same concentration range. In contrast,  $\alpha$ naphthylisothiocyanate (ANIT) and 4, 4'-methylene dianiline (MDA) in the 1-200  $\mu$ M range induced

BEC proliferation (assessed by H&E staining and BrdU immunohistochemistry) at most concentrations and BEC necrosis at the highest concentrations. These compound-induced effects were either absent or less severe in control tissues throughout the incubations, and the severity of each identified effect was concentration-dependent. These observations encourage more extensive examination of this precision-cut liver slice system as a general model for biliary cell effects in addition to hepatotoxicity. Supported by NIH grant R21/R33 CA93262.

**1909 IMPAIRED G1 TO S-PHASE SIGNALING EXPLAINS INHIBITED TISSUE REPAIR IN THIOACETAMIDE-TREATED TYPE 1 DIABETIC RATS.**

S. S. Devi and H. M. Mehendale. *Toxicology, The University of Louisiana at Monroe, Monroe, LA.*

A nonlethal dose of thioacetamide (TA, 300 mg/kg) causes 90 % mortality in diabetic (DB) rats primarily due to impaired tissue repair (-50% inhibition of S-phase). Objective of the present study was to investigate the molecular events that orchestrate G1 to S-phase progression of the cell cycle to explain inhibited tissue repair in TA-treated DB rats. Immunoblotting revealed that EGFR-MAPKs pathway was upregulated in the TA-treated nondiabetic (NDB) group. DB-associated down regulation of EGFR-MAPKs pathway was further downregulated after TA treatment. EGFR-MAPKs stimulate transcription factor NF-kB, activating transcription of CD1. Gel shift assay revealed adequate NF-kB/DNA binding in the TA-treated NDB liver, resulting in higher CD1 gene expression. In contrast, in the DB group receiving the same dose of TA, down regulation of EGFR/MAPK pathway inhibited NF-kB/DNA binding, resulting in lower CD1 gene expression as measured by real time RT-PCR. Furthermore, microarray analysis revealed that gene expression of extracellular matrix (ECM) proteins like integrin, laminin, collagen IV, which are known to stimulate CD1 expression were also upregulated in the TA-treated NDB rats. In contrast, gene expression of ECM proteins was inhibited in the TA-treated DB group, leading to inhibited CD1 expression. In association with cdk4 and cdk6, CD1 phosphorylates retinoblastoma (Rb) and G1 to S-phase progression. Immunoblotting revealed that higher CD1 expression, coupled with higher cdk4 and cdk6 in the NDB group, led to phosphorylation of Rb, explaining prompt and efficient tissue repair. Whereas inhibited expression of CD1, cdk5 and Rb explains inhibited hepatic tissue repair in the TA-treated DB rats. These findings suggest that impaired CD1-centred signaling underlies inhibited tissue repair and higher sensitivity of DB rats to TA hepatotoxicity. These findings suggest that impaired CD1-centred signaling may be utilized as a risk assessment tool for screening novel antidiabetic drugs for potential hepatotoxicity in DB patients.

**1910 MOLECULAR MECHANISMS OF INHIBITED COMPENSATORY LIVER REPAIR UPON HEPATOTOXIC CHALLENGE IN TYPE 2 DIABETIC RATS.**

S. P. Sawant<sup>1</sup>, A. V. Dnyanmote<sup>1</sup>, J. R. Latendresse<sup>2</sup>, A. Warbritton<sup>2</sup> and H. M. Mehendale<sup>1</sup>. <sup>1</sup>*The University of Louisiana at Monroe, Monroe, LA* and <sup>2</sup>*NCTR, Jefferson, AR.*

Earlier we showed that higher sensitivity to CCl<sub>4</sub> hepatotoxicity and mortality in type 2 diabetes is due to inhibited liver tissue repair. The objectives of present studies were to investigate the molecular mechanisms of higher sensitivity of type 2 diabetic (DB) rats to CCl<sub>4</sub> hepatotoxicity and to further characterize the sensitivity of type 2 DB rats to hepatotoxicants other than CCl<sub>4</sub>. MAPK pathway was investigated (0 to 24 h) after CCl<sub>4</sub> treatment. Expression and activation of ERK 1/2 were down regulated while p38 activation was increased as early as 3 h in the DB rats after CCl<sub>4</sub> administration. Furthermore, NF $\kappa$ B-DNA binding was high in the DB rats at 0 h compared to non-DB rats but was severely inhibited following CCl<sub>4</sub> administration. Cyclin D1 and CDK 4/6 expression were low in the DB rats compared to the non-DB rats following CCl<sub>4</sub> administration, resulting in decreased phosphorylation of retinoblastoma protein. Thus, down regulation of mitogenic signaling in the DB rats leads to problems at the G<sub>0</sub>/G<sub>1</sub> to S phase advance, impeding cell cycle progression needed for stimulation of tissue repair thereby explaining the progression of liver injury after CCl<sub>4</sub> administration. Time course (0 to 96 h) study of thioacetamide (TA, 300 mg/kg, ip) toxicity revealed higher liver injury in DB rats. Interestingly, covalent binding of <sup>14</sup>C-TA to liver tissue of DB rats did not differ from the non-DB rats, indicating identical bioactivation-based liver injury. Compensatory cell division measured via <sup>3</sup>H-T pulse labeling and PCNA immunohistochemistry was inhibited in DB rats leading to progression of injury, liver failure (hyperbilirubinemia), and death (100% mortality) between 36 to 48 h after TA administration. Investigation of whether MAPK pathway plays a role in potentiation of TA-induced liver injury in DB rats is underway. In conclusion, type 2 diabetes increases sensitivity to structurally and mechanistically dissimilar hepatotoxins (CCl<sub>4</sub> and TA) due to impaired compensatory tissue repair.

**1911**

PPAR $\beta$ -MEDIATED HEPATOTOXICITY IN A DIETARY MODEL OF NONALCOHOLIC STEATOHEPATITIS (NASH).

M. A. Peraza, W. Shan, M. J. Kennett and J. M. Peters. *Veterinary Sciences, Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA.*

NASH, an advanced stage of liver injury associated with obesity, type 2 diabetes, and hyperlipidemia, is characterized by hepatic steatosis associated with lipid peroxidation, inflammation, and fibrogenesis and can progress to cirrhosis and liver cancer. The mechanisms that mediate transition from steatosis to NASH remain unclear. Recent studies linked peroxisome proliferator-activated receptor $\beta$  (PPAR $\beta$ ) to attenuation of liver toxicity induced by environmental chemicals. The present study investigated the function of PPAR $\beta$  in a mouse model of dietary-induced NASH. Wild-type and PPAR $\beta$ -null mice were fed a methionine and choline deficient (MCD) diet and a marginal MCD diet for 5 weeks, and markers of hepatotoxicity were evaluated. Wild-type mice treated with the marginal or the MCD diets exhibited hepatocellular injury, indicated by elevated serum ALT levels (~10-fold and ~40-fold) as compared to controls. PPAR $\beta$ -null mice fed the marginal MCD diet exhibited a similar extent of liver injury as the wild-type mice but were not as severely affected by the MCD diet as were the wild-type mice. Both the marginal and the MCD diets induced lipid peroxidation in wild-type mice (~3.75-fold and ~5-fold) and to a lesser extent in PPAR $\beta$ -null mice (~1.5-fold and ~3.25-fold). As a measure of hepatic redox status, the ratio of reduced to oxidized glutathione was determined. In wild-type mice, glutathione ratios were decreased as compared to controls with both the marginal and the MCD diets (by ~36% and ~74%). In PPAR $\beta$ -null mice, glutathione ratios were decreased to the same extent by both diets (by ~54%). While these data indicate that PPAR $\beta$  may mediate increased lipid peroxidation and oxidative stress, histological evidence from mice fed the marginal MCD diet showed the presence of hyperplastic lesions in PPAR $\beta$ -null mice but not in wild-type mice, suggesting that PPAR $\beta$  attenuates hepatic injury. Additional studies are underway to delineate the mechanism contributing to this disparity.

**1912**

INDUCTION OF CYTOTOXICITY IN PRIMARY RAT HEPATOCYTES AND HUMAN HEPG2 CELLS BY SELECTED PPAR $\gamma$  AGONISTS.

L. Guo<sup>1</sup>, L. Muskhelishvili<sup>2</sup>, E. Blann<sup>1</sup>, S. Dial<sup>1</sup>, E. Hermann<sup>3</sup> and Y. Dragan<sup>1</sup>. <sup>1</sup>*Systems Toxicology, National Center for Toxicological Research, Jefferson, AR*, <sup>2</sup>*Molecular Pathology Branch, Charles River Laboratories at NCTR, Jefferson, AR* and <sup>3</sup>*Center for Drug Evaluation and Research, Jefferson, AR*.

Peroxisome proliferator activated receptor gamma (PPAR $\gamma$ ) agonists are used to treat insulin resistant diabetes and type 2 diabetes. These agents have a proven efficacy for reducing plasma glucose levels in type 2 diabetic patients. Several members of the thiazolidinedione (TZDs) class are PPAR $\gamma$  agonists. Three TZDs have been approved by FDA. However, troglitazone was removed from the market due to idiosyncratic drug toxicity. In order to gain insight into the mechanism of hepatic toxicity of some members of this class of agents, we investigated the relative toxicities of five PPAR $\gamma$  agonists, troglitazone, ciglitazone, rosiglitazone, pioglitazone, and JTT-501 to primary rat hepatocytes and HepG2 cells. Toxicity was assessed by use of the MTT assay. Exposure of primary rat hepatocytes and HepG2 cells to five PPAR $\gamma$  agonists for 2, 6 and 16 hours at various concentrations (0, 1, 5, 10, 20, 40 and 100 $\mu$ M) demonstrated that troglitazone, ciglitazone, and JTT-501 exhibited a dose and time dependent cytotoxicity. The TUNEL assay was used to demonstrate that the observed cell death was apoptotic in nature. The observed toxicity was independent of PPAR $\gamma$  activation based on RNAi experiments and on comparison of the rank order of the published relative binding affinity and the IC<sub>50</sub> of the observed hepatotoxicity.

**1913**

INDUCTION OF EARLY FIBROGENESIS IN PRECISION-CUT HUMAN AND RAT LIVER SLICES AFTER CARBON TETRACHLORIDE TOXICITY.

M. van de Bovenkamp<sup>1</sup>, G. M. Groothuis<sup>1</sup>, A. L. Draisma<sup>1</sup>, M. T. Merema<sup>1</sup>, D. K. Meijer<sup>1</sup>, S. L. Friedman<sup>2</sup> and P. Olinga<sup>1</sup>. <sup>1</sup>*Pharmacokinetics and Drug Delivery, University of Groningen, Groningen, Netherlands* and <sup>2</sup>*Division of Liver Diseases, Mount Sinai School of Medicine, New York, NY*. Sponsor: A. Vickers.

**Introduction:** Hepatic stellate cell (HSC) activation is a key event in the development of fibrosis. Current *in vitro* models for liver fibrosis contribute significantly to the understanding of HSC biology and fibrogenesis but lack a physiologic milieu that can incorporate effects of cell sociology and extracellular signals. We have developed a liver slice system in which HSC activation following injury by standard hepatotoxins can be studied in a more physiologic context, both in human and rat liver tissue. **Methods:** Precision-cut rat (RPCLS) or human liver slices (HPCLS) were incubated for 3 or 16 hours with carbon tetrachloride (CCl<sub>4</sub>). Expression of

markers for HSC and for early fibrogenesis was studied using real-time PCR. Viability was assessed by ATP-content or LDH leakage. **Results:** Liver slices remained viable during control incubation. Incubation with CCl<sub>4</sub> led to a decrease of viability, which was observed at lower doses in RPCLS. Both in RPCLS and HPCLS mRNA expression of the early fibrogenesis/HSC-activation markers heat-shock protein 47 and  $\alpha$ B-crystallin was induced 3 hours after addition of CCl<sub>4</sub> and further increased after 16 hours of incubation (induction: rat 2.1 $\pm$ 0.1 and 16.4 $\pm$ 113.3; human 10.1 $\pm$ 2.8 and 28.6 $\pm$ 15.0, all  $P$ <0.05). In HPCLS higher doses of CCl<sub>4</sub> were needed to induce HSC activation. Gene expression of synaptophysin (HPCLS) and desmin (RPCLS), markers for quiescent as well as activated HSC, was only modestly increased after CCl<sub>4</sub> treatment (1.4 $\pm$ 0.1,  $P$ <0.05, and 1.6 $\pm$ 0.5) indicating a relatively constant number of HSC in the liver slices. **Conclusion:** We developed a method to induce and track early HSC activation in precision-cut liver slices that can be applied to both human and rat liver tissue. This model enables to study activation of HSC within their physiological milieu and provides the unique opportunity to investigate species-specific mechanisms underlying early fibrogenesis.

**1914**

HUMAN LIVER AND KIDNEY SLICE VIABILITY IS EXTENDED AND PATHWAYS OF FIBROSIS ARE CHARACTERIZED.

A. E. Vickers<sup>1</sup>, R. L. Fisher<sup>2</sup> and P. Olinga<sup>3</sup>. <sup>1</sup>*Safety Evaluation, Allergan, Inc., Irvine, CA*, <sup>2</sup>*Vitron Inc., Tucson, AZ* and <sup>3</sup>*Department Pharmacokinetics & Drug Delivery, University Groningen, Groningen, Netherlands*.

The extension of human liver slices (7 days) and kidney slices (11 days) expands the use of this *in vitro* model for studying pathways of injury and repair, including fibrosis. Organ slice quality is sustained by preparing slices in a preservation solution, from organs perfused and maintained in a preservation solution, and with slice intracellular K<sup>+</sup> levels >70  $\mu$ moles/mg slice wet weight. In culture the organ slices are supported by a cellulose filter atop the titanium mesh roller-insert, which contributes to a stabilization of slice wet weight throughout the culture time. Medium is replaced daily to mimic multiple dosing. The slices are metabolically active, maintaining slice ATP and glutathione levels, and organelle integrity is preserved. By 72 hr of culture the organ slices begin to exhibit pathways of repair and a fibrogenic response. An increased deposition of collagen IV is evident at 72 hr and remains elevated for the duration of the cultures. Global gene expression profiling using U133A Affymetrix gene chip arrays revealed an increased expression of extracellular matrix genes including collagens, laminins, contractile proteins, and markers of proliferation in both liver and kidney slices. Some metabolic genes and lipoprotein genes were repressed in the liver slices only. The data supports the activation of tissue stellate cells in the induction of fibrogenic pathways. The recent improvements in organ acquisition and slice preparation and culturing methods demonstrates that slice viability, integrity and morphology is extended for several days in culture. The 3-dimensional cellular complexity increases the utility of this *in vitro* model system to study pathways of injury and repair including fibrosis, and can be extended to understanding mechanisms of fibrotic liver and kidney diseases.

**1915**

THE EFFECT OF THE PPAR $\alpha$  AGONIST WY-14, 643 ON MITOCHONDRIAL MEMBRANE POTENTIAL IN HUMAN AND RODENT LIVER CELL LINES.

S. Barnes<sup>1</sup>, S. E. Boldt<sup>2</sup>, A. K. Hubbard<sup>1</sup>, J. Singh<sup>2</sup> and D. E. Amacher<sup>2</sup>.

<sup>1</sup>*Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT* and <sup>2</sup>*Drug Safety Evaluation, Pfizer Inc., Groton, CT*.

PPAR $\alpha$  agonists have been found to induce peroxisome proliferation and hepatomegaly in rodents. Due to the coordinated function of peroxisomes and mitochondria in fatty acid metabolism and the occurrence of skeletal muscle toxicity in rodents treated with PPAR $\alpha$  agonists, it is possible that some of these compounds may also have mitochondrial effects in some species. The ability of the PPAR $\alpha$  agonist WY-14, 643 to affect the mitochondrial membrane potential in human (Fa2N-4) and rat (Clone 9) liver-derived cell lines was monitored using the fluorescent probe JC-1. These changes could be monitored by measuring either an increase in JC-1 monomer or a decrease in aggregated JC-1 molecules. Measuring levels of JC-1 monomer was far more sensitive than measuring levels of the aggregate. The PPAR $\alpha$  agonist elicited a dose dependent increase in mitochondrial membrane permeability in the rat cell line after a 20 minute exposure. This effect was more pronounced in the rat cell line than in the human cell line. Changes in cell viability from this compound were also measured in both rat and human cells at 1 and 24 hrs using either the ATP production luminescence assay or the MTT viability assay. Changes in cell viability using the more sensitive ATP assay were also more pronounced in the rat cells. Thus, an association between changes in mitochondrial membrane permeability and induction of cell death was best monitored within a 1 hr exposure period in rat liver cells. In addition, it can be concluded that the PPAR $\alpha$  agonist WY-14, 643 causes a decrease in the mitochondrial membrane potential in the Clone 9 cell line, but not in the Fa2N-4 cell line, as measured by an increase in JC-1 monomer. Research funded by Pfizer Global Research and Development.

IN SITU QUANTITATIVE EVALUATION OF PEROXISOMAL PROLIFERATION IN THE NON-HUMAN PRIMATE LIVER VIA LASER SCANNING CYTOMETRY (LSC).

L. A. Ober<sup>1</sup>, V. Kostrubsky<sup>1</sup>, C. Okerberg<sup>1</sup>, J. Wijsman<sup>1</sup>, E. Urda<sup>1</sup>, J. Hanson<sup>1</sup>, K. Toy<sup>1</sup>, W. Collard<sup>1</sup>, W. Maier<sup>1</sup>, R. Bell<sup>1</sup>, L. Zwick<sup>2</sup>, S. Frantz<sup>2</sup>, R. Dunstan<sup>1</sup> and R. Adler<sup>1</sup>. <sup>1</sup>WWSS, Pfizer Inc., Ann Arbor, MI and <sup>2</sup>MPI Research, Mattawan, MI.

Laser scanning cytometry (LSC) and biochemical markers were employed to evaluate the effect of a peroxisome proliferator-activated receptor (PPAR) mixed beta/alpha agonist under development for the treatment of dyslipidemia. Two- to 3.5-year old male cynomolgus monkeys received test compound at 0, 0.1, 0.3, 1, 3, or 10 mg/kg by oral gavage for 28 consecutive days. At necropsy, there were no drug-related gross pathologic findings. Immunohistochemical staining for the peroxisomal membrane protein (PMP70) within the hepatocytes was qualitatively increased in drug-treated monkeys compared to controls. Quantitative evaluation of the immunohistochemical labeling of peroxisomes via LSC confirmed an increase in peroxisomal labeling in all dose groups, which plateaued at drug levels  $\geq$  0.3 mg/kg. Similarly, liver biochemical analyses revealed increased peroxisomal beta-oxidation and acyl CoA oxidase activities in all dose groups, which also plateaued at  $\geq$  0.3 mg/kg. These changes correlated with increases in absolute and relative liver weights. The liver weight changes corroborated the histopathologic findings (hepatocellular hypertrophy) at  $\geq$  0.3 mg/kg. The hepatocellular hypertrophy was characterized by an increase in cell size due to increased quantities of granular eosinophilic cytoplasm. Interestingly, the plasma and liver concentrations of the test compound increased with increasing dosage. However, the above data suggests that maximal peroxisomal activity was achieved at 0.3 mg/kg indicating a saturation effect. In conclusion, quantitative evaluation of hepatocellular peroxisome levels was achieved *in situ* via LSC, which correlated well with biochemical activities, organ weight changes, and histopathology.

COMPARISON OF ALDEHYDE DEHYDROGENASE (ALDH) ACTIVITY IN THE LIVER AND LUNG.

M. Yoon<sup>1,2</sup>, M. C. Madden<sup>2</sup> and H. A. Barton<sup>2</sup>. <sup>1</sup>NRC, The National Academies, Washington, DC and <sup>2</sup>NHEERL, USEPA, Research Triangle Park, NC.

Aldehydes are highly reactive molecules present in the environment and can be produced during biotransformation of xenobiotics. Aldehyde dehydrogenases (especially classes 1, 2 and 3) are important in their detoxification catalyzing oxidation to carboxylic acids. The lung is a major target for aldehydes toxicity. However, ALDH activity in the lung has been poorly studied compared to the liver. In this study, ALDH activity was measured in 4 subcellular fractions from liver and lung to compare the enzymatic capacity of aldehyde removal. Adult (60 days) female Wistar-Han-IGS rats were used to prepare S1 (postnuclear fraction), mitochondrial, cytosol, and microsomal fractions. Propionaldehyde or hexanal (50 uM) were used as substrates for mitochondrial ALDH2 or microsomal ALDH3, respectively. Propionaldehyde (10mM) was used to measure total ALDH activity in each subcellular fractions. ALDH activity in S1 fractions was considered to be an indicator of the total ALDH in the tissue. In the liver, the mitochondrial ALDH2 showed the majority of ALDH activity (i.e., 52% of the total S1 activity). Activity in the cytosol and microsomes was 37% and 29% of the total S1 activity, respectively. In the lung, however, the major ALDH activity was found in the cytosol showing 56% of total S1 activity. Total mitochondrial ALDH activity contributed 41 % of total lung S1 activity. Compared with the liver, lung had 15 % of total S1 ALDH activity. Mitochondrial ALDH2 and microsomal ALDH3 activities were 5 and 10 fold higher in the liver than in the lung, respectively. These data show that the liver and lung had differences in distribution of ALDH among subcellular fractions. Greater cytosolic contribution to the total ALDH activity in the lung indicates that the major isoform(s) in the lung may be different from the liver. These finding indicates that aldehyde metabolizing capacity may respond differently to environmental and/or physiological factors in the lung compared with liver. (Supported by EPA-NRC #CR82879001. This abstract may not represent official EPA policy.)

ETHANOL HAS BIPHASIC EFFECTS ON EXPRESSION OF STEROL REGULATORY ELEMENT BINDING PROTEIN-1 (SREBP-1) IN RAT FGC-4 HEPATOMA CELLS WITH INHIBITION AT HIGH DOSES RESULTING IN INDUCTION OF ADH CLASS I.

L. He<sup>1,3</sup>, M. J. Ronis<sup>2,3</sup>, F. A. Simmen<sup>1,3</sup> and T. M. Badger<sup>1,3</sup>. <sup>1</sup>Physiology & Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR, <sup>2</sup>Pharmacology & Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR and <sup>3</sup>Arkansas Children's Nutrition Center, Little Rock, AR.

SREBPs are transcription factors which regulate fatty acid and cholesterol metabolism. Ethanol has long been known to perturb lipid homeostasis. However, effects of ethanol on SREBP expression have been an area of dispute with some investiga-

tors reporting a significant increase and some a decrease. In the current study we examined the dose responsive effects of ethanol on expression of SREBP-1 in the rat FGC-4 hepatoma cell line with which we previously demonstrated ethanol induction of ADH class I gene transcription. Ethanol had a biphasic effect on expression of the mature form of SREBP-1 protein in cellular homogenates. At low doses of ethanol (< 10 mM) SREBP-1 expression was increased ( $p \leq 0.05$ ) with a 2-fold increase evident at 5 mM. In contrast, at higher doses of ethanol a dose-dependent decrease in SREBP-1 expression was observed and this correlated with increased expression of ADH class I ( $p \leq 0.05$ ). The liver X-receptor agonist T0901317, a known activator of SREBP-1 transcription, was shown to produce a dose-dependent decrease in ADH expression which was completely abolished by ethanol. These data confirm in an *in vitro* model that SREBP-1 is a negative regulator of ADH transcription and that ethanol at high doses induces ADH via suppression of SREBP-1 protein expression. (Supported in part by R01 AA088645 TMB).

ETHANOL INDUCES RAT HEPATIC ALCOHOL DEHYDROGENASE (ADH) CLASS I BY INTERFERING WITH POST-TRANSLATIONAL REGULATION OF STEROL REGULATORY ELEMENT BINDING PROTEIN-1 (SREBP-1).

T. M. Badger<sup>1,3</sup>, L. He<sup>1,3</sup>, F. A. Simmen<sup>1,3</sup> and M. J. Ronis<sup>2,3</sup>. <sup>1</sup>Physiology & Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR, <sup>2</sup>Pharmacology & Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR and <sup>3</sup>Arkansas Children's Nutrition Center, Little Rock, AR.

Continuous intragastric infusion of ethanol as part of total enteral nutrition results in pulses of blood and urine ethanol with a 6-7 d. cycle. The cycle is driven by cyclical changes in transcription of the liver ADH Class I gene. Electrophoretic mobility shift analysis of the ADH I promoter revealed decreased binding of nuclear proteins from ethanol-exposed rats to two canonical sterol response element sites at -63 to -53 and -52 to -40 base pairs relative to the transcription start site on the ADH promoter ( $p \leq 0.05$ ). Specificity of SREBP-1 for the response element was confirmed by chromatin immunoprecipitation (ChIP). Transcriptional inhibition of ADH by SREBP-1 was confirmed by showing the stimulatory effects of SREBP-1 antibodies in *in vitro* transcription assays. SREBP-2 antibodies had no effect on *in vitro* transcription of ADH. Although ethanol treatment elevated the SREBP target genes fatty acid synthase and cholesterol 7-alpha hydroxylase ( $p \leq 0.05$ ) in liver, this appears to be due to increased expression of SREBP-2 ( $p \leq 0.05$ ). Mature SREBP-1 protein levels in nuclear extracts were suppressed by ethanol ( $p \leq 0.05$ ) but SREBP-1 mRNA levels were unaffected suggesting an ethanol inhibition of post-translational processing of this transcription factor. (Supported in part by R01 AA088645 TMB).

MICE WITH HEPATOCYTE-SPECIFIC RXR $\alpha$  DEFICIENCY HAVE ALTERED ALCOHOL METABOLISM.

M. G. Kocsis, A. J. Mendy, G. Dai and Y. Y. Wan. Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS.

There is substantial overlap between vitamin A and alcohol metabolism and their mediated signaling pathways. First, the same enzymes metabolize vitamin A and ethanol. Second, alcohol toxicity and vitamin A deficiency cause the same congenital abnormalities. Third, alcohol ingestion depletes vitamin A stored in the liver. Retinoic acid (RA) is the active metabolite of vitamin A and retinoid X receptor alpha (RXR $\alpha$ ) mediates the action of RA. To investigate the interaction between alcohol and RA, alcohol metabolism and alcohol-induced liver disease were studied in hepatocyte-specific RXR $\alpha$ -deficient mice. Hepatocyte RXR $\alpha$  deficiency resulted in 50% more liver alcohol dehydrogenase (ADH) activity. Consistent with this finding, RXR $\alpha$ -deficient mice exhibited a higher rate of ethanol clearance. However, none of the seven genes that comprise the five-family mouse ADHs showed elevated mRNA. Additionally, antibodies against yeast ADH and human ADH1 showed no difference in ADH level between mutant and wild type (WT) mice. Thus, it appears that the increase in ADH activity might be a result of post-translational ADH enzyme regulation or an increase in activity of the microsomal ethanol oxidizing system. Hepatocyte RXR $\alpha$  deficiency also resulted in a 20% reduction in acetaldehyde dehydrogenase (ALDH) activity. The expression of *aldb1A1* and *aldb3A2*, but not *aldb2*, mRNA was lower in hepatocyte RXR $\alpha$ -deficient mice. In agreement with enzyme activity and mRNA level, western blot analysis demonstrated that ALDH1A1 protein was lower in the mutant mice. These findings indicate that RXR $\alpha$  might regulate expression of the *aldb1A1* and *aldb3A2* genes. Morphological analysis showed that hepatocyte RXR $\alpha$ -deficient mice were more susceptible to ethanol-induced liver damage than the WT mice, presumably because of higher levels of acetaldehyde in the liver resulting from the increase in ADH, and decrease in ALDH, activity. Taken together, our data demonstrate the importance of the vitamin A/RA signaling pathway in regulating alcohol metabolism. (supported by NIH AA014147 and CA053596)

TEMPORAL AND ZONAL EXPRESSION PATTERNS OF LIVER MRP4 AND NTCP FOLLOWING HEPATOTOXICANT EXPOSURE.

L. Aleksunes<sup>1</sup>, G. Scheffer<sup>2</sup> and J. Manautou<sup>1</sup>. <sup>1</sup>Pharmaceutical Sciences, University of Connecticut, Storrs, CT and <sup>2</sup>Pathology, University Hospital Free University, Amsterdam, Netherlands.

Hepatic membrane transporters are important in the disposition of xenobiotics and endogenous compounds. Following acute chemical injury to the liver, hepatocytes are generally more resistant to toxicant re-exposure. Alterations in the expression of transporters may contribute to this resistance by preventing the accumulation of oxidative products or potentially toxic chemicals. Previous data showed the concomitant reduction of uptake transporters and induction of efflux transporters mRNA expression during chemical liver injury. Notably, administration of carbon tetrachloride ( $CCl_4$ ) resulted in 70% reduction in mRNA expression of the uptake transporter  $Na^+$  taurocholate co-transporting polypeptide (Ntcp) and 37-fold increased mRNA levels of the efflux transporter multidrug resistance protein 4 (Mrp4). This study further characterizes the expression of Mrp4 and Ntcp protein in mouse liver following  $CCl_4$  treatment. Male C57BL/6J mice received a hepatotoxic dose of  $CCl_4$  (25  $\mu$ l/kg). Liver samples were collected at 6, 24 and 48 hrs for western blot and immunofluorescence analysis. Hepatic Ntcp protein expression was reduced 50 and 30% at 24 and 48 hrs, respectively. Conversely, induction of Mrp4 protein was prominently detected in  $CCl_4$ -treated mice at 24 and 48 hrs in comparison to almost unnoticeable expression in control mice. Double immunofluorescence staining of liver sections demonstrated the simultaneous down-regulation of Ntcp and up-regulation of Mrp4 in centrilobular hepatocytes. These localized changes in immunofluorescence coincided with areas of necrosis in  $CCl_4$  treated mice. These data suggest that centrilobular hepatocytes attempt to limit intracellular accumulation of Mrp4 and Ntcp substrates (i.e., bile acids, oxidative by-products and xenobiotics) in response to damage. The selective zonal expression of transporters may reduce the overall chemical burden of an injured liver during repair and regeneration and contribute to the resistance of hepatocytes to subsequent toxicant exposure.

METHYLENEDIANILINE INJURY TO LIVERS OF TR<sup>-</sup> [LIVER CANALICULAR MRP2 TRANSPORTER-DEFICIENT] RATS IS NOT LINKED TO OXIDATIVE STRESS.

M. F. Kanz, B. Ramasubramanian, Y. Chen, F. Nayem and M. Treinen-Moslen. Pathology, University of Texas Medical Branch, Galveston, TX.

**Background.** Methyleneedianiline (DAPM) is an industrial chemical used in the production of polyurethanes and epoxy resins. DAPM initially injures biliary epithelial cells (BEC) in rats with normal canalicular transport mechanisms. In contrast, DAPM injury is shifted from BEC to hepatocytes in mutant transport-deficient (TR<sup>-</sup>) rats, which lack expression of the canalicular multispecific organic anion transporter (cMOAT or MRP2) and have an impaired capacity for biliary excretion of organic anions, GSH and GSH conjugates. Because DAPM hepatic injury in TR<sup>-</sup> rats is both rapid and severe, our objective was to assess the effects of DAPM exposure on parameters indicative of oxidative stress. **Methods.** Female TR<sup>-</sup> rats (19-22 wks old) were given 50 mg DAPM/kg po in 35% ethanol and sacrificed at 16 hr. Liver and blood were removed for analysis; liver mitochondria were isolated by differential centrifugation. **Results.** Serum Serum ALT levels of DAPM rats were elevated ~5-fold without an increase in serum bilirubin and bile salt levels. **Histology.** Liver weights in treated females were only mildly increased ( $p > 0.08$ ). Livers of DAPM rats showed mild inflammatory infiltrate around central veins and scattered, small foci of apparently oncotic cells in centrilobular to midzonal regions. Midzonal hepatocytes were frequently vacuolated, reminiscent of mild fatty change. BEC injury was not observed. **Oxidative Stress.** Reduced (GSH) and oxidized (GSSG) glutathione levels in livers were comparable between control and treated rats. Similarly, mitochondrial GSH and GSSG levels were not altered by DAPM treatment. Immunohistochemical staining for 4-HNE was not discernably increased in liver sections of DAPM-treated rats. **Conclusion.** The observed lack of detectable changes in indices of oxidative stress, namely GSH, GSSG, and 4-HNE, after DAPM treatment suggests that oxidative stress is not an important mechanism for the hepatocellular injury induced by this toxin in TR<sup>-</sup> rats. PLASMA ESTERASE ACTIVITY PROTECTS AGAINST COCAINE HEPATOTOXICITY IN FEMALE MICE.

M. S. Abdel-Rahman<sup>1</sup>, R. M. Turkall<sup>1,2</sup> and T. Visalli<sup>1</sup>. <sup>1</sup>Pharmacology/Physiology UMDNJ, Newark, NJ and <sup>2</sup>Clinical Laboratory Sciences, School of Health Related Professions UMDNJ, Newark, NJ.

Oral cocaine administration results in hepatic necrosis, increased plasma transaminase concentration, and decreased anti-oxidative capability which is potentiated by lipopolysaccharide (LPS) in male CF-1 mice. Females administered the same treat-

ment regimen display none of the hepatotoxic effects seen in their male counterparts. This study was conducted to further dissect the mechanisms responsible for this gender difference in cocaine hepatotoxicity (CH) and lipopolysaccharide potentiation of CH. Male and female CF-1 mice were orally administered 20 mg/kg cocaine hydrochloride once daily for seven days. Four hours after the last cocaine administration the mice were administered  $12 \times 10^6$  EU LPS intraperitoneally. The activity of plasma esterase (butyrylcholinesterase), the enzyme responsible for the major pathway of cocaine metabolism to non-hepatotoxic metabolites, was measured. Aminotransferase release and histological analysis were used to determine hepatotoxicity. The concentration of the hepatotoxic precursor norcocaine was measured in the plasma and liver. Regardless of treatment, males were shown to have only 30% of the plasma esterase activity displayed by females. In addition, administration of testosterone to ovariectomized females resulted in a 70% reduction in plasma esterase activity when compared with surgically unaltered females. Moreover, hepatic norcocaine was not detected in the plasma or liver of surgically unaltered female animals while it was present in males and testosterone supplemented ovariectomized females. These results indicate that plasma esterase activity is heavily influenced by sex hormones, predominantly testosterone, in CF-1 mice. Suppression of plasma esterase by testosterone correlates with decreased norcocaine production and is therefore responsible, in part, for the increased CH seen following oral administration with and without LPS exposure in male CF-1 mice.

IDENTIFICATION OF NOVEL SUBSTRATES AND INHIBITORS OF SOLUBLE EPOXIDE HYDROLASE N-TERMINAL PHOSPHATASE ACTIVITY BASED ON ITS SUBCELLULAR LOCALIZATION.

A. Enayetallah<sup>1</sup>, P. Srivastava<sup>1</sup>, M. Barber<sup>2</sup>, P. Mungalachetty<sup>1</sup>, B. Luo<sup>1</sup> and D. Grant<sup>1</sup>. <sup>1</sup>Pharmaceutical sciences, University of Connecticut, Storrs, CT and <sup>2</sup>Biotechnology/Bioservices Center, University of Connecticut, Storrs, CT.

Recently, soluble epoxide hydrolase (sEH) has been found to possess an N-terminal phosphatase activity in addition to its C-terminal epoxide hydrolase activity. Endogenous hydrolase substrates include linoleic acid and arachidonic acid epoxides, some of which have been suggested to be involved in regulating blood pressure and inflammation. However, there are limited data regarding possible endogenous substrates for the N-terminal phosphatase. In this study, we applied immunofluorescence and confocal microscopy techniques using markers for different subcellular compartments to evaluate sEH co-localization in an array of human tissues. We then evaluated possible substrates based on our sEH subcellular localization findings. Results showed that sEH is both cytosolic and peroxisomal in human hepatocytes and renal proximal tubules. Isoprenoid phosphate metabolites, which are synthesized in peroxisomes as precursors for cholesterol biosynthesis and protein isoprenylation were found to be substrates of the N-terminal phosphatase, with farnesyl monophosphate having a  $K_m$  of 24.16 ( $\pm 7.85$ )  $\mu$ M and  $V_{max}$  of 684.2 ( $\pm 92.7$ ) nmole/min/mg. Based on the isoprenoid phosphate structure we were able to identify several N-terminal phosphatase inhibitors with IC<sub>50</sub> values in the low micromolar range. To our knowledge, this is the first report showing 1) the subcellular localization of sEH in a wide array of human tissues 2) farnesyl, geranyl and geranylgeranyl mono- and pyrophosphates as possible endogenous substrates of the sEH N-terminal phosphatase and 3) sEH phosphatase inhibitors. Our data suggests a possible role of sEH in the cholesterol biosynthesis pathway and/or protein isoprenylation. These results warrant further investigation of the biological significance of sEH in these pathways.

EFFECTS OF BETAINE SUPPLEMENTATION ON HEPATIC METABOLISM OF SULFUR-CONTAINING AMINO ACIDS IN MICE.

Y. C. Kim<sup>1</sup> and S. K. Kim<sup>2</sup>. <sup>1</sup>College of Pharmacy, Seoul National University, Seoul, South Korea and <sup>2</sup>College of Pharmacy, Chungnam National University, Daejeon, South Korea. Sponsor: G. Carlson.

We previously reported that acute betaine treatment induced significant changes in the hepatic glutathione and cysteine levels in mice and rats. The present study was aimed to determine the effects of dietary betaine supplementation on the metabolism of sulfur-containing amino acids. Alterations in the enzyme activities and metabolites involved in the transsulfuration reactions were determined in male mice supplemented with betaine (1%) in drinking water for two weeks. Betaine intake increased hepatic methionine, S-adenosylmethionine, and S-adenosylhomocysteine levels significantly, whereas homocysteine, cystathione, and taurine were decreased. Hepatic methionine adenosyltransferase activity was elevated to 3-fold of control. Cysteine dioxygenase activity was decreased suggesting an inhibition of cysteine catabolism to taurine. Glycine levels in liver and plasma were decreased significantly, but hepatic serine was elevated. Despite the significant changes in the transsulfuration reactions, neither hepatic cysteine nor glutathione level was altered by betaine intake. The results indicate that betaine supplementation enhances recycling of homocysteine for the generation of methionine and S-adenosylmethionine

while reducing its utilization for the synthesis of cystathione and cysteine in liver. However, the hepatic level of cysteine or glutathione is not changed due to the depression of cysteine catabolism to taurine in betaine-fed mice. The pharmacological/toxicological significance of this finding is discussed.

1926

APPLICATION OF QSARS TO EVALUATE MOLECULAR MECHANISMS OF HALOBENZENE INDUCED CYTOTOXICITY IN RAT HEPATOCYTES.

K. Chan and P. J. O'Brien. *Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada.* Sponsor: G. Cherian.

Halobenzenes are ubiquitous environmental contaminants, which are hepatotoxic in rodents and humans. Their toxicological effects however, are believed to be mediated by their metabolites. Accordingly, an understanding of the molecular mechanism of halobenzene induced cytotoxicity is desirable. We applied quantitative structure-activity relationships (QSAR) and accelerated cytotoxicity mechanism screening (ACMS) to evaluate the cytotoxicity of halobenzene congeners in rat hepatocytes. Rat hepatocytes were freshly isolated by 2-step collagenase perfusion method, and maintained at 37°, in a 95%O<sub>2</sub>/5%CO<sub>2</sub> atmosphere. Cytotoxicity was determined by trypan blue exclusion tests. The LD<sub>50</sub> of 16 halobenzene congeners in rat hepatocytes *in vitro* at 2 h determined by ACMS correlated to the hepatotoxicity, measured as plasma ALT levels, reported in rats *in vivo*. ACMS revealed that halobenzene cytotoxicity was markedly increased by sulfotransferase, UDP-glucuronosyl transferase and NADPH:Quinone Oxidoreductase inhibitors suggesting that toxicity was due to P450 oxidation to phenols and quinones and not epoxides. We derived a QSAR and found that the cytotoxicity of halobenzene LD<sub>50</sub> values correlated with dipole moment,  $\mu$ (symmetry), and log  $P$ (hydrophobicity): log LD<sub>50</sub>(2h)=−0.641(±0.124) $\mu$ −0.685(±0.205)log  $P$ +5.713. The most cytotoxic halobenzenes were those that had asymmetrically distributed halogen substituents and were more hydrophobic. This suggests that unsymmetrical halobenzenes were well activated by microsomal metabolizing enzymes to phenols and quinones whereas symmetrical halobenzenes were poorly activated by metabolizing enzymes. In conclusion, the derived QSAR implies that halobenzene cytotoxicity depends on P450 activation to reactive metabolites.

1927

ACTIVATION OF PROMUTAGENS WITH HUMAN LIVER S9 AND HUMAN HEPATOCYTES USING CHINESE HAMSTER OVARY MICRONUCLEUS ASSAY.

S. K. Roy<sup>1</sup>, A. P. Li<sup>2,3</sup>, B. Chris<sup>4</sup>, K. Paul<sup>1</sup> and A. Thilagar<sup>1,2</sup>. <sup>1</sup>SITEK Research Laboratories, Rockville, MD, <sup>2</sup>The ADMET Group, LLC, Rockville, MD, <sup>3</sup>In Vitro ADMET Laboratories, LLC, Rockville, MD and <sup>4</sup>Tissue Transformation Technologies Inc., Edison, NJ.

*In vitro* genetic toxicity test systems require the addition of external metabolic activation sources to detect promutagens or proclastogens. The use of induced rat liver S9 is a well established metabolic activation system for detection of potential genotoxic activity of xenobiotics. However, species often respond differently to a variety of chemical carcinogens. Species-specific differences in drug metabolism are believed to be a key determinant of differences in drug toxicity. For the genetic safety assessment of human pharmaceuticals, the use of human liver S9 and/or human liver may be more appropriate than to use induced rat liver S9. This would have greater relevance to human exposure as it would result in the metabolism of drug closer to human *in vivo* condition. We evaluated the proficiency of human hepatocytes and human liver S9 to activate three different class of promutagens cyclophosphamide (CP), dimethylnitrosamine (DMN) and dimethylbenzanthracene (DMBA) using Chinese hamster ovary cells. We used cytokinesis-blocked *in vitro* micronucleus assay. Multiple endpoints e.g. apoptosis, necrosis, multinucleated cell, induction of micronuclei, and cell proliferation were evaluated in this assay. Our results indicate that all three promutagens formed genotoxic metabolites in presence of human hepatocytes and human liver S9. Results also indicated CP as a strong inducer of apoptosis and necrosis (2-3 folds) in comparison to DMN and DMBA. Results were comparable to that of Rat S9. Results of the study suggest that human hepatocytes and human liver S9 can activate efficiently various classes of promutagens and may be applied in routine *in vitro* genotoxicity assays.

1928

RUBRATOXIN B INDUCED TISSUE INHIBITOR OF METALLOPROTEINASES (TIMP)-1 SECRETION IN HEPG2 CELLS.

H. Nagashima<sup>1</sup>, K. Maeda-Nakamura<sup>1</sup>, K. Iwashita<sup>1</sup> and T. Goto<sup>2</sup>. <sup>1</sup>National Food Research Institute, Tsukuba, Ibaraki, Japan and <sup>2</sup>Faculty of Agriculture, Shinshu University, Minamiminowa, Nagano, Japan. Sponsor: M. Fukayama.

Rubratoxin B is a potent hepatotoxic mycotoxin produced by various *Penicillium* fungi. Last annual meeting, we reported that stress-activated MAP kinases (SAPKs) regulate rubratoxin B-caused cytotoxicity and cytokine secretion in human he-

patoma cell line HepG2. In this study, the effect of rubratoxin B on the secretion of tissue inhibitor of metalloproteinases (TIMP)-1 was investigated using HepG2 cells. TIMP-1 has several physiological activities such as promotion of cell proliferation and anti-apoptosis activity. Furthermore, TIMP-1 is considered to be in charge of liver fibrosis and cancer metastasis. Rubratoxin B apparently induced TIMP-1 secretion in HepG2 cells. According to RT-PCR, it is likely that rubratoxin B-induced TIMP-1 secretion is chiefly regulated transcriptionally. We previously reported that active (phosphorylated) forms of SAPKs were detected in rubratoxin B-treated HepG2 cells, indicating the possibility that SAPKs (JNKs and p38s) are involved in rubratoxin B-induced TIMP-1 secretion. JNK inhibitor SP600125 did not affect rubratoxin B-induced TIMP-1 secretion. Conversely, p38 inhibitor SB203580 augmented rubratoxin B-induced TIMP-1 secretion. The results of RT-PCR showed that SB203580 increased the amount of TIMP-1 mRNA. However, compared with the increase in TIMP-1 secretion, the increase in mRNA was not significant, suggesting that p38 impairs rubratoxin B-induced TIMP-1 secretion both transcriptionally and post-transcriptionally. Our results lead us to the hypothesis that rubratoxin B causes liver fibrosis via the increase in TIMP-1 secretion. In fact, the treatment of rubratoxin B increased TIMP-1 secretion in mice sera. This result supports our hypothesis.

1929

FUMONISIN B<sub>1</sub> AND TNF $\alpha$  INDUCED INCREASES IN SPHINGANINE AND SPHINGOSINE IN HEPG2 HEPATOCYTES ARE ATTENUATED BY SP600125, A JNK INHIBITOR.

S. Hsiao<sup>1</sup>, P. D. Constable<sup>2</sup>, M. E. Tumbleson<sup>3</sup> and W. M. Haschek<sup>1</sup>. <sup>1</sup>Veterinary Pathobiology, University of Illinois at Urbana-Champaign, Urbana, IL, <sup>2</sup>Veterinary Clinical Medicine, University of Illinois at Urbana-Champaign, Urbana, IL and <sup>3</sup>Agricultural and Biological Engineering, University of Illinois at Urbana-Champaign, Urbana, IL.

Sphinganine and sphingosine, the most common sphingolipid bases in mammalian cells, are important mediators in fumonisin B<sub>1</sub> (FB1) toxicity and tumor necrosis factor  $\alpha$  (TNF $\alpha$ ) mediated transplant rejection and cardiovascular dysfunction. *In vivo*, we have shown that FB1 induces hepatotoxicity, cardiotoxicity and alteration of sphingolipids in pigs and horses. *In vitro*, we have demonstrated a sustained increase in sphinganine and a transient increase in sphingosine in HepG2 hepatocytes after 24 hr exposure to FB1 and TNF $\alpha$ , respectively. To determine the signaling pathway responsible for the alteration in sphingolipid metabolism, we investigated the effects of c-Jun N-terminal kinase (JNK) inhibitor, SP600125 (10  $\mu$ M), and transcription factor NF- $\kappa$ B inhibitors, Helenalin (1  $\mu$ M) and Bay 11-7082 (10  $\mu$ M), on the amounts of sphinganine and sphingosine in HepG2 cells following 24 hr treatment with FB1 (10 M) and TNF $\alpha$  (10 ng/mL). Pretreatment (30 min) of HepG2 cells with the JNK inhibitor, SP600125, decreased intrinsic sphingosine, and attenuated FB1 and TNF $\alpha$  induced increases in sphinganine and sphingosine, respectively. In contrast, pretreatment with NF- $\kappa$ B inhibitors Helenalin and Bay 11-7082 did not affect the increases in sphinganine and sphingosine. The results suggest an interaction between the JNK signaling pathways and the sphingolipid metabolic pathways in HepG2 cells, and a potential novel application of JNK inhibitors for the treatment of FB1 and TNF $\alpha$  mediated diseases. Supported by the Society of Toxicologic Pathology/Abbott Laboratories Clinical Research Award and International Life Sciences Institute.

1930

AUGMENTATION OF LIPOPOLYSACCHARIDE-INDUCED GENE EXPRESSION AND LIVER INJURY BY RANITIDINE BUT NOT FAMOTIDINE.

J. P. Luyendyk<sup>1</sup>, L. D. Lehman-McKeeman<sup>2</sup>, D. M. Nelson<sup>2</sup>, V. Bhaskaran<sup>2</sup>, B. D. Car<sup>2</sup>, G. H. Cantor<sup>2</sup>, C. M. North<sup>1</sup>, S. W. Newport<sup>1</sup>, J. E. Maddox<sup>1</sup>, P. E. Ganey<sup>1</sup> and R. A. Roth<sup>1</sup>. <sup>1</sup>Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI and <sup>2</sup>Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ.

Rats cotreated with nonhepatotoxic doses of lipopolysaccharide (LPS) and ranitidine (RAN) develop liver injury, whereas LPS/famotidine (FAM)-cotreated rats do not. This result matches the relative propensity of these two drugs to precipitate idiosyncratic liver injury in humans. We tested the hypotheses that 1) early changes in hepatic gene expression could distinguish LPS/FAM-cotreated rats from rats cotreated with LPS/RAN and 2) cotreatment with RAN but not FAM alters the expression of some LPS-regulated genes. Rats were treated with a nontoxic dose of LPS (44 x 10<sup>6</sup> EU/kg, iv) or its vehicle, then two hours later with RAN (30 mg/kg, iv), FAM (6 mg/kg; a pharmacologically equi-efficacious dose, or 29 mg/kg; an equimolar dose, iv), or vehicle. They were killed 2 or 6 h after drug treatment for evaluation of hepatotoxicity and liver gene expression (2 h only). Hierarchical clustering of gene expression data from Affymetrix Rat Genome 230 2.0 arrays identified the LPS-treated rats as a unique group. RAN-treated groups were distinguishable from FAM-treated groups in the animals co-treated with LPS and also in the

animals co-treated with Veh. Relative to the Veh/Veh group, a similar set of transcripts was altered in the groups treated with LPS alone and with LPS/FAM. For the vast majority of these transcripts (6307 of 6321), the magnitude of change was similar in these two groups. Within this group of probe sets, LPS/RAN cotreatment either enhanced or prevented the LPS-induced change in expression of several genes encoding inflammatory mediators, transcriptional regulators, and others. The results suggest that LPS/RAN cotreatment, but not LPS/FAM cotreatment, alters the expression of some genes regulated by LPS. Protein products of several of these genes (e.g., COX-2 and MIP-2) have actions that could play a role in LPS/RAN-induced liver injury (Supported by NIH grant DK061315).

### 1931

#### 1H-NMR BASED METABONOMICS STUDY OF GALACTOSAMINE, METHYLENE DIANILINE, AND CLOFIBRATE IN RATS.

N. Katsutani and T. Aoki. *Eisai Co., Ltd., Drug Safety Research Laboratories, Hashima, Gifu-ken, Japan.*

Efficacy of 1H-NMR based metabolomics was studied in rat liver toxicity models. Galactosamine (GAL), methylene dianiline (4, 4'-diaminodiphenylmethane; DAPM), or clofibrate (CLO) was intraperitoneally (GAL) or orally (DAPM and CLO) administered to male Crj:CD (SD) IGS rats (8 weeks old) on Day 1. Control animals received the vehicle in the same manner. The following examinations were conducted: blood chemistry on Days 2, 3, and 5, 24-hour urine samples for 1H-NMR from Day 1 (pretreatment) to Day 5, and histopathology. After administration, apparent increases in liver enzymes were shown in animals given GAL or DAPM, and histopathology revealed typical changes following hepatocyte deaths and bile duct damage in animals given GAL and DAPM, respectively. Principle component analysis of 1H-NMR spectra showed differences between treatment and control groups, and in addition, the CLO treated group was discriminated from the GAL and DAPM treated groups. Changes in the 1H-NMR spectra over time showed characteristic peaks that suggested possible biomarkers for the respective toxicities.

### 1932

#### EVALUATION OF A NOVEL ANTI-TUMOR DRUG USING *IN VITRO* TOXICITY SCREENING IN RAT HEPATOMA (H4IIE) CELLS, NORMAL RAT KIDNEY (NRK) CELLS, AND RAT PRIMARY HEPATOCYTES.

P. C. Wilga, J. M. McKim, Jr., J. F. Pregenzer and D. K. Petrella. *CeeTox, Kalamazoo, MI.*

Cytoreg® is a novel drug candidate shown to have cytotoxic activity against cancer cells. The compound is acidic in nature and has the potential of being an effective first line treatment for various cancer indications. This study was designed to identify potential cytotoxicity not related to the pharmacology and to determine whether the drug can distinguish tumor from non-tumor cells. Rat primary hepatocytes, normal rat kidney (NRK) cells and rat hepatoma (H4IIE) cells were used as the test systems. *In vitro* toxicity assays were used to measure membrane leakage, cell number, mitochondrial function, oxidative stress, and apoptosis. Dosing was based on a series of sponsor-requested dilutions, including dilutions of 2000, 1000, 500, 100, 50, 10, and 1. The highest dilution represented the lowest exposure concentration. The effect of pH in the absence of drug was also determined. Cells were cultured in 96-well plates and exposed for 6 and 24 hr. In H4IIE cells, the compound was lethal to more than 90% of the cells at the 500 dilution at 24 hr. These effects occurred prior to any cytotoxic effect related to low pH. Dilutions of 100 and lower showed cytotoxicity that could not be distinguished from effects due to low pH. Rat primary hepatocytes were used to investigate cytotoxic effects on non-tumor cells. Exposure dilutions of 2000, 1000, and 500 did not produce any acute cytotoxicity in these cells, as was observed in H4IIE cells at the 500 dilution, but did produce effects on the mitochondria. NRK cells were evaluated to investigate specificity and selectivity in another non-tumor cell line. No cytotoxic effects were observed up to and including the 500 dilution after 6 and 24 hr. Significant effects were observed on the mitochondria at dilutions of 100 and lower, consistent with effects due to low pH. These data indicate that the tumor cell line under conditions of near physiologic pH is considerably more sensitive to the cytotoxic effects of Cytoreg® than are non-tumor cells based on cell number and membrane integrity.

#### UPREGULATION OF STEM CELL-DERIVED TYROSINE KINASE (STK) EXPRESSION IN LIVER MACROPHAGES AND ENDOTHELIAL CELLS DURING ACUTE ENDOTOXEMIA IS INDEPENDENT OF TUMOR NECROSIS FACTOR RECEPTOR-1.

L. C. Chen, J. Laskin and D. Laskin. *Joint Graduate Program in Toxicology, Rutgers University and UMDNJ-RWJMS, Piscataway, NJ.*

Acute endotoxemia is associated with tissue injury caused by excessive release of proinflammatory and cytotoxic mediators from activated liver macrophages and endothelial cells. Macrophage stimulating protein (MSP) is an immunoregulatory

growth factor produced mainly by hepatocytes that is thought to play a critical role in inflammation and tissue repair. MSP exerts its action by binding to a membrane receptor kinase, stem cell-derived tyrosine kinase (STK), on responsive cell types. In the present studies, we analyzed STK expression in liver macrophages and endothelial cells during acute endotoxemia. The role of TNF- $\alpha$  in STK expression was also evaluated. Macrophages and endothelial cells were isolated from the livers of wild type (WT) and TNF- $\alpha$  receptor (TNFR1, p55) knockout mice treated i.p. with 3 mg/kg endotoxin or control. We found that freshly isolated macrophages and endothelial cells from control WT and TNFR1-/- mice constitutively expressed STK mRNA as determined by real time RT-PCR. Treatment of mice with endotoxin caused a time-dependent increase in STK mRNA expression in both hepatic macrophages and endothelial cells, which was maximal at 3 hr. No major differences were noted between the mouse strains. In endothelial cells isolated from WT mice 24 hr after endotoxin administration, TNF- $\alpha$  (5 ng) or IL-1 $\beta$  (5 ng) treatment (24 hr) upregulated STK expression. This was not observed in cells from control animals. These data suggest that MSP may play a role in nonparenchymal cell activation and tissue injury during acute endotoxemia. However, this activity is independent of TNFR1. Upregulation of STK in endothelial cells by TNF- $\alpha$  may occur via activation of alternative cell surface receptors. Supports: NIH GM34310, ES04738 and ES05022.

#### EVALUATION OF SYSTEMIC TOXICITY IN MIXTURES OF TRICHLOROETHYLENE (TCE), HEPTACHLOR (HEPT), AND DI(2-ETHYLHEXYL)PHTHALATE (DEHP) ASSESSED IN A 5X5X5 DESIGN.

J. Simmons<sup>1</sup>, S. Yeatts<sup>2</sup>, J. Zhao<sup>2</sup>, C. Gennings<sup>2</sup>, A. McDonald<sup>1</sup> and R. MacPhail<sup>1</sup>. <sup>1</sup>NHEERL/ORD, USEPA, Research Triangle Park, NC and <sup>2</sup>Department Biostatistics, VCU, Richmond, VA.

While a large number of experiments have evaluated the interactive toxicity of environmental chemicals with the same mechanism or similar modes of action, fewer have examined the interactions of chemicals with diverse modes of action. This study examined the interactive toxicity of three diverse chemicals: TCE, DEHP and HEPT. Female F-344 rats were dosed daily by gavage for 10 consecutive days. A 5x5x5 full-factorial design with 125 treatment groups (n=10/group) was used in which rats received either one of five dose levels of TCE alone (0, 40, 200, 800, 1200 mg/kg/day), DEHP alone (0, 50, 100, 150, 200 mg/kg/day) or HEPT alone (0, 1, 3, 10, 14 mg/kg/day) or else one of the possible binary and tertiary combinations. Eleven endpoints (body weight loss, brain weight, relative thymus weight, relative adrenals weight, relative spleen weight, relative kidney weight, relative liver weight, serum bilirubin, serum alanine aminotransferase, liver pathology and kidney pathology) were analyzed by response-surface methodology. The overall test for interaction was significant for seven endpoints. Ten of the 33 binary interaction terms were statistically significant; nine of these ten were less than response additive and one (the interaction of TCE and DEHP on liver pathology) was greater than response additive. Three-way interactions were detected for three endpoints (relative liver weight, relative kidney weight and bilirubin); their effect was a dose-dependent decrease in the magnitude of the antagonistic two-way interactions. In summary, nonadditive binary interactions were frequently detected; most were less than additive. Three-way interactions were less frequent and acted to lessen the severity of the antagonistic binary interactions. Response-surface experiments are labor- and time-intensive, in conduct, analysis and interpretation, pointing out the need for more efficient mixtures designs and analyses. ### 1935

#### FIRST-PASS EFFECTS ON THE BIOAVAILABILITY OF HISTAMINE DIHYDROCHLORIDE. A MULTIPLE-CANNULAE DOG MODEL FOR INVESTIGATION OF HEPATIC ELIMINATION.

B. M. Richard<sup>1</sup>, T. M. Tuell<sup>1</sup>, R. R. Lane<sup>1</sup>, J. M. Trang<sup>2</sup>, S. Authier<sup>3</sup>, C. A. Zerouala<sup>3</sup>, S. J. Watson<sup>3</sup>, L. Berryman<sup>3</sup> and S. A. Tonetta<sup>1</sup>. <sup>1</sup>Nonclinical, Maxim Pharmaceuticals, San Diego, CA, <sup>2</sup>PK/PD, PK/PD International, Tucson, AZ and <sup>3</sup>Toxicology, LAB Pre-Clinical Research International, Laval, QC, Canada.

Histamine dihydrochloride, (Ceplene™, 2-(1H-imidazol-4-yl) ethanamine) is a synthetic analog of histamine, which is being tested subcutaneously in cancer patients. An oral formulation (HD-O) is being developed to target liver diseases. Animal models are an essential aspect of the testing of alternative formulations of histamine due to its extensive first-pass effect. A dog model was developed for investigation of the hepatic elimination of histamine. The study involved intra-duodenal (ID) infusion in conscious animals of HD-O with or without aminoguanidine sulfate (AGS), a potent diaminoxidase inhibitor. Following a 10-minute infusion with saline or AGS (50 mg/kg), HD-O (0.5 to 15 mg/kg) was infused for 10 minutes. Histamine concentrations were measured in portal (PV), caval (CV)

and jugular vein (JV) up to 4 hours. The hepatic extraction ratios (ER) were calculated as the difference between PV and CV histamine levels relative to PV values. Maximum oral bioavailability (OBA) was calculated as 1-ER. The intrinsic hepatic clearance ( $Cl_{H_2}$ ) was calculated as  $LPF \times ER$  where LPF is the estimated liver plasma flow. Mean arterial pressure (MAP) was measured indirectly. The mean ER values for histamine were 0.94 and 0.79 with or without AGS, respectively indicating that HD-O exhibited an extensive first-pass effect. Mean OBA values ranged from 5.9 to 21.3%. Mean  $Cl_{H_2}$  ranged from 0.69 to 1.03 L/hr/kg. This data indicate that the disposition of HD-O could be influenced by changes in liver blood flow. Based on pharmacokinetic/pharmacodynamic (PK/PD) analyses, a significant reduction in MAP from baseline (as low as 40 mmHg) was observed which correlated with plasma histamine levels in both JV ( $p=0.004$ ) and CV ( $p=0.024$ ). The present data demonstrate the utility of this model for the investigation of hepatic first-pass effects on histamine as well as PK/PD correlations.

### 1936

#### REACTIVITY AND MODELING STUDIES PREDICT THAT FLUORINATED AMINOPHOSPHONATES (FAP) INHIBIT CHOLINESTERASES (CHE) VIA P—C BOND CLEAVAGE.

G. F. Makhaeva<sup>1</sup>, A. Y. Aksinenko<sup>1</sup>, V. B. Sokolov<sup>1</sup>, A. N. Razdolsky<sup>1</sup>, N. N. Strakhova<sup>1</sup>, V. V. Malygin<sup>1</sup>, J. W. Kampf<sup>2</sup>, F. A. Nasser<sup>3</sup> and R. J. Richardson<sup>3</sup>. <sup>1</sup>*Institute of Physiologically Active Compounds RAS, Chernogolovka, Russian Federation*, <sup>2</sup>*Chemistry Department, University of Michigan, Ann Arbor, MI* and <sup>3</sup>*EHS Department, Toxicology Program, University of Michigan, Ann Arbor, MI*.

Previous kinetic studies showed that FAP of general formula  $(RO)_2P(O)C(CF_3)_2NHS(O)_2C_6H_5$  irreversibly inhibit CHE, despite their lack of a typical leaving group. QSAR, x-ray, and chemical reactivity studies of FAP phosphinate analogs suggested that FAP inhibition of CHE proceeds by P—C bond cleavage. The present research examined the molecular properties of FAP using chemical reactivity studies and molecular modeling, with a view toward understanding their mechanism of inhibition of CHE. <sup>19</sup>F and <sup>31</sup>P NMR showed that heating an equimolar mixture of the diethyl (diEt)-FAP and water in dimethylformamide yields mainly diEt phosphate,  $(EtO)_2P(O)OH$ , and the amide,  $(CF_3)_2CHNHS(O)_2C_6H_5$ , demonstrating the high lability of the P—C bond in FAP. To determine why this bond is unusually labile, a conformational search was performed for the most probable 3D structures with subsequent quantum-chemical calculations of FAP and the isosteric molecule  $(EtO)_2P(O)C(CH_3)_2NHS(O)_2C_6H_5$ , diEt-AP, which does not have  $CF_3$  groups. Energy barriers (kcal/mol) for breaking bonds in diEt-FAP assessed through virtual stretching of covalent bonds from 1.5 to 3.5 Å, were 33.1 (P—C), 76.0 and 101.8 (P—O), and 80.7 (N—S). Thus, the P—C bond was the most labile. In contrast, the energy barrier for breaking the corresponding P—C bond in the diEt-AP molecule (58.2 kcal/mol) was far greater. Moreover, modeling results showed that the P—C bond in diEt-FAP had significant lengthening (1.946 Å) compared with the corresponding P—C bond in diEt-AP (1.679 Å), in agreement with x-ray studies. The results support the hypothesis that CHE inhibition by FAP proceeds by cleavage of the P—C bond, which is stabilized by the presence of two  $CF_3$  groups. (Supported by CRDF RB2-2035 & RB2-2488 and ARO DAAD19-02-1-0388).

### 1937

#### X-RAY CRYSTAL STRUCTURES OF FLUORINATED AMINOPHOSPHONATE (FAP) COMPOUNDS SHOW AN ELONGATED P—C BOND AND DIMERIZATION.

F. A. Nasser<sup>1</sup>, J. W. Kampf<sup>2</sup>, G. F. Makhaeva<sup>3</sup>, A. Y. Aksinenko<sup>3</sup>, V. B. Sokolov<sup>3</sup>, N. N. Strakhova<sup>3</sup>, V. V. Malygin<sup>3</sup> and R. J. Richardson<sup>3</sup>. <sup>1</sup>*EHS Department, Toxicology Program, University of Michigan, Ann Arbor, MI*, <sup>2</sup>*Chemistry Department, University of Michigan, Ann Arbor, MI* and <sup>3</sup>*Institute of Physiologically Active Compounds RAS, Chernogolovka, Russian Federation*.

FAP compounds,  $(RO)_2P(O)C(CF_3)_2NHS(O)_2C_6H_5$ , R = alkyl, inhibit serine esterases. It is thought that inhibition involves phosphorylation of the active site serine, although this mechanism would involve an unusual reaction requiring scission of the P—C bond. Moreover, FAP compounds exhibit a time-dependent increase in anti-esterase potency after being dissolved in organic solvents, while their NMR spectra do not change. To gain insight into the unusual properties of FAP compounds, the x-ray crystal structures of the ethyl, *n*-propyl, isopropyl, and *n*-butyl analogs were determined. X-ray intensities were measured at 113 K and refined to R values of 0.028-0.035. The structural studies revealed that the compounds have an elongated P—C bond (1.897 Å) compared to the normal P—C ( $\sigma^3$ ) bond (1.844 Å). In addition, all of the compounds form dimers due to intermolecular H-bonding (P=O—H—N). Dimerization is favored by the geometry of the  $CF_3$  groups. Using the ethyl analog as an example, the  $CF_3$ —C— $CF_3$  angle is 109.3°. This angle allows for close intermolecular proximity of the N—H and P=O moieties without incurring steric hindrance from the  $CF_3$  groups. Whereas the intermolecular H-bond distance is 2.0 Å, the intramolecular H-bond distance is 2.3 Å.

Furthermore, the intramolecular H-bond angle is 119.0°, while the intermolecular H-bond angle is 157.7°. The intermolecular H bond angle is more open and stronger than the relatively closed and weaker intramolecular H bond. The observed dimerization may explain why FAP compounds require prolonged solvation for maximum inhibitory potency. Moreover, the elongated (and therefore weaker) P—C bond supports the hypothesis that this bond is cleaved during inhibition of serine hydrolases. (Supported by CRDF RB2-2035 & RB2-2488 and ARO DAAD19-02-1-0388).

#### MASS SPECTROMETRY REVEALS THAT SERINE ESTERASES ARE PHOSPHORYLATED AND AGED BY FLUORINATED AMINOPHOSPHONATE (FAP) COMPOUNDS.

N. D. Miller<sup>1</sup>, J. S. Pierce<sup>1</sup>, P. Glynn<sup>2</sup>, R. M. Worden<sup>3</sup>, J. Sun<sup>3</sup>, G. F. Makhaeva<sup>4</sup>, A. Y. Aksinenko<sup>4</sup>, V. B. Sokolov<sup>4</sup>, V. V. Malygin<sup>4</sup> and R. J. Richardson<sup>4</sup>. <sup>1</sup>*University of Michigan, Ann Arbor, MI*, <sup>2</sup>*University of Leicester, Leicester, United Kingdom*, <sup>3</sup>*Michigan State University, East Lansing, MI* and <sup>4</sup>*Institute of Physiologically Active Compounds RAS, Chernogolovka, Russian Federation*.

Serine esterases are inhibited by dialkyl FAP compounds of general formula,  $(RO)_2P(O)C(CF_3)_2NHS(O)_2C_6H_5$ , where R = alkyl. It has been hypothesized that the active site serine attacks the phosphoryl moiety resulting in formation of a dialkyl phosphate adduct that can age by net loss of an R group. However, this mechanism would require an unusual inhibition reaction involving scission of a P—C bond. The present work tested this hypothesis by identifying FAP adducts on serine esterases before and after aging using peptide mass mapping with surface enhanced laser desorption/ionization time-of-flight mass spectrometry (SELDI-TOF MS). Esterases were horse serum butyrylcholinesterase (BChE) and human neuropathy target esterase catalytic domain (NEST). Dialkyl FAP compounds included R = ethyl, *n*-propyl, isopropyl, and *n*-butyl. For the diethyl analog, mass shifts (mean  $\pm$  SE, average mass  $m/z$  for inhibited and aged, respectively) were 135.6  $\pm$  0.6 and 106.9  $\pm$  0.5 Daltons (Da) for BChE ( $n \geq 8$ ), and 135.5  $\pm$  0.3 and 107.4  $\pm$  0.4 Da for NEST ( $n = 2$ ). These values were statistically identical to the theoretical mass shifts for the intact and aged diethyl phosphoryl adduct of 136.1 and 107.0 Da, respectively, presuming aged species are deprotonated. Similarly, mass shifts for intact and aged adducts of the other FAP analogs on BChE and NEST were within 0.0–0.8 Da of their respective theoretical values. The results support the hypothesis that both BChE and NEST are inhibited by scission of the P—C bond, in agreement with predictions from computational modeling and x-ray studies. Furthermore, aging occurs in each case yielding a monoalkyl phosphoryl adduct. Determination of the protonation state of the aged species detected by MS will require further research. (Funded by CRDF RB2-2035, 2488; ARO DAAD19-02-1-0388).

### 1939

#### COMPARISON BETWEEN ELLMAN AND RADIOMETRIC METHODS FOR ASSESSING CHOLINESTERASE (CHE) INHIBITION IN RATS TREATED WITH *N*-METHYL CARBAMATE INSECTICIDES.

D. L. Hunter<sup>1</sup>, D. Chen<sup>4</sup>, R. S. Marshall<sup>1</sup>, S. Padilla<sup>1</sup>, W. Setzer<sup>2</sup>, V. C. Moser<sup>1</sup> and A. Lowit<sup>3</sup>. <sup>1</sup>*NTD, USEPA, Research Triangle Park, NC*, <sup>2</sup>*ETD, USEPA, Research Triangle Park, NC*, <sup>3</sup>*OPP, USEPA, Arlington, VA* and <sup>4</sup>*Enloe High School, Raleigh, NC*.

Carbamylated ChE is unstable and readily reactivates. This reactivation, promoted by increasing temperature and dilution, could have an impact on *ex vivo* ChE assays by decreasing apparent ChE inhibition. To assess the best method for measuring ChE inhibition in brain and RBCs from animals treated with one of 5 different carbamate insecticides, ChE was analyzed using both the Ellman method (encourages reactivation through tissue dilution and higher temperature) and a radiometric method (limits reactivation with lower tissue dilution and lower temperature). All tissues were prepared in exactly the same manner, and only diluted immediately before assay. Each tissue was assessed using both assays on the same day. Adult male rats were dosed orally with carbaryl, methomyl, methiocarb, oxamyl, or propoxur. At the time of peak effect, following a single dose of these compounds, the Ellman method underestimated the level of ChE inhibition; the degree of reactivation depended on the carbamate and ranged from 10-40% for the brain and 10-45% for the RBCs. Comparison of the dose-response curves showed an even greater difference between the methods: at the extreme, the Ellman method showed no brain ChE inhibition in any propoxur dose group, whereas radiometric data showed a significant, predictable dose-response relationship. In addition, the variability in the data was increased using the Ellman method. The combined coefficients of vari-

ation (CV; (StDev/mean) x 100) for all dosage groups for all compounds were 11% (brain) and 25% (RBC) for the radiometric method, but for the Ellman method, CVs were increased: 21% (brain) and 38% (RBC). These data indicate that the radiometric method is far superior to the Ellman method for assessing ChE inhibition in animals treated with *N*-methyl carbamate insecticides. This is an abstract of a proposed presentation and does not reflect Agency policy.

1940

TIME COURSE AND DOSE RESPONSE ASSESSMENT OF CHOLINESTERASE (CHE) INHIBITION IN ADULT RATS TREATED ACUTELY WITH CARBARYL, METHOMYL, METHIOCARB, OXAMYL OR PROPOXUR.

S. Padilla<sup>1</sup>, R. S. Marshall<sup>1</sup>, D. L. Hunter<sup>1</sup>, P. Phillips<sup>1</sup>, K. McDaniel<sup>1</sup>, V.C. Moser<sup>1</sup> and A. Lowit<sup>2</sup>. <sup>1</sup>NTD, USEPA, Research Triangle Park, NC and <sup>2</sup>OPP, USEPA, Arlington, VA.

To compare the toxicity of 5 *N*-methyl carbamates, the time course and dose response profiles for ChE inhibition were established for each. For the time course comparison, adult male Long Evans rats (n=5 dose group) were dosed orally with either carbaryl (CB; 30 mg/kg in corn oil), methomyl (MM; 3 mg/kg in water); methiocarb (MC; 25 mg/kg in corn oil); oxamyl (OM; 1 mg/kg in water) or propoxur (PP; 20 mg/kg in corn oil). Brain and blood were taken at 0.5, 1.0, 2.0, 4.0 and 24 hrs after dosing for analysis of ChE activity using a radiometric method which limits the amount of reactivation of the ChE activity. This level of dosing produced at least 40% brain ChE inhibition with all compounds. The time-course study revealed that the time of peak effect (brain and RBC ChE inhibition) was very similar for all 5 carbamates: 0.5-1.0 hr after dosing. Two compounds, methomyl and oxamyl, however, showed significant recovery by 1.0 hr after dosing. By 24 hours after dosing, brain and RBC activity in all animals had returned to normal levels. For the dose-response study, each compound was administered at 5 different levels (plus vehicle control) and the tissues (brain and RBC) taken at 40 minutes after dosing for assessment using the radiometric assay. The lowest dose that significantly inhibited ChE activity in RBC was 15 mg/kg (CB); 1.25 mg/kg (MM); 25 mg/kg (MC); 0.5 mg/kg (OM) and 10 mg/kg (PP), and for brain was 7.5 mg/kg (CB); 0.6 mg/kg (MM); 2 mg/kg (MC); 0.5 mg/kg (OM) and 3 mg/kg (PP). Although linear regressions comparing ChE inhibition in brain and RBCs showed generally close correspondence, brain ChE was usually the more sensitive measure, especially at the lower dosages. The exception was OM where RBC ChE inhibition appeared to be more sensitive than brain ChE inhibition. *This is an abstract of a proposed presentation and does not reflect Agency policy.*

1941

COMPARISON OF ACUTE NEUROBEHAVIORAL EFFECTS OF *N*-METHYL CARBAMATE INSECTICIDES.

V. C. Moser<sup>1</sup>, P. M. Phillips<sup>1</sup>, K. L. McDaniel<sup>1</sup>, R. S. Marshall<sup>1</sup>, S. Padilla<sup>1</sup> and A. Lowit<sup>2</sup>. <sup>1</sup>NTD/NHEERL, USEPA, Research Triangle Park, NC and <sup>2</sup>HED/OPP, USEPA, Arlington, VA.

The acute neurobehavioral and cholinesterase (ChE)-inhibiting effects of *N*-methyl carbamate insecticides have not been systematically compared. We evaluated five carbamates - carbaryl (CB), propoxur (PP), oxamyl (OM), methomyl (MM), and methiocarb (MC). Adult male Long-Evans rats (n=10/dose) were dosed by oral gavage with either CB (3-50 mg/kg), PP (0.3-20 mg/kg), OM (0.07-1.5 mg/kg), MM (0.1-2.5 mg/kg) or MC (0.5-25 mg/kg). Ten minutes after dosing, rats were scored for obvious signs of cholinergic toxicity ("tox score"). Horizontal (HA) and vertical (VA) activity were tabulated during subsequent 20-minute sessions in a figure-eight chamber. Brain and blood tissues were taken immediately thereafter to determine ChE activity. Exposure to each of the carbamates resulted in decreased motor activity. Based on no-effect levels (NOELs), activity was equally (PP, MC) or less (CB, OM, MM) sensitive than ChE inhibition. Within-subject regressions indicated a better correlation between motor activity and brain ChE inhibition than with blood ChE. Activity measures decreased faster than did the brain ChE activity (i.e., slope<1), with the exception of CB (slope=1). The VA dose-response curves were significantly different from HA, with greater decreases in VA at the higher doses. Nonetheless, the correlation between HA and VA was good, indicating a high concordance of effect on both measures. The ranking of toxicity as measured by the tox score ranged from no effect (CB, MC, OM) to a dose-related increase in the incidence and severity (PP, MM). Thus, some carbamates showed pronounced effects on motor activity at doses that produced little or no obvious toxicity as evaluated by this crude score. This illustrates that observable signs of cholinergic toxicity are not predictive of the magnitude of behavioral neurotoxicity. Furthermore, activity, especially VA, is a very sensitive outcome of ChE inhibition produced by carbamates. This is an abstract of a proposed presentation and does not reflect Agency policy.

1942

THE ORGANOPHOSPHOROUS INSECTICIDE FENTHION DOES NOT AFFECT PHAGOCYTOSIS OF ROD OUTER SEGMENTS BY RETINAL PIGMENT EPITHELIUM CELLS IN CULTURE.

A. M. Geller and L. L. Degn. *Neurotoxicology, USEPA, Research Triangle Park, NC.*

Exposure to the organophosphorous insecticide fenthion has been associated with retinal degeneration in occupational studies. It has also been associated with pigmentary changes of the retina. Because retinal degeneration and pigmentary changes may be due to dysfunction of the retinal pigment epithelium (RPE) at the back of the eye, we tested RPE cell function and viability with exposure to fenthion. Human-derived RPE cells, ARPE-19, were grown to confluence in 12 well plates. Cells were exposed for 24 hours to  $10^{-7}$  -  $10^{-5}$  M fenthion, a range of concentrations that has been shown to affect cell viability and function in other neurally-derived cell lines. Cell viability was assayed with a calcein/propidium iodide live/dead (L/D) assay. The ability of the RPE cells to phagocytize rod outer segments (ROS), one of the important homeostatic functions of the RPE, was tested by co-incubating the cells with ROS labeled with fluorescein isothiocyanate, then evaluating them with fluorescent phase microscopy. Phagocytosis was also evaluated under conditions that enhance (incubation with insulin) or inhibit this function (incubation in cold or in serum-free medium). ARPE-19 cells showed no decrease in viability after treatment with  $10^{-7}$  -  $10^{-5}$  M fenthion. Positive control experiments with hydrogen peroxide demonstrated the sensitivity of the L/D assay. This concentration range of fenthion also had no notable effect on phagocytosis of ROS. Phagocytosis could be enhanced by incubation with insulin or inhibited by cold or incubation in serum-free medium. Exposure to the OP fenthion did not produce dramatic effects on RPE cell viability or their ability to phagocytize ROS. Further work will establish the sensitivity of these cells to the oxon metabolite of fenthion. ARPE-19 cells appear to be less sensitive than neuroblastoma and PC-12 cells to the effects of fenthion. This abstract does not reflect USEPA policy.

1943

CONCURRENT EXPOSURE TO REPEATED STRESS AND CHLORPYRIFOS ALTERED NMDA AND TOTAL MUSCARINIC RECEPTOR RESPONSES IN HIPPOCAMPUS, CEREBRAL CORTEX AND HYPOTHALAMUS.

T. Pung, K. Fuhrman, B. Klein, D. Blodgett, B. S. Jortner and M. Ehrlich. *Virginia Tech, Blacksburg, VA.*

Sustained stress causes reversible impairment to the hippocampus, possibly related to glutamatergic effects. Effects of concurrent repeated stress and chlorpyrifos (CPF) on NMDA and total muscarinic receptors in the brain were studied in Long-Evans rats. Groups of rats (n=8) were handled 5 days/week (control); restrained 1 hour/day for 5 days/week; swum 30 minutes for 1 day/week; or restrained 4 days/week and swum for 1 day/week, for 28 days. On day 24, each group was injected either with corn oil or CPF 160 mg/kg sc 4 hours after restraint. On day 28, blood samples were collected for plasma corticosterone. Brains were dissected into hippocampus, cerebral cortex, and hypothalamus to determine maximum binding density (Bmax) and equilibrium dissociation rate constant (Kd) of NMDA and total muscarinic receptors. Swim and restraint with swim elevated plasma corticosterone more than handling and restraint alone. Restrained rats (1.839 +/- 0.140 nM) had higher Kd of NMDA receptors in the hippocampus than control (1.386 +/- 0.150 nM) and restrained with swim rats (1.333 +/- 0.140 nM); however, Bmax was similar. CPF decreased Bmax and Kd of total muscarinic receptors in the cerebral cortex of swum rats (237.64 +/- 17.36 fmol/mg protein, 0.216 +/- 0.023 nM) and CPF also decreased Bmax of total muscarinic receptors in the cerebral cortex of restrained rats (229.08 +/- 17.36 fmol/mg protein). There were no effects of stress, CPF, and interactions of stress and CPF on NMDA receptors in the cerebral cortex and on total muscarinic receptors in the hippocampus although CPF down-regulated total muscarinic receptors of swum and restrained rats. Therefore, restraint stress increased binding affinity of NMDA receptors in the hippocampus and decreased Bmax of total muscarinic receptors in the cerebral cortex. Restraint with swim decreased both Bmax and Kd of total muscarinic receptors in the cerebral cortex.

1944

NEUROTROPHIN CONCENTRATION AFTER *IN VIVO* EXPOSURE TO NEUROPATHIC AND NON-NEUROPATHIC ORGANOPHOSPHATES.

M. J. Pomeroy-Black, M. F. Ehrlich and B. S. Jortner. *Laboratory for Neurotoxicity Studies, Department of Biomedical Science and Pathobiology, Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA.*

Organophosphorous (OP) esters are used as insecticides, petroleum additives, and modifiers of plastics (Ecobichon, 2004), and have also been employed as weapons of terrorism. Exposure to OP compounds that inhibit neurotoxic esterase (NTE)

induces a delayed neuropathy (OPIDN) characterized by Wallerian-like degeneration of long axons in certain animals, including humans. A previous study in our laboratory (Pope et al., 1995) discovered neurite outgrowth comparable to that of cells exposed to nerve growth factor (NGF) occurred 24 hours after incubation of SH-SY5Y neuroblastoma cells with spinal cord extracts from chickens with active OPIDN. Further studies showed that NGF, brain-derived neurotrophic factor (BDNF), and neurotrophin-3 (NT-3) are expressed in the lumbar spinal cord of chickens after neuropathic OP exposure (Pomeroy et al., SOT 2004, Abstract 1102). We hypothesized that fiber degeneration induced by neuropathic OP administration causes upregulation of neurotrophins, particularly NGF, BDNF, and NT-3, in susceptible regions of the nervous system prior to clinical signs. We exposed juvenile chickens to a neuropathy-inducing OP (PSP, 2.5mg/kg), an OP compound that does not induce neuropathy (paraoxon, 0.10 mg/kg), and vehicle (DMSO, 0.5ml/kg) intramuscularly. By day 8, all PSP-treated birds demonstrated clinical signs of OPIDN. Chickens were sacrificed by pentobarbital overdose at 4, 8, 24, and 48 hours, and 5 and 10 day post-treatment. We confirmed NTE inhibition in birds treated with PSP and performed enzyme-linked immunosorbant assays to determine the concentrations of NGF, BDNF, and NT-3 in lumbar spinal cord. Data indicate that levels of BDNF and NT-3 did not increase following neuropathy-inducing OP exposure; NGF concentration increased 24 hours post-dosing in all treatment groups. These data suggest that NGF, BDNF, or NT-3 are not individually responsible for *in vitro* neurite outgrowth.

#### 1945 CHLORPYRIFOS INDUCES APOPTOSIS IN OLIGODENDROCYTE PROGENITOR (CG-4) CELLS.

S. O. Heyliger<sup>1</sup>, M. D. Saulsbury<sup>1</sup>, D. J. Johnson<sup>1</sup>, D. P. Round<sup>1</sup>, J. K. Morse<sup>1</sup> and S. Green<sup>2</sup>. <sup>1</sup>*Pharmaceutical Sciences, Hampton University, Hampton, VA* and <sup>2</sup>*Pharmacology, Howard University School of Medicine, Washington, DC*.

Virtually all children in the United States have detectable levels of the organophosphate pesticide, Chlorpyrifos (CPF), in their bodies. Although, CPF has been shown to be relatively safe in adult animals, newly discovered evidence suggests that juveniles (animals and humans) may be more sensitive to CPF toxicity than adults. In young animals, CPF inhibits neural cell replication, interferes with cell differentiation, evokes oxidative stress, and alters synaptic neurotransmission. The adverse effects of CPF on neurons have been relatively well documented; however, few studies have focused on the developmental effects of chronic exposure to CPF on glial cells. Because glial cells are integral to neuronal survival and function, we studied the effects of CPF and its metabolites on oligodendrocyte viability. The viability assays utilizing Alamar Blue and Crystal Violet yielded results in which Chlorpyrifos (CPF) and its metabolite Chlorpyrifos-oxon (CPO) caused dose-dependent cytotoxicity within seventy-two (72) hours of exposure. The IC50 values for CPF and CPO were approximately 62.5  $\mu$ M and 31  $\mu$ M respectively. Nuclear morphological staining with Hoechst 33342 revealed that exposure to both CPF and CPO produced nuclear condensation as well as fragmentation, which are indicative of apoptosis. Wortmannin and PD98059 failed to reverse CPF- and CPO-induced cytotoxicity suggesting that CPF- and CPO-induced apoptosis occurs independently of PI-3 kinase and p42/44 MAP kinase activation. Taken collectively, the experimental results suggest that oligodendrocytes are sensitive to CPF and its, metabolite CPO. Furthermore, preliminary results suggest that CPF-induced neurotoxicity may be mediated, in part, by the disruption of oligodendrocyte survival and function.

#### 1946 ROLE OF A-ESTERASES IN THE AGE-RELATED DIFFERENCES IN ORGANOPHOSPHATE DETOXICATION.

E. C. Meek<sup>1</sup>, H. Chambers<sup>2</sup> and J. E. Chambers<sup>1</sup>. <sup>1</sup>*Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS* and <sup>2</sup>*Department of Entomology and Plant Pathology, Mississippi State University, Mississippi State, MS*.

The role of the calcium dependent A-esterases in the detoxication pathways of organophosphate (OP) insecticides was investigated in rats with respect to age. The OP compounds chosen for the study were the active metabolites (oxons) of commercial insecticides or model compounds. The OP compounds were either dimethyl or diethyl phosphates and had a variety of "leaving groups". The detoxication of 12 OP compounds by liver homogenates of adult male rats was determined by comparing the decrease in OP concentration following a 15 min incubation in homogenate containing 1.0mM  $\text{Ca}^{++}$  to that containing 1.0mM EDTA. In both preparations, carboxylesterase activity was eliminated using 3 $\mu$ M 4-nitrophenyl diphenylphosphinate. The OP's were assayed at concentrations near their IC80 for bovine brain AChE, the enzyme used to quantify the residual OP concentration. Only five OP's tested were significantly detoxified by liver A-esterase. Four OP's were selected for subsequent studies with adult serum and 12-day old rat liver and serum. Because of limited tissue available, only two OP's were tested with 1-day old rat liver. As expected based on paraoxonase activities using 5mM paraoxon as a sub-

strate, detoxication of OP's tested was greater in liver than in serum, and was highest in adult tissues. Results agree with findings of greater sensitivity of young animals to the acute toxicity of some OP insecticides. (Supported by NIH ES R01 ES 11287).

#### EFFECT OF ORGANOPHOSPHATE INSECTICIDE EXPOSURE ON DOPAMINE METABOLISM IN STRIATAL SLICES.

J. A. Whitehead<sup>1</sup>, E. C. Meek<sup>1</sup>, J. E. Chambers<sup>1</sup>, S. C. Sistrunk<sup>1</sup>, H. W. Chambers<sup>2</sup> and N. M. Filipov<sup>1</sup>. <sup>1</sup>*Center for Environmental Health Sciences, Coll. Vet. Med., Mississippi State University, Mississippi State, MS* and <sup>2</sup>*Entomology, Mississippi State University, Mississippi State, MS*.

Chlorpyrifos (CP) and parathion (PT) are organophosphate (OP) insecticides which, after metabolic activation to chlorpyrifos-oxon (CPO) and paraoxon (PO), respectively, act as cholinesterase (ChE) inhibitors. While most of the neurotoxic effects associated with exposure to OPs are a direct consequence of ChE inhibition, non-cholinergic effects have been proposed. Limited evidence indicated that CP has a direct, ChE inhibition-independent, effect on brain development. Epidemiological studies have associated exposure to certain pesticides with increased incidence of Parkinson's Disease (PD), but OPs, despite their widespread use, have not been implicated in PD. The present study had two objectives: (1) to determine whether selected OPs, CP and PT, have an effect on dopamine (DA) metabolism, and (2) to assess whether the eventual effects on DA metabolism are associated with ChE inhibition. Rat striatal tissues were exposed *ex vivo* to various concentrations of CP, PT, CPO, and PO for 4 h. At the end of exposure, concentrations of DA and its metabolites DOPAC and HVA in the media and tissue were determined. In addition, tissue ChE activity was analyzed. Overall, CP and CPO were more potent than the PT and PO in decreasing tissue DA and DOPAC levels, but otherwise behaved similarly, *i.e.*, the parent compound was just as potent as the oxon. Only the highest (500  $\mu$ M) dose of PT reduced tissue DA and DOPAC levels, whereas PO, even at 500  $\mu$ M, was ineffective. On the other hand, as expected, CPO and PO were far more potent in inhibiting cholinesterase than the CP and PT. Taken together, results from this study suggest that (1) CP and its oxon are more effective in modulating DA metabolism than PT and its oxon, (2) the DA modulating effects appear to be independent of cholinesterase inhibition, and (3) rather large amounts of OPs, especially PT, are required for DA metabolism to be affected. Supported in part by: NIH T35 RR07071.

#### 1948

#### THIOFLAVIN-T, AN ACETYLCHOLINESTERASE PERIPHERAL SITE LIGAND, DECREASES NG108-15 CELL PROLIFERATION.

H. M. Campanha and E. J. Flynn. *Pharmacology and Physiology, UMD-New Jersey Medical School, Newark, NJ*.

Acetylcholinesterase (AChE) is widely studied for its role in the hydrolysis of acetylcholine. This enzymatic activity is inhibited by a number of organophosphate insecticides. Allowable human exposure to insecticide levels are set by their ability to inhibit AChE enzymatic activity and cause varying degrees of cholinergic symptoms. However, recent evidence has accumulated indicating AChE may also have a non-cholinergic function. Concern has been raised that this non-cholinergic function of AChE may be altered from exposure to environmental pesticides and lead to effects on neuronal development. Furthermore, studies have implicated the peripheral anionic binding site of AChE in its noncholinergic, neurotrophic action. Thioflavin-T binds selectively to the AChE peripheral site. In order to investigate whether this binding alters the non-cholinergic function of AChE in the nervous system, we used a cultured hybrid mouse neuroblastoma-rat glioma cell line, NG108-15, which expresses AChE in its undifferentiated and differentiated state. These cells were grown on tissue culture plates on a substratum containing varying amounts of AChE and the degree of growth assessed by counting adherent viable cells. The change in cell number over time was quantitated by calculating the Area Under the Curve (AUC) and the maximum concentration of cells (Cmax) achieved. Previously, an increase in cell adhesion was found when these cells were grown on AChE coated plates and this increase was blunted by the presence of Thioflavin-T. However, there was no change in the AUC or the Cmax of adherent viable cell numbers when cells were grown on a substratum containing AChE compared to controls. In addition, Thioflavin-T decreased both the AUC and the Cmax of NG108-15 cell growth at concentrations as low as 500 nM. This decrease in cell growth in the presence of Thioflavin-T was found both in control plates and tissue culture plates coated with AChE. The decrease in AUC (35%) and Cmax (36%) was lower than the AUC (76%) and Cmax (36%) for cells grown on the substratum containing AChE.

TOXICITY OF CHLORPYRIFOS AND CHLORPYRIFOS OXON IN A TRANSGENIC MOUSE MODEL OF THE HUMAN PARAOXONASE (PON1) Q192R POLYMORPHISM.

T. B. Cole<sup>1, 2, 3</sup>, B. J. Walter<sup>1</sup>, D. M. Shih<sup>4</sup>, A. Tward<sup>4</sup>, A. J. Lusis<sup>4</sup>, L. G. Costa and C. E. Furlong<sup>2, 3</sup>. <sup>1</sup>*Environmental and Occupational Health Sciences, University of Washington, Seattle, WA*, <sup>2</sup>*Medicine, Division of Medical Genetics, University of Washington, Seattle, WA*, <sup>3</sup>*Genome Sciences, University of Washington, Seattle, WA* and <sup>4</sup>*Microbiology and Molecular Genetics, UCLA, Los Angeles, CA*.

The Q192R polymorphism of paraoxonase (PON1) has been shown to affect the hydrolysis of organophosphorous compounds *in vitro*. PON1Q192 and PON1R192 exhibit equivalent catalytic efficiencies of hydrolysis for diaxonon, the oxon form of the pesticide diazinon. However, PON1R192 has a higher catalytic efficiency of hydrolysis than does PON1Q192 for chlorpyrifos oxon (CPO), the oxon form of chlorpyrifos (CPS). Here, we examined the relevance of the Q192R polymorphism for exposure to CPS and CPO *in vivo*, through the use of a novel transgenic mouse model. Using BAC clones comprised of the entire human PON1 gene and its 5 prime and 3 prime regulatory regions, transgenic mice were generated that expressed either human PON1Q192 or PON1R192 at equivalent levels in the absence of endogenous mouse PON1. Dose response and time course experiments were performed on mice exposed dermally to CPS or CPO. After exposure, brain and diaphragm cholinesterase (ChE) activities were measured and morbidity was assessed. Mice expressing PON1Q192 were significantly more sensitive to CPO, and to a lesser extent CPS, than were mice expressing PON1R192. Compared to PON1Q192 mice, PON1R192 mice required nearly twice the dosage of CPO for 50% inhibition of brain ChE. The time course of inhibition following exposure to 1.2 mg/kg CPO revealed maximum inhibition of brain ChE at about 6 hours, with PON1Q192 and PON1R192 mice exhibiting 65% and 40% ChE inhibition, respectively. These results indicate that individuals carrying the PON1Q192 allele are more sensitive to the adverse effects of CPO or CPS exposure, especially if combined with lower plasma levels of PON1, which can vary as much as 13-fold among individuals. EFFECTS OF DIAZINON AND CYPERMETHRIN ON DIFFERENTIATING NEURONAL AND GLIAL CELL LINES.

M. Sachana<sup>1</sup>, W. Harris<sup>3</sup>, J. Tack<sup>3</sup>, J. Flaskos<sup>2</sup> and A. J. Hargreaves<sup>3</sup>. <sup>1</sup>*Veterinary Pathology, University of Liverpool, Neston, United Kingdom*, <sup>2</sup>*Laboratory of Biochemistry and Toxicology, Faculty of Veterinary Medicine, Aristotelian University, Thessaloniki, Greece* and <sup>3</sup>*School of Science, Faculty of Science and Land Based Studies, Nottingham Trent University, Nottingham, United Kingdom*. Sponsor: R. Gupta.

The main objective of the work was to study key morphological and proteomic changes associated with exposure of differentiating neuronal (N2a) and glial (C6) cells to sub-lethal concentrations of the sheep dip pesticides diazinon and cypermethrin. This was addressed by a combination of molecular and morphological approaches to the analysis of differentiating cells and cell extracts prepared following exposure of cells to sheep dip pesticides. Mouse N2a neuroblastoma and rat C6 glioma cells were induced to differentiate by serum withdrawal and the addition of cAMP or sodium butyrate, respectively, in the presence and absence of various concentrations of each pesticide. Exposure of cells was under co-differentiation (4 h or 24 h after the toxin was added at the point of induction of cell differentiation) or post-differentiation (cells were pre-differentiated for 24 h prior to exposure for 4 h) conditions. Concentration up to 10  $\mu$ M of both compound had no significant effect on the viability of either differentiating cell line, as determined by MTT reduction assays. Concentrations of 1  $\mu$ M and 10  $\mu$ M diazinon but not cypermethrin caused a significant decrease in neurite outgrowth in N2a cells but only after 24 h exposure under co-differentiation conditions. By contrast, no major changes were observed in the morphology of differentiating C6 cells. The results indicate that exposure to diazinon but not cypermethrin causes inhibition of axon outgrowth in differentiating N2a cells. In current work we are studying the molecular basis of these effects by indirect immunofluorescence and western blotting analysis, using antibodies that recognize specific cytoskeletal and axon-growth associated proteins.

GLUCOSE CONSUMPTION ENHANCES PARATHION TOXICITY: FUNCTIONAL AND NEUROCHEMICAL CORRELATES.

J. Liu, A. Abbey and S. Karanth. *Physiological Sciences, Oklahoma State University, Stillwater, OK*.

Sugar feeding increases the toxicity of the organophosphorus (OP) insecticide, parathion. OP insecticides elicit toxicity by acetylcholinesterase (AChE) inhibition, leading to accumulation of acetylcholine (ACh) in the nervous system. We studied the effects of sugar feeding and parathion exposure on brain ACh levels using *in*

*vivo* microdialysis. Guide cannulae were surgically implanted in the striatum four days prior to beginning glucose feeding (15% in drinking water for 5 days), and OP was given after three days. Experimental groups (n= 5-6 per group) included: 1) drinking water only and vehicle (peanut oil, 1 ml/kg, sc), 2) glucose and vehicle, 3) drinking water and parathion (18 mg/kg), and 4) glucose and parathion. Body weight and cholinergic signs of toxicity (SLUD signs and involuntary movements) were monitored throughout. Two days after OP, dialysis probes were inserted (under isoflurane) and perfused with artificial cerebrospinal fluid (1.5  $\mu$ l/min). After 42 min, six dialysis samples (40 min each) were collected. Rats were then decapitated and the frontal cortex, striatum, hippocampus, and diaphragm were collected for AChE measurement. Cholinergic signs following parathion treatment were significantly greater in rats drinking glucose compared to those drinking water. Parathion caused extensive AChE inhibition (>85%) in all tissues, but no statistical differences were noted between water and sugar-fed groups. In contrast, extracellular ACh levels following parathion were significantly higher in glucose-fed vs. water only rats (2, 906  $\pm$  711 vs. 965  $\pm$  338 fmole/fraction). There was a trend (p=0.09) towards a correlation between striatal AChE and acetylcholine levels in treated rats. The results indicate that regulation of synaptic acetylcholine turnover is modified by sugar feeding. While difficult to demonstrate statistically, a minimal further decrease in synaptic AChE activity in glucose-fed rats could be biologically important, leading to further accumulation of synaptic ACh and enhanced toxicity. (Supported by OSU Board of Regents and OSU College of Veterinary Medicine).

IMMEDIATE EARLY ALTERATION AND DIFFERENTIAL PERSISTENCE OF PKA (PROTEIN KINASE A) / P-CREB (PHOSPHORYLATED CREB) PATHWAY IN THE CENTRAL NERVOUS SYSTEM OF HENS DEVELOPING DELAYED NEUROTOXICITY (OPIDN) BY A SINGLE DOSE OF DIISOPROPYLPHOSPHOROFLUORIDATE (DFP) TREATMENT.

T. V. Damodaran, R. Gupta and M. Abou-Donia. *Pharmacology/ Pediatrics, Duke University Medical Center, Durham, NC*.

Diisopropylphosphorofluoridate (DFP) produces OPIDN in the chicken that results in mild ataxia in 7-14 days and severe or paralysis as the disease progresses with a single dose. Hens were treated with DFP (1.7 mg/kg, sc) after prophylactic treatment with atropine (1 mg/kg, sc) in normal saline and eserine (1 mg/kg, sc). Control groups were treated with vehicle (propylene glycol, 0.1 ml/kg, sc). The hens were sacrificed at 2, 4, and 8 hours as well as 1, to 20 days, and the tissues cerebrum and spinal cord were quickly dissected and frozen. Subcellular fractionation, SDS-PAGE and immunoblotting of the nuclear and supernatant fractions were done according to standard protocols. Protein levels of PKA, CREB and p-CREB were assessed. Histological sections of the brain and spinal cord prepared from a similar treatment approach, were subjected to immunostaining for p-CREB. There was an increase in PKA level in spinal cord nuclear fraction after 4 hrs (130%) and 8 hrs (133%), while cerebrum nuclear fraction showed decrease (77%) at 4 hrs and remained at the same level at 8 hrs. No change was seen in either spinal cord or cerebrum soluble fraction at any time points. There was an increase CREB level in the supernatant (133%) after 5 days, while nuclear and supernatant fraction of the cerebrum did not show any alterations at any time point. P-CREB was induced in the spinal cord nuclear fraction, after 1 day (150%) and 5 days (173%) of treatment, in contrast to the decreased levels P-CREB (72%) at 10 days in cerebrum nuclear fraction. Supernatant fraction of spinal cord and cerebrum did not show any changes. Immunohistochemistry data confirmed the differential alteration of P-CREB. Thus, the differential protein expression of PKA, CREB, P-CREB, reflect the susceptibility of the tissues studied, thereby confirming a role in the pathogenesis of OPIDN.

ACTIONS OF PYRETHROID INSECTICIDES ON THE SPONTANEOUS RELEASE OF GLUTAMATE FROM CULTURED HIPPOCAMPAL NEURONS.

D. A. Meyer<sup>2</sup> and T. J. Shafer<sup>1</sup>. <sup>1</sup>*Neurotoxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC* and <sup>2</sup>*Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC*.

Pyrethroid insecticides increase the excitability of the central and peripheral nervous systems. Modulation of voltage-gated sodium channels is likely to play a primary role in this effect, but recent studies have suggested that pyrethroid effects on other ion channels may contribute to increased excitability of neurons. Pyrethroid modulation of neuronal excitability, regardless of the target site, ultimately manifest as changes in neurotransmitter release. However, very few studies have utilized neurophysiological approaches to examine directly pyrethroid effects on neurotransmitter release in either the central or peripheral nervous systems of mammals. The present studies examined the effects of two pyrethroids on glutamate release using whole-cell patch clamp recordings from pyramidal neurons in mixed hippocampal

cultures. Under control conditions, spontaneous action potential-induced glutamate release was observed as regular bursts of excitatory post-synaptic currents with average interevent intervals of 143 msec (range = 50 - 300 msec, n = 33 neurons). In the presence of both the Type I pyrethroid permethrin and the Type II pyrethroid deltamethrin, the average interevent interval within each burst increased in a concentration dependent manner between 10 nM and 10  $\mu$ M with approximate EC<sub>50</sub>s of 710 and 37 nM for permethrin (n = 3-5 neurons/concentration) and deltamethrin (n = 3-6 neurons/concentration), respectively. At 10  $\mu$ M, interevent intervals were  $\geq$  90% by deltamethrin (n = 3) and permethrin, (n = 3), respectively. This increase in time between events within individual bursts of glutamate release indicates that exposure to these pyrethroids alters the basal pattern of glutamate release from hippocampal neurons in culture. The role of various ion channels in this effect remains to be investigated. (This abstract does not necessarily reflect EPA policy).

#### 1954 EFFECT OF PYRETHROIDS ON GLUTAMATE RELEASE IN THE HIPPOCAMPUS OF FREELY MOVING RATS.

H. Kobayashi<sup>1,3</sup>, M. M. Hossain<sup>1,3</sup>, T. Suzuki<sup>1,3</sup>, I. Sato<sup>1,3</sup>, T. Takewaki<sup>3</sup> and K. Suzuki<sup>2</sup>. <sup>1</sup>*Veterinary Medicine, Iwate University, Morioka, Iwate, Japan*, <sup>2</sup>*Agro-bioscience, Iwate University, Morioka, Iwate, Japan* and <sup>3</sup>*Graduate School of Veterinary Sciences, Gifu University, Gifu, Gifu, Japan*. Sponsor: G. Corcoran.

We have been studying effects of pyrethroids on the release of various neurotransmitters in brain regions of freely moving rats. In the present study, we investigated the effect of pyrethroids on the hippocampal glutaminergic transmission. Pyrethroids, allethrin (type I), cyhalothrin (type II) and deltamethrin (type II) were found to affect the release of glutamate differently in the hippocampus of freely moving rats as measured by *in vivo* microdialysis. The basal release of glutamate of untreated rats was 0.312 pmol/20  $\mu$ l/10 min. Control vehicle injections had no effect on the efflux of glutamate in any of the experiments. Allethrin had interesting dual effects on glutamate release, at the doses of 10 and 20 mg/kg i.p. increasing the efflux to about 175 and 150% of baseline with a peak time of 60 min and decreasing it to about 50% of baseline at 60 mg/kg i.p. up to 3 hrs after administration. Cyhalothrin 10, 20 and 60 mg/kg i.p. inhibited the release of glutamate dose-dependently to about 60, 50 and 30% of baseline, respectively, with a peak time of 40-60 min after administration. Deltamethrin 10 and 20 mg/kg i.p. increased the efflux of glutamate to about 190% of baseline with a peak time of 40 min after administration and 60 mg/kg i.p. increased it to about 275% of baseline and remained at a steady level during the rest of the 3 hr experiment. Above results suggest that these pyrethroids are able to alter the release of glutamate in opposite direction than GABA release, which will be presented by a co-author at this section, in the hippocampus of rat brain.

#### 1955 EFFECTS OF EXPOSURE TO THE PESTICIDE ATRAZINE ON STRIATAL NEUROCHEMISTRY IN MALE C57BL/6 MICE ARE AGE-DEPENDENT.

N. M. Filipov, A. Coban, S. C. Sistrunk and A. B. Norwood. *Center for Environmental Health Sciences, Basic Sciences, Coll. Vet. Med., Mississippi State University, Mississippi State, MS*.

Young and/or aged animals appear to be more sensitive than adults to certain neurotoxicants. We recently demonstrated that the herbicide atrazine (ATR) decreased striatal dopamine (DA) levels in striatal slices. The present study had the objective of investigating the ability of ATR to modulate DA metabolism *in vivo* in the context of age. One, 3, and 10-month-old male C57BL/6 mice were exposed to ATR by daily gavage for 14 days at doses of 5, 25, 125, 250 mg/kg x BW<sup>-1</sup>. Groups of mice were sacrificed and brains collected at 1, 7 and 49 d post termination of ATR exposure. Sub-groups of mice were challenged with 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP; 4 X 10 mg/kg). DA and its metabolites, 3, 4-dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA), were analyzed in the striatum by HPLC. At 1, but not at 7 d, after the last dose, ATR (125 and 250 mg/kg) decreased striatal DA, DOPAC and HVA levels in the 1, but not in the 3- and 10-month-old mice. As expected, MPTP decreased striatal levels of DA and its metabolites in all mice with the degree of decrease being the greatest in the 10-month-old mice. The decrease of DOPAC and HVA, but not of DA, was greater in the young mice that were exposed to ATR prior to the MPTP challenge; only HVA levels were decreased further in the 3-month-old mice, and no interaction between MPTP and ATR was observed in the 10-month-old mice. Thus, it appears that, pertaining to striatal neurochemistry, young mice are more sensitive to ATR than both adult and older animals and that previous ATR exposure enhances the dopaminergic toxicity of MPTP mainly by augmenting its effects on DA metabolism. Supported by: P20 RR017661 (NIH).

#### 1956

#### EFFECTS OF 14-DAY EXPOSURE TO THE HERBICIDE ATRAZINE ON DOPAMINE NEURONS IN THE SUBSTANTIA NIGRA AND VENTRAL TEGMENTAL AREA OF JUVENILE MALE C57BL/6 MICE.

A. Coban, A. B. Norwood and N. M. Filipov. *Center for Environmental Health Sciences, Basic Sciences, Coll. Vet. Med., Mississippi State University, Mississippi State, MS*.

Recently, using *ex vivo* striatal slices, we demonstrated that the herbicide atrazine (ATR; a commonly used pesticide in the US) decreased striatal dopamine (DA) levels. Moreover, ATR altered striatal neurochemistry in experiments with juvenile male C57BL/6 mice *in vivo*. Daily gavage with ATR, at doses of 5, 25, 125, 250 mg/kg-BW<sup>-1</sup> for 14 days decreased striatal DA levels, as well as the levels of its metabolites DOPAC and HVA on day 15 at the two highest doses. This effect was evident on day 22, but not on day 64 of the experiment and only on the DA metabolites, but not on DA itself. An MPTP challenge on day 15 to sub-groups of mice resulted in significant decreases of striatal DA, DOPAC, and HVA on day 22; in the case of DOPAC and HVA the decreases were potentiated by ATR. To extend these findings, using the same dosing paradigm, we analyzed the number of the dopaminergic (tyrosine hydroxylase [TH]-positive) neurons in the substantia nigra (SN) and ventral tegmental area (VTA), as well as the number of all neurons (cresyl violet [CV]-positive) in these areas for specific (SN/VTA) and non-specific (CV) neuronal loss by unbiased stereology. Up to date, brains collected at days 15 and 22 were processed immunohistochemically for neuronal counting, whereas day 64 samples are currently being analyzed. Our preliminary findings suggest that ATR decreases the number of TH-positive neurons in both SN and VTA with the effect in the SN being more prominent. In addition, in the juvenile mice we used here, there does not appear to be a synergy between MPTP and ATR. Because the number of CV-positive neurons was not affected by ATR, it appears that dopaminergic neurons, more so in the SN than in the VTA, are uniquely sensitive to the effects of ATR. Supported by: P20 RR017661 (NIH).

#### 1957

#### DECREASE OF THE STRIATAL DOPAMINE RELEASE CAUSED BY ACUTE ATRAZINE EXPOSURE IS BLOCKED BY HALOPERIDOL ADMINISTRATION.

V. M. Rodriguez, M. Thiruchelvam and D. A. Cory-Slechta. *Environmental and Community Medicine, Environmental and Occupational Health Sciences Institute, The University of Medicine and Dentistry of New Jersey and Rutgers, Piscataway, NJ*.

The herbicide atrazine (ATR) is widely used to control weeds and grass in a wide variety of crops. Given its abundant use, ATR has been found as a contaminant in ground and surface water and results in human exposure. Previous rodent studies have reported that chronic atrazine exposures cause hormonal, behavioral and neurochemical disruptions. Chronic ATR decreases levels of striatal dopamine and hypothalamic serotonin. Acute ATR decreases basal striatal DA release as measured by microdialysis, decreases also present following a high potassium solution (60 mM) challenge to the system. To examine potential mechanisms in this study by which ATR decreases DA release, rats implanted with microdialysis probes in the dorsal striatum were exposed to either 1% methyl cellulose (vehicle) or 100 mg/kg ATR i.p. and then challenged with a low autoreceptor active dose of 0.01 mg/kg haloperidol or saline s.c. Haloperidol alone increased striatal DA release. However, co-administration of ATR and haloperidol reversed the decrease in DA release produced by ATR alone, producing DA levels similar to control. No significant changes in the DA metabolites DOPAC or HVA, were observed. Two possible mechanisms for the decreases in DA release caused by ATR exposure may be the inhibition of tyrosine hydroxylase or a decrease in the firing rate of dopaminergic neurons. Both of these effects are known to be blocked by D2 specific antagonists acting on presynaptic autoreceptors, which increase dopamine synthesis and subsequently release. This data also demonstrates that although the effects of ATR on the DA system may be subtle, a further challenge to this system can uncover adverse effects. Given the widespread use of ATR and its deleterious effects on the central nervous system, understanding its mechanism of action holds important implications in particular for risk assessment. #### 1958

#### GENDER DIFFERENCES IN A PESTICIDE MODEL OF PARKINSON'S DISEASE.

M. Thiruchelvam, H. Mehta, B. Winnik, B. Buckley, E. K. Richfield and D. A. Cory-Slechta. *EOHSI, UMDNJ - Robert Wood Johnson Medical School, Piscataway, NJ*.

Epidemiological and clinical studies have demonstrated that the incidence of Parkinson's disease (PD) is greater in men than women, suggesting that female gender may be protective for the development of PD. It has been suggested that estrogen plays a role in modulating PD with it being neuroprotective, symptomatic or both. We have developed a combined pesticide exposure model of PD where a po-

tentiated decrease in dopamine function is observed in mice treated with paraquat (PQ) + maneb (MB) compared to either alone in male mice. To examine the possible gender-related differences in this model, male and female mice were exposed to saline, 10 mg/kg PQ, 30 mg/kg MB or PQ+MB twice a week for 6 weeks. Both male and female mice exposed to PQ+MB demonstrated a significant decrease in locomotor activity immediately after exposure. These male mice also failed to recover 24hrs after exposure from the 6th injection onwards, whereas females exposed to PQ+MB showed recovery at this time point. Similarly, 7 days after the last pesticide exposures, only males treated with PQ+MB still exhibited significant decreases in locomotor activity. Additionally, male mice treated with PQ+MB demonstrated greater striatal dopamine and metabolite loss compared to their female counterparts. When lipid peroxidation levels in the midbrain were evaluated, both PQ alone and PQ+MB increased lipid peroxides in both genders. However, this increase was greater in males compared to females for both treatment groups. The concentration of PQ in the striatum was similar between males and females following an acute exposure to PQ. However, only the males showed an elevation in PQ levels in the striatum following acute PQ+MB compared to PQ alone. This suggests that there are gender-related differences in toxicokinetics of PQ, partially explaining the difference in susceptibility. Studies to further understand the differential gender vulnerability are crucial in determining the mechanism of neuroprotection. Moreover, this could lead to new and better therapeutic interventions for PD. Supported by ES10791

#### SIGNALING PATHWAYS OF PARAQUAT-INDUCED APOPTOSIS: A MODEL FOR PARKINSON'S DISEASE.

H. M. Klintworth<sup>1</sup> and Z. Xia<sup>1, 2</sup>. <sup>1</sup>Env. & Occ. Health Sciences, University of Washington, Seattle, WA and <sup>2</sup>Pharmacology, University of Washington, Seattle, WA.

Parkinson's disease (PD) is the second most common age-related neurodegenerative disorder. It is characterized by a loss of dopaminergic neurons in the substantia nigra which leads to decreased dopamine production in the brain. Such a loss can result in bradykinesia, tremor at rest, loss of postural reflex, and a shuffling gait. Currently, the causes and mechanisms underlying PD are still unknown. Epidemiological studies have suggested a link between pesticide use and PD. Paraquat (PQ) is an herbicide of particular interest because of its structural similarities with MPTP, a known neurotoxicant that produces Parkinson-like symptoms. Furthermore, PQ has been shown to cause Parkinson-like symptoms in animal studies *in vivo*. In this study, we use PC12 cells, a rat dopaminergic cell line, and PQ as a model to study mechanisms of cell death induced by environmental toxins in PD. Two mitogen-activated protein (MAP) kinase signaling pathways of interest are the p38 and the stress-activated protein kinase/ Jun-N-terminal kinase (SAPK/JNK) pathways. These pathways have been shown to be activated in response to stress and toxicants to cause apoptosis. Such information could prove important for better understanding of the mechanisms of PD and elucidating new drug targets. PC12 cells were dosed with 50-200uM PQ for varying time points and analyzed for cell death. Apoptosis was scored by evaluating nuclear morphology via Hoechst staining and visualization through DAPI filter. In addition, TUNEL and MTS assays were performed to further confirm apoptosis and cell viability. Activation of the p38 and JNK pathways was determined by western blot analysis and attenuation by DN constructs. Immunocytochemistry for JNK was performed to determine nuclear translocation of JNK with PQ exposure. Ventral mesencephalic cultures from embryonic day 14 rat will be used to determine if results from PC12 cell experiments apply to real neurons.

#### THE ORGANOCHLORINE PESTICIDE METHOXYCHLOR ALTERS BRAIN MITOCHONDRIAL RESPIRATION, H<sub>2</sub>O<sub>2</sub> PRODUCTION AND CALCIUM/CAMP RESPONSE ELEMENT BINDING PROTEIN LEVELS.

R. A. Schuh<sup>3, 1</sup>, T. Kristian<sup>1</sup>, J. Flaws<sup>3</sup> and G. Fiskum<sup>1</sup>. <sup>1</sup>Anesthesiology, University of Maryland Baltimore, Baltimore, MD, <sup>2</sup>Anesthesiology, University of Maryland Baltimore, Baltimore, MD, <sup>3</sup>Epidemiology and Experimental Therapeutics, University of Maryland Baltimore, Baltimore, MD and <sup>4</sup>Anesthesiology, University of Maryland Baltimore, Baltimore, MD.

Methoxychlor, an environmental contaminant widely used as an insecticide is implicated in decreasing antioxidant enzyme activity and increasing hydrogen peroxide production resulting in oxidative stress. Phosphorylation of the Ca<sup>2+</sup>/cAMP response element binding protein (CREB) has been demonstrated in many studies to increase in response to oxidative stress. In the current study, we tested the hypothesis that methoxychlor inhibits mitochondrial respiration, increases mitochondrial hydrogen peroxide production and alters the phosphorylation state of mitochondrial CREB. When isolated rat or mouse brain mitochondria were exposed to increasing concentrations of methoxychlor (1-10 µg/mL), state 3 (ADP-stimulated) O<sub>2</sub> consumption was inhibited and respiration-dependent H<sub>2</sub>O<sub>2</sub> production was stimulated in a dose-dependent manner. Analysis by ELISA demonstrated a dose-

dependent increase in phosphorylated CREB in the mitochondrial lysates in the absence or presence of respiratory substrates. These results suggest that *in vitro*, acute methoxychlor application causes mitochondrial metabolic and oxidative stress. Methoxychlor also increases mitochondrial pCREB but in a manner that does not require mitochondrial H<sub>2</sub>O<sub>2</sub> generation. (Supported by NIH grants ES07263 (R.S.) and NS34152 (G.F.), and USAMRMC grant DAMD 17-99-1-9483 (G.F.))

#### DIELDRIN EXPOSURE CAUSES OXIDATIVE DAMAGE IN DOPAMINE NEURONS.

J. M. Hatcher<sup>1</sup>, T. S. Guillot<sup>1</sup>, J. R. Richardson<sup>1, 2</sup> and G. W. Miller<sup>1, 2</sup>. <sup>1</sup>Center for Neurodegenerative Disease, Emory University, Atlanta, GA and <sup>2</sup>Environmental and Occupational Health, Rollins School of Public Health, Emory University, Atlanta, GA.

Numerous epidemiological studies suggest that pesticide exposure is a significant risk factor for Parkinson's disease (PD). In particular, elevated levels of the organochlorine pesticide dieldrin have been found in the brains of post-mortem PD patients. However, the mechanism(s) by which dieldrin damages the dopaminergic system are not well established. *In vitro* studies have determined that dieldrin is capable of generating free radicals and causing oxidative damage. In this study, we used immortalized rat mesencephalic cells (N27) and mice repeatedly exposed to dieldrin to determine whether dieldrin promotes oxidative damage and dopaminergic dysfunction. Exposure of N27 cells to 60 or 100 µM dieldrin for 6 hr resulted in a 36% and 62% increase in protein carbonyl formation without causing cell death. In mice treated with 1 or 3 mg/kg of dieldrin every 3 days for 1 month, protein carbonyl levels in the striatum were increased by 56 and 90%. Similar to the cell culture experiments, there appeared to be no overt dopaminergic neuron loss in the striatum, as tyrosine hydroxylase levels were unchanged. However, dieldrin exposure significantly increased striatal dopamine transporter levels (DAT) by 25 and 60%. We have previously demonstrated that the organochlorine pesticide heptachlor similarly increases DAT levels in mice, while acting as an inhibitor of the vesicular monoamine transporter (VMAT2) *in vitro*. As DAT is responsible for transport of dopamine into the cell and VMAT2 sequesters cytosolic dopamine, alteration of these transporters by dieldrin may increase cytosolic dopamine resulting in oxidative damage. These results suggest that dieldrin may specifically damage the dopamine system through up-regulation of DAT and enhanced oxidative damage which may provide mechanistic insight to the epidemiological link between organochlorine exposure and PD. (Supported by NIH U54ES012068 (GWM) and F32ES013457 (JRR)).

#### MECHANISM OF SELECTIVE TOXICITY OF IVERMECTIN IN INSECTS AND MAMMALS.

T. Narahashi<sup>1</sup>, X. Zhao<sup>1</sup>, V. L. Salgado<sup>2</sup> and J. Z. Yeh<sup>1</sup>. <sup>1</sup>Molecular Pharmacology and Biological Chemistry, Northwestern University Medical School, Chicago, IL and <sup>2</sup>Bayer CropScience, Global Biology Insecticides, Monheim, Germany.

Ivermectin is a broad-spectrum anthelmintic drug that has been widely used in domestic animals and in humans. Ivermectin is thought to act on glutamate-activated chloride channels (GluCls) and GABA-activated receptors. However, the mechanism of selective toxicity in invertebrates over mammals is not fully understood. The present study was conducted to further elucidate the mechanism of agonistic and modulatory actions of ivermectin on ligand-activated chloride channels in cockroach and rat neurons using the whole-cell patch clamp technique. Ivermectin induced chloride currents with slow activation, slow deactivation and slow desensitization in cockroach neurons with an EC<sub>50</sub> of ~50 nM, and in rat neurons with an EC<sub>50</sub> of ≥ 300 nM. In cockroach neurons, the GABA receptors and the slow desensitizing GluCls, but not the fast desensitizing GluCls, were desensitized by ivermectin, and the ivermectin-induced currents were only partially blocked by picrotoxinin and fipronil at the concentrations that would completely block GABA receptors and GluCls. After exposure to ivermectin, GABA receptors and GluCls were became less sensitive to picrotoxinin or fipronil block. In rat neurons, ivermectin also activated and modulated the GABA<sub>A</sub> receptors, but unlike cockroach neurons, picrotoxinin completely blocked ivermectin-induced currents. In conclusion, ivermectin has agonistic and modulatory actions on ligand-activated chloride channels in cockroach neurons, and the higher sensitivity of cockroach neurons than rat neurons is partially responsible for the selective toxicity of ivermectin. Supported by NIH grant NS14143.

#### SULFONE METABOLITE OF FIPRONIL BLOCKS GABA- AND GLUTAMATE-ACTIVATED CHLORIDE CHANNELS IN MAMMALIAN AND INSECT NEURONS.

X. Zhao<sup>1</sup>, J. Z. Yeh<sup>1</sup>, V. L. Salgado<sup>2</sup> and T. Narahashi<sup>1</sup>. <sup>1</sup>Molecular Pharmacology and Biological Chemistry, Northwestern University Medical School, Chicago, IL and <sup>2</sup>Bayer CropScience, Global Biology Insecticides, Monheim, Germany.

Fipronil sulfone is a major metabolite of fipronil in mammals and insects. To better understand the insect and mammalian toxicology of fipronil, we examined the effects of fipronil sulfone on GABA- and glutamate-activated chloride channels

(GluCls) in cockroach thoracic ganglion neurons and in rat dorsal root ganglion neurons, using the whole-cell patch clamp technique. Fipronil sulfone blocks of both fast desensitizing and slow desensitizing GluCls in the cockroach required receptor activation. Furthermore, channel activation was required for unblock of the fast desensitizing GluCls, but not for the slow desensitizing GluCls. The  $IC_{50}$  of fipronil sulfone against activated slow desensitizing GluCls was 8.8 nM. In cockroach and rat neurons, fipronil sulfone blocked GABA receptors in both activated and resting states. The  $IC_{50}$  for blocking the activated GABA receptors were 15.4 nM and 46.6 nM, respectively, for cockroach and rat. Kinetic analysis of fipronil sulfone block of the activated chloride channels revealed that its blocking and unblocking rate constants for cockroach GABA receptors were similar to those for fipronil, explaining their similarity in blocking potency. The blocking rate constant of fipronil sulfone for rat  $GABA_A$  receptors was 7-fold larger than that of fipronil explaining the sulfone's higher blocking potency. In conclusion, fipronil sulfone is a potent inhibitor of cockroach GABA receptors and GluCls, and a weaker inhibitor of rat  $GABA_A$  receptors. Its potent blocking action on insect GluCls appears to contribute to selective toxicity against insects over mammals. Since fipronil sulfone is rapidly formed *in vivo*, the toxicological effects are likely due to the sulfone. Supported by NIH grant NS14143.

## 1964

### IMMORTALIZED MICROGLIAL CELLS AS A MODEL SYSTEM FOR OXIDATIVE STRESS: PESTICIDE-INDUCED GENOMIC CHANGES.

J. E. Royland<sup>1</sup>, P. R. Kodavanti<sup>1</sup>, M. Pooler<sup>2</sup>, O. Makwana<sup>2</sup> and B. Veronesi<sup>1</sup>.

<sup>1</sup>Neurotoxicology Division, USEPA, Durham, NC and <sup>2</sup>Toxicology Program, NC State University, Raleigh, NC.

In risk assessment there is a need to accelerate toxicological evaluation of vast numbers of chemicals. New programs focus on identifying common modes of action and on model systems for rapid screening. In this study we address both these issues. Oxidative stress is a good candidate as a mode of action for neurotoxicity testing. A role for reactive oxygen species has been well documented in both disease (e.g. Parkinson's disease, Alzheimer's disease, etc.) and toxicity (e.g. Paraquat) of the nervous system. Microglial cells are the major mediator of the brain's immune system. When activated in response to injury, they release an oxidative burst that is initially protective, but may become toxic in excess. We are investigating the use of immortalized murine microglial cells as a model test system for identifying chemicals that elicit the oxidative burst. Microglia were treated with the herbicide, Paraquat (1.0  $\mu$ M), or the insecticide, Rotenone (0.125  $\mu$ M), as prototypic compounds that generate reactive oxygen species (ROS). Hydrogen peroxide (0.002 mM) and lipopolysaccharide (25 ng/ml) are chemicals known to elicit oxidative stress in cell culture and were used as positive controls. Four hours after exposure, RNA was extracted for analysis on Affymetrix mouse genome 430 2.0 chips. Preliminary analysis showed similar numbers of up and down regulated genes across treatment groups with approximately equal distribution across ontology areas. The greatest proportions of genes identified were related to signal transduction (~41%), enzymes (~20%) or cell communication (~18%). Cluster analysis showed good correlation between samples from a given treatment group. However, only 5 genes were up regulated 2 or more fold by all 4 treatments and only 9 were down regulated. These data support oxidative stress as a mode of action where multiple pathways can contribute to a single outcome. (This abstract does not necessarily reflect USEPA policy).

## 1965

### NEUROTOXIC EFFECTS OF MANCOZEB AND MANEB *IN VIVO* AND *IN VITRO*.

L. M. Domico<sup>1,2</sup>, G. Zeevalk<sup>2</sup>, M. Thiruchelvam<sup>2</sup> and K. R. Cooper<sup>1</sup>. <sup>1</sup>Joint Graduate Program in Toxicology, Rutgers, The State University of New Jersey, Piscataway, NJ and <sup>2</sup>University of Medicine and Dentistry of New Jersey, Piscataway, NJ.

Mancozeb (MZ), an ethylene-bis-dithiocarbamate fungicide, is widely utilized on golf courses, residential lawns, and agricultural lands in the US. The adverse effects of MZ on humans and other living organisms have not been widely studied. Other dithiocarbamate fungicides, including maneb (MB), have been implicated in selective dopaminergic neurotoxicity in cell culture, rodents, and humans (Ferraz et al., 1988; Morato et al., 1989; Soleo et al., 1996; Thiruchelvam et al., 2000; Zhang et al., 2003). Consistent with this, we found a dose-dependent decrease in dopamine (DA) and an increase in DA metabolites and GABA levels in mice (C57BL/6J) exposed to 30-120 mg/kg MZ for 1-72 hrs. It has been postulated that these dithiocarbamates exert toxicity via mitochondrial inhibition (Zhang et al., 2003; Zhou et al., 2004). Primary mesencephalic cells isolated from Sprague-Dawley E15 rat embryos were exposed *in vitro* to MZ or MB to better understand the mechanism of toxicity of these compounds. To assess toxicity, a functional assay of selective transporter activity was performed in cells exposed to 0-60  $\mu$ M of MZ or MB for 24 hrs.

Exposures resulted in a dose-dependent decrease in the uptake of both DA and GABA, with MB being more potent than MZ. Despite findings that MZ (60  $\mu$ M) and MB (60  $\mu$ M) inhibited oxygen consumption by 42% and 78% respectively in whole mitochondria preparations isolated from adult rats, ATP levels as analyzed by a bioluminescent ATP assay and lactic acid production were not altered by fungicide exposure in cells. In conclusion, our findings suggest that while MZ and MB have toxic effects in DA neurons *in vitro* and *in vivo* and can inhibit mitochondrial respiration in isolated mitochondrial preparations, *in situ* their toxic effects are exerted via mechanisms other than mitochondrial inhibition. Alternative mechanisms of action for these fungicides will be evaluated in future studies. This research is supported by the NIEHS training grant and the Cook College NJAES grant.

## 1966

### EFFECT OF PYRETHROIDS ON GABA RELEASE IN THE HIPPOCAMPUS OF FREELY MOVING RATS.

M. M. Hossain<sup>1,3</sup>, T. Suzuki<sup>1,3</sup>, I. Sato<sup>1,3</sup>, T. Takewaki<sup>3</sup>, K. Suzuki<sup>2</sup> and H. Kobayashi<sup>1,3</sup>. <sup>1</sup>Veterinary Medicine, Iwate University, Morioka, Iwate, Japan, <sup>2</sup>Agro-bioscience, Iwate University, Morioka, Iwate, Japan and <sup>3</sup>United Graduate School of Veterinary Sciences, Gifu University, Gifu, Gifu, Japan. Sponsor: G. Corcoran.

Previously, we reported that pyrethroids, allethrin (type I), cyhalothrin (type II) and deltamethrin (type II) modulate the ACh release in the hippocampus of freely moving rats. In the present study, we studied changes in outflow of extracellular level of GABA in the hippocampus of conscious rats after the exposure of three pyrethroids as measured by *in vivo* microdialysis. GABA was detected by high performance liquid chromatography with electrochemical detector. A microdialysis probe was implanted into the left hippocampus of male SD rats. Rats were treated i.p. with pyrethroids or the same volume of vehicle. Control vehicle injections had no effect on the efflux of GABA in any of the experiments. The extracellular level of GABA was decreased by 10 and 20 mg/kg allethrin to about 50% of baseline and increased to about 250% of baseline by 60 mg/kg with a peak time of 90 min after injection. Cyhalothrin 10, 20 and 60 mg/kg stimulated GABA release dose-dependently to about 130, 210 and 300% of baseline, respectively with a peak time of 40-90 min after administration. Deltamethrin 10, 20 and 60 mg/kg inhibited GABA release dose-dependently to about 75, 55 and 40% of baseline, respectively with a peak time 60-90 min after injection. Local infusion of tetrodotoxin (1 micro M) with Ringers solution through the dialysis probe completely prevented the effect of allethrin, cyhalothrin and deltamethrin, but not the effect of deltamethrin at 60 mg/kg on GABA release. Our results suggest that there may be a relationship between cholinergic and GABAergic neuronal network in hippocampus which plays a role in the neurotoxicity of pyrethroids.

## 1967

### EFFECTS OF PHENYL SALYGENIN PHOSPHATE (PSP) AND PHENYLMETHANE SULFONYL FLUORIDE (PMSF) ON RAT DORSAL ROOT GANGLIA (DRG) CULTURES.

E. Brigo<sup>1</sup>, A. Moretto<sup>1</sup>, P. Glynn<sup>2</sup>, D. E. Read<sup>2</sup> and M. Lotti<sup>1</sup>. <sup>1</sup>Medicina del Lavoro, Università di Padova, Padova, Italy and <sup>2</sup>Toxicology Unit, MRC, Leicester, United Kingdom.

PSP is a direct acting organophosphate that causes axonal degeneration (organophosphate induced delayed polyneuropathy, OPIDP). The mechanism involves inhibition of neuropathy target esterase (NTE) and subsequent aging of the phosphorylase enzyme. PMSF is a direct inhibitor of esterases that does not cause OPIDP. PMSF protects from OPIDP when given before the neuropathic OP because it causes NTE inhibition that is not followed by aging. However, PMSF exacerbates OPIDP when given after the neuropathic OP and this effect is related to the interaction with another target. Cultures of rat DRG were tested as a possible model for protection and exacerbation of OPIDP. Desheathed DRGs from 13-16 day old rats were dissected and plated on poly-L-lysine precoated dishes. Neuronal processes were allowed to grow for 72 hours before incubation with inhibitors. PSP caused massive degeneration of neuronal processes at 100  $\mu$ M for 3 hours and no effect at 10  $\mu$ M for 24 hours or more. Intermediate effects were seen at 50-70  $\mu$ M. PMSF caused no effect (1 mM), partial (1.5 mM) or massive (2 mM) degeneration of the processes. At 2 mM maximum effect was obtained with incubations of 24 hours or more but no effect for incubations of less than 5 hours. No significant cell death was observed with either compound. The morphological characteristics of axonal degeneration were different: PSP caused a beading-like damage whereas PMSF caused a rapid dying-back-like damage. When PMSF (1 mM) was added 24 hours before PSP (50  $\mu$ M) incubation minimal effects were observed. When PMSF (1.5 mM) was added 6 or 24 hours after incubation with 10  $\mu$ M PSP there was a dying-back-like massive destruction of processes. Different concentrations and times of incubation as well as other compounds with different characteristics need to be tested.

## 1968 CROSS-SPECIES TOXICOLOGY IN THE AGE OF GENOMICS.

W. B. Mattes<sup>1</sup> and T. P. Ryan<sup>2</sup>. <sup>1</sup>*Toxicogenomics, Gene Logic Inc., Gaithersburg, MD* and <sup>2</sup>*Investigative Toxicology, Eli Lilly and Company, Greenfield, IN*.

While animal models have been the cornerstone of experimental toxicology and safety assessment for the last two centuries, the question often arises whether the results seen in one species are relevant to what may be expected in another, particularly when the extrapolation is being made to man. Genomic information could change this problem dramatically. At one level, comparisons of coding regions and upstream regulatory regions across genomes can provide clues as to similarities and differences between species vis-à-vis the molecular components of a cell and their regulation. One example where this approach has provided valuable insights is the nuclear receptor gene family. These genomic comparisons can also be used to inform the use of non-mammalian models of toxicity such as *Caenorhabditis elegans*. Complementary to such genomic comparisons, mRNA profiling with microarrays allows a global view of toxicant-induced transcriptome alterations in various cell types, tissues and species, and allows an experimental view of similarities and differences in signaling and response pathways. Thus transcriptome alterations can be compared *in vivo* between rat and canine models, and *in vitro* between rat, canine, and human hepatocytes. The promise is that such tools will allow for any given toxic response a truly molecular assessment of the relevance of various animal models to one another and to man.

## 1969 INSIGHTS INTO EVOLUTION OF XENOBIOTIC METABOLISM IN MAMMALS FROM COMPARATIVE GENOMICS OF THE NUCLEAR RECEPTOR GENE FAMILY.

D. A. Wheeler<sup>1,2</sup>, A. J. Cooney<sup>3</sup> and Z. Zhang<sup>1</sup>. <sup>1</sup>*Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX*, <sup>2</sup>*Molecular and Human Genetics, Baylor College of Medicine, Houston, TX* and <sup>3</sup>*Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX*. Sponsor: W. Mattes.

The partial and complete sequencing of 3 mammalian genomes has enabled detailed comparative studies of the nuclear receptor gene family and genes with which they interact. Overall, the nuclear receptors have changed very slowly on the time-scale of mammalian evolution. Pregnen X receptor (PXR;NR1I2) and constitutive androstane receptor (CAR;NR1I3) manifest a rate of change 5-10 times the average rate for the family. Structural analysis of ligand binding domain of PXR from mouse, rat and human reveals a cluster of variable amino acids in the ligand binding pocket and another cluster along alpha helix 9. The cytochrome P450 genes regulated by PXR and CAR have also evolved rapidly, suggesting the possibility of co-evolution of two major gene families that cooperate in xenobiotic metabolism in mammals.

## 1970 COMPUTATIONAL AND EMPIRICAL INVESTIGATION OF ESTROGEN AND DIOXIN ELICITED EFFECTS: A COMPARATIVE ANALYSIS.

T. Zacharewski. *Biochemistry & Molecular Biology, Center for Integrative Toxicology, National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI*.

Emerging omic technologies, novel computational approaches, and the availability of human, mouse and rat genome sequences has provided unprecedented opportunities to investigate mechanisms of toxicity at the molecular level that support risk assessment. The incorporation of comparative methods provides a more powerful approach to identify conserved responses that play important roles in toxicity and facilitate the elucidation of the underlying biochemical networks and mechanisms of action. In this presentation, comparative empirical and computational approaches will be presented that describe (i) the use of homology models and estrogen receptor - ligand binding preferences for multiple species (i.e. human, mouse, chicken, *Xenopus laevis*, green anole and rainbow trout) to identify critical residues within the binding pocket that are important for endocrine disruptor interactions, (ii) differences in estrogen elicited genome-wide gene expression in human and rodent models using customized orthologous cDNA microarrays, and (iii) the computational identification of 5763, 3539, and 1190 putative DREs in 17, 882 human, 11, 697 mouse, and 3, 896 rat genes, respectively. Results from these studies not only further our molecular knowledge of estrogen receptor and Ah receptor-mediated toxicity, but also begin to address the validity of risk assumption extrapolations between surrogate test species to human and ecological relevant species based on the current understanding of the molecular mechanisms of action. This work is supported by the United States Environmental Protection Agency (826301) and the National Institutes of Health (ES11271 and ES12245).

## 1971 GENOMIC CHARACTERIZATION OF THE ACUTE PHASE RESPONSE IN MICE, DOGS, AND RATS.

T. P. Ryan. *Investigative Toxicology, Eli Lilly and Company, Greenfield, IN*.

Genome-scale analysis using microarrays is a powerful means to characterize responses in model systems. Genomic tools to monitor responses in species most often utilized in drug development are now available (and of sufficient quality) where interspecies physiological responses to insult can be mapped. To characterize these responses and search for biomarkers of target organ toxicity that could be applied in preclinical drug development, microarray data from LPS treated rat, mouse, and dog were compared. LPS was administered to mice (4.0 mg/kg), rats (1.0 mg/kg), and dogs (0.2 mg/kg) using doses designed to produce 'equivalent' inflammatory responses, and liver gene expression was assessed using commercial or internally developed microarrays. The kinetics of hepatotoxicity associated with LPS administration differed markedly between species. Gene expression of the acute phase reactants serum amyloid A and alpha-2-macroglobulin correlated with protein levels measured in serum. The expression levels of other transcripts, such as cytochrome c, correlated with hepatic damage as measured by serum ALT. Comparing gene expression between the liver and kidney of LPS-treated dogs revealed differential expression of vascular markers such as E-selectin. These findings begin to describe mechanistic details of differential organ toxicity observed in response to LPS. Although cross-species annotation with murine, rat, and canine microarrays posed a significant challenge, analysis of these data have proven to be important in interpreting species-specific responses to inflammatory stimuli.

## 1972 CROSS-SPECIES COMPARISONS OF TRANSCRIPTIONAL RESPONSES IN PRIMARY HEPATOCYTES.

W. B. Mattes, K. Daniels, D. L. Mendrick and M. S. Orr. *Toxicogenomics, Gene Logic Inc., Gaithersburg, MD*.

Primary hepatocytes offer a unique system for examining the molecular and transcriptional responses to toxicant treatment. Furthermore, the availability of primary hepatocytes from humans as well as species commonly used in preclinical testing allows direct comparisons of dysregulated genes and pathways across species under similar conditions of exposure. Such comparisons can provide insight into the relevance to humans of a particular toxic response in a non-clinical species. For example, Wy-14643 belongs to a class of compounds that elicit peroxisome proliferation (PP) as well as hepatocarcinogenesis in rodents. The weight of evidence is that the PP response to these compounds is rodent-specific. To examine the species-specific responses on a genome-wide basis, cultures of primary rat hepatocytes or primary human hepatocytes were treated with 100 microM or 200 microM WY-14643, respectively, for 24 hr, and mRNA levels were analyzed on Affymetrix GeneChips®. Cross-species analysis was accomplished by matching genes on the human Hu-133A GeneChip® with those on the rat RG\_U34A GeneChip® by protein homologies: by this analysis about 3000 non-redundant genes are present in common on both microarrays. Using standard statistical cut-offs, 166 non-redundant genes were regulated by WY-14643 treatment of rat hepatocytes, in contrast to 20 for treatment of human hepatocytes. And while 135 Wy-14643-regulated rat genes were also present on the human array, only 2 of these were also regulated in human hepatocytes by Wy-14643 treatment. Such studies offer evidence for species-species responses and provide a mechanistic approach to using animal data for assessment of human risk.

## 1973 TOXICO- AND PHARMACOGENETIC ANALYSIS IN A NOVEL MODEL OF PARKINSON'S DISEASE: DOPAMINE NEURON DEGENERATION IN *C. ELEGANS*.

R. Nass, C. Nichols, M. Fullard, M. Garrett and M. Marvanova. *Anesthesiology and Pharmacology, and Center for Molecular Neuroscience, Vanderbilt University Medical Center, Nashville, TN*. Sponsor: B. Mattes.

Most animal models for idiopathic Parkinson's disease (PD) rely on inducing nigrostriatal damage in mammals with the neurotoxins 6-hydroxydopamine (6-OHDA) or MPP<sup>+</sup>, or overexpressing the presynaptic protein  $\alpha$ -synuclein. The dopamine transporter DAT, which is the target for many psychoactive drugs, provides the cellular gateway for the accumulation of the neurotoxins that evoke neuronal death and Parkinson-like syndrome and has been shown to interact with  $\alpha$ -synuclein. We have recently established a novel model system using *C. elegans* to evaluate *in vivo* dopamine (DA) neuron degeneration (Nass et al., PNAS, 2002; Nass and Blakely, Annu. Rev. Pharmacology Toxicol., 2003). We have shown that a brief exposure to 6-OHDA causes selective loss of the DA neurons, pharmacological agents that interfere with DAT or genetic ablation of the transporter blocks the degeneration, and that the degeneration likely occurs via a novel cell death pathway.

We have also shown that overexpressing human wild-type (WT) or mutant A53T  $\alpha$ -synuclein in *C. elegans* also confers DA neuron degeneration. We have now instituted genetic and chemical screens for regulators of toxin- and  $\alpha$ -synuclein-mediated cell death, and we have isolated several mutants and compounds that suppress the neurodegeneration. We have also identified several heavy metals that exasperates the neurodegeneration. Finally we have instituted genome-wide microarray analyses of gene expression in WT, DAT knockout, and human A53T  $\alpha$ -synuclein-expressing animals following exposure to control or 6-OHDA. Our studies suggest that genes that modulate DA production, DA regulation, cell signaling, and oxidative stress play a role in the neurotoxicity. These results will also be presented in the context of utilizing this system via high throughput screening assays to explore the molecular basis of toxin-induced neurodegeneration in mammals.

 **1974** ONTOGENY OF HUMAN HEPATIC PHASE I AND PHASE II ENZYMES: IMPLICATIONS FOR DIFFERENTIAL TOXICANT SUSCEPTIBILITY.

R. N. Hines<sup>1</sup> and M. A. Runge-Morris<sup>2</sup>. <sup>1</sup>*Pediatrics, Medical College of Wisconsin, Milwaukee, WI* and <sup>2</sup>*Inst. Envir. Health Sciences, Wayne State University, Detroit, MI*

Over the past several years, there has been considerable interest in the dynamic changes that occur in toxicokinetic factors during early life stages and how these changes may impact differential toxicant susceptibility. Advances in molecular and analytical techniques have allowed a better characterization of these changes, as well as some of the underlying control mechanisms. The objectives of this symposium are to: 1) present examples of the information gained about major members of the oxidative Phase I enzymes and how this information has led to the identification of common developmental themes; 2) present information on the developmental expression of two conjugative phase II enzyme classes, N-acetyl transferases and sulfotransferases, and how, combined with the information regarding phase I enzymes, can inform regarding possible differential susceptibility during ontogeny; and 3) demonstrate how such information regarding developmental expression can be integrated into physiological-based toxicokinetic models for predicting temporal-specific changes in toxicant disposition useful for early life stage risk assessment. These advances offer the promise and challenge of predicting changing dose-response relationships during early life and the possible prevention of developmental toxicity.

 **1975** HUMAN HEPATIC PHASE I ENZYME DEVELOPMENTAL EXPRESSION.

R. N. Hines. *Pediatrics, Med. Col. Wisconsin, Milwaukee, WI*.

The phase I enzymes are important for prototoxicant bioactivation and toxicant bioinactivation. Earlier studies suggested significant phase I enzyme expression changes during human hepatic development. Such temporal-specific expression would impact toxicant susceptibility. To gain a better understanding of phase I enzyme ontogeny, a tissue bank was established containing 240 human liver samples representing ages from 8 wks gestation to 18 yrs. Information available on most postnatal samples and many fetal samples included age, ethnicity, gender, body weight, liver weight, postmortem interval, and cause of death. Tissue samples from individuals succumbing to diseases involving liver pathology were excluded. Using recombinant protein standards and regression analysis, enzyme specific contents were measured by western blot. Specific activity determinations were performed where probe substrates were available. As an example, an examination of the two major hepatic forms of the CYP2C gene family revealed low CYP2C9 expression in some individuals from 8-24 wks gestational age (GA) with increasing expression levels during the remainder of gestation. In contrast, CYP2C19 was detectable at 8 wks GA, but values were similar throughout gestation. CYP2C9 expression increased in a birth-dependent process such that 50% of individuals <4 mos postnatal age (PNA) expressed near-adult values. However, the first 4 mos PNA represented a period of high interindividual variability. Unlike CYP2C9, 2C19 values increased linearly over the first 5 mos PNA to adult values in most individuals, suggesting birth was necessary but not sufficient for increased expression. From 5 mos to 10 yrs, CYP2C19 expression was highly variable. The ontogeny of CYP2C9 and 2C19 were dissimilar among both fetal and 0-4 mos postnatal samples. These 2 examples highlight common themes observed across many phase I enzyme systems, including: windows of hypervariability due to interindividual differences in expression onset or timing of increased expression, and temporal asynchrony among members of the same gene family suggesting different developmental regulatory mechanisms (PHS CA53106 & GM68797).

 **1976** SULFOTRANSFERASE EXPRESSION: IMPLICATIONS FOR PRENATAL TOXICITY.

M. Runge-Morris. *Inst. Envir. Health Sciences, Wayne State University, Detroit, MI*.

In the developing human, hepatic sulfotransferase (SULT) expression represents a primary early defense system against xenobiotic insult. The sulfonation of toxic endogenous intermediates and harmful exogenous species by members of the SULT

gene family is a critical step in xenobiotic detoxification. In addition, since sulfonated hormones are generally receptor inactive, the differential expression of SULT enzymes affects the delicate balance of hormone homeostasis in developing organs. Knockout mouse models demonstrate that the inactivation of estrogen sulfotransferase (SULT1E) produces a condition of estrogen excess and leads to significant reproductive abnormalities. Human aryl sulfotransferase (SULT1A1) sulfonates thyroid hormones and therefore is essential to the progression of normal embryonic growth. Because of the impact of sulfonation on reproductive outcome, the immunoreactive expression of SULT1E, SULT1A1 and hydroxysteroid sulfotransferase (SULT2A1) was examined in pre- and post-natal liver samples using quantitative ECL immunoblot analysis. Human hepatic SULT enzymes were determined to be differentially expressed during development. SULT1A1, a major conjugating enzyme in adult human liver, was variably expressed in both pre and postnatal liver samples. SULT1E was most robustly expressed during early periods of hepatic gestation. By contrast, the levels of human hepatic SULT2A1 increased following birth, and unlike in rodent species, did not demonstrate a gender-dependent pattern of expression. The results of this study shed light on the determinants of prenatal toxicity and hormone homeostasis in the developing human.

 **1977** DEVELOPMENTAL EXPRESSION OF HUMAN AND MURINE ARYLAMINE N-ACETYLTRANSFERASES(NAT): IMPLICATIONS FOR AROMATIC AMINE GENOTOXICITY.

C. A. McQueen. *University of Arizona, Tucson, AZ*.

Children and adults often respond differently to xenobiotics. This may be due, at least in part, to alterations in the expression of biotransformation enzymes. The isoforms of NAT, NAT1 and NAT2, catalyze the acetylation of therapeutic drugs and environmental carcinogens. Pre- and postnatal human liver samples were evaluated using antibodies generated against human NAT sequences. NAT isoforms were found at an estimated gestational age of 73 days to age 18 years. NAT1 was detected in the first trimester, increasing with gestational age. There was no significant change in the early neonatal period followed by higher levels in the first year of life. NAT2 was also expressed in the first trimester showing an increase with age. There were no differences in samples from premature or full-term births indicating that expression of NATs are not dependent on changes triggered by birth. The age-related differences in NATs could affect susceptibility to chemical toxicity by altering the formation of reactive and non-toxic products. This was tested in a mouse model with 4-aminobiphenyl (4ABP). Activation of 4ABP to genotoxic products can occur via NATs. In C57Bl/6J mice, NAT1 and NAT2 mRNAs and functional enzymes were detected pre- and postnatally showing a pattern of hepatic expression similar to what was observed in human liver. Neonatal exposure to 4ABP resulted in levels of 4ABP-DNA adducts significantly lower than in adult liver. The magnitude of changes in expression of genes associated with responses to genotoxicity was less in young animals than adults. The data illustrate that lower expression of NAT1 and NAT2 occurring in neonates limits acetylation, a key reaction in the activation of 4ABP, and contributes to decreased susceptibility to 4ABP genotoxicity compared to adults. Based on the similarities in expression of NATs in mice and humans, children would be predicted to have a higher risk of toxicity for chemicals that are inactivated by NATs compared to adults but lower risk for xenobiotics activated by these enzymes. (ES09812, ES10047)

 **1978** DEVELOPMENT OF PHYSIOLOGICALLY-BASED TOXICOKINETIC MODELS FOR EARLY LIFE STAGES: IMPLICATIONS FOR DIFFERENTIAL TOXICANT SUSCEPTIBILITY.

D. Hattis<sup>1</sup>, G. Ginsberg<sup>2</sup>, B. Sonawane<sup>3</sup> and K. Walker<sup>4</sup>. <sup>1</sup>*Clark University, Worcester, MA*, <sup>2</sup>*CT Department of Public Health, Hartford, CT*, <sup>3</sup>*USEPA, Washington, DC* and <sup>4</sup>*Clark University, Worcester, MA*.

Immaturities in metabolic and renal function have been associated with slower clearance of numerous therapeutic drugs in the first months of life. These immaturities and other developmental factors are likely to affect the internal dose of environmental toxicants. This presentation describes PBTK inputs we use for children's modeling and presents case studies where this has been applied to therapeutic drugs (caffeine and theophylline) and an environmental toxicant (acrylamide). Caffeine and theophylline are oxidized primarily by CYP1A2 to demethylated products. In spite of their close structural similarity, caffeine clearance is 3 times slower in neonates than theophylline. This inter-drug differential does not exist in adults, who clear both drugs considerably faster than neonates. PBTK modeling was able to simulate caffeine and theophylline metabolic and renal clearance in both neonates and adults. The considerably faster metabolic clearance for theophylline is explained by a novel methylation pathway for theophylline that is not available for caffeine and is not detectable in adults. This points out the potential importance of

novel metabolic pathways in neonates which can become predominant due to immaturities in the major pathway (CYP1A2) in adults. Acrylamide is a neurotoxicant and multi-site carcinogen to which there is widespread human exposure. Both the parent compound and a CYP2E1 metabolic product (glycidamide) are active toxicants, with glycidamide the best candidate for genetic activity/cancer. Both compounds are detoxified via glutathione conjugation and epoxide hydrolase can also detoxify glycidamide. PBTK modeling of the dosimetry of acrylamide and glycidamide has been calibrated to hemoglobin adduct levels found in exposed rats and adult humans. This modeling has been adapted to early life stages to determine how child/adult differences in key distributional factors and metabolic steps may affect internal dose and carcinogenic risk.

## 1979 SYSTEMS BIOLOGY: APPROACHES AND APPLICATIONS TO TOXICOLOGY.

W. Slikker<sup>1</sup> and T. B. Knudsen<sup>2</sup>. <sup>1</sup>*Division of Neurotoxicology, NCTR/FDA, Jefferson, AR* and <sup>2</sup>*Department of Molecular, Cellular and Craniofacial Biology Birth Defects Center, University of Louisville, School of Dentistry, Louisville, KY.*

Genomics and proteomics provide information on the cellular reaction to drug and chemical exposures but this is only part of what is needed to understand complex developing systems, where susceptibilities to exposure may advance through transitional states of varying susceptibilities. The NIH Director's Road Map has focused on the need to provide new tools to investigators, to speed the process of discovery, to encourage interdisciplinary research, and to promote translational research. Systems biology will contribute to this mission. Systems biology is the application of systems theory to solving biological problems and is a means to analyze complex behavior in a composite system that may be decomposed into subsystems to facilitate understanding and modeling. In toxicology, it provides a means for identifying pathways that are critical to disease and to discovering on- and off- target effects of compounds. Devising computational models and integrating these models with empirical data provide important insight into complex systems-level behaviors, ultimately striving to deliver the mechanism connecting small molecules (drug or chemical) with a clinical endpoint (phenotype or disease) with regards to metabolic and regulatory networks. The integrative topic of systems biology and application examples focused on several organ systems and stages of development will interests toxicologists with backgrounds in mechanisms, reproduction, development, neuroscience, modeling, and safety and risk assessment.

## 1980 EXTRACTING MEANING FROM EXPRESSION DATA.

J. Quackenbush. *Institute for Genomic Research, Rockville, MD.* Sponsor: T. Knudsen.

The popular literature is rife with proclamations regarding the coming genomics revolution, but the application of genome scale techniques, including genome sequencing, transcript profiling, proteomics, and metabolomics, have largely been to cataloging response rather than developing a mechanistic interpretation of the patterns involved. While many balk at the challenges posed by "too much data," in fact the problem may be not enough data. The value of large datasets is that they can reveal features of the underlying biology provided they are filtered appropriately, and one approach that has proven successful is to integrate large datasets with other large datasets. In this way, genetic mapping and microarray data can be used to identify genes that are differentially expressed and genetically linked to a particular phenotype. Or changes in gene expression can be linked to changes in protein representation or metabolic flux. Similarly, prior knowledge about gene functional classes, or pathway membership, or interaction can be used as additional constraints on the data, as can constraints posed by evolutionary conservation of genes and pathways. The challenge moving forward is not one of collecting and analyzing data, but of integrating data to produce a comprehensive understanding of the biological systems under study.

## 1981 MODELING GENE NETWORKS IN THE NEURONAL ADAPTATION TO ALCOHOL.

J. S. Schwaber. *Department of Pathology, Anatomy and Cell Biology, Thomas Jefferson University, Philadelphia, PA.* Sponsor: W. Slikker.

The mammalian neuronal response to environmental inputs typically involves coordinated transcriptional regulatory responses <2-fold for large numbers of genes. Microarray technology can provide global datasets for systems approaches but for smaller changes is limited by precision and accuracy. We engineered several modifications to enhance quantitative reliability of microarray data and also developed bioinformatics tools and analysis approaches to improve our ability to derive networks, pathways and relationships for modeling and simulation of cellular dynam-

ics. This integrated approach was applied to chronic alcohol exposure in a region of the rat brain associated with addiction and withdrawal (nucleus tractus solitarius). Initially 542 genes were found differentially expressed ( $p < 0.05$ ); these were further analyzed to produce a list of associated transcription factors (TF) and attendant transcriptional regulatory network. We performed meta-analysis for sensitive dependence of the results on initial conditions to determine robustness of the networks. The surviving interaction results are input to associative network building tools using (1) natural language processing (NLP) of literature and databases to associate genes with known protein relationships and (2) a searchable database of hand-curated gene and pathway associations to build an initial model network containing differentially expressed genes, relevant transcription factors, cellular signaling processes and functional interactions in the context of relevant cellular pathways, e.g. p38 MAPK, NF- $\kappa$ B, ERK-MAPK. Results include hypothesized integrated functional systems influenced by alcohol adaptation and withdrawal, critical predictions of gene-TF-pathway interactions for experimental verification, and qPCR, ChIP, and pathway inhibitor results.

## 1982 SYSTEMS BIOLOGY AND DOSE RESPONSE ASSESSMENT.

M. Andersen. *Division of Biomathematics and Physical Sciences, CIIT, Research Triangle Park, NC.*

Systems biology involves the quantitative evaluation, through laboratory experiments and computer modeling, of the organization of components in biological systems that give rise to biological function. Toxicity is a perturbation in those biological processes that lead to adverse responses. These perturbations are often related to chemically-induced activation or silencing of specific signaling pathways through non-linear switches embedded in transduction cascades. The goal in toxicology is to define those doses where perturbations are expected to be large enough to pose a risk in an exposed population. Systems biology methodologies now provide the ability to understand the molecular basis of toxicant dose-response relationships and produce detailed biological models of signal transduction systems that predict dose-response relationships. This talk begins with several examples of receptor auto-regulation and kinase cascades to demonstrate the manner in which signaling networks can produce specific, non-linear dose-response relationships. The second part of the talk will discuss the set of genomic and computational tools available for delineating and modeling signaling networks that are targets for perturbations in cells and tissues. Methods for deconvoluting signaling pathways include a variety of traditional and emerging genomic tools including microarray analysis and high coverage reverse genetic screens using full-length gene sets and inhibitory RNA libraries. Bioinformatic tools are used to store results in relational databases and assemble the cellular components static network diagrams. The static signaling networks are parameterized and converted into computational models to simulate the temporal and dose response behavior of the system. This talk emphasizes the integration of high coverage genomic methods with bioinformatic tools and computational modeling to implement a systems biology approach in toxicology and dose-response assessment. We will also discuss the approach in reference to current work with NF- $\kappa$ B signaling in kidney epithelial cells and steroidogenesis in mouse Leydig cells.

## 1983 AN $\pm$ OMICS $\pm$ APPROACH TO ELUCIDATE MECHANISMS OF DISRUPTED NEPHROGENESIS AND FUNCTIONAL INTERACTIONS BETWEEN AHR AND WILMS $\pm$ TUMOR SUPPRESSOR GENE.

K. S. Ramos. *Department of Biochemistry and Molecular Biology, University of Louisville, Louisville, KY.*

Supported by NIH grant ES04917 and NRSA — Loss of aryl hydrocarbon receptor (AHR) function by gene deletion, as well as unregulated activation of AHR signaling following ligand binding, are associated with deficits in murine nephrogenesis. Disrupted nephrogenesis *in vitro* is evidenced by changes in the ratio of Wilms $\pm$ tumor suppressor gene (Wt1) splice variants following AHR activation. To evaluate these interactions,  $\pm$ omics $\pm$  approaches were used to study the role of AHR during mesenchymal-to-epithelial transition (MET) and identify gene networks controlled by AHR and WT1 in embryonic kidney cells. Using organ cultures of E11.5 metanephric blastema from C57BL/6 AHR $+/+$  and AHR $-/-$  mice treated for 4 consecutive days with 3 micromolar benzo(a)pyrene (BaP) identified glial derived neurotrophic factor, frizzled receptor, insulin-like growth factor, insulin-like growth factor binding protein (ILGFBP), syndecan, laminin, Sry, oncostatin M, pinin, GATA-3, Sox-18, Nrf-2, cyclin G and fibulin as targets of developmental interference. Co-determination of transcriptional states and multivariate nonlinear coefficient of determination revealed strong interactions between AHR, opn and ILGFBP among others. Glycolysis, the tricarboxylic acid cycle, and amino acid metabolism were implicated as metabolic targets of developmental interference by

using NMR and GC-MS. AHR knockdown by small interfering RNA was associated with significant accumulation of +exon5 Wt1 splice variant and a shift in WT1 expression from a predominant 52 kDa isoform toward a smaller 40 kDa isoform. A subset of signature genes essential for nephrogenesis, including genes regulated by Wt1, was found to be regulated by AHR. These data suggest that *omics* approaches can help elucidate molecular mechanisms of developmental interference by environmental agents.

#### 1984 COMPUTATIONAL SYSTEMS ANALYSIS OF DEVELOPMENTAL TOXICITY.

T. B. Knudsen and A. V. Singh. *Department of Molecular, Cellular and Craniofacial Biology, University of Louisville, Louisville, KY.*

The availability of genomic sequences from a growing number of human and model organisms has fueled an explosion of data, information and knowledge regarding biological systems and disease processes. Database Network infrastructure is needed that can enable high volume data processing and management as applied to dynamical biological attributes, such as the embryo's reaction to drug and chemical exposures. Birth Defects Systems Manager (BDSM) is being developed as a resource to advance this goal for developmental toxicology. The BDSM prototype is a mid-level E-server for storage/retrieval of applications and data as well as tools for research discovery efforts, computational, and theoretical analysis of developmental processes and toxicities. In the long-term BDMS aims to capture systems-level properties of the developing mouse embryo, encapsulate these properties as network objects, and map possible outcomes following a point of molecular dysfunction. Holistic genomic data, for example, can lead to computational gene network prediction models for the chemical interactions between adaptive (homeostatic) and isothermal (developmental) processes but the key challenge is to build comprehensive network identification libraries that cross platforms, studies, and even species. From here, statistical methods can begin to assign probabilities of dysfunction based on actual experimental evidence regarding phenotypes and appropriate experiments to test for interesting relationships that are descriptive of potential outcomes. Funded by NIH grants AA13205 and ES09120

#### 1985 CELLULAR/MOLECULAR MECHANISMS INVOLVED IN ENVIRONMENTAL CHEMICALS- INDUCED DOPAMINERGIC NEUROTOXICITY AND THE CONSEQUENCES ON NEURODEGENERATIVE DISEASES.

A. G. Kanthasamy. *Iowa State University, Ames, IA.*

Environmental neurotoxic chemical exposures are increasingly recognized as dominant risk factors in the etiology of many neurodegenerative disorders including Parkinson's disease, Alzheimer's disease Amyotrophic Lateral Sclerosis and Huntington's disease. Exposure to environmental neurotoxic agents (metals, pesticides, PCBs and others) is often superimposed with the pathological hallmarks of neurodegenerative disorders. In recent years, cell death mechanisms have been investigated extensively. Despite this growing amount of information regarding the cell death process, little effort has been made to integrate this body of knowledge with the area of neurotoxicology and establish its relevance to neurodegenerative diseases. This workshop is designed to fill this gap by entertaining discussion of key cell death signaling molecules and other cellular targets during neurotoxic chemical exposures that may impact the disease process of neurodegenerative disorders. Specifically, novel findings obtained from both *in vitro* and *in vivo* models of neurotoxicity using state-of-the-art approaches including toxicogenomics, transgenics, knock-outs, and RNA interference (RNAi) will be presented at this workshop. The workshop presentations are expected to uncover unifying concepts and set the groundwork for translation of key analogies between neurotoxicology research and neurodegenerative disorders. Also, questions provided by the speakers will serve as catalysts for discussion with the audience. Overall, this workshop is likely to accelerate understanding of the role of environmental neurotoxic agents in the etiopathogenesis of neurodegenerative disorders as well as to foster the development of novel therapeutic strategies.

#### 1986 OXIDATIVE STRESS-SENSITIVE KINASE IN NEUROTOXINS-INDUCED SELECTIVE DOPAMINERGIC CELL DEATH: RELEVANCE TO PARKINSON'S DISEASE.

A. G. Kanthasamy. *Biomedical Sciences, Iowa State University, Ames, IA.*

Environmental exposure to pesticides and metals has been linked to the etiopathogenesis of Parkinson's disease. The cellular mechanisms underlying the selective degeneration of nigral dopaminergic neurons following environmental neurotoxin ex-

posure remain elusive. Recent studies from our laboratory demonstrate that dopaminergic neurotoxins such as MPP+, manganese and diethdrin induce apoptosis in dopaminergic cells via caspase-3-dependent proteolytic activation of the proapoptotic kinase PKC $\delta$ . Also, we examined the expression pattern of PKC $\delta$  and its functional role in the degenerative process associated with chemical-induced Parkinson's disease. Western blot analysis revealed a high expression level of PKC $\delta$  in rat mesencephalic dopaminergic neuronal cells (N27 cells) as well as in the substantia nigra of the mouse brain. Confocal imaging revealed co-localization of PKC $\delta$  in TH-positive neurons in primary rat mesencephalic neuronal cultures, and distribution of PKC $\delta$  in the cell body as well as in the dendrites. Double labeling of TH and PKC $\delta$  further confirmed their co-localization in the mouse substantia nigra. To further examine the functional consequence of PKC $\delta$  activation in environmental chemicals-induced dopaminergic degeneration, we employed the RNA interference (RNAi) gene silencing procedure. Dopaminergic neurotoxins proteolytically activated PKC $\delta$  in a caspase-3 dependent manner in rat mesencephalic dopaminergic neuronal cells. The proteolytically cleaved catalytic fragment of PKC $\delta$  (PKC $\delta$ -CF) further translocated to the nucleus and subsequently initiated DNA fragmentation. Furthermore, specific knock down of PKC $\delta$  by siRNA rescued dopaminergic cells from neurotoxins-induced apoptosis, demonstrating the proapoptotic role of PKC $\delta$  in dopaminergic degeneration. Collectively, these results suggest that PKC $\delta$  is highly expressed in dopaminergic neurons and the activation of this oxidative stress sensitive kinase might contribute to the selective degenerative processes in Parkinson's disease [NIH grants ES10586 and NS 45133].

#### 1987 ROLE OF PROINFLAMMATORY CYTOKINES IN CHEMICALLY-INDUCED DOPAMINERGIC NEURODEGENERATION.

J. O'Callaghan. *Neurotoxicology Laboratory, CDC/NIOSH, Morgantown, WV.*

The pathogenic mechanisms underlying Parkinson's disease (PD) remain enigmatic. In an effort to identify early molecular events associated with PD, we profiled genomic and proteomic changes in the MPTP mouse model of PD. Specifically, we focused on the role of TNF- $\alpha$ , IL-1 $\alpha$ , IL-6 and MCP-1, since enhanced expression of these proinflammatory cytokines and chemokines have been found in association with glial cells of patients with PD. MPTP caused a time-dependent increase in the mRNA expression of these cytokines in the striatum, but not in the hippocampus, and their expression preceded striatal dopaminergic degeneration (loss of dopamine and tyrosine hydroxylase), activation of JAK/STAT3 pathway and astrogliosis (upregulation of GFAP). Deficiency of the IL-6 gene did not alter striatal nerve terminal loss, but attenuated astrogliosis. However, in transgenic mice lacking TNF $\alpha$  receptors (TNFR-DKO), loss of striatal dopaminergic markers, phosphorylation of STAT3, upregulation of GFAP and astrocyte hypertrophy were nearly abolished. Interestingly, the lack of TNF $\alpha$  receptors exacerbated hippocampal neuronal damage (increased Fluoro Jade-B staining and loss of MAP-2 immunoreactivity) after MPTP. These findings implicate a region-specific role for TNF- $\alpha$  in the brain: a promoter of neurodegeneration in striatum and a protector against neurodegeneration in hippocampus. From a Parkinson's disease perspective, these findings are suggestive of a primary role for TNF- $\alpha$  in the pathogenesis of this disorder. As deficiency of TNF receptors or IL-6 gene attenuated phosphorylation of JAK-STAT3 and upregulation of GFAP, the findings implicate these signaling pathways in upregulation of GFAP. Since the activation of these pathways are early events in MPTP neurotoxicity, they may serve as potential therapeutic targets for modulation of neuronal loss and/or glial response following dopaminergic neurodegeneration.

#### 1988 BIOLOGICAL BASES FOR PCB INDUCED ALTERATION IN DOPAMINE-MEDIATED NEUROLOGICAL FUNCTION.

R. F. Seegal<sup>1</sup>, K. L. Marek<sup>3</sup>, S. A. Factor<sup>4</sup>, R. J. McCaffrey<sup>5</sup>, R. F. Hasse<sup>5</sup> and A. G. Kanthasamy<sup>1</sup>. <sup>1</sup>*Biomedical Sciences, Iowa State University, Ames, IA*, <sup>2</sup>*New York State Department of Health, Wadsworth Center, Albany, NY*, <sup>3</sup>*Institute of Neurodegenerative Disorders, New Haven, CT*, <sup>4</sup>*Albany Medical Center, Albany, NY* and <sup>5</sup>*University of Albany, Albany, NY*.

Polychlorinated biphenyls (PCBs) are associated with developmental deficits in children and behavioral and neurochemical changes in laboratory animals. These latter changes include reductions in dopamine (DA) concentrations and the number of tyrosine hydroxylase positive neurons in the substantia nigra of adult rodents and non-human primates (NHPs). This loss of function involves inhibition of monoamine transporters, including the vesicular monoamine transporter, metabolism of free cytosolic DA, induction of oxidative stress and cell death. Indeed, in a midbrain DA cell line (N27), PCBs induce oxidative stress and apoptotic cell death, thus supporting the hypothesis that PCBs alter DA-mediated neuronal function and behavior. In order to test this hypothesis we are studying the neurological,

behavioral and structural consequences of prior long-term high level exposure to PCBs in a cohort of former workers. We will determine if prior PCB exposure alters DA mediated behaviors, including motor function, memory and the density of basal ganglia DA terminals using  $\beta$ -CIT SPECT imaging. This epidemiological study will allow us to begin to determine whether laboratory-derived data demonstrating that PCBs lead to DA neuronal dysfunction and cell death can be extrapolated to humans, thus providing additional evidence for the role of environmental neurotoxicants in the etiology of neurodegenerative disorders, including Parkinson's disease. (Supported by grants from the US Army Medical Research and Materiel Command, NIEHS and EPA to RFS, and NIH to AGK).

 **1989** ROLE OF NITRIC OXIDE IN METHAMPHETAMINE-INDUCED DOPAMINERGIC NEUROTOXICITY IN MICE.

S. F. Ali<sup>1</sup> and Y. Itzhak<sup>2</sup>. <sup>1</sup>*Division of Neurotoxicology, NCTR/FDA, Jefferson, AR* and <sup>2</sup>*Department of Psychiatry and Behavioral Sciences, University of Miami School of Medicine, Miami, FL.*

Methamphetamine (METH) induced dopaminergic neurotoxicity is thought to be associated with the generation of reactive oxygen species (ROS) and reactive nitrogen species (RNS). Recently, we have reported that copper/zinc(Cu/Zn)-superoxide dismutase transgenic mice are resistant to METH- induced neurotoxicity. In the present study, we examined the role of the neuronal nitric oxide synthase (nNOS), susceptibility of nNOS knockout (KO) in mice after neurotoxic doses of METH. Male Swiss Webster mice were treated with or without 7-nitroindazole (7-NI) along with METH (5 mg/kg, ip, q 3h X 3) and were sacrificed 72 h after the last METH injection. Dopamine (DA) and dopamine transporter (DAT) binding sites were determined in striatum from saline and METH-treated animals. 7-NI completely protected against the depletion of DA, and DAT in striatum. In follow up experiments nNOS KO mice along with appropriate control (C57BL/6N, SV129 and B6JSV129) mice were treated with METH (5 mg/kg, ip, q 3hX3) and were sacrificed 72 h after dosing. This schedule of METH administrations resulted in only 10-20% decrease in tissue content of DA and no apparent change in the number of DAT binding sites in nNOS KO mice. However, this regime of METH resulted in a significant decrease in the content of DA as well as DAT binding sites in the wild type animals. Therefore, these studies strongly suggest the role of nitric oxide, nNOS, peroxynitrite and DA system in METH-induced neurotoxicity.

 **1990** SAFETY ASSESSMENT OF BIOLOGICAL THERAPEUTIC PRODUCTS — DEFINING THE SCIENTIFIC AND REGULATORY ISSUES.

A. Weir<sup>1</sup> and B. J. Mounho<sup>2</sup>. <sup>1</sup>*FDA/CDER, Rockville, MD* and <sup>2</sup>*Amgen Inc., Thousand Oaks, CA.*

Biological therapeutic products (BTPs) are proteins derived from living organisms or produced via biotechnology means that have provided the medical community with novel, highly targeted therapies for the diagnosis and treatment diseases in humans. An integral part of the safety evaluation of these products is toxicology studies. BTP—induced toxicities are typically limited to their pharmacological mechanism of action; therefore, toxicology studies need to be conducted in an animal model that expresses the receptor or epitope that is recognized by the product. Frequently, a non-human primate (NHP) is the relevant model. In recent years, the quality of NHPs and the availability of methods for assessing toxicity in these animals have increased. In spite of these advances, many challenges remain in the safety assessment of BTPs. For example, only a very limited toxicological assessment can be conducted if the only relevant model is a chimpanzee. In such cases, toxicologists use innovative approaches, including the development of surrogate molecules, to conduct toxicology studies. Therefore, identification of novel methods is an ongoing effort in the BTP arena. Regardless of the animal model used, the potential for animals to mount an immune response to BTPs (immunogenicity) exists. Because immunogenicity can confound interpretation of toxicology studies, it is another challenge facing toxicologists that can result in the need for innovative approaches to safety assessment. Additionally, because immunogenicity can occur in humans receiving BTPs, the development of animal models to predict this effect in humans is an area of ongoing research. The need for innovative, flexible approaches when assessing the safety of BTPs is reflected in USFDA and international regulatory documents. The topics covered in this workshop will provide toxicologists with the most current information on the unique scientific properties of BTPs and with state-of-the-art approaches to safety assessment of BTPs.

 **1991** DIFFERENCES BETWEEN SMALL MOLECULES AND BIOLOGICAL THERAPEUTIC DRUG PRODUCTS.

B. Mounho. *Toxicology, Amgen, Inc., Thousand Oaks, CA.*

The majority of pharmaceutical drugs are chemically-synthesized, small molecular weight products. Over the years, however, biological therapeutic products (BTPs) have been approved for various clinical indications. BTPs are large molecular

weight molecules typically derived from genetic manipulation of living cells, such as bacteria, yeast, or mammalian cells; examples of BTPs include cytokines, growth factors, fusion proteins, and monoclonal antibodies. BTPs have several distinctive properties, which can create unique challenges in conducting nonclinical toxicology studies that typically are not issues for small molecule products; conversely, there are challenges unique to small molecule products (e.g. metabolism) that do not apply to BTPs. Due to the target specificity of BTPs, it is necessary to conduct toxicology studies in a pharmacologically relevant animal model. Relevant animal models for BTPs are often limited to nonhuman primates where limited safety data can be obtained and thus may require the use of alternative models such as transgenic mice or surrogate molecules. BTPs intended for humans are frequently immunogenic in animals, and can result in the formation of anti-drug antibodies; such antibodies can impact the outcome of toxicology studies by altering the pharmacokinetics or neutralizing the pharmacologic activity of the BTP. Because of their unique properties and challenges, the types of nonclinical toxicology studies conducted for BTPs are often science driven and can vary for each agent; regulatory expectations for nonclinical safety studies required for small molecule products, however, are more clearly defined due to the extensive experience and established database with small molecules. Furthermore, because there are fundamental differences between BTPs and small molecule products, the toxicology studies routinely conducted for small molecules (e.g. genotoxicity testing), may not be relevant for BTPs. Likewise, nonclinical studies conducted for particular BTPs (e.g. tissue-cross reactivity for monoclonal antibodies) may be inappropriate for small molecule products.

 **1992** IMMUNOGENICITY- IMPACT ON TOXICOLOGY STUDIES AND BEYOND.

D. Wierda and H. Smith. *Immunotoxicology, Eli Lilly Research Laboratories, Greenfield, IN.*

The design and interpretation of preclinical safety studies with human biotherapeutics are complicated by the formation of antibodies directed against the therapeutic molecule. A first design consideration is the selection of a toxicology testing species in which the test molecule is pharmacologically active. Most molecules are primate specific, but in cases where it is active in multiple species, the question arises as to whether a non-primate species should be used if immunogenicity is expected. Another consideration is the relative half-life of a molecule, especially with monoclonal antibodies, since a wash out period should be included to allow for clearance and to avoid free drug interference in the immunoassay. Longer lead times are also required for immunoassay development and to allow for the generation of positive antibody controls. Each of these factors significantly lengthens the timeline for conducting preclinical safety studies. In some cases, consideration must be given to the use of surrogate antibodies, or immunodeficient rodents, to avoid antibody neutralization of pharmacology. In safety studies, the principal impact of immunogenicity is on whether or not the antibodies neutralize pharmacology or alter pharmacokinetics as these could invalidate the toxicology study. The next consideration is whether any adverse effects are associated with an unexpected immune response such as immune complex deposition, allergy or, in the case of recombinant proteins, neutralization of endogenous proteins. It has been customary to dismiss the latter findings as an artifact due to differences in species homology, but recent experiences with protein replacement therapies such as erythropoietin demonstrate that such findings in animal studies may be predictive of potential clinical sequelae. These clinical findings indicate that further efforts are warranted for developing less immunogenic molecules and better models for predicting immunogenicity.

 **1993** THE NONHUMAN PRIMATE AS AN ANIMAL MODEL FOR THE SAFETY EVALUATION OF BIOLOGICAL THERAPEUTIC PRODUCTS.

J. Kapeghian. *Discovery and Development Services, Charles River Laboratories, Sierra Division, Sparks, NV.*

The nonhuman primate has become the default "species of choice" for the nonclinical development of biological therapeutics primarily for two reasons: 1) the therapeutic target is often expressed at levels comparable to humans and "monitorable" within the confines of IND-enabling toxicology studies, and 2) the phylogenetic similarities of nonhuman primates to humans reduces the potential for immunogenicity. Although many species of nonhuman primate are used in safety evaluation studies, the nonclinical safety of biologics have been typically tested in young adult rhesus and cynomolgus monkeys. The chimpanzee is important in selected types of disease and research programs; however, it is rarely used in toxicology studies due strict protection as a highly-threatened species. Essentially all nonhuman primates used for nonclinical research are now purpose-bred, and are imported from offshore colonies; there are also, however, domestic breeding sources within the US for laboratory use of these species. Due to recent supply shortages and increased cost of

rhessus monkeys, the cynomolgus monkey, a closely-related macaque, became the primary nonhuman primate species used in nonclinical studies within the US. Both the rhesus and cynomolgus are Old World species and have been well-characterized from a "historical data perspective" to allow relatively low numbers of animals to be used in toxicology test designs, and often, these animals provide the only relevant nonclinical safety data prior to dosing humans with biological therapeutics. For this reason, pharmacokinetic/pharmacodynamic, immunologic, and clinical pathology endpoints are routinely modeled in macaques for comparable monitoring in human trials, often with correlative predictive value. The similarities in genetic, physiologic, and pharmacologic responses between humans and macaques used in nonclinical safety evaluation of biologic therapeutics add to the rising importance of the rationale for the use of nonhuman primates in this role.

**1994 ALTERNATIVE METHODS FOR THE SAFETY EVALUATION OF BIOLOGICAL THERAPEUTIC PRODUCTS — SURROGATE ANTIBODIES AND BEYOND.**

*J. Clarke, BiogenIdec, Cambridge, MA.*

The safety evaluation of biological therapeutic products (BTPs) can be challenging because it can necessitate the use of alternative methods due to the pronounced species specificity and immunogenic potential of these products. BTPs being developed for chronic indications such as psoriasis, peripheral neuropathy or rheumatoid arthritis present toxicologists with the challenge of assessing the potential for reproductive toxicity and carcinogenicity. Novel approaches to this challenge include conducting toxicology studies using surrogate molecules and/or in knock-out or knock-in models. Surrogate molecules are specific for the epitope or receptor expressed in the desired species of laboratory animal. This approach, while it has gained acceptance and been used for several BTPs, remains a challenging and customized technique, highly influenced by the pharmacology and physical properties of the BTP. Examples will be discussed including Raptiva, a monoclonal antibody to LFA-1 for the treatment of psoriasis, and Remicade, a monoclonal antibody for the treatment of Crohn's Disease. Assessing the carcinogenic potential of BTPs remains challenging for toxicologists, but recent, highly novel approaches are being investigated, including tumor xenograft models and specialized mouse strains. Finally, as in other areas of toxicology, transcriptional profiling of cells and tissues using DNA arrays is an unfolding area in terms of its application to BTPs.

**1995 SAFETY ASSESSMENT OF BIOLOGICAL PRODUCTS — A REGULATORY PERSPECTIVE.**

*H. Ghantous, FDA/CDER/ODEVI/DTBIMP, Rockville, MD.*

The development of biological therapeutic products (BTPs) for the diagnosis and treatment of human diseases is a cooperative effort between biopharmaceutical companies and regulatory agencies. In the US, USFDA's Center for Drug Evaluation and Research (CDER) is responsible for regulating monoclonal antibodies for human use, cytokines, enzymes, growth factors, thrombolytics, and extracted proteins in addition to small molecular-sized drugs. The types of pharmacology and toxicology studies considered scientifically appropriate to support the safe development and, ultimately, the approval of BTPs are defined in a series of guidance documents. These documents include those generated within the International Conference on Harmonisation (ICH) process and within CDER. Due to the relatively unique properties of BTPs (e.g. large molecular size, target specificity, and immunogenicity), their safety assessment differs from that of small molecular-sized drugs. The scientific need for this different approach is reflected in the guidance documents. For example, the ICH S6 document, Preclinical Safety Evaluation of Biotechnology-Derived Pharmaceuticals, is specific for BTPs. In addition, other guidance documents define the relevance of specific types of studies (e.g. safety pharmacology) to BTPs. This presentation will address how the available guidance documents define a scientifically sound path for the development of BTPs.

**1996 NOVEL REPORTER GENE ASSAY FOR DEVELOPMENTAL TOXICITY TESTING.**

*S. Schwengberg<sup>1</sup>, A. Ehlich<sup>1</sup>, H. Marquardt<sup>2</sup>, J. Hescheler<sup>3</sup> and H. Bohlen<sup>1</sup>.  
<sup>1</sup>Axiogenesis AG, Cologne, Germany, <sup>2</sup>Toxicology, University Hospital, Hamburg, Germany and <sup>3</sup>Neurophysiology, University Hospital, Cologne, Germany.*

Animal-based developmental toxicity testing is often a bottleneck in compound development in the chemical and pharmaceutical industry. *In vivo* tests need large amounts of compounds, are time- and cost-consuming, and lack public acceptance. During the last years, *in vitro* alternatives have been examined to overcome the limitations of the current test strategies, among which the embryonic stem cell test is

the only animal-free test based on mammalian cells (Spielmann H et al., *In Vitro Toxicol* 1997, 10:119). However, this test is not suitable for screening large compound libraries. We have developed two different reporter gene assays based on the differentiation of mouse embryonic stem cells towards cardiac tissue (R.E.Toxicology FL: GFP expression, R.E.Toxicology SL: expression of a soluble enzyme). In a double-blind study, we have tested 70 compounds either recommended by ECVAM (Brown NA, ATLA 2002, 30:177) or tested by the National Toxicology Program (<http://ntp-server.niehs.nih.gov/htdocs/pub-TT0.html>). 93% of all compounds were identified correctly by R.E.Toxicology (strong embryotoxic: 100%, weak embryotoxic: 85%, non embryotoxic: 94%). Moreover, the effect of Thalidomide can be clearly demonstrated by R.E.Toxicology, although its teratogenicity cannot be detected in rodents *in vivo*. Compounds that are not classified correctly belong mainly to chemical classes that need metabolic activation (e.g. glycolethers and some phthalates). Therefore, the addition of a metabolic system (e.g. S9 mix, precirculation with hepatocytes) should be considered to further enhance the significance of the assay. In conclusion, R.E.Toxicology allows the monitoring of embryotoxic and teratogenic effects of chemicals, pharmaceuticals, and environmental agents in an animal-free, time- and cost-effective assay. Moreover, R.E.Toxicology needs only minimal amounts of compounds, which allows shifting developmental toxicity testing to early stages of compound development.

**1997 VALIDATION STATUS OF THE HENS EGG TEST-CHORIOALLANTOIC MEMBRANE (HET-CAM) TEST METHOD.**

*N. Choksi<sup>1,2</sup>, D. Allen<sup>1,2</sup>, C. Inhof<sup>1,2</sup>, J. Truax<sup>1,2</sup>, R. Tice<sup>1,2</sup> and W. Stokes<sup>1</sup>.  
<sup>1</sup>NICEATM, NIEHS, Research Triangle Park, NC and <sup>2</sup>ILS, Inc., Research Triangle Park, NC.*

Concerns about animal welfare and interest in higher throughput testing have led researchers to develop alternative *in vitro* test methods for the current rabbit eye test. NICEATM evaluated four *in vitro* ocular test methods for their ability to identify substances that cause irreversible or severe irritation or corrosion. One of these test methods, HET-CAM, is a model that is proposed to mimic the mucosal tissues of the eye. The ability of HET-CAM to correctly identify ocular corrosives and severe irritants using available HET-CAM data that evaluated the time to appearance of endpoints and corresponding *in vivo* eye irritation data was evaluated according to current hazard classification schemes for the USEPA (n=54), the European Union (n=54), and the UN Globally Harmonized System (n=52). Depending on the classification scheme used, HET-CAM had a false positive rate of 20-27%, and a false negative rate of 0-7%. Lack of published intra- and interlaboratory data for this analysis method precluded an evaluation of test method reliability. A proposed standardized test method protocol and a proposed recommended list of reference substances have been developed for future validation and testing studies to further assess the accuracy, reliability, and the applicability domain of HET-CAM for the detection of ocular corrosives and severe irritants. HET-CAM may be useful in a tiered-testing strategy where positive results can be used to classify and label a substance, while substances with negative results would undergo additional testing to identify false negative ocular corrosives/severe irritants and to identify those chemicals with reversible ocular effects. This approach would reduce the number of animals used for eye irritation testing and reduce the number of animals experiencing pain and distress by identifying substances that are severe irritants/ corrosives. ILS staff supported by NIEHS contract N01-ES 35504.

**1998 GENE EXPRESSION SIGNATURES FOR CADMIUM, MERCURY, AND ACRYLAMIDE EXPOSURE IN CAENORHABDITIS ELEGANS.**

*D. Jackson<sup>1</sup>, M. Szilagyi<sup>2</sup>, E. Gehman<sup>2</sup> and E. Clegg<sup>1</sup>. <sup>1</sup>US Army Center for Environmental Health Research, Fort Detrick, MD and <sup>2</sup>Geo-Centers, Inc., Fort Detrick, MD.*

To ascertain whether distinct biological responses to different chemical toxicants could be discerned at the level of gene expression in the nematode *C. elegans*, we exposed synchronized cultures of mid-L4 larvae to two heavy metals, cadmium chloride, and mercuric chloride, and to the chemically dissimilar compound, acrylamide. Exposures were for 4 and 8 h. We used doses sufficient to reproducibly arrest development of approximately 10%, 50% or 90% of the larvae in the L4 stage 24 h after exposure. Unexposed worms molt and enter the adult stage about 17 h after the mid L4 stage. Exposures were performed in triplicate in axenic medium to eliminate potential confounding effects due to using *E. coli* as food source for the worms. Microarray analyses were performed with RNA isolated from whole control and exposed worms using Affymetrix whole genome *C. elegans* GeneChips. As judged by ANOVA, each chemical induced a distinct pattern of

gene expression, even within metabolic pathways, such as glutathione synthesis, which are affected by all the chemicals. While there were some developmental differences between worms exposed for 4 or 8 h, toxicant induced alterations in gene expression were generally similar at both exposure durations. Disclaimer: The views, opinions, and/or findings contained in this report are those of the authors and should not be construed as official Department of the Army position, policy, or decision, unless so designated by other official documentation.

**1999**

**CYTOKINE SECRETION PROFILES OF MOUSE DENDRITIC CELLS: IMPACT OF CELL TRAUMA.**

G. Beckwith<sup>1</sup>, C. J. Betts<sup>1</sup>, C. A. Ryan<sup>2</sup>, F. Gerberick<sup>2</sup>, R. J. Dearman<sup>1</sup> and L. Kimber<sup>1</sup>. <sup>1</sup>Syngenta CTL, Macclesfield, United Kingdom and <sup>2</sup>Procter & Gamble, Cincinnati, OH.

Cutaneous immune responses such as chemical contact allergy are regulated by cytokines produced by skin cells including Langerhans cells (LC) and keratinocytes. LC-like DC can be generated in culture from precursor cells, facilitating investigations of alternative approaches for skin sensitization hazard identification. DC were generated from bone marrow cells of BALB/c strain mice and cytokine secretion profiles measured following 24h culture with the water soluble allergen dinitrobenzene sulfonic acid (DNBS) and the non-sensitizing analogue, benzene sulfonic acid (BSA). Cells were exposed to concentrations of DNBS (0.05 and 0.5mM) or BSA (5 and 50mM) that were without effect on cell viability or that provoked significant cytotoxicity (40 to 100% cell death), respectively. Control cells were cultured with medium alone or with 1 µg/ml bacterial lipopolysaccharide (LPS), a potent stimulator of DC that is without effect on cell viability. In the majority of experiments (n=8), DC expressed constitutively interleukin (IL)-1β, IL-1α, IL-6, IL-12 p40 and IL-12 p70. Compared with medium alone, culture with high dose DNBS up-regulated IL-6 and IL-12 p40 secretion (5- and 20-fold). In contrast, culture with high dose BSA provoked increases in IL-1α (2-fold) and IL-1β (3-fold) expression. Culture of DC with 1µg/ml LPS resulted in marked increases in cytokine expression, with for example a 260-fold increase in IL-6 secretion and a 46-fold increase in IL-12 production compared with medium controls. In addition, increased levels of tumor necrosis factor-α, IL-10 and IL-17, cytokines that were not expressed constitutively, were provoked by treatment with LPS. These data show that the modest cytokine production induced by chemical is dependent, in this instance, upon cytotoxicity. Under conditions of equivalent cell injury, different cytokine profiles were induced by sensitizers and non-sensitizers, suggesting that it may be possible to identify chemical allergens on the basis of differential cytokine secretion.

**2000**

**MATRIX METALLOPROTEINASES AS BIOMARKERS FOR DIOXIN EXPOSURE IN DEVELOPING JAPANESE MEDAKA (ORYZIAS LATIPES).**

V. L. Prince, V. LaPrete, C. M. Villano and L. A. White. *Biochemistry and Microbiology, Rutgers University, New Brunswick, NJ.*

Dioxin like compounds (DLC), such as 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), are global environmental contaminants that are particularly toxic to early stages of vertebrate development. In the developing fish, TCDD disrupts cardiovascular development and function that is manifested in decreased blood flow and edema in the caudal region, in addition to edema in the pericardium and/or yolk sac. Our hypothesis is that TCDD and related DLCs disrupt vascular formation and function through activation of the matrix metalloproteinases (MMPs). MMPs are a family of endopeptidases that degrade the proteins of the extracellular matrix. Expression and activity of the MMPs are required for tissue remodeling, and are expressed during vascular development and wound regeneration. We propose that MMP expression is a pre-lesion biomarker for dioxin exposure, and that activation of MMP expression and activity is a critical step in resulting lesions. Reports demonstrate that developmental TCDD exposure of medaka (*Oryzias latipes*) results in hemorrhaging and edema. Our data further define the sensitive period of TCDD exposure to between 30 and 80 hpf. Medaka embryos exposed to TCDD from 1-2 hpf (hours post fertilization) or from 30 hpf resulted in hemorrhaging by 120 hpf and 83-87% pre-hatch mortality. Medaka embryos exposed from 80 hpf, showed similar lesions, however, fewer embryos were affected (59%). Using quantitative RT-PCR, we show that MMP-2 and MMP-9 are expressed at critical times for vascular development, with MMP-2 having two peaks at 30 hpf and 120 hpf. Following TCDD exposure, CYP1A1 expression was increased over vehicle control, demonstrating activation of the AhR pathway. MMP-2 expression was increased in response to TCDD (2-5 fold) at 120 hpf. TCDD-induced expression of MMP-9 was not observed at this time, but was observed at 216 hpf. This suggests that TCDD activation of the AhR pathway alters MMP expression and activity, resulting in abnormal vascular development and edema.

**2001**

**EPIOCULAR™ HUMAN CELL CONSTRUCT: TISSUE VIABILITY AND HISTOLOGICAL CHANGES FOLLOWING EXPOSURE TO SURFACTANTS.**

M. E. Blazka<sup>1</sup>, M. Diaco<sup>2</sup>, J. W. Harbell<sup>2</sup>, H. Raabe<sup>2</sup>, A. Sizemore<sup>2</sup>, N. Wilt<sup>2</sup> and D. M. Bagley<sup>1</sup>. <sup>1</sup>Colgate-Palmolive Co, Piscataway, NJ and <sup>2</sup>Institute for In Vitro Sciences, Inc., Gaithersburg, MD.

The ability of the EpiOcular™ construct to predict the eye irritation potential of surfactants and surfactant-based formulations has been the subject of a formal validation program. EpiOcular™ correlates a test article's potential for ocular irritation with the time it takes to reduce tissue viability by 50% (ET<sub>50</sub>) as measured by the tissue's ability to reduce MTT. An algorithm is used to convert the ET<sub>50</sub> value to a 'predicted Draize' score which can then be compared to *in vivo* data. This study investigated whether the histological changes following exposure are in agreement with the MTT results. Eight surfactants were selected from the validation study; 4 surfactants whose *in vitro* ocular irritation potential agreed with the *in vivo* data (cetyl alcohol; 3% sodium lauryl sulfate; 50% didecyldimonium chloride; sodium sulfolaurate mixture) and 4 whose *in vitro* data differed from the *in vivo* data (10% cetylpyridinium bromide; 3.2% benzethonium chloride; C10-12 alcohol ethoxylate; quaternium-18). Exposure times used in this study bracketed ET<sub>50</sub> values established in the validation study. For all surfactants, the results showed a good relationship between the degree of histological damage with changes in tissue viability. An increase in the depth and severity of tissue damage was associated with a decrease in tissue viability. Histological changes ranged from subtle cellular changes such as vacuolization and punctate chromatin condensation to overt tissue loss and cell necrosis. Loss of or damage to the surface squamous epithelium was associated with <20% decrease in viability, while the degree of damage to the central squamous epithelium was directly related to a 20-80% decrease in viability. In conclusion, the nature and severity of the histological changes were in agreement with the MTT results. Understanding the progression and types of cellular changes associated with tissue damage may be able to help distinguish the degrees of ocular irritation.

**2002**

**LONG TERM REPRODUCIBILITY OF EPIOCULAR™, A THREE-DIMENSIONAL TISSUE CULTURE MODEL OF THE HUMAN CORNEAL EPITHELIUM.**

M. Klausner, J. E. Sheasgreen, J. Kubilus and P. J. Hayden. *MatTek Corporation, Ashland, MA.*

The EpiOcular tissue model (OCL-200) is an organotypic model of the human corneal epithelium (HCE) cultured from normal human keratinocytes using serum free medium. Paraffin embedded, H & E stained histology cross-sections show the structure of EpiOcular closely parallels that of the HCE; large nucleated basal cells lie beneath 5-6 stratified cell layers which progressively flatten out, ending with a highly squamous, non-keratinized layer at the tissue's apical surface. Since commercial introduction in 1995, EpiOcular has been increasingly used by many personal care and household product companies to determine the ocular irritancy of their products without using animals. Currently, validation of the EpiOcular model as a replacement for the Draize rabbit eye test is underway in the US. In addition, a validation study sponsored by ECVAM is scheduled to begin in 2005. For commercial and regulatory purposes, it is very important to know that the model is reproducible both within a given lot and between lots, especially over extended periods. Quality control of weekly batches of EpiOcular is performed using the MTT assay, which historically has been the *in vitro* endpoint of choice for European and US regulators. The exposure time needed to reduce the viability to 50% (ET-50) for 0.3% Triton X-100 is determined. Yearly average ET-50 values have ranged from 20.6 minutes (2000) to 25.0 minutes (1998). The coefficients of variation (CV) for the negative control tissue (exposed to ultrapure H<sub>2</sub>O) have averaged under 6% for every year since 1997. In addition, the yearly average CV for all tissues has never exceeded 6.5%. These results over the past 8 years of commercial production show EpiOcular to be a highly reproducible, stable toxicological model that is ideally suited for industrial and regulatory ocular irritancy studies.

**2003**

**HIGH-THROUGHPUT *IN VITRO* MODELS OF HUMAN EPIDERMIS AND OCULAR EPITHELIUM FOR PRECLINICAL SAFETY AND EFFICACY TESTING OF CONSUMER PRODUCTS AND PHARMACEUTICALS.**

G. R. Jackson, J. Kubilus, M. Klausner, J. E. Sheasgreen and P. J. Hayden. *MatTek Corp., Ashland, MA.*

Prior to introduction of new consumer products and cosmetics, or human testing of new therapeutics, animal experiments are traditionally utilized to screen for safety and efficacy. However, large numbers of lead candidates generated by modern high throughput technologies renders animal testing expensive and impractical. A growing need exists for high throughput *in vitro* models which can provide rapid, reliable safety and efficacy screening. The current poster describes development of

*in vitro* models of human epidermal and ocular cultures in 96-well high-throughput screening (HTS) formats compatible with robotic manipulation. The HTS models are derived from normal human cells cultured at the air/liquid interface in 96-well microporous membrane plates to produce three-dimensional organotypic cultures. Culture histology of both models was evaluated by H&E staining of formalin fixed paraffin sections. The epidermal model displays a stratified and cornified differentiated structure, similar to native epidermis. The 96-well HTS ocular cultures are stratified squamous epithelium typical of *in vivo* ocular epithelium. Well to well (intraplate) and plate to plate (interlot) variability, as determined by the MTT viability assay, was generally found to be less than 10%. The HTS ocular model was also evaluated for compatibility with the EpiOcular Prediction Equation developed for predicting *in vivo* Draize ocular irritation scores with MatTek Corporation's standard EpiOcular product(OCL-200). When tested with various concentrations of chemicals including sodium dodecyl sulfate, Triton X-100, benzalkonium chloride, sodium hydroxide and others, the HTS ocular model gave predicted Draize scores that correlated well with standard EpiOcular predicted Draize scores and historical *in vivo* Draize scores. HTS epidermal and ocular models such as these may thus help to lessen bottlenecks currently encountered in safety and efficacy testing of consumer products and topical therapeutics. This work was supported by NIEHS grant 5R44 ES010237-03.

## 2004

### EVALUATION OF A TISSUE ENGINEERED HUMAN SKIN EPIDERM 3-D CULTURE AS A MODEL TO STUDY IRRITATION AFTER JET FUEL EXPOSURE.

A. Chatterjee, R. Babu and M. Singh. *Florida A&M University, Tallahassee, FL*.

The purpose of the present study was to evaluate human skin epiderm 3-D culture, EPI-200 (MatTek Corp, Ashland, MA) as a model to study the skin irritation of various jet fuels. Upon receipt, EPI-200 tissues were placed in six-well plates containing maintenance medium (EPI-100-NMM) and incubated for 24-72h. The cultures were subjected to different doses (5, 10, 50  $\mu$ l) of JP-8 and JP-8+100. After each exposure, the tissue viability was measured by MTT assay and the morphology was studied by hematoxylin and eosin (H&E) staining of histological sections. The expression of IL-1  $\alpha$  in the tissue culture media was determined by enzyme immunoassay (EIA). The EPI-200 exposures showed an interesting dose dependent relationship between IL-1 $\alpha$  release and cell viability. At the lowest dose (5 $\mu$ l) of JP-8 and JP-8+100, there was no cell kill at 24 h, but at 48 and 72 h both the chemicals reduced the tissue viability to 61-65 %, with no significant difference between the two time points. JP-8 and JP-8+100 exposures at 24h significantly increased the expression of IL-1 $\alpha$  to 13 and 51 folds respectively over the control. This finding was very interesting considering the fact that there was no cell kill detected after 24 h. At 48 and 72h the IL-1 $\alpha$  level was lower than at 24h which was due to reduction in the cell viability. After 24h, 10 $\mu$ l of JP-8 and JP-8+100 exposures demonstrated around 45-50% cell viability while 50  $\mu$ l of the jet fuels reduced the cell viability to zero. Control tissues were 100% viable at all time points. H&E staining of the tissues after 24h indicated that the jet fuels disrupted the barrier function of stratum corneum. The effect was more severe after 48h, while after 72h the tissue started losing their integrity. The findings with EPI-200 correlate well with our earlier findings from skin irritation studies conducted on CD Hairless rats with JP-8 and JP-8+100. Overall, our experiments demonstrate that EPI-200 can be used as a valuable model to evaluate the skin irritation potential of jet fuels and hydrocarbon chemicals.

## 2005

### VALIDATION STATUS OF THE BOVINE CORNEAL OPACITY AND PERMEABILITY (BCOP) TEST METHOD.

C. Inhof<sup>1,2</sup>, N. Choksi<sup>1,2</sup>, D. Allen<sup>1,2</sup>, J. Truax<sup>1,2</sup>, R. Tice<sup>1,2</sup> and W. Stokes<sup>1</sup>.  
<sup>1</sup>NICEATM, NIEHS, Research Triangle Park, NC and <sup>2</sup>ILS, Inc., Research Triangle Park, NC.

Concerns about animal welfare and an interest in higher throughput testing have led researchers to develop alternative *in vitro* test methods for the current rabbit eye test. NICEATM evaluated four *in vitro* ocular test methods for their ability to identify substances that cause irreversible or severe irritation or corrosion. One of these test methods, BCOP, is an organotypic model that provides short-term maintenance of normal physiological and biochemical function of the cornea in an isolated system. The ability of BCOP to correctly identify ocular corrosives and severe irritants using available BCOP and corresponding *in vivo* eye irritation data was evaluated according to current hazard classification schemes for the USEPA (n=101), the European Union (n=141), and the UN Globally Harmonized System (n=104). Depending on the classification scheme used, BCOP had a false positive rate of 20-26%, and a false negative rate of 22-26%. In terms of reliability, the assay was determined to have acceptable intra- and inter-laboratory reproducibility. A proposed standardized test method protocol and a proposed recommended list of reference substances have been developed for future validation and testing studies to further assess the accuracy, reliability, and the applicability domain of BCOP for the detection of ocular corrosives/severe irritants. Investigators should consider using BCOP prior to eye irritation testing in animals. BCOP may be useful in a tiered testing strategy where positive results can be used to classify and label a sub-

stance, while substances with negative results would undergo additional testing to identify false negative ocular corrosives/severe irritants and to identify those chemicals with reversible ocular effects. This approach would reduce the number of animals used for eye irritation testing and reduce the number of animals experiencing pain and distress. ILS staff supported by NIEHS contract N01-ES 35504.

## 2006

### ASSESSMENT OF THE SKINETHIC RECONSTITUTED HUMAN EPIDERMAL MODEL FOR THE PREDICTION OF THE DERMAL IRRITATION POTENTIAL OF PHARMACEUTICAL PROCESS MATERIALS.

C. W. Seaman<sup>1</sup>, R. L. Guest<sup>2</sup>, A. Whittingham<sup>2</sup>, B. De Wever<sup>3</sup>, M. Cappadore<sup>3</sup>, B. Bertino<sup>3</sup> and E. Adriena<sup>4,1</sup>.  
<sup>1</sup>GlaxoSmithKline, Ware, United Kingdom, <sup>2</sup>SafePharm Laboratories, Derby, United Kingdom, <sup>3</sup>SkinEthic Laboratories, Nice, France and <sup>4</sup>University of Ghent, Ghent, Belgium.

Occupational dermatitis is an ongoing issue and identification of the irritant potential of materials is an important component in chemical control. Traditionally, testing for irritation has relied upon *in vivo* models. Recent developments, including ethical and scientific concerns regarding the rabbit model and availability of new technologies, have driven the development of promising systems for the prediction of dermal irritation. This report describes a study to assess the performance of a reconstituted human epidermal (RHE) model produced by SkinEthic Laboratories, Nice, France when tested with 23 diverse pharmaceutical process materials at two separate laboratories. The collection included chemicals producing a range of reactions from non-irritant to severe irritation *in vivo*. Untreated cultures were used as negative controls and 0.1% Triton as a positive control. Substances were applied topically, as supplied to triplicate RHE cultures for periods of 4 or 24-hours. At the end of treatment, cultures were assessed for viability (MTT), histological change and IL-1 alpha and IL-8 release. Results for MTT, histopathology and interleukin-1 alpha were shown to be reliable and reproducible, both within and between laboratories. Results for interleukin-8 showed greater variation. Concordance with *in vivo* results at the two laboratories was excellent, being 78% and 83% respectively, as were values for sensitivity and specificity. Absence of cytotoxicity at 24 hours was shown to be a reliable predictor of non-irritant chemicals. Time-related cytotoxicity (at 24-hours only) may be a useful model for mild irritants. RHE cultures are shown to have promise as an alternative for the identification of the dermal irritation hazard of pharmaceutical process materials.

## 2007

### VALIDATION STATUS OF THE ISOLATED CHICKEN EYE (ICE) TEST METHOD.

D. Allen<sup>1,2</sup>, N. Choksi<sup>1,2</sup>, C. Inhof<sup>1,2</sup>, J. Truax<sup>1,2</sup>, R. Tice<sup>1,2</sup> and W. Stokes<sup>1</sup>.  
<sup>1</sup>NICEATM, NIEHS, Research Triangle Park, NC and <sup>2</sup>ILS, Inc., Research Triangle Park, NC.

Concerns about animal welfare and interest in higher throughput testing have led researchers to develop alternative *in vitro* test methods for the current rabbit eye test. NICEATM evaluated four *in vitro* ocular test methods for their ability to identify substances that cause irreversible or severe irritation or corrosion. One of these test methods, ICE, is an organotypic model that provides short-term maintenance of normal physiological and biochemical function of the eye in an isolated system. The ability of ICE to correctly identify ocular corrosives and severe irritants using available ICE and corresponding *in vivo* eye irritation data was evaluated according to current hazard classification schemes for the USEPA (n=91), the European Union (n=121), and the UN Globally Harmonized System (n=93). Depending on the classification scheme used, ICE had a false positive rate of 8-10% and a false negative rate of 30-40%. In terms of reliability, the assay has acceptable interlaboratory reproducibility; intralaboratory reproducibility could not be assessed. A proposed standardized test method protocol and a proposed recommended list of reference substances have been developed for future validation and testing studies to further assess the accuracy, reliability, and the applicability domain of ICE for the detection of ocular corrosives/severe irritants. Investigators should consider using ICE prior to eye irritation testing in animals. When used in a tiered testing strategy, positive results could be used to classify and label a substance, while substances with negative results would undergo additional eye irritation testing to identify false negative ocular corrosives/severe irritants and to identify those chemicals with reversible ocular effects. This approach would reduce the number of animals used for eye irritation testing and reduce the number of animals experiencing pain and distress. ILS staff supported by NIEHS contract N01-ES 35504.

## 2008

### VALIDATION STATUS OF THE ISOLATED RABBIT EYE (IRE) TEST METHOD.

J. Truax<sup>1,2</sup>, N. Choksi<sup>1,2</sup>, C. Inhof<sup>1,2</sup>, D. Allen<sup>1,2</sup>, R. Tice<sup>1,2</sup> and W. Stokes<sup>1</sup>.  
<sup>1</sup>NICEATM, NIEHS, Research Triangle Park, NC and <sup>2</sup>ILS, Inc., Research Triangle Park, NC.

Concerns about animal welfare and interest in higher throughput testing have led to the development of alternatives to the current rabbit eye test. NICEATM evaluated four *in vitro* ocular test methods for their ability to identify irreversible or se-

were irritants/corrosives as alternatives to the rabbit eye test. One of these test methods, IRE, is an organotypic model that maintains normal physiological and biochemical function of the isolated eye. The ability of IRE to correctly identify ocular corrosives/severe irritants using available IRE and corresponding *in vivo* irritation data was evaluated according to current hazard classification schemes defined by the USEPA (n=77), the European Union (n=149), and the UN Globally Harmonized System (n=81); accuracy (48-86%), and false positive (22-59%)/false negative (0-57%) rates varied widely but consistently across regulatory systems. When fluorescein retention and/or epithelial integrity assessment were included (EU system only; n=65), accuracy was 77-86%; false positive and false negative rates were 23-34% and 0%, respectively. Lack of published intra- and interlaboratory data for this assay version precluded an evaluation of reliability. A proposed standardized test method protocol and a proposed recommended list of reference substances have been developed for future validation/testing studies to further assess the accuracy, reliability, and the applicability domain of IRE for the detection of ocular corrosives/severe irritants. IRE may be useful in a tiered testing strategy where positive results can be used to classify and label a substance, while substances with negative results would undergo additional testing to identify false negative ocular corrosives/severe irritants and to identify those chemicals with reversible ocular effects. This approach would reduce the number of animals used for eye irritation testing and reduce the number of animals experiencing pain and distress. ILS staff supported by NIEHS contract N01-ES 35504.

## 2009

### ASSESSMENT OF THE SKINETHIC RECONSTITUTED HUMAN CORNEAL EPITHELIUM MODEL FOR PREDICTION OF THE OCULAR IRRITATION POTENTIAL OF PHARMACEUTICAL PROCESS CHEMICALS.

R. L. Guest<sup>1</sup>, C. Seaman<sup>2</sup>, B. De Wever<sup>3</sup>, M. Cappadoro<sup>3</sup>, B. Bertino<sup>3</sup>, A. Whittingham<sup>1</sup>, N. Warren<sup>1</sup> and E. Adriams<sup>1</sup>. <sup>1</sup>SafePharm Laboratories Ltd., Derby, United Kingdom, <sup>2</sup>GlaxoSmithKline, Ware, Hertfordshire, United Kingdom, <sup>3</sup>SkinEthic Laboratories, Nice, France and <sup>4</sup>Ghent University, Ghent, Belgium.

New process chemicals are continually required to develop novel drugs and to improve synthesis of existing medicines. Determination of the eye irritancy potential of process chemicals is essential because of the serious effects that could occur after accidental workplace exposure to severe irritants. Despite the development of several promising *in vitro* methods for assessment of eye irritancy, none has yet been fully validated and the use of animals is still necessary. Following an initial trial in 2003, the skinethic reconstituted human corneal model (RHC) was assessed for its predictive ability with regard to the irritancy of 21 process chemicals. Testing was conducted blind at two laboratories, SafePharm, UK and SkinEthic, France. Based on *in vivo* or *ex vivo* data 7/21 chemicals had previously been classified as irritant (EU R36 or R41). Chemicals were applied topically to triplicate rhc cultures for periods of 5, 10 and 60 minutes. Triplicate tissues were similarly treated with a buffered salt solution (negative control) or SDS 0.5% or 1% (positive control). At the end of treatment cultures were assessed for viability (MTT), histological changes and cytokine release (IL-1 $\alpha$ ). Results for MTT were shown to be the best indicator of irritancy. Histological changes were nearly always associated with decreased viability. IL-1 $\alpha$  release was low and was not considered useful for classification purposes. Some variability was noted between results obtained in the two laboratories. However, using data from safePharm, a concordance of >80% and sensitivity of 100% was obtained. Furthermore, 2/3 R36 irritants were correctly identified and a third was overpredicted as R41. The concordance was improved by evaluation of the results in conjunction with other safety data available for the chemicals. The RHC model shows promise for identification of irritant pharmaceutical process chemicals.

## 2010

### MELANOCYTE CONTAINING HUMAN ORGANOTYPIC EPIDERMIS AS A MODEL TO EVALUATE TOXICITY OF MELANIN BINDING SUBSTANCES.

F. Straube<sup>1</sup>, U. Junker<sup>2</sup>, S. Kretz<sup>1</sup> and A. Wolf<sup>1</sup>. <sup>1</sup>Biomarker Development, Novartis Pharmacology, Basel, Switzerland and <sup>2</sup>Preclinical Safety, Novartis Pharmacology, Basel, Switzerland.

The present study was performed in order to investigate how the presence of melanocytes alters toxicity of the melanin binding substance chloroquine in reconstituted organotypic human epidermis *in vitro*. To this aim, effects in two slightly different human epidermis constructs were compared; i) the well described epidermis produced by SkinEthic Laboratories and ii) the epidermis model containing melanocytes in addition to keratinocytes. Both tissues were generated at SkinEthic using the same stock of keratinocytes and kept in culture like described earlier (De Brugerolle de Fraissinette A et al. 1999). Both tissues were treated in parallel in five replicates with 0.019, 0.19 and 1.9mM of chloroquine or the non-toxic control substance trizma (= Tris buffer) dissolved in the culture medium. Sodium lauryl sul-

fate (SLS, 1.7mM) served as severely cytotoxic control. After 24h treatment the release of lactate dehydrogenase (LDH) and of the pro-inflammatory cytokines IL-1 $\alpha$  and IL-8 were determined. SLS induced severe cytotoxicity independently from the presence or absence of melanocytes as indicated by strong LDH release, whereas trizma treatment in all tested concentrations did neither induce cytokine nor LDH release. The melanin binding substance chloroquine induced release of LDH and IL-1 $\alpha$  in all tested concentrations in the absence of melanocytes. When melanocytes were present chloroquine was less toxic, causing LDH and IL-1 $\alpha$  release only at the highest concentration tested. In conclusion, melanocytes reduced toxic effects of the melanin binding substance chloroquine in human reconstituted epidermis. The melanocyte containing epidermis models may be a useful model to investigate toxicity of melanin binding substances.

## 2011

### VALIDATION OF A FLOW CYTOMETRY-BASED PHOTO-LOCAL LYMPH NODE ASSAY (PHOTO-LLNA) FOR THE IDENTIFICATION AND CHARACTERIZATION OF PHOTO-ALLERGENS.

M. K. Reeder, T. L. Ripper, D. R. Cerven and G. L. DeGeorge. *MB Research Laboratories, Spinnerstown, PA*.

The increasing concerns of both industry and regulatory agencies to identify and protect consumers from the photosensitizing properties of substances (chemical plus UVR exposure-induced allergic contact dermatitis) has driven the need for the development of photo-allergy (photosensitization) screening assays. Rapid, cost-effective tests that can identify and distinguish photo-allergic from photo-irritating or sensitizing substances, are totally lacking. Currently, the Photo-Buehler Guinea Pig Sensitization Assay, a subjective test that uses a large amount of animals, is commonly used to assess photosensitization potential of chemicals. This Photo-LLNA test is based on our recently validated "Enhanced Local Lymph Node Assay using Flow Cytometry" (eLLNA). Although the LLNA has been validated by both EU and USA regulatory agencies, and is now the "default, preferred test method" for the OECD and EPA, the use of radioactivity has limited its widespread application. The eLLNA, as well as the Photo-LLNA, substitutes the use of BrdU, a thymidine analog, in place of 3H-thymidine for measuring proliferation, eliminating the need for hazardous radioactivity. Other advantages of the Photo-LLNA include: 1) reduction of the number of test animals used, 2) decreased time and expense of testing, and 3) reduced pain and distress to test animals. The Photo-LLNA increases the discriminating power of the basic LLNA and GP photo-allergy assays by including immunophenotyping of lymphocyte subpopulations (CD3+ and B220+) and measuring "activation marker expression" such as CD69 and I-Ak. Using these additional endpoints, the Photo-LLNA identifies and discriminates photosensitizers from non-photosensitizers with over 92% accuracy.

## 2012

### COMPARISON OF ALTERNATIVE TOXICITY TEST METHODS FOR OCULAR IRRITATION USING THE AVIAN CHORIOALLANTOIC MEMBRANE: HET-CAM VS. CAMVA.

A. C. Gilotti, D. R. Cerven, S. Craig and G. L. DeGeorge. *MB Research Laboratories, Spinnerstown, PA*.

Industry and some regulatory agencies are seeking alternatives to the Draize Eye Irritation Test in rabbit to address the three R's of decreased animal testing. Decades of research and validation have produced two non-animal-based ocular toxicity tests, the CAM Vascular Assay (CAMVA) and the Hen's Egg Test-CAM (HET-CAM). The HET-CAM assay has been nominated by the EPA for evaluation as an alternative to the Draize test for ocular irritancy in rabbits. In the HET-CAM assay, test substances are applied topically to the CAM (at 10, 2.5 and 1% w/v). Ocular irritancy is predicted by calculating an irritation score (IS) based on the length of time until the exposure results in hemorrhage, lysis or coagulation. This reaction time is determined by visual inspection of the CAM through the test chemical. Turbid test chemicals prevent the reaction time from being determined, and thus they cannot be evaluated in the HET-CAM assay. This presents a serious problem for determining the ocular irritancy potential of mixtures and cosmetic formulations. We routinely use the CAM Vascular Assay (CAMVA) to evaluate turbid or insoluble formulations of cosmetics and other products. In the CAMVA, the CAMs are exposed to various concentrations of a test substance for 30 minutes and vascular effects are monitored to determine a RC50 for each test substance. We have used a 5-minute exposure time in the HET-CAM assay to determine the RC50 of various test chemicals. HET-CAM derived RC50 values were comparable to those determined in the CAMVA. In addition, the IS scores of translucent test substances were compared to the HET-CAM derived RC50 values to develop a model for predicting ocular irritancy based on a concentration-dependent modification to the HET-CAM protocol.

**2013****EXPOSURE OF MUCOCILIARY HUMAN LUNG EPITHELIAL CULTURES TO WHOLE CIGARETTE SMOKE.**

A. Richter, J. Phillips, N. Newland and E. D. Massey. *R&D, British American Tobacco, Southampton, United Kingdom.* Sponsor: J. Seagrave.

We have designed an exposure system for investigating the biological effects of whole cigarette smoke on lung epithelial cultures. In this study, primary human bronchial epithelial cells were differentiated to generate 3-dimensional mucociliary cultures resembling the normal tracheobronchial epithelium. The cultures were exposed to serial dilutions of mainstream cigarette smoke at an air-liquid interface for 1 hour. In addition, control cultures were exposed to filtered air. The cells were then incubated for a further 20 hours in serum-free medium. The trans-epithelial electrical resistance (TER) of the cultures was then determined and cell viability measured by the active uptake of neutral red dye. The levels of interleukin-8 (IL-8), interleukin-6 (IL-6), interleukin-1beta (IL-1beta) and matrix-metalloprotease-1 (MMP-1) in the conditioned medium were determined by enzyme-linked immunoassay. High concentrations of smoke reduced cell viability in a dose-dependent manner. Cytotoxicity was paralleled by a reduction in TER. Cigarette smoke stimulated the secretion of IL-8, IL-6 and MMP-1 from the epithelial cultures. By comparison, IL-1beta was not detectable in the conditioned medium of control or treated cultures. This study demonstrates a new experimental system for whole smoke exposure of cells at an air-liquid interface that may be useful for studying the molecular basis of smoking-related lung disease. Moreover, it may be adaptable for studying the effects of other aerosols and the use of such an *in vitro* system could potentially reduce use of animals for inhalation toxicology.

**2014****USE OF PLATEABLE CRYOPRESERVED RAT HEPATOCYTES AS A MODEL TO ASSESS HEPATOTOXICITY AND DRUG-DRUG INTERACTIONS.**

T. A. Moeller, S. Lloyd, P. M. Silber and N. S. Jensen. *In Vitro Technologies, Baltimore, MD.*

Freshly isolated rat hepatocytes are widely used to study drug metabolism, toxicity, and drug-drug interactions. However, the preparation of fresh rat hepatocytes is labor- and time-intensive and can be subject to interday variability with respect to both the quantity and quality of the isolated hepatocytes. We have recently identified cryopreserved rat hepatocytes (PCRH) that form monolayers on collagen-coated plates, and which can be used to assess long-term (>24 hour) toxicity and drug-drug interactions. To evaluate the PCRH model, hepatocytes from SD rats were thawed, and allowed to attach to collagen-coated plates overnight in a 37°C, 5% CO<sub>2</sub> incubator. Plates were then washed to remove nonadherent cells. After washing, all hepatocyte monolayers were >70% confluent. Hepatotoxicity was determined by treating hepatocyte monolayers with tamoxifen (0-100 µM), followed by measurement of MTT reduction and intracellular ATP levels at 24- and 48-hour time points following dosing. Tamoxifen demonstrated hepatotoxicity that was both dose and time dependent with an LD<sub>50</sub> of 23 µM and 15 µM at 24 and 48 hours, respectively when measured by MTT reduction. The LD<sub>50</sub> as measured by ATP levels was 30 µM and 18 µM at 24 and 48 hours, respectively. These results demonstrated the increased sensitivity of these hepatocytes to hepatotoxins with increasing exposure time. PCRH were also evaluated for their ability to support induction of cytochrome P450 1A activity. Hepatocyte monolayers were dosed with β-naphthoflavone (10 µM) on days 3 and 4 post plating. The metabolism of ethoxresorufin was measured on day 5. An 8-fold increase in ethoxresorufin O-deethylase (EROD) activity was observed following treatment with β-naphthoflavone as compared to the untreated vehicle controls. Viability as measured by MTT reduction remained high throughout the 5-day culture. In summary, PCRH combine the benefits of fresh and cryopreserved rat hepatocytes, and allow the long-term study of drug toxicity, metabolism, and drug-drug interactions in a reproducible model.

**2015****THE SLUG MUCOSAL IRRITATION TEST: A USEFUL TOOL FOR EVALUATING THE LOCAL TOLERANCE OF PHARMACEUTICAL FORMULATIONS.**

E. Adriaens, M. Dhondt and J. Remon. *Lab. Pharmaceutical Technology, Ghent University, Gent, Belgium.* Sponsor: C. Seaman.

Several studies have shown that the Slug Mucosal Irritation (SMI) test is a useful tool for evaluating the local tolerance of pharmaceutical formulations. The mucosal irritation potency can be estimated by the mucus production (MP) and the release of proteins and enzymes from the body wall of the slug *Arion lusitanicus* after treatment with the substances. During a 5-day procedure the slugs are daily placed on the undiluted substance for 30 min. After each contact period the MP, protein and enzyme release (LDH and ALP) are measured. Based on the 4 endpoints a classifi-

cation prediction model was developed that distinguishes into irritation and membrane damage. The MP is used to classify the formulations into 4 irritation classes (NI, mild, moderate and severe) whereas the release of proteins and enzymes is a measure of membrane damage (No, slight, moderate and severe). In this study the mucosal irritation potency of 13 nasal, 4 buccal and 16 vaginal or rectal formulations covering different irritation classes was evaluated with the SMI test. The classifications obtained with the SMI test were compared with published *in vitro* and *in vivo* (animal and clinical) data on the nasal, buccal, vaginal and rectal irritation potency of the formulations. There was an excellent agreement between the SMI and the *in vivo* data, only one vaginal formulation was overestimated. The SMI test can be used early in the R&D phase of new pharmaceuticals and this can result in the reduction of the use of laboratory animals.

**2016****ESTABLISHING THE TOXICOLOGY OF SELENIUM IN THE MODEL ORGANISM, CAENORHABDITIS ELEGANS.**

M. A. Nascarella and S. M. Presley. *Department of Environmental Toxicology, Texas Tech University, Lubbock, TX.*

Selenium is an essential component in a number of proteins, and is a required element for normal immune system function. Selenium levels that exceed both nutritional requirements and endogenous detoxification mechanisms are highly toxic; animals chronically exposed to these levels have physiological insults ranging from hair loss and nail brittleness to severe developmental and neurological abnormalities. The nematode *Caenorhabditis elegans* is a widely used model organism whose response to selenium has not been characterized. The aim of this study was to establish the baseline response of *C. elegans* (wild-type N2 strain) to selenium, with a future goal of evaluating the role of selenium in nematode immune system function. We have exposed both adults and embryos to concentrations of sodium selenite ranging from 0 to 1000 ppm (w/v selenium). Adult worms can tolerate acute (24 hr) exposure in selenium concentrations as high as 1000 ppm, with an approximate LC<sub>50</sub> of 14 ppm. *C. elegans* embryos that are exposed to 10 ppm of selenium are able to develop into apparently healthy adults, but are 85% smaller than control animals. Embryos exposed to concentrations exceeding 10 ppm fail to develop into viable ovigerous adult worms. These animals have shortened, often malformed bodies with disproportionately corpulent heads. At concentrations above 214 ppm, embryonic development is arrested and eggs fail to hatch. Our results show that selenium exposure above 10 ppm may cause both developmental arrest and congenital malformations to *C. elegans*. These findings are similar to reports in other animals (including humans) that are exposed to high concentrations of selenium.

**2017****PROTEOMIC INDICATORS OF PESTICIDE TOXICITY IN A CAENORHABDITIS ELEGANS MODEL.**

J. A. Lewis<sup>1</sup>, W. E. Dennis<sup>1</sup>, M. Szilagyi<sup>1</sup> and D. A. Jackson<sup>2</sup>. <sup>1</sup>*Geo-Centers, Inc., Ft. Detrick, MD* and <sup>2</sup>*US Army Center for Environmental Health Research, Ft. Detrick, MD.*

A comparative proteomic analysis using *C. elegans* was performed to determine if there are signature protein changes that are indicative of exposure to each of three pesticides. The toxicants are all classical acetylcholinesterase (AChE) inhibitors but are structurally distinct, and only two of them, aldicarb and dichlorvos, inhibit AChE reversibly; phenamiphos does not. Synchronized cultures of mid-L4 larvae grown in axenic medium were exposed for eight hours to three doses of each chemical. Axenic medium was used to eliminate the confounding effect of having *E. coli* in the culture as a food source. Exposure time was limited to 8 hrs since the unexposed worms molt and mature into adults about 17 hours after the mid-L4 stage. Exposure concentrations were set at a level that prevented a percentage of larvae (10%, 50% or 90%) from developing into adults within 24 hours. Protein extracted from whole worms was analyzed using 2-D gel electrophoresis and mass spectrometry to quantify differences between exposures and identify the proteins. Phenotypically, there was little distinction between the effects of the three chemicals; each produced a stumpy morphology, protruding vulva, abnormal cuticle formation and motility abnormalities. At the molecular level, a subset of the proteins shows a similar perturbation for all three chemicals, but substantial differences are also present that can distinguish among the three pesticides. Disclaimer: The views, opinions, and/or findings contained in this report are those of the authors and should not be construed as official Department of the Army position, policy, or decision, unless so designated by other official documentation.

**2018****ZEBRAFISH: A GOOD MODEL FOR DETECTING OTOTOXICITY.**

C. Ton and C. Parng. *Phylonix Pharmaceuticals, Inc., Cambridge, MA.* Sponsor: D. Monteith.

Drug-induced ototoxicity can lead to hair cell death, causing hearing loss and vestibular disorders. Currently, there is no *in vivo* quantitative method to determine drug-induced hair cell damage. Using zebrafish as a model organism, we aim to de-

velop a rapid, quantitative *in vivo* assay to assess drug effects on inner ear hair cell and screen protective agents for ototoxicity. The mechanosensory hair cells of zebrafish neuromasts are very similar in structure and function to the hair cells of the inner ear in mammals. These hair cells are comprised of bundles of hairlike projections that bend in response to sound waves. Cells convert this mechanical force into electrical impulses that are carried by the auditory nerves to the brain. Since zebrafish larvae are optically clear, hair cells can be visually assessed after DASPEI staining providing a rapid assessment of pharmacological effects. To examine hair cell damage, apoptosis and proliferation, we used DASPEI, acridine orange and BrdU staining to examine hair cell morphology after drug treatment. We showed that both aminoglycosides and cisplatin induced apoptosis and caused neuromast hair cell loss supporting the utility of zebrafish in inner hair cell assessment. In addition, we tested different classes of antioxidants for their ability to protect zebrafish against gentamicin and cisplatin-induced ototoxicity. These antioxidants, which have shown efficacy in mammals, include glutathione and its precursors and free radical scavengers. Zebrafish are treated with gentamicin or cisplatin alone or in combination with these compounds. DASPEI staining is used to stain hair cells and morphometric analysis is used to semi-quantify the fluorescent intensity. The results show that co-treatments of antioxidants and cisplatin significantly increase hair cells survival in a dose-dependent manner, whereas only methioninebenzoic acid and glutathione protect hair cell loss-induced by gentamicin. The results suggest that the toxicity of gentamicin and cisplatin are mediated by different pathways and demonstrate the utility of zebrafish in assessing potential ototoxicity and screening hair cell protective agents.

## 2019

### THE ROLE OF RECOMBINANT ZEBRAFISH CYP1A IN THE METABOLIC ACTIVATION OF BENZO(A)PYRENE (BaP) AND IN THE GENERATION OF REACTIVE OXYGEN SPECIES.

W. Chung, C. L. Miranda, J. Wang, T. Musafia-Jaknic, W. M. Baird and D. R. Buhler. *Environment & Molec. Toxicology, Oregon State University, Corvallis, OR*.

The zebrafish is a sensitive non-mammalian model for polycyclic aromatic hydrocarbon (PAH)-induced chemical carcinogenesis. The susceptibility of zebrafish to PAH-induced carcinogenesis might be related to the ability of the zebrafish P450s to activate these carcinogens. As a part of our overall effort to identify the various P450 enzymes that are involved in the activation and detoxification of PAHs in zebrafish, we have examined the ability of recombinant zebrafish CYP1A (zCYP1A) expressed in yeast (Chung et al., *Aquat. Toxicol.*, in press) to metabolize BaP *in vitro*. Like rainbow trout CYP1A1, cDNA-expressed zCYP1A was found to oxidize BaP to phenols, quinones and diols (BaP-7, 8-diol and BaP-9, 10-diol). BaP-7, 8-diol is the precursor of the ultimate carcinogen, BaP-7, 8-diol-9, 10-epoxide (BaPDE). The ability of zCYP1A to activate BaP was confirmed by the formation of DNA adducts when calf thymus DNA was added to the incubation mixture. BaP-DNA binding was enhanced by the addition of human epoxide hydrolase to the incubation mixture. HPLC analysis of the [<sup>33</sup>P]-post-labeled DNA adducts showed the formation of two major adducts by zCYP1A, one of which was identified as anti-BaPDE. zCYP1A also mediated the binding of BaP to protein, providing further evidence that this enzyme is capable of oxidizing BaP to reactive metabolites that bind to macromolecules. In addition, the metabolism of BaP by zCYP1A in the presence of NADPH resulted in the generation of reactive oxygen species as indicated by the formation of hydrogen peroxide in the incubation medium. Taken together, these results suggest that zCYP1A may play a role in BaP-induced carcinogenesis in the zebrafish model by catalyzing the sequential formation of the ultimate carcinogenic metabolites (diol epoxides) of BaP and by increasing the generation of active oxygen species which are known to contribute to chemical carcinogenesis. (Supported by NIH grants Nos. ES 00210 and ES 11587).

## 2020

### DEVELOPMENT OF SPECIFIC ANTIPEPTIDE ANTIBODIES AGAINST ZEBRAFISH XENOBIOTIC METABOLISING FORMS OF CYTOCHROME P450.

J. Wang-Buhler<sup>1</sup>, W. Chung<sup>1</sup>, H. Tseng<sup>2</sup>, C. L. Miranda<sup>1</sup>, C. Hu<sup>2</sup>, T. Hsue<sup>3</sup> and D. R. Buhler<sup>1</sup>. *Environment & Molec. Toxicology, Oregon State University, Corvallis, OR*, <sup>2</sup>*Institute of Marine Biotechnology, National Taiwan Ocean University, Keelung, Taiwan* and <sup>3</sup>*Department of Life Science, National Tsing-Hua University, Hsinchu, Taiwan*.

Nine zebrafish putative xenobiotic metabolizing cytochrome P450s (CYPs) have been cloned in our laboratories. They are CYP1A, 1B1, 2AD3, 2K6, 2K7, 2K8, 2V1, 3A65 and 3C1. Since we are interested in studying the translational expression of those CYPs, the close structural similarities among the CYPs persuaded us to use antipeptide antibodies for our research. Here we report the preliminary development and testing of specific antipeptide antibodies against each CYP. Peptide sequences were 16-20 amino acids, selected with consideration of hydrophobicities

from alignments of the 9 CYPs. Each short peptide region selected was unique to that specific gene. High titer antibodies, as judged by ELISA, were produced in rabbits immunized with these peptides coupled to keyhole limpet hemocyanin. Antipeptide antibodies were affinity purified from antisera using CNBR-activated peptide-Sepharose 4B. Immunoblotting studies using yeast or baculovirus/insect cells expressed recombinant CYPs are being used to examine the specificities and cross-reactivity of the antipeptide antibodies. We have produced these antipeptide antibodies with the intention of using them in the investigation of their translational expression of the corresponding CYPs in immunohistochemical studies. (Supported by NIH grants Nos. ES 00210 and ES 11587).

## 2021

### ORAL ABSORPTION OF WATER SOLUBLE AND LIPOPHILIC CONTAMINANTS IN THE JAPANESE MEDAKA.

I. Schultz, E. Muirhead, S. Reed and A. Pratt. *Battelle PND, Sequim, WA*.

Small aquarium fish such as the Japanese Medaka (*Oryzias latipes*), are increasingly used as an alternative to mammalian models for chronic toxicity testing. The most common exposure route used in Medaka and other chronic dosing studies with fish is continuous water exposure, which is physiologically analogous to bronchial (inhalation) exposure in mammals. This limits the utility of fish models by preventing direct comparisons with rodent studies, which typically rely on oral dosing. Also, chronic exposure to certain toxicants such as those with low water solubility can be difficult and costly to maintain. Orally dosing fish can be challenging, particularly with water soluble contaminants which can leach into the aquarium water prior to ingestion. We developed a method of bioencapsulation using newly hatched Artemia to study the toxicokinetics of two classes of contaminants in the Medaka: a series of five chlorinated and brominated halogenated acetic acids (HAAs), which are drinking water disinfection by-products and a polybrominated diphenyl ether (BDE), which are a class of highly lipophilic compounds used as flame retardants. The HAAs and BDE were bioencapsulated by freshly hatched Artemia nauplii after incubation in concentrated solutions of the study chemicals for 4-18 hr. Aliquots of the nauplii were quantitatively removed for chemical analysis and fed to individual fish. We observed that an adult Medaka would consume 500 nauplii in less than 5 min, simulating a bolus dose. At select times after feeding (up to 96 hrs for HAAs and 21 days for BDE), fish are euthanized, the GI tract removed and the HAA or BDE content separately determined by GC-ECD. The absorption of HAAs was qualitatively similar to previous studies in rodents: rapid absorption with peak body levels occurring within 1 hr of dosing then rapidly declining with elimination half-life of 3-6 hrs depending on HAA. BDE was more slowly absorbed with an apparent lag-time of 2 hr before absorption began with peak levels occurring by 12 hr. BDE was very slowly eliminated with a elimination half-life > 14 days.

## 2022

### INTERACTION TRAPPING WITH A NON-TCDD BINDING ARYL HYDROCARBON RECEPTOR FROM *MYA ARENARIA*.

R. Butler and R. J. Van Beneden. *University of Maine, Orono, ME*.

The aryl hydrocarbon receptor (AHR) is typically associated with TCDD-induced toxicity. However, there is increasing evidence suggesting AHR has a role independent of dioxin binding and conversely, that TCDD can exert toxic effects through non-AHR mediated pathways. AHR is the only member of the PAS superfamily of transcriptional regulators to be ligand activated. However, previous work demonstrated an apparent significant divergence in function between the vertebrate and invertebrate AHRs: *M. arenaria*, *D. melanogaster* and *C. elegans* AHR homologues lack the ability to bind prototypical ligands ([<sup>3</sup>H]TCDD and [<sup>3</sup>H]β-naphthoflavone). Therefore, one might speculate that the invertebrate AHR homologues may not have the same requirement as vertebrate AHRs for ligand activation. Further investigation into the expression of *Mya arenaria* AHR revealed a positive correlation between AHR protein levels and the stage of ovogenesis. To better understand AHR function in the female clam reproductive tissue, a truncated AHR (amino acids 1-400) was used as the 'bait' protein to screen a yeast two-hybrid cDNA expression library prepared from the gonad of a female with mature gametes. Yeast colonies containing potential interactors were selected up to 6 days post-plating. Positive yeast yielded plasmids bearing library cDNA for 117 potential AHR interactors. Sequence homology has revealed an array of putative AHR-interacting proteins, several of which have been previously identified by others as essential for early zebrafish, yeast, worm and fly development (e.g. ribonucleoside reductase small subunit, ribosomal proteins L7 and L13, nascent polypeptide-associated complex αsubunit and zinc finger 183). We hypothesize that interaction with one or more of these critical developmental genes may indicate an endogenous function for the AHR. Work in our laboratory continues to verify the initially positive clam AHR interactors.

**2023****GENOMICS RESPONSES AND TOXICOLOGICAL ENDPOINTS AMONG FISH SPECIES EXPOSED TO ESTROGEN AND POTENTIAL EXTRAPOLATION OF FISH TOXICITY ASSAYS TO MAMMALIAN SPECIES.**

P. Cline<sup>1</sup>, N. Denslow<sup>2</sup> and P. Larkin<sup>3</sup>. <sup>1</sup>CH2M Hill, Gainesville, FL, <sup>2</sup>University of Florida, Gainesville, FL and <sup>3</sup>EcoArray, Inc., Alachua, FL.

The National Research Council (1998) has recommended the use of fish toxicity testing to evaluate the viability of augmenting drinking water supplies with reclaimed water. A consideration includes the ability to capture a range of effects, including responses to estrogen. Recognizing the clear differences in physiology and pharmacodynamics, the use of considering a simple screening assay using fish may provide insights into potential human impacts. The increasing use of genomics data can provide additional tools in the interpretation of potential mechanisms of action of selected chemicals that may be present in complex mixtures. Comparison of the gene expression profiles by microarray analysis in fathead minnows, bass and sheepshead minnows exposed to 17- $\beta$  estradiol revealed several similarities, including robust up-regulation of vitellogenin, the egg precursor protein. The production of vitellogenin as a biomarker of estrogenic exposure has been shown among numerous other fish species. Some notable differences were also observed, one of which included robust up-regulation of choriogenin genes in the liver tissue of both largemouth bass and sheepshead minnow, but not in fathead minnows. It is speculated that the choriogens, which form the covering of the egg, are expressed in the gonadal tissue and not the liver of fathead minnows. The specificity and sensitivity of these molecular responses were also compared to dose response studies and endpoints reported for these and other fish species. These traditional toxicity studies have illustrated differences in endpoints and sensitivity among various fish species. While the clear physiological differences in the responses in fish as compared to humans, the NRC suggests information on underlying control mechanisms may be identified. This supports the necessity to incorporate microarray data with traditional endpoints identified in the numerous dose-response studies that may be available.

**2024****THE USE OF A ROTAROD IN CNS SAFETY PHARMACOLOGY STUDIES – A COMPARISON OF TRAINING AND TESTING METHODS.**

H. Penton and S. Mason. *Safety Pharmacology, CTBR BioResearch Inc., Senneville, QC, Canada.* Sponsor: C. Banks.

The Rota-Rod is a useful technique to assess motor-coordination in rodents. Given that Rota-Rod performance is considered to be an acquired behavior dependent on skill (Cartmel et al 1991), the intent of this study was to evaluate the use of an accelerating versus fixed speed rotarod for use as a motor performance assessment tool as well as to design a suitable training regime for rats used on these studies. Morphine (5 mg/kg IV) and diazepam (1.5 mg/kg IV) were selected for use as reference compounds in this study due to their known ability to decrease motor performance (Cartmel et al 1991, Capacio et al 1992). Male Sprague-Dawley rats, approximately 7 weeks of age were selected as the test system. Prior to performance of the study, animals were placed through one of the following training regimes: 1) no training, 2) one day of acclimation to a fixed speed of 12 rpm (which occurred the day prior to dosing) and 3) pre-selection and additional training. Various rejection criteria were employed for animals undergoing the different selection and training methodologies, however in all cases repetitive falls from the rod lead to exclusion of that animal from the study. For the final motor performance study, rats were assessed 15, 30 and 45 minutes after dosing. Animals were tested using either a fixed speed of 12 rpm over 2 minutes or with the rod accelerating from 0 to 12 rpm over the 2 minute period. In both cases, the duration of time spent on the rod was recorded. For both morphine and diazepam treated animals, a marked decrease in motor performance was noted at 15 and 30 minutes post dose when compared to the control (saline) group, however performance on the fixed-speed rod was better than for the accelerating system. Animals that received more training were seen to have performed the Rota-Rod task with a greater success rate for both systems. The results were consistent with the literature and the accelerating Rota-Rod, preceded by selection and training is considered the best approach for motor performance assessments of this type.

**2025****EVALUATION OF AN INTEGRATED TELEMETRY SYSTEM (ITS) FOR MEASUREMENT OF CARDIOVASCULAR AND RESPIRATORY PARAMETERS IN CYNOMOLGUS MONKEYS.**

M. Niehoff, P. Nowak, U. Zuehlke, W. Mueller, F. Vogel and G. Weinbauer. *Covance Laboratories GmbH, 48163 Muenster, Germany.*

The telemetric measurement of cardiovascular and respiratory parameters in conscious, freely moving animals is an essential component of safety pharmacology studies. It is well known that heart rates as well as blood pressure values are differ-

ent when measured in freely moving rather compared to restrained and/or anaesthetized animals. Hence, data obtained by telemetry are considered to reflect the physiological condition. The aim of this study was to evaluate an ITS system for the measurement of aortic blood pressure, ECG waveforms, temperature and intra-thoracic-pressure (ITP). Two mature, male cynomolgus monkeys (>6.0 kg) were dosed on two successive days with sotalol, ketamine, theophylline and chlorpromazine, respectively with saline as the corresponding vehicle. Biopotential signals were measured two hours before dosing and for a 6 hour period thereafter. Ketamine at 20 mg/kg caused a marked decrease in body temperature and in maximum ITP. QT-interval was markedly prolonged, heart rates and mean-arterial-blood-pressure were decreased at 10 mg/kg sotalol. Respiratory rate was decreased whereas the minimum ITP was slightly elevated following 25 mg/kg chlorpromazine administration. Theophylline at 20 mg/kg elicit no effect. On repeated occasions, pair- and single-housing of the two animals were compared: Heart rates were reproducibly lower during pair-housing compared to single housing, whereas blood pressure remained unaltered. In conclusion, our findings suggest that the ITS system is a valid tool for the selective detection of drug induced changes in cardiovascular and respiratory parameters in conscious, freely moving cynomolgus monkeys.

**2026****VALIDATION OF SAFETY PHARMACOLOGY ASSESSMENT OF CARDIOVASCULAR FUNCTION IN CONSCIOUS DOGS WITH TWO POSITIVE CONTROLS (SOTALOL AND IBUTILIDE).**

Y. Chen, M. Lindeblad and A. Lyubimov. *Toxicology Research Laboratory, University of Illinois at Chicago, Chicago, IL.*

Drug-induced effects on the QT-interval with the possibility of inducing fatal arrhythmias have become a new challenge for the drug development and regulatory approval. Antiarrhythmic class III drugs have been associated with development of a polymorphic ventricular tachycardia (PVT) known as torsades de pointes. The purpose of this study was to validate the method of safety pharmacology assessment of cardiovascular function using two class III agents, ibutilide and d, l-sotalol, in a conscious telemetric canine model. The duration of QT-interval has been used as the major determinant of the risk of drug-induced PVT. A telemetry transmitter (D70-PCI) from Data Sciences International (DSI) was implanted subcutaneously into the flank of each dog following the standard surgical procedures. The animals blood pressure, ECG, heart rate, body temperature and locomotor activity were continuously monitored for at least 24 hours prior to and following a single bolus intravenous dosing of saline (vehicle control). The d, l-sotalol at 10 mg/kg or ibutilide at 0.15 mg/kg were injected intravenously three days later. ECG waveforms and above cardiovascular parameters were recorded simultaneously for at least 24 hours following each drug administration. The heart rate-adjusted QT intervals (Fridericia correction QTc) were determined using the rate-correction formula in DSI PhysiostatTM ECG analysis program. Both sotalol and ibutilide significantly increased QT-interval with similar pattern in the beagle dogs. These data demonstrated that the assay is capable of detecting relevant changes in cardiovascular function in conscious beagle dogs. This validated telemetry canine model and either sotalol or Ibutilide as a positive control can be used to study the potential undesirable pharmacodynamic effects of the test compounds on QT-interval for assessing clinical benefits and risks in accordance to the ICH safety pharmacology S7B guideline.

**2027****INTEGRATED ASSESSMENT OF SMALL MOLECULE INTERACTION WITH THE HERG CHANNEL: WHAT DOES THE HERG BINDING ASSAY MISS?**

C. M. Doherty, V. Sasseville, P. Bouchard, C. L. Alden, P. F. Smith and V. J. Kadambi. *Drug Safety and Disposition, Millennium Pharmaceuticals, Inc., Cambridge, MA.*

Block of the hERG channel, a voltage gated potassium channel responsible for the current ( $I_{Kv}$ ) which produces the rapid phase of ventricular repolarization, is the basis of QT interval prolongation and predisposes individuals to Torsades de Pointes (TdP). The hERG binding assay, a competitive radioligand displacement assay using membranes from HEK293 cells stably transfected with hERG channel cDNA, offers a high-throughput screen for small molecule interaction with the hERG channel. A study was undertaken to compare the results of this assay with other *in vitro* methods of assessing hERG interactions. Data from the hERG binding assay is well correlated with electrophysiology data ( $r^2 = 0.83$ ). Safety ratios calculated for marketed compounds run in these two assays allowed rank ordering of compounds in a similar fashion. Because QT interval prolongation may also be precipitated by a reduction in native  $I_{Kv}$  current resulting from interference with trafficking of the mature hERG protein to the cell membrane, the HERG-lite assay (Chantest, Inc.) monitors channel block along with hERG channel surface expression. Of 26 compounds evaluated, the HERG-lite assay and the hERG binding assay correctly predicted for the clinical outcomes of 19 and 16 compounds, respectively. Arsenic trioxide, which was not shown to interact with the hERG chan-

nel by patch-clamp or binding methods, was shown to interfere with hERG trafficking in the hERG-lite assay. hERG-lite was more adept at predicting the pro-arrhythmic potential of compounds for which there are rare reports of TdP, such as nifedipine and kentaserin, which were missed by the hERG binding assay. Ebastine and diltiazem, for which there are no reports of TdP, appeared as false positives in the hERG-lite assay but classified correctly by the hERG binding and patch-clamp assays. A paradigm including all three of these assays may offer the best hope for the selection of a drug candidate free of hERG interaction and potential for *in vivo* QT prolongation.

## 2028

### MEASUREMENT OF CARDIOVASCULAR EFFECTS OF PHARMACEUTICALS IN MINIPIGS USING TELEMETRY.

A. Makin, H. Saxtorph and R. J. Harling. *Toxicology and Pharmacology, Scantox A/S, Lille Skensved, Denmark.*

The use of the Gottingen minipig as a non-rodent species in pre-clinical safety testing is increasing. Because of this it is logical that this species should also be used in safety pharmacology. We have therefore performed a cardiovascular study in minipigs using a telemetric system (Data Science International (DSI)). The objective of this study was to establish our ability to measure blood pressure, heart rate, ECG and temperature in minipigs, and to measure effects on these parameters following administration of three compounds, Propranolol, Isoprenalin and Sotalol. These compounds have a known effect upon blood pressure, heart rate, and ECG. Dose levels intended to cause measurable effects were chosen. Propranolol is a highly potent beta-receptor blocker with no intrinsic sympathomimetic activity. Its known effect is to decrease the force and the rate of heart contractions by blocking beta-adrenergic receptors of the autonomic nervous system. Isoprenalin is a synthetic sympathomimetic amine. It is a beta-adrenergic agonist that can increase the heart rate, increase cardiac contractility and decrease diastolic pressure. Sotalol is a class III antiarrhythmic drug which, in addition to increasing action potential duration (APD) by blocking K<sup>+</sup> channels, also competitively antagonizes beta-adrenergic receptors. This antiadrenergic activity can depress slow channel tissue by decreasing cAMP-dependent calcium entry. Sotalol is known to decrease the atrioventricular node automaticity by prolonging atrioventricular node APD and decreasing contractility leading to decreasing heartbeat and prolonging the QT interval. Because of the current focus on potential of drugs to prolong QT interval, this was an important aspect of the study. The study was performed as a cross over study with a minimum of 7 days wash out period between each phase. Measurements were made for up to 4 hours after dosing. The data presented demonstrate that the minipig is a suitable model for use in standard cardiovascular safety pharmacology studies.

## 2029

### VALIDATION OF A RADIOTELEMETRIC SYSTEM FOR THE MEASUREMENT OF CARDIOVASCULAR PARAMETERS AND TEMPERATURE IN THE CONSCIOUS CYNOMOLGUS MONKEY.

J. L. Fogleman and C. B. Spainhour. *Calvert Laboratories, Inc., Olyphant, PA.*

The current ICH S7A guidelines state that 'in conducting *in vivo* studies it is preferable to use unanesthetized animals' and that 'data from unrestrained animals that may be chronically instrumented for telemetry or other suitable instrumentation methods for conscious animals...are preferred.' Conscious restrained animals of all species have artificially elevated heart rates and sympathetic drive that can easily confound interpretation of cardiovascular data. Similarly, unconscious animals typically exhibit depressed cardiovascular parameters that may permit the oversight of meaningful, drug-induced changes. However, before any particular animal model is used for the generation of GLP data, the test system must be fully-validated. To this end we would like to report on the validation of a telemetry system for the monitoring of cardiovascular parameters and temperature in conscious nonhuman primates, macaca fascicularis. The primary objectives of this study were to biologically validate the ITS telemetry system and evaluate its effectiveness in detecting toxicologically-induced changes in the cardiovascular system through the use of specific selected pharmacologic agents. Four male cynomolgus monkeys, each approximately 6 years old weighing 5-8 kg, were surgically implanted with telemetric transducers (Integrated Telemetry Systems). Pharmacologic standards were then selected to test the ability of the system to clearly define quantifiable changes in blood pressure, heart rate and electrocardiographic parameters as well as temperature. The specific pharmacologic agents used were: ketamine, an anesthetic agent; d, l-sotalol, a nonselective beta-antagonist used as an antiarrhythmic agent; and isoproterenol, a beta-1, beta-2 adrenergic agonist. The data presented demonstrate that the ITS telemetry system provides a sensitive, specific, and precise means for the measurement of quantifiable drug induced changes in cardiovascular parameters including the assessment of QT Interval Prolongation and body temperature in conscious cynomolgus monkeys.

## 2030

### A REVIEW OF THE RELATIONSHIP BETWEEN HEART RATE AND QT INTERVAL IN THE BEAGLE DOG.

J. Budnik<sup>1</sup> and B. N. Olivier<sup>2</sup>. <sup>1</sup>*Toxicology, CTBR, Senneville, QC, Canada* and <sup>2</sup>*Michigan State University, East Lansing, MI.*

Electrocardiography is now one of the standard investigations performed in pre-clinical toxicology studies. One of the key parameters is the QT interval, as certain types of drugs have the capacity to delay cardiac repolarization, an effect seen in the electrocardiogram traces as a prolongation of the QT interval. This is an undesired effect when caused by non-cardiac drugs, and has lead to drugs such as Astemizole®, Sertidole® and Grepafloxacin® being removed from the market. Even when this effect is part of the therapeutic mechanism of an anti-arrhythmic drug, excessive QT interval prolongation is also undesirable as this can provoke new arrhythmias (torsades de pointes) and sudden death. The detection of drug induced QT interval changes is sometimes masked by concurrent heart rate changes and therefore it is normalized by means of various formulae (such as Bazetts, Frederica, Van der Waters and Linear regression analysis) into a heart rate independent corrected value known as the QTc interval. The purpose of this publication is to present electrocardiography data obtained from naive beagle dogs (*Canis familiaris*) from two North American suppliers and from control animals during the course of toxicology studies at CTBR (N=652) between February 2001 and February 2004. A plot of QT versus heart rate was prepared for the whole data set. Linear regression analysis was performed to describe the HR-QT relationship. The relationship between QT-RR was tested and a correlation coefficient of -0.70 was obtained for the whole data set. The analysis was also applied to the data sets for the different suppliers and values of -0.71 and -0.73 were obtained, indicating no difference between the two suppliers. Access to such a comprehensive background data base may help put individual study results into context where individual variation in control animals may mask drug related effects.

## 2031

### DEVELOPMENT OF THE METHODOLOGY FOR RESPIRATORY RATE AND VOLUME ASSESSMENT USING LINEAR PNEUMATACHS AND BUXCO BIOSYSTEM XA SYSTEM IN THE CONSCIOUS DOG AND CYNOMOLGUS MONKEY.

C. M. Kelly, M. Miyamoto, S. Cracknell and S. J. Gosselin. *Safety Assessment, Huntingdon Life Sciences, East Millstone, NJ.*

The purpose of this study was to establish the methodology to perform respiratory rate, tidal volume and minute volume assessments which are required by ICH S7A guideline in conscious dogs and monkeys or may be a required parameter in inhalation toxicology studies. The dogs and monkeys, which had been previously trained and/or acclimated, were manually held with a dental rubber diaphragm sealed face mask over their nose and mouth while standing on a cart (dog) or restrained in a purpose built non-human primate restraint chair (monkey). Air exhaled into the mask was directly through a calibrated in-line linear pneumatach (Hans Rudolph Model Number 3500A-calibrated flow range 0-35 L/min). Room air was allowed to freely enter and leave the facemask through the two-way valves and exited through the pneumatach into the room air. Pressure data from the pneumatach was passed to a Buxco Max II preamplifier, which was used to convert the signal to the range from 0 to -5V DC. The output from the preamplifier was connected to a computer loaded with Buxco BioSystem XA integrating software. Respiratory rate and tidal volume were evaluated by the software package and the respiratory minute volume was derived for each animal. These values were determined for a continuous period of at least 60 seconds; however, if the period of data capture was interrupted by vocalization or struggling, the target parameters were determined from data for a number of shorter intervals. Values obtained in this study in dogs and monkeys were within acceptable ranges for these species. In conclusion, we have demonstrated the suitability of using linear pneumatachs and Buxco BioSystem XA system in dogs and cynomolgus monkeys to assess respiratory pumping apparatus function for toxicology and safety pharmacology assessments in our Testing Facility environment.

## 2032

### USE OF GAMMA SCINTIGRAPHY FOR THE STUDY OF GASTRIC EMPTYING IN SAFETY PHARMACOLOGY.

X. Manciaux<sup>1</sup>, S. Milano<sup>1</sup>, H. Barraud<sup>1</sup>, V. Roger<sup>1</sup>, S. Lerondel<sup>2</sup>, A. Lepape<sup>2</sup> and J. Descombes<sup>3</sup>. <sup>1</sup>*MDS Pharmacology Services, Saint Germain s/L'Arbresle, France*, <sup>2</sup>*Functional Imaging of Transgenic Mice, CDTA-CNRS, Orleans, France* and <sup>3</sup>*Poison Center, Lyon, France.*

Gastric emptying is a useful parameter to assess gastrointestinal motility for physiological or pharmacological purposes. In rats, phenol red recovery is the gold standard for the determination of gastric emptying. However, this method requires the sacrifice of the animal and yields data at only one time point. In contrast, scintigraphy, the gold standard method in humans, allows sequential and serial measurements of gastric emptying in the same subject. Here, gastric emptying measured

with a dedicated gamma camera in unanesthetized rats was compared with phenol red recovery. Normal values for the gastric emptying of semi-liquid (methylcellulose), solid (egg white) and fatty meals were established. The effects of L-NAME, an inhibitor of gastric emptying, and cisapride, a prokinetic drug, were quantified using both methods. Raw data included absorbance by spectrophotometry for phenol red and the activity of the regions of interest for scintigraphy. Both were converted into % of gastric retention. The calculation of the half emptying time ( $T_{1/2}$ ) by non linear regression was used to evaluate gastric emptying. The gastric emptying of methylcellulose measured by scintigraphy ( $T_{1/2}=8.4$  min;  $n=5$ ) did not differ from that measured by phenol red recovery in non-treated animals ( $T_{1/2}=9$  min;  $n=20$ ). The inhibitory effect of L-NAME on methylcellulose emptying was demonstrated by scintigraphy ( $T_{1/2}=18.1$  min;  $n=5$ ). The effect of cisapride on methylcellulose could only be demonstrated with the phenol red method ( $T_{1/2}=5.5$  min;  $n=20$ ). Scintigraphy also confirmed that solid ( $T_{1/2}=49.8$  min;  $n=4$ ) and fatty meals ( $T_{1/2} > 300$  min) are emptied more slowly than semi-liquid meals ( $T_{1/2}=8.4$  min;  $n=5$ ). Dedicated rodent gastric-emptying scintigraphy is a reliable tool to investigate gastrointestinal function in safety pharmacology and significantly reduces the number of animals needed for statistical analysis.

## 2033

### EFFECTS OF TCDD ON THE LEVELS OF BIOGENIC AMINES IN DIFFERENT BRAIN REGIONS OF RATS AFTER SUBCHRONIC EXPOSURE.

K. Masters, J. Byers and E. A. Hassoun. *Pharmacology, The University of Toledo, Toledo, OH.*

The effects of subchronic exposure to TCDD on the levels of biogenic amines and their metabolites in different brain regions have been studied in rats. Groups of female Sprague-Dawley rats were administered p.o. either TCDD at doses of 22 and 46 ng/kg/day (treated groups) or the vehicle used to dissolve TCDD (control group), for 90 days. The rats were sacrificed at the end of the exposure period and their brains were dissected into different regions including, hippocampus, cerebral cortex, cerebellum, and brain stem. The concentrations of different biogenic amines, including, nor epinephrine (NE), dopamine (DA), 3, 4-dihydroxy phenyl acetic acid (DOPAC), 5-hydroxy indole 3-acetic acid (5-HIAA), 5-hydroxy tryptamine (5-HT) and 4-hydroxy, 3-methoxy-phenyl acetic acid (HVA) were determined in those brain regions, using a High Performance Liquid Chromatography (HPLC) system with an electrochemical detector. Results of analyses indicate significant increases in the levels of DA, DOPAC and HVA in the hippocampus and cerebral cortex but not in cerebellum or brain stem in response to the two doses of TCDD, as compared with the corresponding controls. However, the level of NE was significantly increased in the hippocampus and cerebral cortex of rats treated with 46 ng TCDD /kg/day and also in the cerebellum of rats treated with either doses of TCDD, when compared with the corresponding controls. These results are well-correlated with the previously observed increases in oxidative stress in the brain regions of rats in response to TCDD and may suggest the contribution of those biogenic amines to the observed increases in the biomarkers of oxidative stress in those regions. (Supported by NIH/NIEHS grant ES11048).

## 2034

### IGF-1 MEDIATES THE EFFECTS OF TCDD AND HxCDD ON BODY WEIGHT AND THE INHIBITION OF PEPCK.

C. R. Crouth<sup>1</sup>, M. Lebofsky<sup>1</sup>, P. F. Terranova<sup>2</sup> and K. K. Rozman<sup>1,3</sup>.

<sup>1</sup>*Pharmacology Toxicology and Ther, University of KS Med. Center, Kansas City, KS,*  
<sup>2</sup>*Center for Reprod. Sciences. and Mol. and Integrative Phys., University of KS Med. Center, Kansas City, KS and*<sup>3</sup>*Environment Toxicology, GSF-Institut für Toxikologie, Neuherberg, Germany.*

TCDD affects rat intermediary metabolism with effects on glycemia, gluconeogenesis and circulating thyroid hormone levels. These effects combined with a reduction in feed intake, culminate in a decrease in body weight in 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD)-treated rats. In this study, we investigated the effects of steady state levels of TCDD (loading doses of 0.0125, 0.05, 0.2, 0.8, and 3.2  $\mu$ g/kg) or iso-equivalent doses of 1, 2, 3, 4, 7, 8-hexachlorodibenzo-*p*-dioxin (HxCDD) (loading doses of 0.3125, 1.25, 5, 20, and 80  $\mu$ g/kg) on body weight and biochemical effects after 2, 4, 8, 16, 32, 64, and 128 days of administration. At the 0.05 and 1.25  $\mu$ g/kg dose of TCDD and HxCDD, respectively, there was a slight increase in body weight by day 64, while at the 3.2 and 80  $\mu$ g/kg dose of TCDD and HxCDD, respectively, by day 32 the body weight gain of the rats was significantly decreased and remained decreased throughout the remainder of the study. TCDD and HxCDD dose-dependently inhibited PEPCK activity at time-points after day 16 through day 128. PEPCK RNA and protein were also decreased at doses and the time point which inhibited PEPCK activity. Serum IGF-I levels of the 3.2 and 80  $\mu$ g/kg TCDD- and HxCDD- treated rats after day 16 decreased by about 60% of the levels seen in controls by day 16, remaining low for the duration

of the study. There was no effect with any dose of TCDD or HxCDD on circulating insulin or glucose. The 3.2  $\mu$ g/kg dose of TCDD significantly decreased circulating total thyroxine (TT4) as compared to rats which received 0.05  $\mu$ g/kg TCDD or corn oil alone. Hepatic phosphorylated AMP kinase- $\alpha$  protein was increased in a dose-dependent manner with TCDD or HxCDD administration although at low doses it appeared to be decreased. In conclusion, at a dose of TCDD or HxCDD where there is an inhibitory effect on body weight gain in female rats, there is also an inhibitory effect on gluconeogenesis, IGF-I and TT4 levels.

## 2035

### COMPARATIVE 14-WEEK TOXICITY STUDIES OF 2, 3, 7, 8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD) IN FEMALE HARLAN SPRAGUE-DAWLEY (HSD) AND FISCHER 344 (F344) RATS.

M. Hejtmancik<sup>1</sup>, L. Fomby<sup>1</sup>, D. Vasconcelos<sup>1</sup>, M. Ryan<sup>1</sup>, M. Vallant<sup>2</sup>, D. Orzech<sup>2</sup>, R. Chhabra<sup>2</sup>, A. Nyska<sup>2</sup>, H. Toyoshiba<sup>2</sup>, N. Walker<sup>2</sup> and M. Hooth<sup>2</sup>.  
<sup>1</sup>*Battelle Columbus, Columbus, OH and*<sup>2</sup>*ETP, NIEHS, Research Triangle Park, NC.*

The purpose of the study was to determine if the TCDD response in female HSD rats is predictive of the response in female F344 rats. In a previous NTP study, female HSD rats (10 rats/group) were administered TCDD in corn oil:acetone (99:1) by gavage at dosages of 0, 3, 10, 22, 46 or 100 ng TCDD/kg body weight for 14 weeks. Mean body weights of 100 ng/kg females were 5% lower than vehicle controls. Thyroxine ( $T_4$ ) levels in groups receiving  $\geq 22$  ng/kg were significantly lower than vehicle controls. In the 46 and 100 ng/kg groups, triiodothyronine ( $T_3$ ) and thyroid stimulating hormone (TSH) levels were significantly higher than vehicle controls. Hepatic EROD, A-4-H and pulmonary EROD activities were significantly higher in all dosed groups; maximal inductions were 70, 6 and 20-fold relative to vehicle controls, respectively. In the F344 rat study, TCDD was administered in corn oil:acetone (99:1) by gavage (10 rats/group) at dosages of 0, 1, 10, 50, 100, and 200 ng/kg for 14 weeks. Mean body weights were 7-10% less than vehicle controls in groups receiving  $\geq 50$  ng/kg. The F344 strain was less sensitive to thyroid hormone alterations. No changes were observed in  $T_3$  or TSH; slight decreases in  $T_4$  levels were observed in the 200 ng/kg group. Hepatic EROD, A-4-H and pulmonary EROD activities were significantly higher in all dosed groups; maximal inductions were 42, 6 and 54-fold relative to vehicle controls, respectively. Hepatocellular hypertrophy was correlated with increased liver weights in both strains. Thymus weights were decreased and thymic atrophy was increased in both strains. Slight differences in histopathology were observed between strains. Hepatic granulomatous and chronic active inflammation and splenic hemosiderin accumulation were only observed in F344 rats. In conclusion, TCDD administration to F344 rats produced similar toxicity as observed in the HSD rat.

## 2036

### EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD) ON PROLACTIN (PRL) GENE EXPRESSION *IN VIVO* AND *IN VITRO*.

J. Cao and S. L. Petersen. *Molecular and Cellular Biology Program, Amherst, MA.*

Exposure to TCDD decreases plasma levels of PRL, a hormone important for reproduction functions in males and females. These effects are likely due, at least in part, to TCDD disruption of pituitary function, but the mechanisms are not clear. The effects of dioxin are mediated by the arylhydrocarbon receptor (AhR), a basic helix-loop-helix PAS transcription found in a variety of tissues, including the pituitary gland. In many of these tissues, TCDD interferes with actions of estradiol (E2), a hormone that directly regulates PRL synthesis. In previous work using cDNA microarrays and Northern blotting, we found that E2-induced increases in PRL gene expression were blocked by TCDD exposure in ovariectomized rats. However, it was not clear whether this was through a direct action of TCDD on the pituitary gland or indirect actions mediated by the hypothalamus. Therefore, in these studies, we performed dual-label *in situ* hybridization and found PRL mRNA and AhR mRNA colocalized in pituitary cells. We then used transient transfection analysis in pituitary-derived GH3 cells to examine the effects of TCDD and E2 on PRL promoter activity. We cloned a region of the PRL promoter that included both an estrogen response element (ERE) and a putative dioxin response element (DRE) into pGL3-basic luciferase reporter vector and transfected it into GH3 cells. Using steroid-free medium conditions for 16 h, transfected GH3 cells were treated with various doses of TCDD and/or E2. Cell lysates were collected after 24 or 48 hours and analyzed using Dual-Luciferase Reporter (DLR) Assay kits. We found that TCDD alone had no consistent effect on promoter activity. However, at 1, 10, and 50 nM TCDD interfered with E2 stimulation of the promoter with maximal effects seen at 48 h. Interestingly, at 500 nM TCDD had no effect on promoter activity at either 24 or 48 h. These findings indicate that TCDD may disrupt PRL secretion by interfering with E2 regulation of PRL gene expression.

INVOLVEMENT OF PROSTAGLANDIN PATHWAY IN CIRCULATION FAILURE INDUCED BY 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN IN DEVELOPING ZEBRAFISH.

H. Teraoka<sup>1</sup>, W. Dong<sup>1,2</sup>, A. Shindo<sup>1</sup>, Y. Harada<sup>3</sup> and T. Hiraga<sup>1</sup>. <sup>1</sup>*School of Veterinary Medicine, Rakuno Gakuen University, Ebetsu, Japan*, <sup>2</sup>*College of Animal science and Technology, Inner Mongolia University for Nationalities, TongLiao, China* and <sup>3</sup>*Graduate School of Medical Science, Kitasato University, Sagamihara, Japan*.

Using zebrafish embryos as a model system for developmental toxicology, we have reported that 2, 3, 7, 8-tetrachlorodibenz-p-dioxin (TCDD) increases the occurrence of apoptosis in dorsal midbrain with very good correlation with a decrease in local blood flow. We also found that mesencephalic circulation failure is associated with an increase in permeability in mesencephalic vein, by which mechanism was unclear. Recently, it has been reported that TCDD promotes prostaglandin (PG) synthesis of the mouse liver cells. In this study, we will show the effects of several prostaglandin synthesis inhibitors on developmental toxicity in zebrafish exposed to TCDD. As the results, TCDD-induced mesencephalic circulation failure was markedly inhibited by NS398, a selective inhibitor for cyclooxygenase 2 (COX2) and by indomethacin, a general inhibitor for COX1 and COX2, but not by nordihydroguaiaretic acid (NDGA), a selective inhibitor for 5-lipoxygenase (5-LOX). Morpholino antisense oligos against COX2 (COX2-MO) also recovered mesencephalic circulation failure by TCDD. On the other hand, pericardial edema caused by TCDD was significantly inhibited by all three inhibitors for COXs and 5-LOX. These results raise the possible involvement of PG synthesis pathway in developmental toxicology by TCDD.

DOSE- AND TIME-DEPENDENT HEPATIC GENE EXPRESSION PROFILING IN FEMALE RATS EXPOSED TO PCB126.

R. J. Foxenberg<sup>1</sup>, B. J. Ovando<sup>1</sup>, K. M. Kransler<sup>1</sup>, C. M. Vezina<sup>2</sup> and J. R. Olson<sup>1</sup>. <sup>1</sup>*Pharmacology and Toxicology, SUNY at Buffalo, Buffalo, NY* and <sup>2</sup>*Pharmacy, University of Wisconsin, Madison, WI*.

DNA microarray analysis was used to identify unique hepatic gene expression patterns in female Harlan Sprague-Dawley rats associated with subchronic (0 or 1000 ng/kg/day for 13 weeks) and chronic (0, 30, 300, or 1000 ng/kg/day for 52 weeks) exposures to 3, 3', 4, 4', 5-pentachlorobiphenyl (PCB126), the most potent dioxin-like PCB. Pathological reports obtained from the National Toxicology Program (NTP) show that both test groups displayed liver inflammation and exhibited a dose dependent increase in hepatocyte hypertrophy. Animals from the 52 week exposure group also displayed a dose dependent increase in the incidence of preneoplastic markers, including multinucleated hepatocytes, cellular pigmentation, and bile duct hyperplasia. Following 2 years of exposure, PCB126 produced cholangiocarcinoma, hepatocellular adenoma, toxic hepatopathy, multinucleated hepatocytes, diffuse fatty change, and liver pigmentation. Global gene expression profiles of the 8, 799 gene probe sets contained on Affymetrix RGU34A GeneChips exhibited a dose-dependent progression when the 52 wk group was analyzed by principal components analysis (PCA). The dose-dependent pattern of global gene expression may be the result of AhR activation and/or the hepatic injury resulting from chronic PCB126 exposure. Many genes were co-expressed during the 13 and 52 wk PCB126 exposures, including classical AhR regulated genes and genes recently characterized by our group as being dioxin-responsive, such as the up-regulation of carcinoembryonic-cell adhesion molecule 4 (C-CAM 4) and the down-regulation of CYP 3A9 (Vezina et al., 2004). Real time RT-PCR confirmed the altered expression of these genes as well as the up- or down-regulation of several other novel dioxin-responsive genes. Dose- and time-dependent gene expression data may provide new biomarkers of exposure and/or effect and help elucidate biological mechanisms for toxicity. (Supported in part by NIEHS ES09440, SOT, and University at Buffalo).

EFFECTS OF AMMONIUM PERCHLORATE ON LIVER ENZYMES AND THE THYROID AXIS OF RATS PRETREATED WITH PCB126.

E. D. McLanahan<sup>1</sup>, J. Campbell<sup>1</sup>, S. Muralidhara<sup>1</sup>, J. Hedge<sup>2</sup>, L. Narayanan<sup>3</sup>, J. Bruckner<sup>1</sup>, K. Crofton<sup>2</sup>, D. Mattie<sup>3</sup>, D. Keys<sup>1</sup>, M. Mumtaz<sup>4</sup>, D. Ferguson<sup>1</sup> and J. Fisher<sup>1</sup>. <sup>1</sup>*Interdisciplinary Toxicology Program, University of Georgia, Athens, GA*, <sup>2</sup>*Neurotoxicology Division, USEPA/ORD/NHEERL, Research Triangle Park, NC*, <sup>3</sup>*AFRL/HEPB, Wright-Patterson AFB, OH* and <sup>4</sup>*Division of Toxicology, ATSDR, Atlanta, GA*.

Ammonium perchlorate and 3, 3', 4, 4', 5-pentachlorobiphenyl (PCB126) are environmental contaminants that are known to disturb thyroid hormone (TH) homeostasis by well defined modes of action that lead to hypothyroidism in the rat. PCB126 increases phase II conjugation of T4 by inducing hepatic enzymes and

perchlorate blocks thyroidal uptake of iodide. To investigate the low dose interaction between perchlorate and PCB126 adult male Sprague-Dawley rats were administered a single oral bolus dose of 0, 7.5, or 75 ug PCB126/kg-bw dissolved in corn oil on Day 0. On Day 9, ammonium perchlorate was administered in drinking water to obtain target doses of 0, 0.01, 0.1, or 1 mg perchlorate/kg-bw per day for 14 days. Rats were euthanized on Day 22. Total P450 levels were significantly higher than controls in rats dosed with 75 ug PCB126/kg and EROD activity, a marker for CYP1A1 activity, was significantly induced by 7.5 and 75 ug PCB126/kg dose groups. Rats exposed to both PCB126 and perchlorate exhibited EROD activity corresponding to that of the PCB126 doses. T4-UDPGT was increased only in the 75 ug PCB126/kg dose group; no significant interaction between PCB126 and perchlorate was observed. A dose related increase in TSH was observed for both compounds. Under these experimental conditions, TSH serum levels of rats that were co-administered PCB126 and perchlorate were less than the sum of the % increase when these chemicals were administered individually. Analyses of serum thyroid hormones and organ 5'-deiodinase activity are ongoing. Biologically based pharmacokinetic models for the thyroid axis in the rat are under development in our laboratory to characterize dose response relationships for endocrine disrupting chemical mixtures such as PCB126 and perchlorate. ATSDR #U61/ATU472105-01

2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN MODULATES A TRANSLOCATION OF PKC- $\beta$ II VIA RECEPTOR FOR ACTIVATED C KINASE (RACK-1) IN DEVELOPING NEURONAL CELLS IN CULTURE.

J. Yang. *Pharmacology/Toxicology, Catholic University of Daegu, Daegu, South Korea*. Sponsor: P. Kodavanti.

2, 3, 7, 8-Tetrachlorodibenz-p-dioxin (TCDD) induces motor dysfunction and cognitive impairment as neurodevelopmental outcomes in humans and animals. PKC signaling pathways have been implicated as important factors in learning and memory processes. PKC requires a binding to receptor for activated C kinases (RACKs) for its activation. Although RACK is important for regulating PKC function and TCDD affects PKC activities, roles of RACK in TCDD-mediated signaling pathways remain unknown. To understand the mechanism of TCDD-induced signaling pathway in developing neurons and identify possible intracellular target molecules, the present study attempted to analyze effects of TCDD on PKC signaling pathways in cerebellar granule cells in culture. Cells exposed to TCDD were fractionated and subsequently immunoblotted against RACK-1 or PKC- $\beta$ II antibody. TCDD induced a significant increase (% of control: 129 $\pm$ 12 at 1nM, 131 $\pm$ 8 at 10nM and 127 $\pm$ 11 at 100nM) of RACK-1 levels. 10nM TCDD induced a significant increase of RACK-1 (% of control: 152 $\pm$ 17 at 5min, 192 $\pm$ 15 at 15 min, 204 $\pm$ 22 at 30min and 168 $\pm$ 28 at 1hr) in a time-dependent manner. The induction was AhR-dependent. TCDD induced a significant decrease of PKC- $\beta$ II in cytosol (% of control: 51 $\pm$ 4 at 1nM and 32 $\pm$ 6 at 10nM) and a significant increase in membrane (% of control: 121 $\pm$ 8 at 1nM and 145 $\pm$ 16 at 10 nM) fractions in a dose-dependent manner. The translocation from cytosol to membrane fractions was AhR-dependent. When TCDD-induced increase of RACK-1 levels was blocked with antisense oligonucleotides against RACK-1, translocation of PKC- $\beta$ II was also blocked. The study demonstrated that TCDD activates PKC- $\beta$ II thru the modulation of RACK-1. It is believed that this study is a first report identifying an adaptor protein, RACK-1, as a possible target molecule for TCDD exposure and contributes to better understanding of TCDD-induced signaling pathways in developing neurons.

TCDD ELICITS TYPICAL DEFENSIVE CELL STRESS RESPONSES FROM MCF10A CELLS: A STUDY ON THE MECHANISM OF ITS CELL RESCUING ACTION FROM UV-INDUCED APOPTOSIS.

F. Matsumura and S. Park. *Center for Health and the Environment, University of California, Davis, Davis, CA*.

It has been previously proposed from this laboratory that one of the action mechanisms of TCDD is to elicit typical cell stress responses. To assess the effectiveness of TCDD as a stressor, we have compared it to other typical stressors with respect to its potency to rescue cells from apoptosis in a human mammary epithelial cell line, MCF10A. We found in this cell line that TCDD can antagonize apoptosis that was induced by a variety of cell damaging treatments, such as UV- and gamma-irradiation, growth factor starvation and trypsinization, or treatments with H<sub>2</sub>O<sub>2</sub>, TGF $\beta$ , and staurosporine. Such anti-apoptotic action of TCDD resembles that of exogenously added EGF or TGF $\alpha$ . Furthermore, other typical inducers of cell stress responses, such as LPS, Fe<sup>3+</sup>, nitric oxide and hypoxia could also antagonize UV induced apoptosis just as in the case of TCDD. The anti-apoptosis action of TCDD was blocked by 1 $\mu$ M of a-naphthoflavone (500  $\mu$ M) or 1,10-phenanthroline (3 $\mu$ M), indicating the essential role of the Ah receptor. Furthermore, the action of

TCDD to induce stereotypical cell stress responses in this cell line has been verified by its action of increase the mRNA expression of cox-2, TNF $\alpha$ , and NF $\kappa$ B in addition to c-Src and ERK as assessed by qRT-PCR. We then tested a variety of diagnostic agents to reverse the effect of TCDD. Antagonists of TCDD which were found to be effective in this way were (a) inhibitors of c-Src kinase, such as PP-2 and CGP77675, (b) those known to block the action of TGF $\alpha$ , such as anti-TGF $\alpha$  antibody and a1-antitrypsin, (c) PD98059, a specific inhibitor of ERK activation, but not SB202190 (an inhibitor of p38 MAPK activation) or SP600125 (a JNK inhibitor). These results indicate that TCDD acts as an anti-apoptotic agent by mimicking the action of EGF through activation of the c-Src/ERK signaling pathway. They also support the idea that there are types of cell stressors including TCDD that elicit typical cell stress response reactions in order to protect cells from apoptosis.

### SELECTIVE MODIFICATION OF *BHLH/PAS* GENE EXPRESSION BY TCDD IN RAT HYPOTHALAMUS.

J. Linden<sup>1</sup>, M. Korkalainen<sup>2</sup>, J. Tuomisto<sup>2</sup> and R. Pohjanvirta<sup>1,3,2</sup>. <sup>1</sup>Department of Food and Environmental Hygiene, University of Helsinki, Helsinki, Finland, <sup>2</sup>Department of Environmental Health, National Public Health Institute, Kuopio, Finland and <sup>3</sup>Kuopio Department, National Veterinary and Food Research Institute, Kuopio, Finland.

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) induces a wide variety of toxic and biochemical effects via an AH receptor (AHR)-mediated signalling pathway. A lethal dose of TCDD leads to a drastically and permanently reduced feed intake and wasting by an unknown mechanism. Both wasting syndrome and acute lethality show a striking sensitivity difference between TCDD-sensitive Long-Evans (Turku/AB) (L-E) and TCDD-resistant Han/Wistar (Kuopio) (H/W) rat strains. We utilized this large difference to study hypothalamic effects of TCDD on expression of bHLH/PAS proteins potentially involved in wasting syndrome. Quantitative RT-PCR-method was used to measure mRNA levels of genes taking part in the signalling cascade of TCDD (AHR, AHRR, ARNT, ARNT2), feed intake regulation (*SIM1*) and circadian rhythmicity (*PER2*). In addition, two well-established target genes of TCDD, *CYP1A1* and *CYP1A2* were also examined. The measurements were done from total hypothalamic blocks, since hypothalamus is known to be one of the major centres of food intake and body weight regulation. At both 6 and 96 h after a single dose of 50  $\mu$ g/kg TCDD (lethal to L-E rats), significant elevations were found in mRNA levels of AHRR, CYP1A1 and CYP1A2, but not those of AHR, ARNT or ARNT2. Likewise, TCDD did not alter the expression of *SIM1*, implicated in the suppressive impact of TCDD on food intake, nor that of *PER2*. Differences between H/W and L-E rats appeared in constitutive levels of AHR and ARNT and in TCDD-induced levels of CYP1A2, AHRR, AHR and ARNT, which all were about two- to fourfold lower in H/W rats. The expression of all principal genes of the AHR-signalling pathway in rat hypothalamus suggests that it might be a critical target for TCDD.

## 2043

### COMPARISON OF THE TCDD-INDUCED CYP1A1 GENE EXPRESSION PROFILE IN LYMPHOCYTES FROM MICE, RATS AND HUMANS.

K. Nohara, Y. Miyamoto, K. Ao, T. Ito and C. Tohyama. National Institute for Environmental Studies, Tsukuba, Japan.

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) exerts its toxicity by binding and activating a transcription factor, the aryl hydrocarbon receptor (AhR). C57BL/6 mice express an AhR that has high affinity for TCDD, and they strongly express target genes, including the most sensitive target, CYP1A1, and develop severe toxic effects when exposed to TCDD. By contrast, DBA/2 mice have a low-affinity form of AhR, weakly express target genes, and are hardly affected by TCDD. Although humans express an AhR whose affinity for TCDD is comparable to that of the AhR of DBA/2 mice and should be refractory to TCDD toxicity, their sensitivity to TCDD has not been precisely investigated. In this study we compared the TCDD-induced CYP1A1 gene expression profiles in lymphocytes from humans, C57BL/6 mice, DBA/2 mice, and SD rats to get a clue for clarifying human sensitivity to TCDD. Lymphocytes were prepared from the blood of individual animals, and after culturing them in the presence of TCDD, total RNAs were prepared. The mRNAs for CYP1A1 and housekeeping genes were measured by RT-PCR or real-time PCR using primers designed for regions that are 100% homologous in the individual genes of all the species. The PCR efficiency for CYP1A1 in the four species yielded similar values, ranging around 1.7 - 1.8. A time-course study showed that TCDD-induced CYP1A1 expression peaked at 2 h in DBA/2 mice and SD rats and at 6 h in C57BL/6 mice and humans. Quantification of the amount of CYP1A1 mRNA at the individual peak times yielded the following order of amount: humans > C57BL/6 mice > DBA/2 mice > SD rats. These results suggest the existence of a major factor(s) that affects the AhR-dependent gene expression in the lymphocytes, in addition to the affinity of the AhR for TCDD. They also suggest that the TCDD sensitivity of human lymphocytes may be similar level to that of the lymphocytes of C57BL/6 mice.

## 2044

### ANALYSIS OF TEQ-EQUIVALENT AROCLOR AND TCDD TREATED RATS REVEALS DIFFERENT GENE DOSE-RESPONSE PROFILES AMONG DIOXIN RESPONSIVE GENES.

K. Illouz<sup>1</sup>, S. Goodwin<sup>3</sup>, A. Possolo<sup>1</sup>, S. B. Hamilton<sup>2</sup>, T. R. Sutter<sup>3</sup> and J. B. Silkworth<sup>1</sup>. <sup>1</sup>GE Global Research, Schenectady, NY, <sup>2</sup>GE Corporate, Fairfield, CT and <sup>3</sup>Feinstone Center for Genomic Research, U Memphis, Memphis, TN.

DNA microarray technology offers a great potential to address questions regarding the characteristic profiles of the multi-gene response to AhR ligands fundamental to validation of the TEQ (dioxin toxic equivalency) approach. TEQ equivalent dosages were administered to SD rats. Rats (n=4) were administered corn oil or 0.3 or 3.0  $\mu$ g/kg TCDD or 0.6, 6.0, or 60 mg/kg Aroclor 1254 mg/kg po for 3 consecutive days. The Aroclor 1254 lot has a TEQ (WHO98) of 46 ppm. Hepatic RNA was analyzed using Affymetrix RG U34 arrays. A dose-response model was fitted to each gene probe set. Treatment (corn oil, TCDD, Aroclor), TEQ dosage, and gender effects were treated as fixed effects and probe number as a random effect. Plausible interactions such as gender x treatment, TEQ x treatment, gender x TEQ, and gender x TEQ x treatment, were incorporated into the model. As expected, the primary early response genes included the CYP1 family genes. When normalized to TEQ, preliminary results show that well characterized AhR responsive genes, CYP1A1, CYP1A2, and CYP1B1, each follow very different response profiles. Further, the observed Aroclor TEQs for CYP1A1, CYP1A2, and CYP1B1 were 8.4, 46, 0.05 ppm, respectively. The CYP1A1 and CYP1B1 dose-response curves showed only treatment dependency; CYP1A2 showed only gender dependency. These results, which are based on measurements of the *in vivo* response of several dioxin responsive genes, demonstrate that the current TEFs used to calculate the Aroclor 1254 TEQ resulted in a 5.5 fold overestimate of the primary dioxin responsive gene, CYP1A1. Further, each gene had a unique response profile that may be a combination of factors including gender, specific ligand, and/or ligand concentration. Findings from these early response indicators do not support the requirement of the TEQ approach of parallel dose-responses across endpoints.

## 2045

### DIOXIN-RESPONSIVE DOWN-REGULATION OF SERPINA7, CYP3A9/3A13, AND CES3 REQUIRES A FUNCTIONAL ARYL HYDROCARBON RECEPTOR.

B. J. Ovando<sup>1</sup>, C. M. Vezina<sup>2</sup> and J. R. Olson<sup>1</sup>. <sup>1</sup>Pharmacology & Toxicology, University at Buffalo, Buffalo, NY and <sup>2</sup>Pharmacy, University of Wisconsin, Madison, WI.

Previously, thyroxin binding globulin (Serpina7), cytochrome P450 3A9 (CYP3A9) and carboxylesterase 3 (CES3) mRNA were demonstrated to be down-regulated in the liver following subchronic (13 week) exposure of female Sprague-Dawley rats to the aryl hydrocarbon receptor (AhR) ligands 2, 3, 7, 8-TCDD, 2, 3, 4, 7, 8-PeCDF and PCB126 (Vezina et al., 2004). No down-regulation of these genes was observed following exposure to the non-AhR ligand PCB153, suggesting that Serpina7, CYP3A9 and CES3 are novel dioxin-responsive genes. To investigate whether this response was a primary event associated with exposure to AhR ligands, the hepatic expression of these genes was investigated in female Sprague-Dawley rats at 24 and 72 hrs following a single exposure to TCDD (5 $\mu$ g/kg, po). Real time RT-PCR confirmed that Serpina7, CYP3A9, and CES3 were down-regulated -3-4, 5-10 and 3-7 fold, respectively. To establish whether the down-regulation of these genes was species- and AhR-dependent, female AhR wild type (AhR +/+) and AhR knockout (AhR -/-) mice were exposed to a single dose of TCDD (5 $\mu$ g/kg, po). At 72 hrs following exposure, hepatic Serpina7, CYP3A13 (the mouse homologue of CYP3A9), and CES3 were down-regulated -18, 2, and 7-fold in AhR +/+ mice, respectively. In AhR -/- mice Serpina7 and CYP3A9 were up-regulated -2-fold and CES3 was unchanged. These results indicate that the dioxin-responsive down-regulation of Serpina7, CYP3A9, and CES3 mRNA is an early, primary response to TCDD exposure that is dependent on a functional AhR. The functional and toxicological significance of these novel AhR-dependent down-regulated genes is currently under investigation. (Supported in part by NIEHS ES09440, SOT, and University at Buffalo).

### COPLANAR POLYCHLORINATED BIPHENYLS ACTIVATE ARYL HYDROCARBON RECEPTOR IN DEVELOPING TISSUES OF TWO TCDD-RESPONSIVE LACZ MOUSE LINES.

J. C. Bemis<sup>1</sup>, D. A. Nazarenko<sup>2</sup> and T. A. Gasiewicz<sup>1</sup>. <sup>1</sup>Environmental Medicine, University of Rochester, Rochester, NY and <sup>2</sup>Toxicology and Applied Biology, Alkemex Inc., Cambridge, MA.

*In utero* exposure to 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) can have an immediate impact on developmental processes that may then lead to long-term deficits in function. To define the tissues affected by TCDD exposure during devel-

opment, our laboratory developed a *lacZ*-reporter gene mouse which models activation of the Aryl Hydrocarbon Receptor (AhR). Exposure of the fetus via maternal oral gavage of 30 µg/kg TCDD on gestational day (GD) 14 results in strong activation of the *lacZ* transgene in numerous tissues including palate, paws, ear and genital tubercle. In order to further establish the utility of our mouse model, fetuses were exposed to selected polychlorinated biphenyls (PCBs) to test for a response to alternative dioxin-like toxicants. The coplanar PCB congeners 3, 4, 5, 3', 4'-pentachlorobiphenyl (C126) and 3, 4, 3', 4'-tetrachlorobiphenyl both induced staining in fetal tissues identical to that observed following TCDD exposure, although C126 was much more effective. Exposure of fetuses to the PCB mixture Aroclor 1254 and the non-coplanar congener 2, 3, 6, 2', 5'-pentachlorobiphenyl did not result in activation of the *lacZ* transgene. In addition to the testing of alternative ligands, another line of reporter mice was generated to determine the potential influence of the site of insertion of the *lacZ* transgene on the reported observations. Both TCDD and the coplanar PCBs induced a similar pattern of staining in the new line as compared to that observed in the original *lacZ* reporter mouse line, suggesting that the site of insertion of the transgene does not mediate the observed response. The ability of AhR ligands, in addition to TCDD, to activate the AhR-mediated *lacZ* transgene, in combination with the insertion-site independence of the response, strengthens the data previously derived from this model and validates the use of this system for investigations examining AhR-mediated events during development. Funded by NIH Grants ES09430, ES07026 and ES01247.

## 2047

### CCN4 AND CCN5 ARE DOWN REGULATED IN RESPONSE TO THE ADIPOGENIC STIMULATION WHILE 2, 3, 7, 8 - TETRACHLORODIBENZO-P-DIOXIN (TCDD) ELEVATES CCN5 MESSAGE IN C3H10T1/2 MOUSE EMBRYO FIBROBLASTS.

M. Cimafranca and C. Jefcoate. *Pharmacology, University of Wisconsin, Madison, WI*  
Adipogenesis in mouse embryo fibroblasts is inhibited at an early stage by 2, 3, 7, 8 - tetrachlorodibenzo-p-dioxin (TCDD). We and others have shown that administration of TCDD inhibits both early and late markers of fully mature adipocytes. The critical window in which TCDD must be present for successful attenuation of the central mediator of adipogenesis, the transcription factor PPAR $\gamma$ , is 6 – 16h after stimulation by an adipogenic hormonal cocktail (IDM); furthermore, we have demonstrated that this TCDD mechanism of suppression is MEK/ERK dependent. To determine what gene expression changes TCDD and MEK/ERK signaling are causing, we have used Affymetrix microarrays. Under adipogenic conditions, the arrays identified 45 genes in which the additional presence of both TCDD and EGF substantially and cooperatively inhibited the IDM stimulation. Changes in expression of some of these 45 genes may be necessary for differentiation and, when blocked by TCDD and EGF, lead to inhibition on adipogenesis; if a gene(s) from this set of 45 is required for the TCDD and EGF mechanism of inhibition, changes in message should occur within the 6 – 16 hour window of TCDD sensitivity. This window also corresponds to a period of IDM-induced cell contraction, which is cooperatively blocked by TCDD and EGF. Quantitative Real Time PCR (qRT-PCR) has been used to establish CCN4 and CCN5 as genes which are both IDM sensitive and are highly responsive in the opposite direction in the additional presence of TCDD and EGF. CCN4 is a typical member of the matrix-associated CCN family, which binds to integrins and affect cell adhesion; CCN5 is unique from other CCN family members because it lacks the integrin binding domain. Notably, both CCN4 and CCN5 are regulated by Wnt signaling, which suppresses adipogenesis. This research addresses whether CCN4 and CCN5 are possible mediators of TCDD inhibition of adipogenesis or are merely responding to these signaling changes.

## 2048

### DEVELOPMENT OF A NEW DIOXIN-ANALOGUE: 2, 3, 7, 8-TETRACHLOROPHENOTHIAZINE.

K. W. Fried<sup>1,2</sup>, G. I. Georg<sup>3</sup>, P. F. Terranova<sup>4,5,6</sup> and K. K. Rozman<sup>1,7</sup>.  
<sup>1</sup>*Pharmacology, Toxicology & Therapeutics, The University of Kansas Medical Center (KUMC), Kansas City, KS*, <sup>2</sup>*Institute of Ecological Chemistry, GSF-National Research Center for Environment & Health, Neuherberg, Germany*, <sup>3</sup>*Medicinal Chemistry, The University of Kansas, Lawrence, KS*, <sup>4</sup>*Center for Reproductive Sciences, KUMC, Kansas City, KS*, <sup>5</sup>*Molecular & Integrative Physiology, KUMC, Kansas City, KS*, <sup>6</sup>*Obstetrics & Gynecology, KUMC, Kansas City, KS* and <sup>7</sup>*Institute of Toxicology, GSF, Neuherberg, Germany*.

Inspired by interest in comparative studies, a new dioxin-analogue was designed and subsequently synthesized. The chemical characterization of the hitherto unknown compound 2, 3, 7, 8-tetrachlorophenothiazine (TCPT) revealed the desired structural resemblance with the archetype 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD). TCPT was synthesized in low yield by an intra-molecular Ullmann-coupling of the corresponding diarylamine. The successful synthesis was accomplished in a three-step process. In addition to spectroscopic and spectrometric methods, the

identity and conformation of TCPT were definitively confirmed by the resolution of the crystal structure. As expected for a phenothiazine, the molecule was found to have a butterfly shape, folded along the heteroatom axis. Thus, its deviation from planarity (by 18.5 °) distinguishes it slightly from the strictly planar dioxins.

## 2049

### COMPARISON OF GC/MS AND CALUX® BY XDS FOR DETECTION OF DIOXIN LIKE COMPOUNDS IN ENVIRONMENTAL SAMPLES.

G. C. Clark<sup>1</sup>, A. C. Chu<sup>1</sup>, J. D. Gordon<sup>1</sup>, M. D. Chu<sup>2</sup> and M. S. Denison<sup>3</sup>.

<sup>1</sup>*Xenobiotic Detection Systems, Inc., Durham, NC*, <sup>2</sup>*Alta Analytical Perspectives, Wilmington, NC* and <sup>3</sup>*Department of Environmental Toxicology, University of California, Davis, Davis, CA*.

The CALUX® by XDS bioassay measures the level of activation of the aryl hydrocarbon receptor (AhR)-dependent gene expression of chemical extracts providing an estimate of the relative potency and toxic potential expressed as Toxic Equivalents (TEQs) for dioxin like compounds. The CALUX® by XDS bioassay detects dioxin like compounds, using mouse hepatoma 6.1 cells stably transfected with an AhR luciferase reporter gene plasmid. A validation study was conducted with ash, soil and exhaust gas samples using both gas chromatography/mass spectrometry (GC/MS) and the CALUX® by XDS bioassay. Samples were sent to the Hiyoshi Corporation of Japan and Xenobiotic Detection Systems, Inc. (XDS) in a double blind study later decoded by a third party statistician. A double blind SITE study was conducted with the EPA and the Battelle Corporation in which soil samples were sent to several labs (including XDS) and a GC/MS lab. Samples from Lockheed Martin, Sumika Corp., and Umea University / Örebro University were sent to XDS for other validation studies. This report shows the cumulative data from all five direct sample comparisons. The results from the SITE study showed a 0.94 R<sup>2</sup> value for dioxins/furans (PCDD/PCDF), and a 0.81 R<sup>2</sup> for PCBs. The average Soil / soil extract correlation was a 0.91 R<sup>2</sup> value for PCDDs/PCDFs. The Ash / ash extracts tested had an average 0.93 R<sup>2</sup> correlation value for PCDDs/PCDFs. Exhaust extract demonstrated an R<sup>2</sup> correlation for PCDDs/PCDFs at 0.94. The solution samples tested demonstrated a 0.91 R<sup>2</sup> correlation for PCDDs/PCDFs. The overall correlation for PCDDs/PCDFs for all samples tested between GC/MS and the CALUX® by XDS bioassay was a 0.95 R<sup>2</sup> correlation. This study has been submitted to the EPA for SW846 validation and clearly demonstrates the CALUX® by XDS assay can be used in the detection of dioxin like compounds and is predictive of GC/MS results.

## 2050

### INDUCTION OF EROD-ACTIVITY *IN VITRO* BY 2, 3, 7, 8-TETRACHLOROPHENOTHIAZINE.

K. W. Fried<sup>1,2</sup>, N. Chahbani<sup>2</sup>, C. Corsten<sup>2</sup>, K. Schramm<sup>2</sup>, A. Kettrup<sup>2</sup> and K. K. Rozman<sup>3</sup>. <sup>1</sup>*Department of Pharmacology, Toxicology & Therapeutics, The University of Kansas Medical Center, Kansas City, KS*, <sup>2</sup>*Institute of Ecological Chemistry, GSF-National Research Center for Environment & Health, Neuherberg, Germany* and <sup>3</sup>*Institute of Toxicology, GSF, Neuherberg, Germany*.

2, 3, 7, 8-Tetrachlorophenothiazine (TCPT), a newly developed dioxin-analogue, was the subject of an investigation for the induction of *in vitro* EROD-activity. Its effects were compared to those of its structural analogue 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), the most potent dioxin congener. The time-dependency of induction was also measured after 24, 48 and 72 h of induction. After 24 h, a 370-times lower potency was calculated for TCPT as compared to TCDD. The efficacy of TCPT to induce EROD-activity was 77.6 % of that of TCDD as indicated by the respective maxima. TCPT appeared to be rapidly metabolized and was not found to be cytotoxic at the applied concentrations. The findings of this study indicate that TCPT is a partial agonist of the aryl hydrocarbon receptor (AhR) despite of its non-planar conformation.

## 2051

### LYMPHOCYTES CHOLINERGIC MUSCARINIC RECEPTORS: *IN VIVO* AND *IN VITRO* EFFECTS OF THE COMBINED EXPOSURE TO POLYCHLORINATED BIPHENYLS AND METHYLMERCURY.

L. Manzo<sup>1,2</sup>, A. F. Castoldi<sup>2</sup>, G. Randine<sup>2</sup> and T. Coccini<sup>1</sup>. <sup>1</sup>*Toxicology Division, University of Pavia, Pavia, Italy* and <sup>2</sup>*IRCCS Maugeri Foundation, Pavia, Italy*.

Cerebral cholinergic muscarinic receptors (MR) have been suggested as a possible common target for the widespread seafood contaminants methylmercury (MeHg) and polychlorinated biphenyls (PCBs). *In vivo*, MeHg has been shown to alter MR binding both in the rat brain and lymphocytes, supporting the use of MR in blood cells as a surrogate marker of CNS changes. The effects of MeHg and PCBs alone or in combination were evaluated on rat lymphocyte MR binding (using [<sup>3</sup>H]QNB as specific muscarinic ligand) *in vivo* and *in vitro*. For comparison, *in*

*vitro* studies were also performed on human lymphocytes. In rat splenic lymphocytes obtained from adult rats orally exposed *in vivo* to 1 mg MeHg/kg/day for 21 days and sacrificed 14 days later, MR density (Bmax) was increased by 240%. PCB153, 20 mg/kg/day, fed for 7 days caused a slight decrease in MR density, and completely masked MeHg effect when given together with it. In *in vitro* studies on human and rat lymphocytes, MeHg caused 20–40% inhibition of MR binding at 1  $\mu$ M. The concentration-dependent effects (from 10 nM to 100  $\mu$ M) of various PCBs (PCB28, PCB77, PCB105, PCB118, PCB153, 4-OH-PCB107) were also evaluated on lymphocyte MR binding in the presence or absence of 1 microM MeHg. In rat splenic lymphocytes, no significant differences in IC50 values were detected among the different PCBs, tested either alone or together with MeHg. All IC50s were about 30  $\mu$ M. Even in human blood lymphocytes, PCBs IC50s were in the high micromolar range (from 20 to 50  $\mu$ M) and unaffected by the presence of MeHg. These *in vivo* results provide evidence of an interaction between PCB153 and MeHg on rat lymphocyte MR binding. However, this interaction does not seem to occur directly at the receptor level because of the negligible direct effect of PCB153 on this endpoint according to our *in vitro* data. The sensitivity of lymphocyte MRs to PCBs was neither species-related (rat and human) nor PCB congener-dependent. (EU Grants: QLK4-CT-2001-00186; FOOD-CT-2003-506543).

## 2052

### THE ROLE OF SUPEROXIDE ANION IN 2', 4, 4'-TETRACHLOROBIPHENYL-INDUCED UPREGULATION OF COX-2 IN HL-60 CELLS.

S. Bezdecny<sup>1, 2, 3</sup>, R. A. Roth<sup>1, 2, 3</sup> and P. E. Ganey<sup>1, 2, 3</sup>. <sup>1</sup>Department of Pharmacology and Toxicology, Michigan State University, Lansing, MI, <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI and <sup>3</sup>National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI.

Polychlorinated biphenyls (PCBs) are persistent environmental contaminants that affect a number of cellular processes in a variety of cells, including neutrophils. Previous studies in a promyelocytic leukemia cell line (HL-60) differentiated with DMSO to a neutrophil-like phenotype have shown that ortho-substituted, non-coplanar PCBs such as 2, 2', 4, 4'-tetrachlorobiphenyl (2244-TCB) cause increased arachidonic acid release and superoxide anion production accompanied by upregulation of cyclooxygenase-2 (COX-2). We tested the hypothesis that PCB-mediated production of superoxide anion is required for upregulation of the COX-2 gene in HL-60 cells. 2244-TCB (30  $\mu$ M) significantly increased superoxide anion levels in both quiescent cells and in cells treated with the immunostimulatory compound, phorbol myristate acetate (PMA). In addition, 2244-TCB treatment increased both [<sup>3</sup>H]-arachidonic acid (<sup>3</sup>H-AA) release and COX-2 mRNA expression. Apocynin, an inhibitor of the superoxide anion-producing enzyme NADPH oxidase, and 4-hydroxy TEMPO (4-HT), an intracellular free radical scavenger, both significantly reduced superoxide anion levels in 2244-TCB-treated cells. Release of <sup>3</sup>H-AA was significantly reduced by apocynin, but not by 4-HT, in vehicle, 2244-TCB-treated or PMA-stimulated cells. COX-2 mRNA was decreased by apocynin in vehicle-treated cells as well as in 2244-TCB-treated cells both in the absence and presence of PMA. 4-HT treatment had no effect on COX-2 mRNA levels under any condition. The results suggest that superoxide anion is not required for 2244-TCB-mediated 3H-AA release or COX-2 expression and that apocynin decreases COX-2 expression through a mechanism independent of inhibition of superoxide anion production. (Supported by ESO4911 and training grant T32 ES007255).

### RYR1 MALIGNANT HYPERTHERMIA POINT MUTATION R615C ENHANCES SUSCEPTIBILITY TO NON-COPLANAR 2, 2', 3, 5'-PENTACHLOROBIPHENYL (PCB 95).

T. N. Ta<sup>1</sup>, B. R. Fruen<sup>2</sup> and L. N. Pessah<sup>1</sup>. <sup>1</sup>VM: Molecular Biosciences, UC Davis, Davis, CA and <sup>2</sup>Department of Biochemistry, Molecular Biology, and Biophysics, Minnesota, MN.

Malignant Hyperthermia (MH) is an inherited pharmacogenetic disease of skeletal muscle in human and animals possessing specific point mutations within the ryanodine receptor (RyR1), which are calcium channels found on the sarcoplasmic reticulum (SR). Since patients with MH point mutations do not always have a fulminant MH episode when exposed to triggering agents, and there are different degrees of severities in patients possessing the same point mutation, we examined the effect of an environmental contaminant, 2, 2', 3, 5'-pentachlorobiphenyl (PCB 95), on <sub>MH</sub>RyR1 compared to that of <sub>wt</sub>RyR1. In this study, we demonstrated that there is no significant difference in ryanodine protein expression level of <sub>wt</sub>RyR1 and <sub>MH</sub>RyR1 in isolated porcine SR membranes (p-value <0.84649 by ANOVA one-way comparison). Using [<sup>3</sup>H]ryanodine receptor binding to access ryanodine receptor function in response to endogenous agonists/antagonists of <sub>wt</sub>RyR1 and <sub>MH</sub>RyR1, we found that <sub>MH</sub>RyR1 is more sensitive to channel activation by  $Ca^{2+}$ , and less sensitive to channel inhibition by  $Ca^{2+}$  and  $Mg^{2+}$  compared to <sub>wt</sub>RyR1. In conditions that mimic resting intracellular  $Ca^{2+}$ , PCB 95 has significantly lower threshold and higher efficacy toward <sub>MH</sub>RyR1 compared to <sub>wt</sub>RyR1. Furthermore, PCB 95 disrupts feedback inhibition of the channel by calcium and magnesium to a greater extent in <sub>MH</sub>RyR1 than <sub>wt</sub>RyR1. In the presence of PCB 95 (2  $\mu$ M), the

shifts in IC50s for  $Ca^{2+}$  and  $Mg^{2+}$  were 3.6- and 2-fold greater in <sub>MH</sub>RyR1 compared to <sub>wt</sub>RyR1, respectively. In summary, our data suggest PCB 95 has a more profound effect on <sub>MH</sub>RyR1 channels than it does to <sub>wt</sub>RyR1. These studies are the first to identify a specific gene-environment interaction that influences PCB neurotoxicity.

## 2054

### ANALYSIS OF THE TUMOR PROMOTING POTENCY OF PCB 28 AND PCB 101 IN RAT LIVER.

S. Kunz<sup>1</sup>, H. Schmitz<sup>1</sup>, M. Schwarz<sup>2</sup>, B. Schilling<sup>3</sup>, O. Paepke<sup>3</sup>, H. Lehmler<sup>4</sup>, L. Robertson<sup>4</sup> and D. Schrenk<sup>1</sup>. <sup>1</sup>Food Chemistry and Environmental Toxicology, University of Kaiserslautern, Kaiserslautern, Germany, <sup>2</sup>Department of Toxicology, University of Tuebingen, Tuebingen, Germany, <sup>3</sup>ERGO Research, Hamburg, Germany and <sup>4</sup>Department of Occupational and Environmental Health, University of Iowa, Iowa City, IA.

Polychlorinated biphenyls (PCBs) are potent persistent environmental pollutants exhibiting neurotoxic, developmental and tumor promoting effects in experimental animal models. Complex technical PCB mixtures have been shown to cause liver cancer in rodents while very few data are available on the carcinogenic potency of individual PCB congeners. Among the ortho-substituted, 'non-dioxinlike' PCBs a few congeners including PCB 28 and 101 are present in environmental and food samples. In this study, the effect of both compounds on the promotion of enzyme-altered hepatic foci was investigated in female Wistar rats after initiation with diethylnitrosamine. After eight and sixteen weeks of PCB treatment at dose levels of 50 and 150  $\mu$ mol/kg body weight per week, both congeners were recovered in the liver according to the dose levels applied, with PCB 28, at the same dose level, showing six- to sixteen-fold higher hepatic levels than PCB 101. Both congeners slightly induced 7-ethoxyresorufin O-deethylase (EROD) and 7-pentoxyresorufin O-depetylase (PROD) activity. The focal volume of adenosine triphosphatase-(ATPase) negative foci, but not the volume of the placental form of glutathione S-transferase- (GSTP) positive foci, was enhanced significantly by treatment with both congeners after sixteen weeks. No significant increase in the number of ATPase-negative or GSTP-positive foci was observed. Our results indicate a weak promoting potency of PCB 28 and 101 in the liver of female rats correlated, in the case of PCB 28, with a significant increase in relative liver weight.

## 2055

### TRANSCRIPTIONAL PROFILING OF RAT HEPATIC RESPONSES TO DIETARY EXPOSURE TO AROCLOR 1254.

T. M. Basford<sup>1, 2</sup> and J. C. Means<sup>1, 2</sup>. <sup>1</sup>Chemistry, Western Michigan University, Kalamazoo, MI and <sup>2</sup>Great Lakes Environmental and Molecular Science Center, Kalamazoo, MI.

Dietary intake is a primary route for biomagnification of environmentally persistent polychlorinated biphenyls (PCBs) within humans and animals. Aroclor 1254, a mixture of PCBs, is associated with a variety of toxic responses in cell culture and in whole animals including alterations in blood and lipid biochemistry, tumor promotion, immune suppression, and impaired neurological function. Pretreatment of cells and live animals with Aroclor 1254, a broad spectrum MFO inducer, has also been used to enhance metabolic activation of mutagens. Measurement of the transcriptional responses to sub-acute and sub-chronic dietary exposure to Aroclor 1254 has not been reported in the literature to date, and is particularly important given the persistence and pervasiveness of PCBs, and the range of toxicities associated with exposure. Changes in expression of hepatic genes in male Fisher 344 rats were assessed by Affymetrix microarray analysis to identify important physiological pathways affected by PCB intake. Seven week old animals were fed control diet or diet containing 10 ppm or 50 ppm Aroclor 1254 for 7 days and 84 days. Three RGU34A arrays were prepared from liver mRNA for each treatment group and time point. Animal health at the time of sacrifice was also assessed by measuring serum levels of cholesterol, triglycerides, bilirubin, ALT, AST, ALP, and GGT. Most of the significant effects of Aroclor treatment on animal health were seen in the high dose groups; these included enlarged livers and elevated cholesterol levels, and decreases in serum ALT and AST. Analysis of microarray data showed upregulation of several cytochrome P450s, oxidative stress response, and detoxification genes in treated animals compared to controls, at one week and after twelve weeks of feeding. Significant changes were also observed in transcription of genes involved in long chain fatty acid transport and metabolism, cell cycle, and transcription.

## 2056

### COMPARISON OF AROCLOR AND TCDD RESPONSIVE GENES BETWEEN *IN VIVO* AND *IN VITRO* EXPOSURES USING DNA MICROARRAYS.

M. Zhao<sup>1</sup>, S. Arunajadai<sup>2</sup>, K. Illouz<sup>1</sup>, A. Possolo<sup>1</sup>, A. Koganti<sup>3</sup>, S. B. Hamilton<sup>4</sup>, S. Goodwin<sup>5</sup>, T. R. Sutter<sup>1</sup> and J. B. Silkworth<sup>1</sup>. <sup>1</sup>Global Research, GE, Schenectady, NY, <sup>2</sup>U.C Berkeley, Berkeley, CA, <sup>3</sup>In Vitro Technologies, Baltimore, MD, <sup>4</sup>GE Corporate, Fairfield, CT and <sup>5</sup>U Memphis, Memphis, TN.

DNA microarrays were used to characterize gene expression in hepatic cells exposed either *in vivo* or *in vitro* to two chemicals known to act through the aromatic hydrocarbon receptor, AhR. Sprague-Dawley (SD) rats were administered corn oil,

TCDD, or Aroclor 1254 *po* for 3 consecutive days. Primary cultures of SD rat hepatocytes were treated with TCDD or Aroclor 1254. RNA samples were analyzed on Affymetrix RG U34 arrays. Only genes whose expression changed significantly ( $p \leq 0.001$ ) by  $>2$  fold were considered. Comparisons were made between chemical treatments, exposure method, single genes, gene networks, and network functions. Of 156 genes responding to TCDD, 16 were common to both *in vivo* and *in vitro* exposures, but 69 were unique to *in vivo* and 71 unique to *in vitro*. Of 225 genes responding to Aroclor, 16 were common to both exposures, but 163 were unique to *in vivo* and 46 unique to *in vitro*. Thirteen of the 16 genes common to both exposures of either TCDD or Aroclor were the same, showing remarkable consistency across chemical and exposure regime. Using Ingenuity Pathways Analysis ([www.ingenuity.com](http://www.ingenuity.com)), each gene was evaluated for its association with other genes, i.e., gene networks. The 13 common genes were strongly associated with the AhR and involved transcription, expression, differentiation, and binding. There were also networks unique to each chemical that were also different *in vivo* or *in vitro*. These generally involved cellular functions such as synthesis, translation, viability, and oxidative stress. This preliminary work suggests that there is useful correlation between the primary pathway genes between *in vivo* and *in vitro* exposures to each of these chemicals. However, this work also indicates that TCDD uniquely influences genes, gene networks, and functions that are different from those affected by Aroclor.

## 2057

### ACCUMULATION OF PBDE-47 IN PRIMARY CULTURES OF RAT NEOCORTICAL CELLS.

W. Mundy<sup>1</sup>, T. M. Freudenrich<sup>1</sup>, K. M. Crofton<sup>1</sup> and M. J. DeVito<sup>2</sup>.

<sup>1</sup>Neurotoxicology Division, USEPA, Research Triangle Park, NC and <sup>2</sup>Experimental Toxicology Division, USEPA, Research Triangle Park, NC.

Studies have examined the actions of PBDEs using *in vitro* cell culture models. However, there is little data reporting the final concentration of PBDEs in cells after *in vitro* exposure. The present study examined the concentration- and time-dependent accumulation of 2, 2', 4, 4'-tetrabromodiphenyl ether (PBDE-47) in primary cultures of rat neocortex. Neuronal cultures were prepared from the neocortex of newborn rats and grown for 7 days *in vitro*. Cells were then exposed to freshly prepared serum-free culture media containing <sup>14</sup>C-PBDE-47. Radiolabel associated with the cells or remaining in the media was determined by liquid scintillation spectrometry. Exposure to 0.01 - 3.0  $\mu$ M PBDE-47 for 60 min resulted in a concentration-dependent accumulation in cells. At each concentration approximately 15% of the applied PBDE-47 was associated with the cells, resulting in a 100-fold magnification of the applied concentration (e.g., exposure to 1  $\mu$ M resulted in 100  $\mu$ M concentration in the cells); 55% of the PBDE remained in the media and 30% was associated with the plastic culture dish. Exposure to 1  $\mu$ M PBDE-47 resulted in a linear increase in PBDE-47 in cells with time for the first 60 min, which began to saturate at 120 min. Addition of serum proteins to the media decreased accumulation; at 10% serum in the media only 3% of the applied PBDE-47 was associated with the cells and 96% remained in the media after 60 min. The volume of exposure also influenced accumulation. Doubling the volume of serum-free exposure media (from 2 ml to 4 ml) but leaving the concentration constant (1  $\mu$ M) resulted in an 1.5-fold increase in PBDE concentration in the cells. These data show that a number of factors, including duration of exposure, volume of exposure, and concentration of serum proteins in the media, can influence the accumulation of PBDE in cells *in vitro*. For this highly lipophilic compound, use of media concentration underestimates tissue concentration by up to 2 orders of magnitude. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy).

## 2058

### MIXTURE EFFECTS OF PCBs AND PBDES WITH OTHER CONTAMINANTS/DRUGS.

H. L. Esch, L. W. Robertson and G. Ludewig, Department of Occupational & Environmental Health, University of Iowa, Iowa City, IA.

Polychlorinated biphenyls (PCBs) and polybrominated diphenyl ethers (PBDEs) are ubiquitous in humans. The troubling question remains whether the toxicity of these contaminants at apparently innocuous concentrations may be enhanced by co-exposure to other chemicals. To gain insight into this question, we exposed cells in culture to three commercial PBDE-mixtures, a PCB mixture, or two PCB congeners alone or in combination with compounds that induce peroxisome proliferation, redox-cycling or reduction of intracellular glutathione (GSH). Three different cell lines were chosen which represent two different tissues and two species, i.e. human colon carcinoma cells (CaCo-2), and hepatoma cells HepG2 (human) and H-4-II-E (rat). Cytotoxicity was determined by Neutral Red uptake and intracellular GSH content by enzyme recycling. No toxicity was observed in HepG2 and CaCo-2 with PCBs or PBDEs at the highest soluble concentration (5 - 50  $\mu$ M). However, H-4-II-E cells were more sensitive, with cytotoxicity of up to 40% (penta-PBDE mixture) and 50% (Aroclor 1254). None of the compounds had an

effect on intracellular GSH levels in H-4-II-E, but all PCBs tested slightly decreased GSH in CaCo-2 cells. The penta- and octa-PBDE mixtures increased GSH in HepG2 cells. Co-incubation with non-cytotoxic concentrations of Dicamba (100  $\mu$ M), Diquat (1  $\mu$ M), or Ciprofibrate (50  $\mu$ M) did not change toxicity and GSH content in any of the cell lines. BSO (0.5 mM) alone completely reduced GSH in all three lines, but the only effect of co-incubation was a slight increase of cytotoxicity with PCB-77 in H-4-II-E cells. Co-incubation with a non-cytotoxic concentration of PFDA (100  $\mu$ M) increased cytotoxicity of all PCB and PBDE exposures in both rat and human hepatoma cells without significantly altering total GSH. This shows that co-exposure of PCBs or PBDEs, with non-toxic concentrations of the peroxisome proliferator PFDA, may cause toxic effects in hepatoma cells, an effect that is not mediated through GSH depletion. ## 2059

### EFFECT OF PBDES ON TCDD-INDUCED CYP1A1 ACTIVITY (EROD) IN PRIMARY HEPATOCYTES OF CYNOMOLGUS MONKEYS.

L. Peters<sup>1</sup>, A. Bergman<sup>2</sup>, J. T. Sanderson<sup>1</sup> and M. van den Berg<sup>1</sup>. <sup>1</sup>Institute for Risk Assessment Sciences, University of Utrecht, Utrecht, Netherlands and

<sup>2</sup>Department of Environmental Chemistry, University of Stockholm, Stockholm, Sweden.

Polybrominated diphenylethers (PBDE) are used as additive flame-retardants in plastics, textiles and circuits boards. Some PBDE congeners have been found world-wide in wildlife and human tissues during the last decades. The structural similarity of certain PBDE congeners to other polyhalogenated aromatic hydrocarbons such as PCBs has raised concerns that these compounds might be agonists for the aryl hydrocarbon receptor (AhR). To study the possible dioxin-like effects of environmentally relevant PBDEs (BDE47, 77, 99, 100, 153, 154, 183, 209), the Ah receptor-mediated induction of CYP1A1 was studied in primary cynomolgus monkey (*Macaca fascicularis*) hepatocytes. The monkeys served as donors for the production of the poliomyelitis vaccine. After the liver was perfused *in situ* with PBS, it was removed and transported to our laboratory where the hepatocytes were isolated using a two-step collagenase perfusion technique. Ethoxresorufin-O-deethylation (EROD) activity was used as a marker for CYP1A1 activity. The cells were seeded in 12-well plates and exposed for 48h to PBDEs (0.01-10  $\mu$ M), the positive control TCDD (0.001-2.5 nM) and negative control (DMSO). There was a concentration-dependent increase in EROD activity measured after 48h exposure to the positive control TCDD. The PBDEs (BDE47, 77, 99, 100, 153, 154, 183) did not show any induction of EROD activity. This indicates that these PBDEs were not agonists of the Ah receptor. The lack of CYP1A1 induction by these PBDEs further supports the exclusion of these compounds in the TEF concept for dioxin-like compounds. However, when the hepatocytes were exposed to various concentrations of BDE77 in combination with TCDD for 48h, there was a concentration dependent inhibitory effect on the TCDD-induced EROD activity. Co-exposure to TCDD (1 nM) and BDE77 (10  $\mu$ M) resulted in a 88% decrease of the TCDD-induced EROD activity. Other PBDEs showed similar effects, although quantitative differences were observed.

## 2060

### 2, 2'-DIBROMODIPHENYL ETHER BINDS AND INDUCES CALCIUM RELEASE THROUGH THE RYANODINE RECEPTOR IN AN FKBP12-DEPENDENT MANNER.

J. Riehl and I. Pessah, School of Veterinary Medicine: Molecular Biosciences, University of California Davis, Davis, CA.

Polybrominated diphenyl ethers (PBDEs) are widely used flame retardants that have been identified as persistent environmental pollutants since the late 1990s. The bioaccumulation and potential neurotoxicity warrant further investigation into their biological activity and mechanism of action. It has previously been reported that the non-coplanar polychlorinated biphenyls (PCBs) specifically bind the ryanodine receptor calcium release channel (RyR). Because of structural and toxicological similarities between the PBDEs and the non-coplanar PCBs, we investigated whether the PBDE congener 2, 2'-dibromodiphenyl ether (BDE-4) also binds to the skeletal isoform of the RyR (RyR1). BDE-4 dose-dependently enhances [<sup>3</sup>H]ryanodine binding to RyR1 (EC<sub>50</sub> = 5.60  $\mu$ M), whereas diphenyl ether and 4, 4'-dibromodiphenyl ether (BDE-15) showed no activation, suggesting ortho substitution is required for activity at RyR1. BDE-4 dose-dependently decreases the EC<sub>50</sub> of RyR1 activation by Ca<sup>2+</sup> (vehicle EC<sub>50</sub> = 1  $\mu$ M Ca<sup>2+</sup> vs 8  $\mu$ M BDE-4 EC<sub>50</sub> = 191 nM Ca<sup>2+</sup>). In addition, inhibition of RyR1 activity by mM Ca<sup>2+</sup> and Mg<sup>2+</sup> was attenuated in the presence of BDE-4 (Ca<sup>2+</sup> inhibition: vehicle IC<sub>50</sub> = 101  $\mu$ M vs 8  $\mu$ M BDE-4 IC<sub>50</sub> = 125  $\mu$ M Ca<sup>2+</sup>; Mg<sup>2+</sup> inhibition: vehicle IC<sub>50</sub> = 190  $\mu$ M vs 8  $\mu$ M BDE-4 IC<sub>50</sub> = 90  $\mu$ M Mg<sup>2+</sup>). Microsomal Ca<sup>2+</sup> flux measurements suggest a similar increase in RyR1 activity with BDE-4. These effects were abolished in the presence of the RyR blocker ruthenium red but was unaffected by inhibition of the SR/ER ATPase by 375 nM thapsigargin, suggesting the effect is specific to alterations of

RyR1 activity. Rapamycin 0 to 50  $\mu$ M selectively prevented activation of RyR1 channels by BDE-4 in both [ $^3$ H]ryanodine binding and microsomal  $\text{Ca}^{2+}$  flux measurements. These results suggest RyR1 is a molecular target for the ortho-substituted BDE-4, and that this activity is FKBP12 dependent.

2061

THE BROMINATED FLAME RETARDANT HBCDD INDUCES CYP2B AND CYP3A BUT NOT CYP1A IN RAT LIVER.

S. Germer<sup>1</sup>, L. van der Ven<sup>2</sup>, A. H. Piersma<sup>2</sup> and D. Schrenk<sup>1</sup>. <sup>1</sup>*Food Chemistry and Environmental Toxicology, University of Kaiserslautern, Kaiserslautern, Germany*, <sup>2</sup>*Laboratory for Toxicology, Pathology and Genetics, National Institute for Public Health and the Environment RIVM, Bilthoven, Netherlands and <sup>3</sup>National Institute for Public Health and the Environment RIVM, Bilthoven, Netherlands.*

Among the major brominated flame retardants (BFRs) hexabromocyclododecane (HBCDD) is found regularly in environmental samples and in mother's milk. Some BFRs have been suspected to act as 'endocrine disrupters' and/or to affect the development of the unborn. Induction of drug metabolism may play a role in such effects by changing the body's homeostasis of hormones such as steroids, thyroxine and others. In this study adult Wistar rats were treated with HBCDD (0.3, 1, 3, 10, 30, 100 mg/kg body weight per day) over 28 days. The effects of treatment on the hepatic levels of cytochrome P450 (CYP) 1A1/2, 2B1/2, and 3A1/3 were analyzed by Real Time PCR, Western blotting, an determination of microsomal 7-ethoxyresorufin O-deethylase (EROD), 7-pentoxyresorufin O-depentylase (PROD), and luciferinbenzylether-debenzylase (LBD) activity, respectively. Doses of up to 100 mg/kg per day did not lead to any effects on CYP1A1/2 expression. There was a significant trend of increase with dosage for CYP2B mRNA in male but not in female animals. Levels of CYP3A mRNA were highly increased in females, more than 20 times at the highest dose. Male samples gave evidence for an inducing trend. LBD activity similarly unveiled high induction for females (up to 9 times), contrarily there was no indication for an increase in male animals. These findings suggest that oral treatment with HBCDD, has a significant inducing effect on the hepatic drug-metabolizing enzymes CYP2B and CYP3A. This pattern of CYP induction may cause sex specific variations in hormone metabolism, thus leading to endocrine effects.

2062

NEONATAL EXPOSURE TO POLYBROMINATED DIPHENYL ETHERS, PBDE 183, PBDE 203, AND PBDE 206, CAUSES NEUROTOXIC EFFECTS IN ADULT MICE.

N. Johansson<sup>1</sup>, H. Viberg<sup>1</sup>, J. Eriksson<sup>2</sup>, A. Fredriksson<sup>1</sup> and P. Eriksson<sup>1</sup>.

<sup>1</sup>*Department of Environmental Toxicology, Uppsala University, Uppsala, Sweden and <sup>2</sup>Department of Environmental Chemistry, Stockholm University, Stockholm, Sweden.*

Polybrominated diphenyl ethers (PBDEs) are used as flame-retardants, and have been shown to increase in the environment and in human mother's milk. Previous studies have shown that lower brominated PBDEs, such as, tetra-, penta-, and hexa-brominated diphenyl ethers, can cause developmental neurotoxic effects. This is also seen for the full-brominated PBDE, deca-brominated diphenyl ether, although the developmental neurotoxic effects are suggested to be caused by a metabolite (possible de-brominated one), of PBDE 209. The present study have shown that 2, 2', 3, 4, 4', 5', 6'-heptaBDE (PBDE 183), 2, 2', 3, 4, 4', 5, 5', 6-octaBDE (PBDE 203) and 2, 2', 3, 3', 4, 4', 5, 5', 6-nonaBDE (PBDE 206), can induce developmental neurotoxic effects, such as aberrations in spontaneous behavior. Neonatal NMR mice were orally exposed on day 3 or day 10 to 15.2 mg PBDE 183/kg body weight, 16.8 mg PBDE 203/kg body weight, or 18.5 mg PBDE 206/kg body weight. These doses are all the same on molar basis (21  $\mu$ mol/kg body weight). Defects in spontaneous behavior (locomotion, rearing or total activity) was observed in 2-month-old mice, neonatally exposed to PBDE 203 and PBDE 206, on postnatal day 10, and to PBDE 183 and PBDE 203, on postnatal day 3. Furthermore, mice exposed to PBDE 203 and PBDE 206 showed also reduced habituation capability. The developmental neurotoxic effects were most pronounced in mice exposed to the octa-brominated diphenyl ether, PBDE 203. These developmental effects are in accordance with earlier reported developmental neurotoxic effects for other PBDEs, and certain PCBs.

2063

EFFECT OF PERFLUOROOCTANE SULFONATE (PFOS) AND PERFLUOROOCTANOATE (PFOA) ON L-TYPE CALCIUM CURRENT IN GUINEA PIG VENTRICULAR MYOCYTES.

K. Harada<sup>1</sup>, F. Xu<sup>2</sup>, K. Ono<sup>2</sup>, T. Iijima<sup>2</sup> and A. Koizumi<sup>1</sup>. <sup>1</sup>*Health Environmental Sciences, Kyoto University Graduate School of Medicine, Kyoto, Japan and <sup>2</sup>Pharmacology, Akita University School of Medicine, Akita, Japan.*

Perfluorooctane sulfonate (PFOS) and perfluorooctanoate (PFOA) are chemicals ubiquitously found in the environment, wildlife and humans. Their toxicity is still unknown. There are several reports that PFOS and PFOA may change physiological properties of cell membranes. These effects on membrane properties, however,

have not been investigated from viewpoint of cellular functions. We herein show the effect of PFOS and PFOA on L-type calcium current in isolated guinea pig ventricular myocytes using the whole cell patch-clamp recording technique. PFOS (1, 3, 10, 30, 100  $\mu$ M) increased the voltage-activated peak amplitude of I(Ca, L) in a concentration-dependent manner. PFOS decreased the maximal activation voltage of I(Ca, L) ( $\text{EC}_{50} = 6.7 \mu\text{M}$ ). PFOS shifted the steady-state inactivation curve of I(Ca, L) to the left ( $\text{EC}_{50} = 12.6 \mu\text{M}$ ). PFOA also had the same effects of PFOS but its dose-response curves shifted to the higher doses by about 10-fold larger than those of PFOS. These effects were also observed in sodium dodecyl sulfate, which is known to change surface charge, suggesting the importance of amphiphilic nature for the effects on Ca-channel. In this study, perfluoroalkyl acids were considered to alter the L-type calcium channel kinetics in ventricular myocytes through the change of surface charge. This surface charge alteration may modify physiological properties of other channels, leading perturbation of signal transduction through various ion channels by PFOS and PFOA. Further studies are needed to bridge over a gap between *in vitro* finding and *in vivo* toxicity.

2064

RENAL CLEARANCES OF PERFLUOROOCTANE SULFONATE AND PERFLUOROOCTANOATE IN HUMANS, AND SPECIES-SPECIFIC EXCRETION OF THESE CHEMICALS.

K. Harada<sup>1</sup>, K. Inoue<sup>1</sup>, A. Morikawa<sup>1</sup>, T. Yoshinaga<sup>1</sup>, N. Saito<sup>2</sup>, M. Kimura<sup>3</sup>, S. Shimbo<sup>4</sup> and A. Koizumi<sup>1</sup>. <sup>1</sup>*Health Environmental Sciences, Kyoto University Graduate School of Medicine, Kyoto, Japan*, <sup>2</sup>*Research Institute for Environmental Sciences and Public Health of Iwate Prefecture, Morioka, Japan*, <sup>3</sup>*Kyoto Prefectural University of Medicine, Kyoto, Japan* and <sup>4</sup>*Kyoto Women's University, Kyoto, Japan*.

Perfluorooctane sulfonate (PFOS) and perfluorooctanoate (PFOA) are chemicals ubiquitously found in the environment, wildlife and humans. However, the bioaccumulation mechanism of perfluorooctanoates in humans are unknown. Half-lives of these chemicals in human were longer than in other species. In rat study, renal clearances of PFOA in female rat were higher than those in male rat, and were regulated by sex hormones. First, we measured the concentrations of PFOA and PFOS in subjects who had lived in Kyoto City for more than 10 yr. The serum concentrations of PFOA and PFOS increased with age in females ( $r=0.460$  and  $r=0.524$ ,  $p<0.05$ , respectively), but not in males. The levels in females caught up in males at ages  $\geq 60$  yr. Second, we determined the renal clearances of PFOA and PFOS in young (20-40 yr of age,  $N=5$  for each sex) and old ( $\geq 60$  yr of age,  $N=5$  for each sex) subjects of both sexes. All the young females had menstruation cycles while the old females did not. The renal clearances were  $10^{-5}$ -fold smaller than the glomerular filtration rate, suggesting almost absence of renal excretion in humans. The sex differences in renal clearance that have been observed in rats and Japanese macaques, were not found in humans. Renal clearance of PFOA in human was about 1000 times lower than in rat and macaque. The lower serum levels of PFOA and PFOS in females than in males might be associated with elimination through menstruation. The results of the present study suggest species-specific renal excretion of these chemicals.

2065

MAMMALIAN METABOLISM AND DISTRIBUTION OF PERFLUOROOCTYL ETHANOL AND ITS OXIDATION METABOLITES.

W. M. Henderson<sup>1,2</sup>, E. J. Weber<sup>2</sup>, S. E. Duirk<sup>2</sup> and M. Smith<sup>1</sup>.

<sup>1</sup>*Interdisciplinary Toxicology Program, University of Georgia, Athens, GA and <sup>2</sup>NERL, USEPA, Athens, GA.*

Perfluorinated compounds (PFCs) have been shown to be globally distributed, bioaccumulative, persistent and potentially toxic. It has been hypothesized that many precursor fluorinated compounds, including the telomer alcohols, degrade or metabolize to the common metabolite PFOA. Currently, little information is available on the mammalian metabolism of the telomer alcohols. Both  $\alpha$  and  $\beta$  oxidation pathways are proposed, resulting in the formation of perfluorononanoic acid (PFNA) and perfluorooctanoic acid (PFOA), respectively. An animal model is needed to fully elucidate the mechanisms of metabolism and translocation as it relates to humans. The objective of this study was to investigate the distribution and metabolism of the telomer alcohol in mice. Male CD-1 mice received a gavage dose of 20 mg 8-2 telomer alcohol/kg BW in a propylene glycol/water (1:1) vehicle. Animals were serially sacrificed at 1, 3, 6, 12 and 24 hours post-treatment and organs excised for PFC analysis. Telomer alcohol and metabolite concentrations were analyzed with EI-GC/MS. Based on preliminary studies, the telomer alcohol temporally decreased becoming non-detectable by 12 hours in both liver and serum. In liver, the telomer alcohol was seen at peak concentrations at 1 hour and in serum was quantifiable only at 1 and 3 hours. In serum the most abundant metabolite was PFOA with a concentration of 186-212 ng/mL at 6 hours post-treatment and decreased by 22% at 12 and 24 hours. In liver, PFOA is also the major metabolite reaching peak concentrations (38-44 ng/g) at 12 hours post-treatment. The highest concentration of PFNA coincides with peak PFOA concentrations and both metabolites decreased at 24 hours. In conclusion, the appearance of PFNA in the liver suggests that  $\alpha$  oxidation occurs although it does not appear to be the pre-

dominant metabolism pathway. However, these results suggest the telomer alcohol is metabolized by both  $\alpha$  and  $\beta$  oxidation pathways. Analysis of the brain, kidney, spleen, gonads and fat is ongoing.

### MEASUREMENT OF THYROID HORMONES IN RAT SERA CONTAINING PERFLUOROOCTANESULFONATE (PFOS).

S. Tanaka<sup>1</sup>, J. Thibodeaux<sup>2</sup>, M. Eastvold<sup>3</sup>, J. Bjork<sup>4</sup>, D. Ehresman<sup>1</sup>, R. Singh<sup>3</sup>, K. Wallace<sup>4</sup>, C. Lau<sup>2</sup> and J. Butenhoff<sup>1</sup>. <sup>1</sup>3M Company, St. Paul, MN, <sup>2</sup>USEPA, Research Triangle Park, NC, <sup>3</sup>Mayo Medical Laboratories, Rochester, MN and <sup>4</sup>University of Minnesota, Duluth, MN.

Perfluorooctanesulfonate (PFOS), a persistent and bioaccumulative acid, is widely distributed in humans and wildlife. Prior studies with PFOS (rats and monkeys) have observed decreased total and free thyroid hormones (TH) in serum without a rise in thyrotropin (TSH). Measurement of serum free TH by analog methods can result in negative bias if serum binding capacity (SBC) and serum protein-bound TH (PBTH) are reduced. We tested the hypothesis (*in vivo* and *in vitro*) that PFOS reduces SBC and PBTH, resulting in a negative bias in analog assays for free TH. *In vivo*, adult female rats (10/group) were given 3 daily oral doses of 5 mg/kg PFOS or vehicle. Sera and liver were harvested and flash frozen 24 hours after the last dose. Both chemiluminescent (CL) and RIA methods were used to measure serum total thyroxine (TT4), free thyroxine (FT4), and TSH. FT4 was also measured by equilibrium dialysis-RIA (ED-RIA), a reference method not subject to negative bias. Hepatic mRNA transcripts for malic enzyme (ME),  $\alpha$ -glycero-3-phosphate-dehydrogenase ( $\alpha$ G3PD) (both responsive to TH), and UDP-GST-1A were quantified by RT-PCR. *In vitro*, rat sera were mixed with PFOS (0-100  $\mu$ g/mL) and assayed for TT4 and FT4 (CL and ED-RIA). *In vitro*, PFOS decreased TT4 and FT4 by CL and RIA. TSH, by CL and RIA, and FT4, by ED-RIA, were comparable to controls. ME and UDP-GST-1A transcripts were elevated 20% ( $p<0.05$ ) and 38% ( $p<0.001$ ), respectively, by PFOS.  $\alpha$ G3PD transcripts were unchanged. *In vitro*, TT4 was unchanged, and FT4 was positively correlated with PFOS concentration by both CL and ED-RIA up to 32% and 89% over control, respectively, at 100  $\mu$ g/mL PFOS. Thus, PFOS in serum resulted in a negative bias in analog FT4 measurements and did not reduce either FT4 by ED-RIA or the liver response to TH. These observations suggest that prior reports of reduced free TH were artifacts of the analog methods. [This does not reflect EPA policy.]

## 2067

### PROLONGATION OF K<sup>+</sup>-INDUCED BACKWARD SWIMMING OF *PARAMECIUM CAUDATUM* BY PFOS AND PFOA.

Y. Yamazaki, K. Harada, A. Morikawa, T. Yoshinaga and A. Koizumi. *Health Environmental Sciences, Kyoto University Graduate School of Medicine, Kyoto, Japan.* *Paramecium caudatum* is a protozoan and has been used to investigate the effects of chemicals on physiological processes. When cells are transferred to a K<sup>+</sup>-rich solution, increase in Ca<sup>2+</sup> conductance by stimulation of Ca<sup>2+</sup>-channel, results in initiation of backward swimming. Cells begin whirling in consequence, when the increase in Ca<sup>2+</sup> conductance is attenuated. Thus if a given chemical has some effects on the processes of Ca<sup>2+</sup>-channel kinetics, a series of swimming behavior will be modified. In the present study, we investigated the effects of perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA) on K<sup>+</sup>-induced swimming behavior. After cultivating for four days, cells were transferred in K<sup>+</sup>-rich solution [20mM KCl, 1mM CaCl<sub>2</sub>, and 1mM Tris-HCl buffer (pH 7.2)], PFOS solutions (1, 10 and 100 ppm in K<sup>+</sup>-rich solution) and PFOA solution (1, 10 and 100 ppm in K<sup>+</sup>-rich solution) and were observed with a stereoscopy. In comparison with a period in K<sup>+</sup>-rich solution (M $\pm$ SE, sec) [25.5 $\pm$ 1.6 (n=10)], backward swimming was significantly prolonged by PFOS: 60.7 $\pm$ 8.8 at 1ppm (n=10), 162.4 $\pm$ 20.3 at 10 ppm (n=10). PFOA prolonged significantly only at 100 ppm [65.85 $\pm$ 3.0 (n=10)]. At 100 ppm PFOS was lethal and all cells died within 5 min. We further investigated the effect of a typical anionic amphiphile, sodium dodecyl sulfate: it also prolonged backward swimming at 10 ppm [317.2 $\pm$ 31.0 (n=5)]. The present study clearly demonstrated that PFOS has effects on Ca<sup>2+</sup> conductance at pharmacological dose levels likely through an action on the cellular membrane. Since the Ca<sup>2+</sup> signaling plays important roles in homeostasis, PFOS may perturb cellular functions through Ca<sup>2+</sup> signaling.

## 2068

### A SIGNIFICANTLY LARGER BIOCONCENTRATION FACTOR OF PFOS THAN THAT OF PFOA IN WILD TURTLES: THE AI RIVER ECOLOGICAL STUDY IN JAPAN.

A. Morikawa<sup>1</sup>, N. Kamei<sup>1</sup>, N. Saito<sup>2</sup>, K. Harada<sup>1</sup>, K. Inoue<sup>1</sup>, T. Yoshinaga<sup>1</sup> and A. Koizumi<sup>1</sup>. <sup>1</sup>Kyoto University Graduate School of Medicine, Kyoto, Japan and <sup>2</sup>Research Institute for Environmental Sciences and Public Health of Iwate Prefecture, Morioka, Japan.

Perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA) are ubiquitously found contaminants. We recently found that surface waters in Kinki district, are more profoundly contaminated with PFOS and PFOA than other districts in

Japan. The Ai River (located in Setsu city, Kinki district), in particular, was found to be most heavily contaminated with PFOA when compared with other reported values in the world so far. In this study, we investigated with bioconcentration factors of PFOS and PFOA in the turtles in the Ai River. Because the turtle is located in the highest rank on the food-chain in the river, this species is considered suitable for predicting biomagnifications of these chemicals through food-chain. *Trachemys scripta elegans* turtles (N=46) and *Chinemys reevesii* turtles (N=51) were captured with baited traps in the Ai River, its branch and other uncontaminated sites from September to October 2003 and from April to June 2004. Surface water samples were collected simultaneously from each site when we caught turtles. Blood samples were collected by heart puncture through the plastron. PFOS and PFOA concentrations were measured by LC/MS. Concentrations of PFOS in serum ranged from 2.4 to 486 ( $\mu$ g/L) and those in the water ranged from 2.9 to 37 ( $\mu$ g/L). The geometric mean (GM) (geometric standard deviation: GSD) of the PFOS bioconcentration factors (BCFs: Serum concentration divided by corresponding surface water concentration) was 10964 (2.5). These data indicate that PFOS is bioconcentrated at 10,000 times in the body of turtle. In contrast, the water level of PFOA ranged from 16.7 to 87100 ( $\mu$ g/L) and the serum level ranged from 0.2 to 870 ( $\mu$ g/L). The GM (GSD) of BCFs of PFOA was 3.7(7.9). Furthermore BCFs of PFOA decreased as contaminations of PFOA increased. Although the chemical structures of PFOS and PFOA are almost the same, PFOS is preferentially bioconcentrated in biota while PFOA is not.

## 2069

### ANALYTICAL METHOD VALIDATION FOR QUANTITATION OF 1, 2, 3, 4, 6, 7-HEXACHLORONAPHTHALENE FROM RAT ADIPOSE TISSUE.

P. Schebler<sup>1</sup>, K. Brackman<sup>1</sup>, K. White<sup>1</sup>, D. Messer<sup>1</sup>, J. Algair<sup>1</sup>, A. Clark<sup>1</sup>, R. Harris<sup>1</sup>, B. Jayaram<sup>2</sup> and C. Smith<sup>2</sup>. <sup>1</sup>Life Sciences Division, Midwest Research Institute, Kansas City, MO and <sup>2</sup>Environmental Toxicology Program, NIEHS, Research Triangle Park, NC.

The compound 1, 2, 3, 4, 6, 7-hexachloronaphthalene (PCN 66) has been used as a dielectric fluid in capacitors, transformers, and cables. Because of its extensive use, PCN 66 has been selected for toxicological evaluation by the NIEHS, Environmental Toxicology Program (ETP). Method development/validation was performed for PCN 66 in rat adipose tissue to support an ETP reproductive toxicology/toxicokinetics study. The method used gas chromatography with micro-electron capture detection (GC/ $\mu$ ECD). A nine-point spiked matrix curve was prepared at a PCN 66 concentration range of  $\sim$  20 to  $\sim$  4000 ng/g in matrix or  $\sim$  2.2 to  $\sim$  450 ng/mL in hexane. Each spiked tissue was extracted with 1.5 mL of hexane, then a 500- $\mu$ L aliquot of the hexane layer and 100  $\mu$ L of isodrin dissolved in hexane (internal standard solution) were transferred to a vial for analysis. The spiked matrix and corresponding solvent curves were found to be linear, with correlation coefficients  $\geq$  0.999; accurate, with recoveries ranging from 96.2 to 101.9 percent of the expected spiked concentration and 77.6 to 89.5 percent relative to the corresponding solvent standards; precise, with percent RSD for n=6 preparations of 6.0 percent at the low concentration. For PCN 66 in rat adipose tissue, the estimated LOD for the method was 0.24 ng/g, the estimated LOQ was 0.80 ng/g, and the ELOQ was 19.335 ng/g. An analysis period stability study was conducted at three concentrations,  $\sim$  219 ng/mL,  $\sim$  36 ng/mL, and  $\sim$  4 ng/mL PCN 66 in rat adipose tissue. A sample from each concentration and a blank were stored under ambient, refrigerated ( $\sim$  5 °C) and freezer ( $\sim$  -20 °C with 3 freeze/thaw cycles) conditions. The percent recoveries were: Ambient, 90.3 to 94.5 percent; Refrigerated, 91.1 to 96.5 percent; Freezer, 88.8 to 93.0 percent (high concentration), 90.3 to 97.0 percent (middle concentration), and 121.4 to 124.2 percent (low concentration). PCN was not detected in any of the blanks.

## 2070

### 14-WEEK COMPARATIVE STUDY OF 1, 2, 3, 4, 6, 7-HEXACHLORONAPHTHALENE (PCN 66) AND 1, 2, 3, 5, 6, 7-HEXACHLORONAPHTHALENE (PCN 67) IN FEMALE HARLAN SPRAGUE-DAWLEY (HSD) AND FISCHER 344 (F344) RATS.

M. Hooth<sup>1</sup>, M. Vallant<sup>1</sup>, N. Walker<sup>1</sup>, A. Nyska<sup>1</sup>, H. Toyoshiba<sup>1</sup>, R. Chhabra<sup>1</sup>, M. Ryan<sup>2</sup>, D. Vasconcelos<sup>2</sup>, M. Hejtmancik<sup>2</sup> and L. Fonby<sup>2</sup>. <sup>1</sup>ETP, NIEHS, Research Triangle Park, NC and <sup>2</sup>Battelle Columbus, Columbus, OH.

The purpose of the study was to compare the toxicity of PCN 66 and PCN 67 in female HSD and F344 rats in order to determine whether the responses are strain dependent. Formulations of PCN 66 or PCN 67 in corn oil:acetone (99:1) were administered by gavage (10 rats/group) at dosages of 0, 1000, 10, 000, 50, 000, 100, 000 and 200, 000 ng/kg for 14 weeks. Two F344 rats receiving 200, 000 ng/kg PCN 66 died before scheduled sacrifice. Mean terminal body weights were 36% lower than vehicle controls in F344 rats receiving 200, 000 ng/kg PCN 66. Body weights for the other PCN 66 groups and all PCN 67 groups were generally

within 5-10% of vehicle controls. Thyroxine ( $T_4$ ) levels were decreased in HSD rats receiving  $\geq 1000$  ng/kg PCN 66 and F344 rats receiving  $\geq 50,000$  ng/kg PCN 66. Triiodothyronine ( $T_3$ ) was decreased 44% from vehicle controls in F344 rats receiving 200,000 ng/kg PCN 66. Thyroid stimulating hormone (TSH) was increased in both strains receiving  $\geq 100,000$  ng/kg PCN 66. Administration of PCN 67 to HSD rats resulted in decreased  $T_4$  and increased TSH. Only  $T_4$  was decreased in F344 rats receiving 200,000 ng/kg PCN 67. Liver weights were increased and thymus weights were decreased in both strains receiving PCN 66 or PCN 67. Hepatocellular hypertrophy, thymic atrophy and lesions in the lymph nodes were observed in both strains receiving PCN 66 or PCN 67. Forestomach epithelial hyperkeratosis was observed in both strains receiving 200,000 ng/kg PCN 66. F344 rats in this dose group also had lesions in the blood vessels, heart and ovary. Increased hepatic EROD, A-4-H and pulmonary EROD activities were observed for both strains receiving PCN 66 or PCN 67. In conclusion, PCN 66 had greater toxicity in both strains relative to equivalent dosages of PCN 67. PCN administration generally resulted in similar target organs but the HSD rat often developed lesions at lower dosages compared to the F344 rat.

## 2071 SOURCES AND DISTRIBUTION OF POLYCYCLIC AROMATIC HYDROCARBONS IN NEW ORLEANS AND DETROIT SOILS.

G. Wang<sup>1</sup>, H. Mielke<sup>2</sup>, Q. Zhang<sup>1</sup>, P. Ma<sup>1</sup>, J. Rowden<sup>1</sup> and C. Gonzales<sup>2</sup>.

<sup>1</sup>Chemistry, Xavier University of Louisiana, New Orleans, LA and <sup>2</sup>College of Pharmacy, Xavier University of Louisiana, New Orleans, LA.

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous organic pollutants that have been found at elevated concentrations in urban environments such as air particulates, soils, and sediments. Incomplete combustion of petroleum products and coal has been identified as the primary source of high concentrations of PAHs in cities. The purpose of the study was 1) to determine and compare the concentration of PAHs in soils taken from two major US cities: New Orleans and Detroit, and 2) to examine the main sources of PAHs in urban soils by diagnostic PAH ratios. A total of 103 Detroit soil samples were taken from 6 different census tracts with 16-19 samples each per census tract. Similarly, some 107 New Orleans soil samples were analyzed for comparison, also from 6 census tracts. The mean total PAH concentration of Detroit soils was measured to be 7843 g/kg, compared to 5100 g/kg for New Orleans soils. Several diagnostic PAH concentration ratios were calculated for source determination, such as phenanthrene/[phenanthrene+anthracene] ratio (0.81 for Detroit and 0.87 for New Orleans), fluoranthene/(fluoranthene+pyrene) ratio (0.56 for Detroit and 0.55 for New Orleans), and indeno (1, 2, 3-cd) pyrene/[indeno (1, 2, 3-cd) pyrene+benzo (g, h, i) perylene] ratio (0.68 for Detroit and 0.64 for New Orleans). The ratios indicate that elevated PAH concentrations found in urban soils are attributable to contamination by pyrolytic sources, mainly automobile exhaust.

## 2072 DIOXINS AND DIOXIN LIKE COMPOUNDS FROM AGENT ORANGE AND OTHER SOURCES IN VIETNAM FROM THE 1970S TO THE PRESENT.

A. J. Schecter<sup>1</sup>, H. T. Quynh<sup>2</sup>, O. Paepke<sup>3</sup>, J. D. Constable<sup>4</sup>, K. C. Tung<sup>1</sup>, R. Malisch<sup>5</sup> and P. Fuerst<sup>6</sup>. <sup>1</sup>Environmental Sciences, University of Texas School of Public Health, Dallas, TX, <sup>2</sup>Center for Cancer Research, Hanoi, Viet Nam, <sup>3</sup>ERGO Research Laboratory, Hamburg, Germany, <sup>4</sup>Harvard Medical School, Boston, MA, <sup>5</sup>State Laboratory for Chemical and Veterinary Analysis, Freiburg, Germany and <sup>6</sup>Chemical and Veterinary Control Laboratory, Muenster, Germany.

The 2, 3, 7, 8-TCDD contaminant of Agent Orange (2, 4-D and 2, 4, 5-T phenoxyherbicides) which was heavily sprayed in parts of the south of Vietnam during wartime as a defoliant during 1962-71 was found in Vietnamese humans, wildlife and food from the 1970s to the present (2004). Levels as high at 1, 850 ppt lipid were found in milk collected in 1970 from heavily sprayed villages and as high as 400+ in blood in 2002. Very high levels were found in fish and other food in 1970s and 2004, the latter demonstrating new contamination 30-40 years after initial dioxin contamination. Elevated TCDD, as high as 1, 100, 000 ppt was found in some soil and elevation of sediment was found also. The 12 plus regions in Vietnam identified to date with elevated TCDD primarily from Agent Orange are referred to as Agent Orange hot spots. Marked variation in human and food TCDD levels are found in the same geographical areas documenting the usefulness of gc-ms analyses compared to Agent Orange spray records alone for exposure assessment. In most of Vietnam, especially in the non-sprayed north, no elevated TCDD from Agent Orange has been found. But areas with PCBs, polychlorinated dibenzofurans, HCH, and HCB in food or humans have been found. These chemicals and others such as organophosphates used in agriculture, complicate human health studies on the effects of Agent Orange (dioxin) on humans in Vietnam. New hot spots with elevated blood TCDD, Tra Noc and Binh My, will be compared to others previously discovered.

## 2073 DEVELOPMENT OF FLORIDA-SPECIFIC RISK-BASED SOIL AND GROUNDWATER CLEANUP TARGETS FOR VOLATILIZATION OF CHEMICALS INTO INDOOR AIR.

E. M. Tufariello<sup>1</sup>, C. M. Saranko<sup>1</sup>, R. Ettinger<sup>2</sup>, S. M. Roberts<sup>3</sup> and J. K. Tolson<sup>1</sup>. <sup>1</sup>Geosyntec Consultants, Tampa, FL, <sup>2</sup>Geosyntec Consultants, Santa Barbara, CA and <sup>3</sup>University of Florida, Gainesville, FL.

Volatile chemicals beneath buildings can diffuse through soil air-spaces and enter building through foundation cracks. The vapor intrusion pathway accounts for the migration of chemicals from subsurface soils and groundwater into overlying buildings. Vapor intrusion is influenced by factors that vary regionally, such as soil moisture content, depth to groundwater, soil temperature, and soil type. Florida may pose a higher concern for vapor intrusion as the State has many conditions favorable for higher vapor intrusion rates (shallow groundwater table, warm average groundwater temperature, and sandy soils). We report the development of soil and groundwater levels protective of the vapor intrusion pathway for chemicals on the Florida's cleanup targets levels (CTLs) list that meet a primary screening criterion for potential volatility and toxicity specified by the USEPA (i.e., Henry's Law constants  $>1E-5$  and vapor concentration of pure phase chemical that poses excess lifetime cancer risk  $>1E-6$  or a hazard quotient  $>1.0$ ). The EPA's version of the Johnson and Ettinger Model was used to evaluate the vapor intrusion pathway. Florida-specific inputs were developed from a soils database for soil bulk density, moisture content, and soil hydraulic conductivity. State-specific information on groundwater table depth, soil temperature, and building characteristics were also used. Our analysis demonstrates that several of chemicals evaluated have CTLs based on the vapor intrusion pathway that are significantly lower than the default residential CTLs for soil and groundwater based on direct exposure. The difference in CTLs is even more significant when vapor intrusion CTLs are compared to Florida's natural attention values, which are based on 10- or 100-fold multipliers of the default CTLs. Vapor intrusion may be an important consideration when contemplating cleanup of contaminated soils beneath buildings at sites in Florida.

## 2074 A ROBUST ALGORITHM FOR CALCULATING OPTIMAL 95% UCLS ON THE MEAN FOR ENVIRONMENTAL DATASETS.

J. K. Tolson<sup>1</sup>, C. J. Saranko<sup>1</sup>, S. M. Roberts<sup>2</sup> and K. M. Portier<sup>2</sup>. <sup>1</sup>Geosyntec Consultants, Tampa, FL and <sup>2</sup>University of Florida, Gainesville, FL.

The upper 95% confidence limit on the mean (95% UCL) is often used as an upper-bound estimate of average contaminant concentration for risk assessments at hazardous waste sites. Numerous statistical methods are available for the calculation of 95% UCLs, however, the choice of the most appropriate statistical test to use in specific situations is not straightforward. Also complicating the decision are sample data that contain a number of values below the detection limit. In the present analysis, we have systematically evaluated the performance of several 95% UCL and censoring techniques using simulated distributions with known population parameters. The UCL methods evaluated were: central limit theorem (CLT), standard bootstrap, bootstrap-t, Students-t, H-statistic (Land's method), MVUE and MLE based, and Chebyshev's methods. The effects of left censoring were evaluated by replacement, parameter estimation, bounding and regression techniques. For each method, 95% UCLs were calculated for simulated datasets of different sample sizes, skewness, and extent of left censoring. By comparing the 95% UCLs with the underlying simulation expected value, the coverage of each technique (i.e., the proportion of times the true population mean lies at or below the 95% UCL) was evaluated. The extent to which the true mean was overestimated by the 95% UCL for each technique was also determined. Based on the results of this analysis, a software tool (FLUCL - Florida UCL Calculator) was created that includes a decision matrix that uses information on sample size, skewness, and degree of censoring to select the optimal UCL technique for site-specific datasets.

## 2075 THE EFFECT OF USING MULTIPLE CONTAMINANT 95% UCLS ON CUMMULATIVE RISK ESTIMATES.

C. J. Saranko, E. M. Tufariello and J. K. Tolson. Geosyntec Consultants, Tampa, FL.

Soil risk assessment guidance from the USEPA and many States recommend the calculation of exposure point concentrations (EPCs) for chemicals of concern based on 95% upper confidence limits (95% UCLs) of the average concentrations within specified exposure units. These EPCs are used to calculate cancer and non-cancer risk estimates for each chemical of concern, which are summed to provide a cumulative excess lifetime cancer risk for carcinogens and a cumulative hazard index (HI) for non-carcinogens for each receptor. A potential flaw in this methodology is that 95% UCLs are not strictly additive in this fashion. As a result, this practice may yield cumulative risk and hazard estimates that are more conservative than the regulatory risk goals (i.e., 1E-6 or HI of 1.0) when multiple chemicals of concern are

present. Similarly, some states require that default risk-based cleanup criteria that are individually based on a defined risk target (i.e., 1E-6), be apportioned (i.e., lowered) when multiple chemicals of concern are present, such that the cumulative risk and/or hazard do not exceed the defined targets. We investigated this scenario by analyzing the effect of combining 95% UCLs from various synthetic lognormally distributed datasets of sizes from 10 to 30 with levels of correlation among the data of 0, 25, 50, and 75%. The simulations (10,000 per run) were performed in Crystal Ball for combinations of 1 to 10 chemicals. The input chemical concentrations were adjusted so that the expected risk levels for each combination of chemicals were held constant. Results indicate that combining upper confidence limits, even for highly correlated data, introduces additional conservatism in the final risk estimates. Similar issues exist for the summation of risks calculated from cancer slope factors, which are also upper percentile estimates. These observations suggest that methodology for summing chemical-specific risks should account for the number of chemicals present and the degree of correlation among the chemical concentrations.

## 2076

### EVALUATION OF THE PREDICTIVITY OF A FISH UPTAKE MODEL FOR MERCURY USING EMPIRICAL DATA.

R. P. Brellenthin<sup>1</sup>, J. K. Tolson<sup>1</sup>, K. Kessler<sup>2</sup> and C. J. Saranko<sup>1</sup>. <sup>1</sup>Geosyntec Consultants, Tampa, FL and <sup>2</sup>Geosyntec Consultants, Atlanta, GA.

An ecological risk assessment was conducted for a former industrial facility located on a coastal estuary where mercury associated with historical industrial operations was released to environmental media including surface water and sediment. The viability of finfishes utilizing the estuarine system was identified as an assessment endpoint for the ERA. The body burden of methyl mercury in Red Drum (*Sciaenops ocellatus*) was identified as a specific measurement endpoint. During the field investigation, no Red Drum were collected from areas of the estuary most impacted by mercury contamination. As a result, regulators required a modeling approach based on the "Lavaca Bay" model (Evans and Engel, 1994) to address this measurement endpoint. This model can be used to estimate the body burden of methyl mercury in Red Drum based on concentrations of total mercury in sediment and surface water. The primary pathway for methylmercury exposure in the model is transfer and bioaccumulation in the aquatic food web. The model calculates a bioaccumulation factor (BAF) that represents the ratio of the uptake of methyl mercury from prey and its reduction via excretion and growth. This BAF is multiplied by the methyl mercury concentration in the diet to yield a concentration of methyl mercury in the Red Drum. For application at this site, the original model was modified so that the modeled concentrations of methyl mercury in prey items were replaced by measured concentrations of methylmercury in killifish, fiddler crabs, and blue crabs collected from the site. The following year Red Drum, Black Drum, and several other species of finfishes were collected and analyzed for methyl mercury. Measured concentrations of methyl mercury in the tissues of red and black drum were approximately 3 to 5 fold lower than modeled estimates using measured prey concentrations. The same measured concentrations were approximately 20 to 35-fold lower than the modeled estimates based on total mercury concentrations in sediment and surface water.

## 2077

### RETROSPECTIVE SCREENING-LEVEL HUMAN HEALTH RISK ASSESSMENT FOR RECREATIONAL EXPOSURE TO CONTAMINATED SEDIMENT.

P. Welsh, M. Pagliarulo and D. A. Manca. Standards Development Branch, Ontario Ministry of the Environment, Toronto, ON, Canada.

A retrospective screening-level human health risk assessment (SL-HHRA) was conducted to evaluate past exposure and assess potential risk to sensitive receptors from recreational exposure to contaminated sediment in a medium sized river. The purpose of this SL-HHRA was to determine if there are any potential human health concerns resulting from past or present exposure to contaminated sediment at this site. The SL-HHRA did not address future conditions as remediation activities are planned that will disrupt viable exposure pathways. The area of interest is characterized by two large floating docks projecting away from the shoreline into an inner harbour region of the river. These docks are primarily used for boat access by rowers associated with a local rowing club. Club members are generally adult and teen rowers, but also include youth aged 10 and over. Swimming and other types of recreational water activities (e.g., wading, fishing) are rare. Contaminants of concern (COCs) were identified by comparing maximum concentrations measured in the sediment to generic soil screening guidelines. PCBs, Sb, As, Be, Fe, Pb, and benzo(a)pyrene were identified as COCs. Exposure to COCs was estimated for model receptors, representing avid club members and summer youth camp members, for the entire period during which the rowing club has been in operation (26

years). Dermal contact with contaminated sediment and incidental ingestion of sediment suspended in water were identified as relevant exposure pathways. Potential health effects were determined by comparing the predicted intake of COCs to appropriate toxicity reference values developed by health-based regulatory agencies for oral exposure (e.g., USEPA, RIVM). Dermal intake was evaluated by correcting for relative absorption via the dermal route. Predicted exposure to COCs from dermal contact and ingestion of contaminated sediment was relatively low and unlikely to result in any adverse health effects (HQ < 1; negligible excess cancer risk).

## 2078

### PROVISIONAL REFERENCE DOSE FOR THE AROMATIC FRACTION OF JET FUEL: REASSESSMENT OF FRACTION RISK AND IMPACT ON RISK BASED CLEANUP LEVELS.

T. R. Sterner<sup>1</sup>, D. J. Vorhees<sup>2</sup>, D. R. Mattie<sup>3</sup>, D. A. Reed<sup>1</sup> and W. H. Weisman<sup>4</sup>. <sup>1</sup>OpTech Corp., Dayton, OH, <sup>2</sup>Menzie-Cura & Assoc., Inc., Winchester, MA, <sup>3</sup>AFRL/HEPB, Wright-Patterson AFB, OH and <sup>4</sup>HQ AF/SGOP, Bolling AFB, DC.

In 1993, the Total Petroleum Hydrocarbon Criteria Working Group (TPHCWG) began developing a practical alternative to non-risk based cleanup standards for petroleum hydrocarbon contaminated sites. The TPHCWG defined all petroleum mixtures as thirteen effective carbon (EC) number range fractions based on expected environmental transport characteristics. EC numbers are derived from relative n-alkane gas chromatograph retention times. By 1997, the TPHCWG had developed preliminary toxicity criteria for each fraction using all available data, prioritizing mixture toxicity information. However, acceptance of such fraction-based approaches for petroleum risk assessment was hampered by the general lack of toxicity data, especially for some fractions. Specifically, few toxicity data were available for the EC<sub>>8</sub> - EC<sub>16</sub> aromatic fraction, which is likely one of the more toxic fractions. To address this data gap, a 90-day oral gavage toxicity study was conducted in female Sprague-Dawley rats and male C57BL/6 mice to characterize the potential toxic effects of the EC<sub>>8</sub> - EC<sub>16</sub> aromatic fraction of Jet Fuel A. Animals were dosed at 0, 20, 100 and 500 mg fraction/kg daily. The no observed adverse effect level (NOAEL) for the mixture was 20 mg/kg/day, based on blood chemistry and behavioral changes at middle and high dose groups in both rats and mice, and enlarged livers in the high dose groups of rats. This NOAEL was used as the point of departure for estimating a preliminary reference dose of 0.02 mg/kg/day for the fraction. When considered with the weight of evidence of toxicity information for individual compounds and mixtures in the fraction, this fraction study and resulting preliminary reference dose help strengthen confidence in the database for the EC<sub>>8</sub> - EC<sub>16</sub> aromatic fraction. This reanalysis should provide a greater acceptance of Tier 1 risk based cleanup levels at petroleum hydrocarbon contaminated sites.

## 2079

### DESIGNATION OF NAPHTHALENE AS A CARCINOGEN: RISK ASSESSMENT FOR INHALATION EXPOSURE PATHWAYS AT HAZARDOUS WASTE SITES.

J. P. Christopher, J. M. Polisini, B. K. Davis and M. J. Wade. Department of Toxic Substances Control, California Environmental Protection Agency, Sacramento, CA.

California EPA has designated naphthalene as a carcinogenic toxic air contaminant with a unit risk factor of 3.4 E-5 (ug/m<sup>3</sup>)-1. Naphthalene is a common pollutant in urban outdoor air. It is found in a number of products, notably diesel and other petroleum-based fuels. We present here a comparison of the impacts of naphthalene and benzene at a hazardous waste site (Site A) in California, where shallow groundwater is contaminated with wastes from refining petroleum and producing manufactured gas. Groundwater at 6-8 ft below ground surface contains benzene and naphthalene at concentrations up to 300 and 3,000 ug/L, respectively. The Johnson & Ettinger vapor intrusion screening model, using groundwater as a source and assuming a vadose zone of coarse sandy soil, predicts indoor air concentrations of 30 ug/m<sup>3</sup> for benzene and 17.4 ug/m<sup>3</sup> for naphthalene. The somewhat lower modeled mobility of naphthalene into indoor air is due to its lower vapor pressure and water solubility, compared to benzene. The Cal/EPA unit risk factor for benzene is 2.9 5 (ug/m<sup>3</sup>)-1, similar to that of naphthalene. Thus, concentrations of naphthalene ten times those of benzene in shallow groundwater yield similar estimates of cancer risk in indoor air in a residential setting (3.6 E-4 vs. 2.4 E-4). The USEPA Reference Concentration (RFC) for benzene is ten times higher than that of naphthalene (30 ug/m<sup>3</sup> vs. 3 ug/m<sup>3</sup>), which yields hazard quotients for non-carcinogenic toxicity of 1 for benzene and 6 for naphthalene for exposures to modeled concentrations in indoor air above Site A. Although naphthalene is less easily mobilized than benzene into indoor air than monoaromatic compounds such as benzene, the relatively high unit risk factor and RFC for naphthalene will probably increase its significance as a groundwater contaminant.

## INORGANIC CHEMICALS IN GROUND WATER AND SOIL: BACKGROUND CONCENTRATIONS AT CALIFORNIA AIR FORCE BASES.

P. M. Hunter<sup>1</sup>, B. K. Davis<sup>2</sup> and F. Roach<sup>3</sup>. <sup>1</sup>Center for Environmental Excellence, Air Force, San Antonio, TX, <sup>2</sup>Toxic Substances Control, Cal EPA, Sacramento, CA and <sup>3</sup>Frontline Systems, Inc., San Antonio, TX. Sponsor: J. Christopher.

Inorganic chemicals have widespread industrial use and are significant contaminants. Risk assessment and risk management must differentiate between background (naturally occurring) and anthropogenic inorganic chemicals. This is important for site characterization, determining chemicals of concern, establishing cleanup levels, and long-term monitoring programs. This paper is an update of our 2001 report on background. The Air Force ERPIMS database was searched for uncontaminated sample locations for soil and ground water at 12 Air Force installations in 10 California counties. Background data for 27 inorganic constituents from 1300 monitoring well locations yielded as many as 4890 ground water samples for individual chemicals, while 3850 boreholes yielded as many as 12,000 soil samples. Medians, 95th, and 99th percentiles are reported for each chemical. Since statistical analysis of soil data indicated that background levels differed significantly with depth, separate background calculations for soil are presented for three depths (less than 3 feet, between 3 and 15 feet, and greater than 15 feet). For groundwater, background statistics for each constituent are given without regard to sampling depth. Some inorganic constituents were detected frequently and at levels that exceed important environmental thresholds such as Maximum Contaminant Levels (MCLs) or Action Levels for drinking water. Background 95th percentile levels equal or exceed federal and/or California MCLs for aluminum, antimony, arsenic, cadmium, chromium, and nickel. The 95th percentile level for lead exceeds the Action Level of 0.015 mg/L for drinking water measured at the tap. This analysis provides background levels that are representative of California Air Force Bases as a group. The background data in this presentation should not be used to replace local background data, but rather provide important benchmarks by which the adequacy of local data can be judged.

## SCREENING FOR POTENTIAL HEALTH RISKS FOLLOWING ACUTE EXPOSURE TO HEAVY METALS IN SOIL AT A FORMER MINING SITE.

M. Pagliarulo and D. A. Manca. Standards Development Branch, Ontario Ministry of the Environment, Toronto, ON, Canada.

A screening-level health risk assessment (SLHRA) was conducted to evaluate potential health risks to visitors acutely exposed to inorganic chemicals in soil at a former mining site. While SLHRAs are generally used to indicate the absence of potential health problems, in the present study this model was used 1) to qualify the likelihood of potential health risks and 2) to support the development of risk management strategies without resorting to a comprehensive and resource-intensive site-specific health risk assessment. Since soil concentrations of various contaminants were substantially higher than current soil guidelines, the SLHRA was conducted using the contaminant presenting the greatest potential for acute health effects. Arsenic (As) was selected based on the highest "soil concentration to soil guideline" ratios at most sampling locations. Two acute reference doses were derived for As in order to assess potential acute health effects to the general population (based on acute human poisoning data) and to pregnant women (based on animal embryotoxicity data). Central tendency (CT) and reasonable maximum exposure (RME) scenarios were developed for receptors of various age groups and pregnant women. Hazard Indexes (HI) were then computed for various As soil concentrations. The SLHRA identified potential effects from acute exposure to As at most sampling locations (RME: HI=1-10 for soil As of 20-200 ppm; CT: HI=1-10 for soil As of 100-1000 ppm). Pregnant women and toddlers (7 mo. - 4 yr.) were identified as the most sensitive receptors. Incidental ingestion and dermal contact were the most relevant exposure routes/pathways. Although numerous uncertainties are generally associated with screening approaches, integration of additional parameters in the current study provides a reasonable degree of confidence that acute health effects would be experienced by visitors at the former mining site, lending support to the development of risk management strategies.

## RISK ASSESSMENT FOR IRON: USING THE INSTITUTE OF MEDICINE'S TOLERABLE UPPER INTAKE LEVEL AS A SURROGATE TOXICITY VALUE FOR IRON.

M. L. Stifelman<sup>1</sup>, L. Ingberman<sup>2</sup>, W. C. Thayer<sup>2</sup> and G. L. Diamond<sup>2</sup>. <sup>1</sup>USEPA, Seattle, WA and <sup>2</sup>Syracuse Research Corporation, Syracuse, NY.

The USEPA has not prepared an iron toxicity value for risk assessment in the Integrated Risk Information System (IRIS). Iron is a frequent cause of acute pediatric poisonings caused by overdoses of iron supplements. Chronic health effects from iron are less well established, but may include an increased risk of cardiovas-

cular disease. As an essential nutrient, iron risks must be assessed for both sufficiency and toxicity. Based on an analysis of NHANES III, iron deficiency affects 10-20% of US reproductive-aged women, with deficiencies twice as severe in blacks and Mexican-Americans compared with white, non-Hispanics. In setting the dietary reference intakes for iron, the Institute of Medicine (IOM) has examined the nutritional needs and toxicity of iron and has derived age, gender, and life-stage specific recommended daily allowances (RDAs) and tolerable upper intake level (ULs). The IOM defines a UL as "The highest average daily nutrient intake level that is likely to pose no risk of adverse health effects to almost all individuals in the general population." The adult UL of 45 mg per day was based on gastro-intestinal upset following daily administration of a 60 mg iron fumarate supplement, plus 10 mg from diet, divided by an uncertainty factor of 1.5. In the same study, heme iron supplements caused GI symptoms similar to the placebo controls. The UL is the basis for a risk assessment dose of 0.6 mg/kg-day. This dose meets the RDA for iron for all groups (RDA range is: 0.1-0.6 mg/kg-day) and protects against acute gastrointestinal symptoms. An intake of 0.6 mg/kg-day corresponds approximately to the 50<sup>th</sup> percentile children aged 1-5 and the 95<sup>th</sup> percentile of adults based on an analysis of NHANES III and FDA TDS. This dose may not be protective for individuals suffering from congenital iron metabolism disorders, such as hemochromatosis. This recommendation is consistent with the USEPA toxicity hierarchy which recommends using publicly available, peer-reviewed studies if an IRIS value is not available.

## DETERMINING SOIL REMEDIAL ACTION CRITERIA FOR ACUTE EFFECTS: THE CHALLENGE OF COPPER.

M. Seeley, C. S. Wells, S. Ren and B. D. Beck. Gradient Corporation, Cambridge, MA.

Soil in the vicinity of copper smelters may contain copper at concentrations that are sufficiently elevated to pose a potential health risk, particularly to young children. Nausea, the primary acute effect of copper, paradoxically occurs at lower exposure levels than hepatotoxicity, the primary chronic effect. Therefore, our aim was to develop a method to determine a soil remedial action criterion (RAC) for copper that would protect against nausea for children living nearby a copper smelter. Nausea due to copper ingestion appears to be primarily a function of copper concentration in the stomach, and generally subsides within an hour. We used Monte Carlo analysis to generate a distribution of hourly RACs for copper based on the amount of soil ingested per hour, the volume of liquid and food in the stomach, and site-specific bioaccessibility. Using this distribution, we identified RACs associated with a high probability of not having nausea in an hour. However, it is more relevant to determine a RAC protective of nausea for a longer time period, such as a year. We therefore generated a new distribution of daily RACs, selected as the minimum hourly RAC constrained by total daily soil ingestion for each day. We then used combinatoric analysis to identify a percentile of the distribution of daily RACs, and the associated RAC, that would result in a high probability of having a minimal number of nausea episodes in a year. Selection of the actual RAC is a risk management decision, based on the number of nausea episodes considered acceptable, and the desired probability that individuals would not exceed that number of episodes. For example, considering the reversibility and relatively mild nature of nausea, it might be acceptable to set a cleanup level based on a 95% probability of having fewer than 10 episodes of nausea per year. Assuming that a child would be exposed to soil for 6 months of the year, as would be typical in a cold climate, our analysis indicates a copper concentration of 4,700 mg/kg would result in a 95% probability of having fewer than 10 episodes of nausea per year.

## PERCUTANEOUS ABSORPTION OF ARSENIC FROM ENVIRONMENTAL MEDIA.

Y. Lowney<sup>1</sup>, M. V. Ruby<sup>1</sup>, R. C. Wester<sup>2</sup>, R. A. Schoof<sup>3</sup>, S. E. Holm<sup>4</sup> and H. I. Maibach<sup>2</sup>. <sup>1</sup>Exponent, Inc., Boulder, CO, <sup>2</sup>University of California, San Francisco, CA, <sup>3</sup>Integral Consulting, Inc., Mercer Island, WA and <sup>4</sup>Georgia Pacific Corporation, Atlanta, GA.

Current knowledge of percutaneous absorption of arsenic is based on studies of Rhesus monkeys using soluble arsenic in aqueous solution, and soluble arsenic mixed with soil (Wester et al. 1993). These studies produced mean dermal absorption rates in the range of 2.0% to 6.4% of the applied dose. Subsequently, questions arose as to whether these results represent arsenic absorption from environmental media. Factors such as chemical interactions, the presence of other metals, and the effects of weathering on environmental media all can affect the nature of arsenic and its potential for percutaneous absorption. This *in vivo* study used the monkey model and methods similar to those of Wester et al. to assess dermal arsenic absorption from environmental media; specifically, environmental soil, and residue on the surface of wood treated with chromated copper arsenate (CCA). Study design considerations included particle size, application rates, means of ensuring skin contact, and appropriate statistical evaluation of the data. This study also included an appli-

cation of arsenic in solution to allow calibration of the model against prior research and to compare to absorption of arsenic from the environmental media. The potential for background exposure to arsenic in the diet possibly obscuring a signal from a dermally applied dose of arsenic was also addressed. Results indicate that the urinary arsenic excretion levels in the animals exposed to arsenic in soil or CCA residue are not elevated above background. Conversely, urinary arsenic excretion in animals exposed to soluble arsenic in solution is significantly greater than background, and greater than the soil and residue exposure groups. We conclude that percutaneous absorption of arsenic from environmental media is negligible compared to soluble arsenic and soluble arsenic mixed with soil. This study is consistent with previous work and suggests that dermal arsenic absorption is not a risk factor for the media tested.

### THE ROLE OF METHYLATED METABOLITES IN INORGANIC ARSENIC-INDUCED CANCER: A SYNTHESIS OF INFORMATION FROM *IN VITRO* AND HUMAN BIOMONITORING STUDIES.

A. Schoen and B. Beck. *Gradient Corporation, Cambridge, MA*.

The precise mechanisms by which inorganic arsenic induces cancer in humans are not well established. As part of efforts to identify a carcinogenic moiety for inorganic arsenic, recent research has focused on the methylated metabolites of inorganic arsenic. Pentavalent methylated metabolites of inorganic arsenic, monomethylarsonic acid (MMAV) and dimethylarsinic acid (DMAV), are relatively non-toxic. Recent *in vitro* research suggests that methylated trivalent arsenic metabolites (i.e., monomethylarsonous acid [MMAIII] and dimethylarsinous acid [DMAIII]) induce comparable or greater cytotoxicity than inorganic arsenic, and may be indirect-acting genotoxins. Using available literature, we analyzed the potential role for methylated arsenic compounds in inorganic arsenic human cancers. This analysis considered results from human epidemiological and biomonitoring studies as well as results from *in vitro* studies. Our evaluation revealed that relatively high concentrations of urinary DMAV (compared to urinary MMAV) were associated with lower disease incidence in populations exposed to inorganic arsenic in drinking water. Due to limitations in study designs and uncertainties in analytical methods for the trivalent metabolites, it is difficult to draw a firm conclusion regarding the relationship between levels of trivalent methylated metabolites in urine and cancer. *In vitro* studies conducted in human and animal cell lines do not support an association between methylation capacity and inorganic arsenic-induced cytotoxicity and transformation. For example, UROtsa cells, a human urothelial cell line that lacks the capacity to methylate arsenic, transforms after incubation with inorganic arsenic. In addition, inorganic arsenic, but not methylated arsenic compounds, induce carcinogenic changes in human keratinocytes and osteosarcoma cells. Our analysis suggests that while the trivalent methylated arsenic compounds are of toxicological interest, there is sufficient evidence to conclude that these compounds do not fully explain the carcinogenicity of inorganic arsenic.

### TOXICOLOGICAL EVALUATION OF 1, 1, 1-TRICHLOROETHANE AND RESULTING MINIMAL RISK LEVELS.

H. Abadin<sup>1</sup>, D. Moffett<sup>1</sup>, A. Dorsey<sup>1</sup>, C. Smith<sup>1</sup> and D. Wohlers<sup>2</sup>. <sup>1</sup>*Agency for Toxic Substances and Disease Registry, Atlanta, GA* and <sup>2</sup>*Environmental Science Center, Syracuse Research Corporation, Syracuse, NY*. Sponsor: B. Fowler.

1, 1, 1-Trichloroethane has been used in many industrial and household applications. Although regulatory actions are in place for an eventual phase-out, production was as high as 500 million pounds in 2002. The central nervous system (CNS) is the most sensitive target for trichloroethane toxicity. Clinical signs of toxicity following high-level exposures include CNS depression, hypotension, cardiac arrhythmia, diarrhea, vomiting, mild hepatic effects, and dermal and ocular irritation. Lower-dose exposures result in more subtle neurological effects such as impaired performance in tests designed to measure variables like manual dexterity, eye-hand coordination, perceptual speed, and reaction time. An acute-duration (? 14 days) inhalation minimal risk level (MRL) of 2 parts per million (ppm) was derived from a study by Mackay et al. (1987) that identified reduced psychomotor performance in humans exposed to 175 ppm for 3.5 hours. Observed performance changes correlated with 1, 1, 1-trichloroethane blood levels. A review of the intermediate-duration (15-364 days) database resulted in the selection of a gerbil study (Rosengren et al. 1985) for MRL development. Rosengren et al. (1985) observed astrogliosis in gerbils exposed to 210 and 1, 000 ppm; an inhalation MRL of 0.7 ppm was derived based on the no-observed-adverse-effect level of 70 ppm. The database for oral exposure to 1, 1, 1-trichloroethane is more limited. A National Toxicology Program feeding study was used to derive an intermediate-duration oral MRL of 20 mg/kg/day for decreased final body weight in B6C3F1 mice exposed for 13 weeks. While body weight is not an optimal endpoint, it is supported by a number of

other studies. These MRLs are also presented and discussed in the Agency for Toxic Substances and Disease Registry's toxicological profile for 1, 1, 1-trichloroethane that was released for public comment in October 2004.

### PEAK EXPOSURE AND KINETICS OF TOLUENE IN MAN INCLUDING PBTK MODELLING EVALUATION.

J. Bessems, A. Freidig, W. Meuling and J. Lammers. *Food and Chemical Risk Analysis, TNO Chemistry, Zeist, Netherlands*. Sponsor: V. Feron.

Occupational exposure to VOC (volatile organic compounds) is often characterised by alternating periods of low and high concentrations (even up to tenfold the TWA-TLV value). Exposure peaks may be reflected in dosimetry and in hazardous effects of VOC. If so, both should be taken into account in determination of a STEL (short-term exposure limit). To assess this, male volunteers were exposed by inhalation to 40 ppm toluene constant (Netherlands TWA-TLV) for 4 h (CONS) and to three peaks of 110 ppm for 0.5 h within 4 h (PEAK), such as that the external dose was similar for both exposure scenarios. Blood toluene concentrations (BTOL) and urinary *o*-cresol excretion rates (OCR) as well as some neurobehavioral parameters were measured. PBTK (physiologically based toxicokinetic) modelling was assessed as to the potential to predict effects of peaks and interindividual variation on dosimetry and as potential tool for incorporating these in STEL setting methodology. In CONS, BTOL increased with time whereas in PEAK, external peaks were reflected by fluctuating BTOL, the highest BTOL being measured at the end of the third peak. Both exhibited washout in approximately 2 h. The average  $AUC_{app}$  of toluene in blood was rather similar in both scenarios, the average  $C_{max}$  value was about 50% higher in PEAK. OCR were substantially higher in PEAK only in the urine excreted directly after exposure, not during exposure. In addition, more than 2-fold and 5-fold interindividual differences in BTOL and OCR were observed, respectively. Some neurobehavioral differences were observed between PEAK and CONS, but their toxicological significance is doubted. Average BTOL were well predicted by PBTK simulations. The model appeared mainly sensitive to changes in  $V_{max}$  and  $K_M$  as well to changes in blood flow to fat and liver. Their heterogeneity in the human population is often known and can be modelled easily. Conclusively, PBTK modelling may be a useful tool in evaluating the value of the toxicokinetic component of the intraspecies uncertainty factor as well as in improved, data-based determination of a STEL.

**2088**

### A META-ANALYSIS OF NEUROBEHAVIORAL DEFICITS FROM LONG-TERM EXPOSURE TO STYRENE.

W. K. Boyes<sup>1</sup>, A. M. Geller<sup>1</sup>, P. J. Bushnell<sup>1</sup>, G. M. Woodall<sup>2</sup> and V. A. Benignus<sup>1</sup>. <sup>1</sup>*NHEERL, USEPA, Research Triangle Park, NC* and <sup>2</sup>*NCEA, USEPA, Research Triangle Park, NC*.

Long-term exposure to styrene is associated with a variety of effects on the nervous system in individual reports from the scientific literature. We have pooled the suitable data from these reports and conducted a meta-analysis in order to evaluate dose-effect relationships across the body of available information. Exposure levels were estimated from a meta-analysis of information relating the concentration of urinary biomarkers to air styrene concentrations. Neurobehavioral outcomes providing a sufficient number of studies for evaluation included simple reaction time (SRT), choice reaction time (CRT) and color perception expressed as the color confusion index (CCI). The data from individual reports were pooled into a single database for each endpoint. The outcome measurements were transformed to a common metric (percent of baseline). Dose-effect relationships were modeled with linear least-squares equations relating styrene exposure to each outcome variable. Statistically-significant relationships were observed between cumulative styrene exposure (expressed as ppm-years) and increased CRT, and also between cumulative styrene exposure and increased CCI. Eight work-years of exposure to 20 ppm styrene was estimated to produce a 6.5% increase in CRT, a slowing of reaction time which has been shown to significantly increase the probability of automobile accidents. The same exposure history was predicted to produce an increase in CCI equivalent to 1.7 additional years of age in men. (This abstract does not necessarily reflect EPA policy).

**2089**

### ROUTE-DEPENDENT EFFECTS OF TOLUENE ON SIGNAL DETECTION BEHAVIOR IN RATS.

P. J. Bushnell<sup>1</sup>, T. E. Samsam<sup>1</sup>, W. M. Oshiro<sup>1</sup>, C. R. Eklund<sup>2</sup> and M. V. Evans<sup>2</sup>. <sup>1</sup>*NHEERL/INTD, USEPA, Research Triangle Park, NC* and <sup>2</sup>*NHEERL/ETD, USEPA, Research Triangle Park, NC*.

The acute effects of toluene and other solvents on behavior are thought to depend upon their concentration in the brain. We have shown previously that inhaled toluene and trichloroethylene disrupt sustained attention in rats as assessed with a

visual signal detection task (SDT). To test the hypothesis that acute toxicity of solvents is mediated exclusively by their internal dose, and to develop a dosing regimen not requiring inhalation equipment, we explored the efficacy of toluene given by the oral route on this task. Toluene was dissolved in corn oil and administered to 25 adult male Long-Evans rats by gavage at doses of 0, 400, 800, 1200, and 1600 mg/kg in two separate studies. Two rats in each study failed to work at the highest dose; toluene did not significantly affect performance of the other rats at any dose. Internal doses of toluene (concentrations in blood and brain) at the times of behavioral assessment were estimated for both exposure routes. Concentrations of toluene in the blood after oral dosing were estimated from published data in the literature, and concentrations in blood and brain during inhalation were estimated using a physiologically-based toxicokinetic (PBTK) model developed in our laboratory. Whereas the effects of inhaled toluene on the SDT (accuracy of signal detection and response time) were monotonically related to the concentration of toluene in blood and in brain, SDT performance was not affected by oral toluene, despite nearly-complete overlap in the range of internal doses produced by the two routes of administration (10 to 50  $\mu$ g/mL in blood). These observations indicate that the momentary concentration of toluene in the brain is an insufficient dose metric for explaining its effects on signal detection behavior, and complicate route extrapolations based on this dose metric. Hypotheses regarding these route-dependent effects are explored in an accompanying poster (Samsam et al.) [This abstract of a proposed presentation does not reflect EPA policy.]

## 2090 WHY DO THE ACUTE BEHAVIORAL EFFECTS OF TOLUENE IN RATS DEPEND ON THE ROUTE OF EXPOSURE?

T. E. Samsam, W. M. Oshiro and P. J. Bushnell, *NHEERL/NTD, USEPA, Research Triangle Park, NC*.

Despite evidence suggesting that the acute effects of organic solvents are related to their concentration in the brain, we have observed route-dependent differences in the acute behavioral effects of toluene. Whereas inhaled toluene disrupts the performance of rats on a visual signal detection task (SDT) that assesses sustained attention, toluene given orally in corn oil does not, even with similar concentrations in the blood (see Bushnell et al.). Several studies in adult male Long-Evans rats were conducted to determine the source of these route differences. Exp. 1 showed that the time course of the rise in toluene concentrations in blood and brain of rats inhaling 2000 ppm toluene (an effective treatment) matched that of rats given 800 mg/kg of toluene in corn oil by gavage (an ineffective treatment). Further experiments used rats previously trained to perform the SDT. Exp. 2 showed that the pre-test exposure interval (10 m vs. 30 m) did not account for the route difference, and Exp. 3 showed that co-administration of oral corn oil and inhaled toluene did not reduce the effect of toluene. Exp. 4 showed that oral administration of sodium benzoate, a toluene metabolite, did not reduce the effect of inhaled toluene. Exp. 5 showed that oral trichloroethylene (TCE) in corn oil (1200 mg/kg), which yields concentrations of TCE in blood of 10 to 30  $\mu$ g/mL (Prout et al., 1985), caused slight impairment on the SDT, relative to previous observations of robust effects of inhaled TCE with blood concentrations of 50 to 125  $\mu$ g/mL. Exp. 6 examined the effects of oral toluene given in a lipophilic but non-absorbable sucrose-esterified fatty acid complex (SEFA soyate). Further experiments will look at the role of physical activity on the kinetics of inhaled and orally-delivered toluene and on the generality of this route dependence across functional endpoints. These findings address the appropriateness of route-route extrapolations in setting reference toxicity values. [This abstract of a proposed presentation does not necessarily reflect EPA policy.]

## 2091 ASSESSING THE IMPORTANCE OF THE BEHAVIORAL EFFECT OF ACUTE EXPOSURE TO TOLUENE IN HUMANS.

V. A. Benignus<sup>1,2</sup>, <sup>1</sup>*Human Studies Division, USEPA, Research Triangle Park, NC* and <sup>2</sup>*Neurotoxicology Division, USEPA, Research Triangle Park, NC*. Sponsor: W. Boyes.

There is increasing interest in being able to evaluate potential benefit-cost relationships of controlling exposure to toxic substances. Behavioral effects of acute toluene exposure could be subjected to benefit-cost analysis if its effects were quantitatively compared to those of ethanol ingestion, which have already been so analyzed. Behavioral effects of inhaled toluene and ingested ethanol were quantified by meta-analysis of studies from the peer-reviewed literature describing their effects on choice reaction time (reaction time in a test requiring a subject to choose among two or more alternatives before responding). The internal doses of these compounds were estimated by a general physiological and toxicokinetic simulation from exposure parameters provided in the reports. The reported effects were converted to a common metric (proportion of baseline) and related to the estimated internal doses of toluene and ethanol, from which dose-effect equations were fitted. Next, a dose-equivalence equation was derived to express, within confidence limits, the dose of toluene as an equivalent dose of ethanol on the basis of equal magnitude

of effect. Finally, a nomogram was constructed to relate the inhaled concentration of toluene to equivalent effects of ethanol internal doses. The resulting function can be used to estimate the monetary value of behavioral deficits caused by a range of exposures to toluene using existing information about monetary consequences of ethanol ingestion. (This abstract does not reflect EPA policy.)

## 2092 CARDIOVASCULAR AND THERMOREGULATORY RESPONSE TO ORAL TOLUENE IN THE RAT.

C. J. Gordon, W. M. Oshiro, T. E. Samsam, P. Becker and P. J. Bushnell, *Neurotoxicology, USEPA, Research Triangle Park, NC*.

Toluene and other volatile organic compounds have often been shown to affect behavior in animals when given by inhalation, and less effective when given orally. Previous work showed that toluene increased heart rate (HR) and motor activity (MA), and reduced core temperature (Tc) in rats inhaling toluene for 1 hour while performing an operant task. It is important to assess the effect of oral toluene on autonomic and motor conditions under resting conditions. To this end, the effects of oral toluene on HR, Tc, and MA in resting, unrestrained rats were determined. Adult rats (male, Long-Evans) were surgically implanted with radiotransmitters to monitor HR, Tc, and MA. Toluene was administered by gavage in corn oil at doses of 0, 0.4, 0.8, and 1.2 g/kg at 11:30 hr while the telemetry data were monitored over 48 hours at 22 °C. Dosing with corn oil led to transient elevations in HR, Tc, and MA, a response attributed to the stress of handling, that recovered within 2 hr. All doses of toluene led to transient increases in HR that exceeded the control response during the first 0.5 hr after dosing. The higher doses of toluene elevated HR for more than 6 hr after dosing. HR remained elevated above controls by approximately 25 and 50 b/min in the 0.8 and 1.2 g/kg groups, respectively. Tc increased above controls for several hours after 0.8 g/kg toluene. There was a transient reduction in Tc below controls following 1.2 g/kg toluene during the first hour followed by a progressive elevation for 4 hr after dosing. MA of the 0.8 and 1.2 g/kg groups increased transiently above controls then recovered. There was a secondary rise in MA in the 1.2 g/kg group persisting for several hours after dosing. Toluene at doses of 0.8 and 1.2 g/kg induced a marked tachycardia, hyperactivity, and hyperthermia. These effects developed in spite of a lack of effect of the same oral doses of toluene on operant behavior. It will be important to compare oral and inhaled toluene exposure in rats maintained under rest and working conditions. This abstract does not reflect EPA policy.

## 2093 BENCHMARK DOSE ANALYSIS BASED ON STYRENE NEUROBEHAVIORAL META-DATA.

G. M. Woodall<sup>1</sup>, W. K. Boyes<sup>2</sup>, A. M. Geller<sup>2</sup>, P. J. Bushnell<sup>2</sup> and V. A. Benignus<sup>2</sup>, <sup>1</sup>*NCEA/ORD, USEPA, Research Triangle Park, NC* and <sup>2</sup>*NHEERL/ORD, USEPA, Research Triangle Park, NC*.

There are a substantial number of research articles on the neurological effects of styrene (CAS 100-42-5) in humans. A meta-analysis of human neurological endpoints was undertaken and is described more fully elsewhere (Benignus et al., Environmental Health Perspectives, In Press; Boyes et al., Toxicologist, 2005); however, this meta-analysis did not directly provide a point-of-departure (POD) suitable for developing a reference concentration (RfC). Of the endpoints considered for analysis, three were judged to have adequate dose-response data on which an analysis could be performed: (1) color confusion index (CCI), (2) simple reaction time (SRT) and (3) choice reaction time (CRT). The analysis described here demonstrates an approach to using data from several studies on a single endpoint in deriving a POD that may be appropriate for the development of an RfC. The Benchmark Dose Software (BMDS, beta version 1.4) was used for that purpose on meta-data obtained from the previously described study. The lower-bound confidence limit of the Benchmark Dose (BMDL) was derived separately for two of the three neurological endpoints included in the meta-analysis (CCI, and CRT), using several approaches for each endpoint; the effect of styrene on SRT did not show a dose-related response and was therefore not evaluated further. The resulting BMDL values were then judged for appropriateness as the POD for deriving an RfC. The results indicate that either endpoint (CCI or CRT) provides similar POD values, and are supportive of the other as the basis for derivation of an RfC. The derivation of a POD using meta-data is rare but not unique in the IRIS database. (This abstract does not necessarily reflect EPA policy.)

## 2094 ACETYLCHOLINESTERASE AS THE CRITICAL EFFECT WHEN ESTIMATING THE SAFE DOSE FOR CHLORPYRIFOS?

Q. J. Zhao, B. Gadagbui and M. Dourson, *Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH*.

Chlorpyrifos is an irreversible inhibitor of cholinesterase (ChE), and inhibition of ChE is believed to be the most sensitive effect in all animal species evaluated and in humans. Recent epidemiology studies reported associations between umbilical

cord plasma chlорpyrifos levels and fetal birth weight decreases among minority women living in New York City during pregnancy. These associations raise questions whether impaired fetal development is the critical effect rather than the inhibition of ChE as is currently believed so. We analyze the available information from epidemiology studies and animal studies in order to identify the relative sensitivity of decreased birth weight and inhibition of ChE from exposure to chlорpyrifos. We find that the positive associations from some epidemiology studies are different from other epidemiology investigations. Moreover, a direct comparison of experimental animal neonatal information shows that cholinesterase inhibition is a more sensitive indicator of adverse effect than reduced body weight, and that neonates are equally, or perhaps less sensitive to cholinesterase inhibition than their maternal parent. We also briefly discuss items relevant to the establishment of a safe dose, such as the choice of appropriate species and study and selection of uncertainty factors.

## 2095

### CHARACTERIZATION OF DELTAMETHRIN (DLT) METABOLISM IN ADULT MALE SPRAGUE-DAWLEY RATS.

S. S. Anand<sup>1</sup>, W. T. Haines<sup>4,3</sup>, J. V. Bruckner<sup>1</sup>, J. W. Fisher<sup>2</sup>, S. Muralidhara<sup>1</sup>, D. L. Hunter<sup>3</sup> and S. Padilla<sup>3</sup>. <sup>1</sup>Department of Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA, <sup>2</sup>Department of Environmental Health Sciences, University of Georgia, Athens, GA, <sup>3</sup>Neurotox. Division, USEPA, Research Triangle Park, NC and <sup>4</sup>Curv. in Toxicology, UNC-CH, Chapel Hill, NC.

DLT, a widely-used type II pyrethroid, is a relatively potent neurotoxicant. While the toxicity of DLT is extensively examined, studies of its toxicokinetics are limited. It is necessary to characterize the major detoxification pathways, as well as their relative importance, in order to construct a physiologically-based toxicokinetic model for DLT. The aim of this study was to characterize the enzymes responsible for DLT metabolism by measuring DLT disappearance following incubation of various concentrations of DLT (2 to 400  $\mu$ M) in plasma (esterases) and liver microsomes (esterases and CYP450s) prepared from 90-day-old male Sprague-Dawley rats (n=4). In plasma, isoOMPA, a known inhibitor of carboxylesterases (CaE), completely inhibited DLT metabolism at low concentrations (2 and 20  $\mu$ M, higher than peak *in vivo* blood levels in intoxicated rats). For CaE-mediated DLT metabolism in plasma,  $V_{max}$ = 275 $\pm$ 53 nmoles/h/ml and  $K_m$ =140 $\pm$ 34  $\mu$ M. In liver microsomes (without CYP450 cofactors), DLT metabolism was completely inhibited by isoOMPA, confirming the role of CaE in DLT metabolism in the liver;  $V_{max}$ =2567 $\pm$ 265 nmoles/h/g liver and  $K_m$ = 244 $\pm$ 22  $\mu$ M. The metabolic rate constants for liver microsomal CYP450-mediated metabolism of DLT were  $V_{max}$ =2040 $\pm$ 120 nmoles/h/ liver and  $K_m$  = 84 $\pm$ 4  $\mu$ M. While plasma and liver CaEs have similar affinity, the liver CaE has higher metabolic capacity. Liver microsomal P450 rate constants, however, show  $V_{max}$  levels similar to the liver CaE and higher than plasma CaE, but the affinity for DLT is greater than liver CaE and similar to plasma CaE. Therefore, the intrinsic clearance ( $V_{max}/K_m$ ) of the liver CaE is higher than plasma CaE; and the intrinsic clearance of liver CYP450 metabolism is greater than either liver or plasma CaE (Supported by EPA STAR Grant R830800). This is an abstract of a proposed presentation and does not imply Agency policy.

## 2096

### RISK OF TERATOGENICITY FROM TRICHLOROETHYLENE (TCE) AND DICHLOROETHYLENE (DCE) IN DRINKING WATER.

B. J. Kelman<sup>1</sup>, B. D. Hardin<sup>2</sup> and R. L. Brent<sup>3</sup>. <sup>1</sup>GlobalTox, Redmond, WA, <sup>2</sup>GlobalTox, Hilton Head Island, SC and <sup>3</sup>Alfred I. DuPont Institute, Wilmington, DE.

Formal assessment of risk requires hazard identification, dose-response and exposure assessments, and risk characterization. "Hazard" in the USA refers to intrinsic toxic properties and "risk" refers to the probability of an adverse outcome. Without hazard, there is no risk. TCE and DCE are sometimes found in drinking water as well as occupational settings where the exposure is primarily by inhalation and secondarily via the skin. Epidemiologic studies of environmental or occupational exposure to TCE do not find an increase in developmental effects in humans. Experimental studies from multiple laboratories, employing many routes of exposure in mice, rats, and rabbits, find no adverse reproductive effects in the absence of maternal toxicity and no teratogenicity even in the presence of maternal toxicity. Only one group of investigators claims exposure to TCE causes developmental toxicity, specifically cardiac malformations. A single epidemiologic study from this group is sometimes cited as demonstrating that TCE in drinking water caused an increase in congenital malformations. Although the authors' confirmed their a priori impression that the prevalence of cardiac defects was elevated, no causal relationship between contamination of water and cardiac defects can be inferred due to inadequacy of exposure data and weaknesses of study design, many of them noted by the authors themselves. This same group published animal studies contending that TCE and DCE are specific cardiac teratogens, producing no other adverse de-

velopmental response. Part of what appears to be replication of studies actually is republication and the remainder rely on inappropriate 1) control groups, 2) experimental models (chick embryo), 3) dosing (*in utero*), and 4) over-diagnosis of variations as malformations. Furthermore, an independent laboratory using that group's microdissection technique found no treatment-related increase in cardiac malformations. Based on a review of these studies, the weight of evidence is that TCE and DCE are not teratogenic and are not specific cardiac teratogens.

## 2097

### DOES TRICHLOROETHYLENE CONTRIBUTE TO CONGENITAL HEART DEFECTS?

R. E. Watson<sup>1</sup>, W. Howard<sup>2</sup> and J. M. DeSesso<sup>1</sup>. <sup>1</sup>Biomedical Research Institute, Mitretek Systems, Falls Church, VA and <sup>2</sup>AFIOH/RSRE, US Air Force, Brooks City-Base, TX.

Trichloroethylene (TCE) is an organic solvent currently used as a metal degreasing agent. TCE is also a common contaminant in the water supply, with levels often exceeding the EPA-defined maximum contaminant level of 5 ppb. Therefore, it is important to identify any risks to human health associated with TCE. Several epidemiological studies have reported links between TCE exposure during pregnancy and health problems including, but not limited to, congenital heart defects. Unfortunately, due in part to the complications involved with conducting retrospective epidemiological studies, several confounding factors make the results difficult to interpret, and epidemiological reports of the pre-natal risks of TCE have been contradictory. Similarly, the results of animal studies examining the potential of TCE to elicit cardiac anomalies have been inconsistent, and have often been performed at doses far exceeding levels found in the water. Nonetheless, the public perception in contaminated areas is that TCE causes heart defects. To determine specifically what is known about the relationship between TCE to the incidence of heart defects, a comprehensive analysis of all available epidemiological data and animal studies was performed. Hill's causality criteria were applied to the epidemiology data. Additionally, *in vivo* and *in vitro* studies examining possible mechanisms of action for TCE were evaluated. In the case of *in vitro* studies, a pharmacokinetic model was used to determine the equivalent *in vivo* doses. Taking all aforementioned data into consideration, there are no indications of a causal link between TCE exposure during pregnancy and heart defects. As a final evaluation, the heart defects reported in animal and human epidemiology studies as being associated with TCE were categorized by the morphogenetic process responsible for the defect. The analysis revealed no single mechanism as being predominantly affected by TCE, thereby providing no support for a likely risk of congenital heart malformation due to TCE exposure during gestation.

## 2098

### HUMAN HEALTH RISK ASSESSMENT FOR 4-CHLORO-1, 2-BENZENEDIAMINE.

V. Bhat, G. Ball, C. McLellan, C. Gilliland and J. Russell. *NSF International, Ann Arbor, MI.* Sponsor: M. Dourouz.

A risk assessment to determine acceptable levels of 4-chloro-1, 2-benzenediamine in drinking water was conducted according to Annex A of NSF International/American National Standards Institute (NSF/ANSI) Standard 60/61. No human data were identified in the scientific literature. Hepatic focal hyperplasia, renal pyelonephritis, and urinary bladder tumors and precursor effects were observed in rats at statistically increased incidences compared to controls after dietary administration of 4-chloro-1, 2-benzenediamine for 78 weeks. Uterine/endometrial hyperplasia was observed in female mice at an increased incidence compared to controls after chronic dietary administration of 4-chloro-1, 2-benzenediamine for 78 weeks, and combined hepatocellular adenomas and carcinomas were observed in male and female mice at statistically increased incidences compared to controls. The weight of evidence suggests that 4-chloro-1, 2-benzenediamine is genotoxic *in vivo* and *in vitro*. Based on the increased tumor incidences in rats and mice fed 4-chloro-1, 2-benzenediamine for two years, and its positive genotoxicity data, the weight of evidence supports that 4-chloro-1, 2-benzenediamine is likely to be carcinogenic to humans. Thus, a 10-5 cancer risk level was extrapolated from the chronic feeding BMCL10 of 45 mg/kg-day, which was based on the combined incidence of urinary bladder tumors and precursors in rats. A unit risk of  $6.3 \times 10^{-8}$  (mg/L) $^{-1}$  was calculated from the slope factor using the default 70 kg body weight and 2 L/day drinking water consumption of an adult. Thus, drinking water containing 16 mg/L of 4-chloro-1, 2-benzenediamine consumed for a lifetime was estimated to result in development of 1 excess tumor per 1,000,000 people. The long-term exposure levels derived include a Total Allowable Concentration of 0.2 mg/L, and a Single Product Allowable Concentration of 0.02 mg/L. A higher Short-Term Exposure Level was not derived, since 4-chloro-1, 2-benzenediamine was assumed to be a linear carcinogen.

## ADVERSE EFFECTS OF CYANOBACTERIAL PEPTIDES ON HUMAN HEALTH.

S. Hoeger and D. Dietrich. *Environmental Toxicology, University of Konstanz, Konstanz, Germany.*

Cyanobacteria (blue-green algae) occur in almost all fresh- or brackish waters worldwide. Certain species of these microorganisms are capable of producing a variety of non-ribosomally synthesized peptides, including the microcystins (MCs). These toxins have caused mortality in animals and are suspected to be responsible for illness in humans. The major health problems with MCs are most likely those associated with chronic intoxications with low MC concentrations via drinking water. However, the consumption of "blue-green algae food supplements" (BGAS), especially those produced from *Aphanizomenon flos-aquae*, is becoming common in the industrialized countries. Four studies on the MC-concentrations of BGAS have been carried out in the last six years. The MC amounts found varied from 0-35,000 ng/g DW. In the study presented here, BGAS from the European market contained distinctly more than 1000 ng MC-LR equivalents/g DW (determined by anti-ADD-ELISA and colorimetric proteinphosphatase assay). In the past years, a broad variety of other cyanobacterial peptides were discovered, suggesting that not only MCs may have an adverse impact on human health. To determine the potential cytotoxicity, peptides of some of these cyanobacterial peptide families were incubated with the HepG2 and the CaCo2 cell line and primary rat hepatocytes. Cell viability was assessed by the MTT-reduction and LDH release assay after various incubation times and peptide concentrations. Preliminary results suggest an effect in primary rat hepatocytes, whereas no effect was observed in continuous cell lines. In light of the high degree of MC contamination of BGAS, the known variability in BGAS consumption, the known risk of contamination of drinking water with low levels of MCs and the currently incalculable toxicological potential of other cyanobacterial peptides, the guideline values for MC and other toxic peptides should be critically reviewed and revised. Furthermore, the data strongly suggest that an increased routine control of water bodies and food supplements for toxin contamination is advisable.

## EXAMINING POTENCY FOR DEVELOPMENT OF THE PRELIMINARY CONTAMINANT CANDIDATE LIST (PRE-CCL).

J. Donhue<sup>1</sup>, S. Kueberuwa<sup>1</sup>, Y. Selby-Mohamadu<sup>2</sup> and J. Shatkin<sup>3</sup>. <sup>1</sup>*Health and Ecological Criteria Division, USEPA, Washington, DC*, <sup>2</sup>*Office of Ground Water and Drinking Water, USEPA, Washington, DC* and <sup>3</sup>*The Cadmus Group, Watertown, MA*. Sponsor: E. Ohanian.

The 1996 Safe Drinking Water Act requires EPA to develop a list of contaminants with potential for regulation on a five-year cycle, and to make regulatory determinations from each list three years after its publication. EPA requested assistance from the National Research Council (NRC) of the National Academy of Sciences (NAS) and a Work Group from the National Drinking Water Advisory Council (NDWAC) in providing recommendations for developing the CCL. The NRC recommendations were published in 2001 and those from the NDWAC Work Group in 2004. Both groups supported a framework in which a Pre-CCL is initially selected from universe of contaminants of concern using screening data on health effects and potential occurrence in drinking water. The CCL is chosen from the Pre-CCL using additional data on attributes for health effects and occurrence. In order to screen contaminants from the Universe for inclusion on the Pre-CCL, the NDWAC Work Group recommended that EPA use measured or QSAR-generated LOAELs, LD50s, and cancer classifications as measures of potency. In conjunction with this recommendation, USEPA assembled a screening data set that included 825 measured and/or modeled LOAEL values, 1, 549 measured and/or modeled LD50 values and the cancer classifications for 745 contaminants. This data set was used to evaluate a variety of Pre-CCL health effects screening approaches. As part of the evaluation, USEPA compared measured with modeled data for LOAEL and LD50 values and examined the impact of a variety of selection criteria on whether or not individual contaminants would be included or excluded from the Pre-CCL based on health effects data. The inclusion of data-rich, regulated contaminants in the data set provided an opportunity to evaluate the effectiveness of various screening criteria in capturing contaminants of known health concern. [The opinions expressed are those of the authors and do not necessarily reflect the opinions of the USEPA.]

## CLASS-BASED DRINKING WATER ACTION LEVEL FOR ALKYL SUBSTITUTED NAPHTHALENES.

A. Gebhart<sup>1</sup>, M. H. Whittaker<sup>2</sup>, T. Clipson Miller<sup>2</sup> and F. Hammer<sup>1</sup>. <sup>1</sup>*Underwriters Laboratories Inc., Northbrook, IL* and <sup>2</sup>*ToxServices, Washington, DC*.

Mono-, Di-, Tri-, and Tetra-C1-C4 alkyl substituted naphthalenes extract into potable water from pipe and tank coatings. When such products are evaluated to a national health effects standard for use with drinking water, chemicals extracting

from these products must be below appropriate action levels. As defined by Standard 61, a Total Allowable Concentration (TAC) is the maximum concentration of a nonregulated contaminant allowed in a public drinking water supply, and the Single Product Allowable Concentration (SPAC) is 10% of the TAC. C1-C4 alkyl substituted naphthalenes comprise a class of chemicals that feature a naphthyl ring with alkyl side chain substitutions, where the substituted group(s) can be any alkyl chain from 1 to 4 carbons. Data on these chemicals comprise genotoxicity, carcinogenicity, and pharmacokinetic data. These data indicate that the lung is a target organ. Genotoxicity assays are consistently negative and indicate that alkyl substituted naphthalenes pose a small risk of genotoxicity. The effects of chronic ingestion of 1- and 2-methylnaphthalene have been evaluated in B6C3F1 mice. These studies identified dose-related pulmonary alveolar proteinosis. Toxicity data on this class of compounds indicates that the smallest chemical (i.e., 2-methylnaphthalene) is the most toxic, and can be considered worst-case. The USEPA derived a reference dose (RfD) of 0.004 mg/kg-day for 2-methylnaphthalene, which was used to evaluate the health hazards of C1-C4 alkyl substituted naphthalenes. The RfD is based on a chronic mouse study that identified dose-related, significant increases in pulmonary alveolar proteinosis. A TAC of 30 µg/L for this class of chemicals was derived by multiplying the USEPA 2-methylnaphthalene RfD by a default 70 kg body weight, a default daily water consumption (2L/Day), and a default 20% relative source contribution factor. Because empirical data relating to the number of drinking water sources containing C1-C4 alkyl substituted naphthalenes were not identified, the SPAC was set at 10% of the TAC (3 µg/L).

## COMPARATIVE RISK ASSESSMENT OF MULTIMEDIA EXPOSURE TO PERCHLORATE AND OTHER AGENTS THAT INHIBIT IODIDE UPTAKE INTO THE THYROID GLAND.

G. M. Bruce and R. C. Pleus. *Intertox, Inc., Seattle, WA*.

Interest has increased in how the thyroid gland might be affected by environmental exposure to perchlorate, which is increasingly being detected in drinking water sources throughout the United States. In addition, several organizations have recently begun to collect data on perchlorate concentrations in a wide variety of food and beverage items, including produce and milk. Perchlorate acts through inhibition of iodide uptake at the sodium-iodide symporter (NIS). This effect is an essential precursor to any other thyroid effects that could occur at much higher doses, including effects on thyroid hormone production. Of particular concern is whether perchlorate could be present during pregnancy at sufficient doses to cause adverse effects to the fetus, especially the nervous system. To address health concerns, a number of agencies, including USEPA, have proposed drinking water guidelines for perchlorate that are well below the threshold level at which perchlorate first begins to cause iodide uptake inhibition (IUI) into the thyroid gland. However, typical American diets and other common sources contain other natural and anthropogenically-added agents, including nitrate and thiocyanate, that act through the same mechanism of action as perchlorate. While these agents are less potent IUI agents than perchlorate, their concentrations in typical diets are substantially greater. To estimate the relative contribution of perchlorate, thiocyanate, and nitrate to total IUI, daily intake rates of these agents were calculated using reported media concentrations, with average daily intake rates from USDA. After adjusting for the relative potency of each agent using *in vitro* and *in vivo* bioassay data, the total IUI contributed by perchlorate is estimated to be a very small fraction of that contributed by other agents. These comparisons suggest that IUI is a mundane, nonadverse event, and indicate a contradiction with assertions that levels of perchlorate currently being detected in the environment pose a health risk.

## HUMAN HEALTH RISK ASSESSMENT FOR THIOCYANATE.

J. Russell, C. McLellan, G. Ball and V. Bhat. *NSF International, Ann Arbor, MI*. Sponsor: M. Dourous.

A risk assessment to determine acceptable levels of thiocyanate in drinking water was conducted according to Annex A of NSF International/American National Standards Institute (NSF/ANSI) Standard 60/61. Data on thiocyanate toxicity were identified in humans and laboratory animals. Thyroid effects were seen in some patients taking therapeutic doses of thiocyanate, but death was also observed without reported thyroid effects. Although most of the animal studies focused on thyroid effects, the doses used were higher than those causing deaths in humans, making them unsuitable for human health risk assessment. A chronic study found an increased incidence of liver tumors, but not thyroid tumors, in rats administered thiocyanate in drinking water, but a subsequent study at higher doses found no increase in liver tumors. No genotoxicity data were located for thiocyanate. The key study followed 246 patients on thiocyanate therapy for hypertension for 2-10 years. Doses ranged from 0.2-0.6 g/day, with the standard dose starting at 0.3 g/day and adjusted depending on therapeutic effectiveness and blood thiocyanate levels. The

LOAEL was considered 0.3 g/day (or 4.3 mg/kg-day), based on transient muscle fatigue, nausea, and vomiting in some patients on initiation of thiocyanate therapy, and lowering of blood pressure in humans taking thiocyanate for hypertension. A total uncertainty factor of 100x was applied to the LOAEL to determine the reference dose (RfD) of 0.04 mg/kg-day. The 100x uncertainty factor included 3x each for intraspecies and LOAEL to NOAEL extrapolation, study duration, and database deficiencies. There is some uncertainty in this risk assessment, because the mechanism of action of thiocyanate-induced toxicity is not fully determined. The long-term exposure levels derived include a Total Allowable Concentration of 0.2 mg/L, and a Single Product Allowable Concentration of 0.02 mg/L. A Short-Term Exposure Level of 0.9 mg/L was also derived. These drinking water levels should be applied as a total for the sum of sodium, potassium, and ammonium salts. Other thiocyanates require separate risk assessments.

## 2104 DERIVATION OF A DRINKING WATER ACTION LEVEL FOR TRIBUTYL PHOSPHATE.

T. Clipson Miller<sup>1</sup>, M. H. Whittaker<sup>1</sup>, A. Gebhart<sup>2</sup> and F. Hammer<sup>2</sup>  
<sup>1</sup>ToxServices, Washington, DC and <sup>2</sup>Underwriters Laboratories Inc., Northbrook, IL.

Tributyl phosphate (TBP) is used as a plasticizer in the manufacturing of cellulose esters, lacquers, plastics, and vinyl resins that come into contact with potable drinking water. When such products are evaluated to a national health effects standard for use with drinking water, any chemical extracting from these products must be below an appropriate action level. As defined by Standard 61, a Total allowable Concentration (TAC) is the maximum concentration of a nonregulated contaminant allowed in a public drinking water supply, and the default Single Product Allowable Concentration (SPAC) is 10% of the TAC. In order to determine an action level for TBP, a comprehensive health effects evaluation was performed. There are no epidemiological data indicating that occupational exposure to TBP results in adverse human health effects other than headache, nausea, and symptoms of skin, eye, and mucous membrane irritation. TBP is not mutagenic nor does it promote chromosomal aberrations in cytogenetic assays performed *in vitro* or *in vivo*. A two-year dietary study in male and female Sprague-Dawley rats identified dose-related increases in the incidence of urinary bladder hyperplasia and neoplastic lesions (comprising urinary bladder papillomas and transitional cells carcinomas) in rats. Two subchronic studies have confirmed the linkage between TBP treatment and the induction of urinary bladder hyperplasia in rats. A review of the toxicological dataset for TBP indicates that urinary bladder hyperplasia and neoplastic lesions are the most sensitive health effects endpoints upon which to base a TAC and SPAC. A multistage model was used to extrapolate to low-dose TBP exposure due to an unknown mode of action for TBP. A TAC of 30 µg/L was derived for TBP, and is based upon an LED10 of 9.35241 mg/kg/day. A SPAC of 3 µg/L was derived by multiplying the TAC by 0.10. These action levels are based upon the most sensitive health effects endpoint, as well as current risk assessment methodologies.

## 2105 CONSIDERATION OF SENSITIVE POPULATIONS FOR RISK ASSESSMENT OF CHEMICALS IN DRINKING WATER.

A. Fan, R. A. Howd and G. Alexeef, OEHHA, Cal/EPA, Oakland, CA.

In consideration of special sensitive populations, public health goals (PHGs) for chemicals in drinking water were developed for five chemicals based on infants or children as the sensitive population; these include copper (170 ppb), fluoride (1 ppm), nitrate (45 ppm), nitrite (10 ppm) and oxamyl (50 ppb). Three are based on female/pregnant women; these are dinoseb (14 ppb), methoxychlor (30 ppb) and perchlorate (6 ppb), the last of which also include the fetus and infants as sensitive subgroups. The risk assessment procedure evaluates cancer and non-cancer endpoints, animal and human data, and specific parameters for infants, children and pregnant women, such as relevant body weight and water intake rate for these groups, where appropriate. Recent passage of AB 2342 requires new risk assessments that involve infants and children to assess the following based on available information: 1) The possibility of disproportionately high exposure of infants and children relative to the general population, such as may occur in the case of bottle-fed infants. 2) Special susceptibility of infants and children to the contaminant relative to the general population. 3) The effects on infants and children of the contaminant and other substances that have similar effects. 4) The interaction of multiple contaminants on infants and children. For the above chemicals, the possible biologic basis for sensitivity is explored, and oral reference values of 0.21 mg/day (total), 0.25 mg/kg-d, 0.01 mg/kg-d, .005 mg/kg-d, and .000037 mg/kg-d were developed for copper, oxamyl, dinoseb, methoxychlor and perchlorate, respectively, for the specific subpopulations. The reference values for nitrate, nitrite and fluoride are the same as the PHGs, based on the concentrations in drinking water that produced no adverse effects involving infants and children, and no further modifications were made to adjust the values.

## 2106 INHALATION EXPOSURE TO NONVOLATILE CHEMICALS DURING SHOWERING D M MANGANARO M S HUTCHESON T ZEWDIE, MASSACHUSETTS DEPARTMENT OF ENVIRONMENTAL PROTECTION, BOSTON MA, USA.

T. Zewdie, D. M. Manganaro and M. S. Hutcheson, *Office of Research and Standards, Massachusetts Department of Environmental Protection, Boston, MA*.

The literature is replete with data on risk assessment of inhalation exposures of volatile chemicals. The typical scenario assumes that volatile chemicals that are present in heated water used for showering volatilize and are inhaled by the individual taking that shower. Risk assessors have historically assumed that inhalation exposure to non-volatile chemicals does not occur. In the last decade, however, a number of studies have emerged in the literature that address the potential for inhalation of aerosols generated by the shower spray. The major topics discussed in these studies include mechanisms of aerosol formation, removal, shifts in size distribution, and amounts of respirable aerosol particles formed and inhaled during showering. Inhaled aerosols are most frequently of various sizes and deposit in the different regions of the respiratory tract based on their sizes. In general a large number of large water droplets (>10 µm) and small aerosols (<10 µm) are produced from shower spray. Aerosols less than 7 µm may reach the gas exchange (alveolar) region and, therefore, contribute significantly to inhalation exposure. The respirable aerosol concentrations generated during showering and the dose delivered through inhalation exposure can be determined from these studies. Based on the above information, this report will identify circumstances under which showering inhalation exposures to nonvolatile chemicals can be of concern. Included will be water concentration limits to protect from inhalation exposures for a variety of nonvolatile chemicals.

## 2107 MEASUREMENT OF AIR CONCENTRATION OF D CIS/TRANS ALLETHRIN GENERATED BY A MOSQUITO REPELLENT LAMP IN AN OUTDOOR ENVIRONMENT.

S. Selim<sup>1</sup> and J.J. Olson<sup>2</sup>, <sup>1</sup>Golden Pacific Laboratory, Fresno, CA and <sup>2</sup>Product Toxicology, S. C. Johnson & Son Inc., Racine, WI.

OFF!® Mosquito Lamps were introduced in the market as an outdoor mosquito area repellent product providing up to 4 hours of protection for a 4.5 m x 4.5 m area downwind from the lamp. This product contains a mat impregnated with the active d cis/trans allethrin (355 mg) placed at the top of the lamp using a candle as the heat source to volatize the active. This study determined the air concentration of active that would be generated as a result of using the OFF!® Mosquito Lamp in an outdoor location of a private residence, simulating actual use conditions. Air samples were collected from 12 locations at three different heights downwind from a lit lamp on a table. A fan was placed on the opposite side of the sample tubes to direct the active emission towards the collection tubes. Samples were collected during the life of the repellent mat (4 hours) and for 2 hours afterwards (post burn). This scenario was to simulate potential high exposure scenario for a child or adult during typical activities, e.g. sitting, standing, playing. The results of the study clearly showed that air concentrations around a mosquito repellent lamp placed outdoors is very low with most of the values below the LOQ (0.2 ng/l of air). Residues of allethrin were detected downwind from the lamp along the wind vector at a distance of 1 m (max. active air conc. 0.9 ng/l) and 2 m (max. active air conc. 0.7 ng/l). Active residues were detected only during the product life phase and not for the post burn phase. This exposure information was used in a product risk assessment demonstrating large safety margins from product use thus far exceeding minimum safety standards.

## 2108 MECHANOTRANSDUCTION IN PARTICLE TOXICOLOGY.

S. C. Brown<sup>1</sup>, M. Kamal<sup>2</sup>, N. Nasreen<sup>2</sup>, V. Antony<sup>2</sup> and B. Moudgil<sup>1</sup>, <sup>1</sup>Particle Engineering Research Center and Department of Materials Science, University of Florida, Gainesville, FL and <sup>2</sup>Division of Pulmonary and Critical Care Medicine, University of Florida, Gainesville, FL. Sponsor: S. Roberts.

Exposure to fiber-like particulate materials has been associated with lung injury; however, the mechanisms involved are not fully understood. It has been proposed that as a particle transverses from an isotropic material to an acicular one, the toxic response resulting from exposure to that material increases. These effects are thought to manifest from a mechanical aggravation of the cells (poking, rubbing, etc.) and/or difficulty in phagocytosis (clearance hindrance, *in vivo*). *In vitro* studies investigating the toxicity of particulate systems in the presence of cyclic mechanical motion have been limited, and these issues ultimately remain unsolved. We have initiated a program investigating the impact of mechanotransduction on particle toxicity. Well-characterized fiber-like (amorphous silica nanorods and asbestos fibers), platy (Talc, Bryan Co.) and isotropic (amorphous silica spheres) have been

exposed to normal mesothelial cells (MET-5A; ATCC, Manassas, VA) at concentrations ranging from 25 to 250 mg/cm<sup>2</sup>. To modulate particle-integrin interactions, the identical exposures were performed with the exception that the particles of interest were either preconditioned with fibronectin or coated with polyethylene glycol (PEG) groups to respectively enhance and mitigate integrin interactions. The cells were incubated for 24hrs at prescribed dosages and pretreatment in Bio-Flex plates under a constant strain of 5% at 1 Hz (Flexercell Strain Unit FX-4000T, FlexCell\* International). Particle cytotoxicity and IL-8 release were monitored via LDH release (Roche Diagnostics) and ELISA (Quantikine). Cyclic stretching in the absence of particles was not shown to lead to a significant increase in LDH or IL-8 release. Preliminary evidence suggests that cell death and IL-8 release increase in the presence of particles with cyclic mechanical cell stretching and that this may be further augmented with enhanced particle-integrin interactions.

**2109**

#### A QUANTITATIVE CANCER RISK ASSESSMENT FOR AIRBORNE ASBESTOS GENERATED BY VEHICULAR TRAFFIC ON A ROAD PAVED WITH ASBESTOS-CONTAINING SERPENTINE ROCK.

J. D. Budroe<sup>1</sup>, R. Fears<sup>2</sup>, F. Collier<sup>2</sup>, A. Salmon<sup>1</sup> and M. A. Marty<sup>1</sup>. <sup>1</sup>*Office of Environmental Health Hazard Assessment (OEHHA), Oakland, CA* and <sup>2</sup>*Department of Toxic Substances Control, Sacramento, CA*.

The California Department of Toxic Substances Control (DTSC) performed a roadside asbestos air monitoring study at Garden Valley (El Dorado County), CA in 2002-2003. The study was designed to address DTSC's concern regarding potential exposure of communities to airborne asbestos fibers resulting from vehicular traffic on unpaved roadways known to contain asbestos. Within Garden Valley, the study site was Slodusty Road, an unpaved road which was surfaced with asbestos-containing serpentine rock. Air samples were collected at distances ranging from 5 to 300 feet away from the edge of the road, on both sides of the road. Two traffic scenarios were utilized: 1) 30 vehicles/hour (vph) driven at a speed of 25 miles per hour (mph); 2) 10 vph at 10 mph. Airborne asbestos was detectable by the air monitor farthest from the road in both the 30 vph/25 mph and the 10 vph/10 mph test scenarios (190 and 130 feet, respectively; asbestos concentrations were  $2.5 \times 10^2$  -  $3.0 \times 10^4$  and  $2.9 \times 10^1$  -  $3.1 \times 10^3$  PCM-equivalent fibers/m<sup>3</sup>, respectively). Time-adjusted airborne asbestos cancer risk estimates for lifetime exposure using those two scenarios ranged from  $2.7 \times 10^{-4}$  to  $3.2 \times 10^{-2}$  and  $3.1 \times 10^{-5}$  to  $3.3 \times 10^{-3}$ , respectively. These data suggest that the airborne asbestos cancer risks for the two vehicle frequency and speed scenarios probably bound the high-end estimated cancer risks to Slodusty Road residents. Airborne asbestos concentrations were resampled after the road was resurfaced to remove serpentine aggregate as a potential asbestos source. Time-adjusted airborne asbestos cancer risks using the 10 vph/10 mph and 30 vph/25 mph scenarios ranged from  $5.3 \times 10^{-6}$  to  $1.5 \times 10^{-4}$  and  $1.3 \times 10^{-5}$  to  $2.9 \times 10^{-4}$ , respectively. The cancer risks associated with the postresurfacing 10 vph/10 mph and 30 vph/25 mph scenarios were 1-2 and 1-3 orders of magnitude less than those of the corresponding preresurfacing scenarios, respectively.

#### IMPROVED DOSIMETRIC ADJUSTMENT FACTORS FOR INTERSPECIES EXTRAPOLATION OF INHALED, POORLY SOLUBLE PARTICLES.

B. Asgharian<sup>1</sup>, O. Price<sup>1</sup>, A. Jarabek<sup>2,1</sup> and F. Miller<sup>1</sup>. <sup>1</sup>*Division of Computational Biology, CIIT Centers for Health Research, Research Triangle Park, NC* and <sup>2</sup>*National Center for Environmental Assessment, USEPA, Washington DC, DC*.

Risk assessment of inhalation exposures to inhaled poorly soluble particles (PSP) frequently relies on the extrapolation of dose-response data obtained from toxicological studies in laboratory animals to human exposure scenarios. Accurate extrapolation requires dosimetry adjustment to account for differences in delivered dose due to differences in airway geometry and ventilation. Default approaches currently rely on empirical models that describe average particle deposition for each lung region. A default duration adjustment is also typically applied to extrapolate the experimental regimen to an equivalent, continuous human exposure scenario. Mechanistic models that account for anatomical and physiological determinants of the spatial heterogeneity explicitly address time-dependent parameters and delivered dose and are expected to increase the accuracy of dose-response analysis and interspecies extrapolation. Airflow distribution models based on lung compliance and airway resistance in humans and uniform lobar expansion in rats were used in a multiple-path, particle dosimetry model (MPPD) (CIIT Centers for Health Research, Research Triangle Park, NC) to calculate particle deposition, clearance, and retention in rats and humans. Realistic asymmetric lung geometries based on airway morphometric measurements were used in the calculations. Human equivalent concentration (HEC) estimates were obtained for various plausible dose met-

rics of PSP toxicity. Each metric was constructed as an expression of an internal dose measure (e.g., particle number) and a normalizing factor (e.g., number of alveolar macrophages). In general, those based on mass per unit area yielded the highest resultant HEC estimates, while a dose metric based on retained mass led to the lowest value of HEC, dependent on particle size. Results obtained from this study will aid in interspecies data extrapolation of data on inhaled PSP and improve the accuracy of health risk assessments.

#### DEVELOPMENT OF A CHRONIC INHALATION REFERENCE EXPOSURE LEVEL FOR RESPIRABLE CRYSTALLINE SILICA.

J. F. Collins, A. G. Salmon, J. P. Brown, M. A. Marty and G. V. Alexeff. *OEHHA, California EPA, Oakland, CA*.

Chronic crystalline silica exposure to workers can result in silicosis, characterized by histologically unique silicotic nodules and by fibrotic scarring of the lung. In California silica is a chemical subject to the Air Toxics Hot Spots Act. We have calculated an inhalation Chronic Reference Exposure Level (cREL) for silica in humans, a level below which no adverse effects would be expected, using a Benchmark Concentration approach with epidemiological data from miners. In the key study Hnizdo and Sluis-Cremer (Am J Ind Med. 24(4):447-57, 1993) investigated silicosis risk retrospectively in a cohort of 2, 235 white male South African gold miners, of whom 313 (14%) developed radiographic signs of silicosis at an average age of 55.9 years. From the data on silicosis incidence in miners versus cumulative silica exposure, we estimated a NOAEL of 600 ( $\mu\text{g}/\text{m}^3$ )-years silica and a  $\text{BMC}_{01}$  of 636 ( $\mu\text{g}/\text{m}^3$ )-yr silica. After time-adjusting the  $\text{BMC}_{01}$  from occupational to equivalent continuous exposure (210  $\mu\text{g}/\text{m}^3$ -yr), dividing by the 24 years of mean occupational exposure, and applying an intraspecies uncertainty factor of 3, a cREL of 3  $\mu\text{g}/\text{m}^3$  for respirable silica (as defined occupationally) was obtained. Data from cohorts of South Dakota gold miners and Chinese tin miners gave similar results. Strengths of the cREL include: the availability of several long-term studies of inhalation in workers at varying exposure concentrations; adequate histopathological and radiologic analysis; adequate follow-up; a dose-response effect in several studies; observation of a NOAEL in the key study; and the power of the key study to detect a small effect. Uncertainties include the general underestimation of silicosis by radiography alone (with resulting higher, less health-protective cREL estimates) and the uncertainties in exposure estimation, especially when reconstructing historical levels of exposure.

#### EFFECT OF ARSENIC AND DIELDRIN ON FEMALE RATS: PRELIMINARY DOSE RANGE STUDIES.

L. Ogden<sup>1</sup>, R. R. Dalvi<sup>1</sup>, M. Mansour<sup>1</sup>, T. Graham<sup>2</sup>, L. Billups<sup>2</sup> and T. Datiri<sup>1</sup>. <sup>1</sup>*Biomedical Sciences, Tuskegee University, Tuskegee, AL* and <sup>2</sup>*Pathobiology, Tuskegee University, Tuskegee, AL*.

This report represents phase one of a 5 year study to evaluate the effect of arsenic(As), dieldrin (Ded) and their mixture on female reproduction. Dose range studies were conducted in As and Ded to define the maximum tolerated dose (MTD) for use in the definitive reproductive study. Adult 60 day old Sprague-Dawley female rats were randomly assigned to groups (6-7/group) and orally gavaged daily for 30 consecutive days with 0, 1, 2, 4, 8, or 16mg/kg of either sodium arsenite or dieldrin. Daily clinical observations, biweekly body weight, and weekly food consumption were recorded. Other parameters including organ weights, pathology, hematology, clinical chemistry, reproductive hormones, T3 and T4, corticosterone, liver cytochrome P450 (1A1 & 2B1) and reactive oxygen species were determined. Arsenic caused mortality at 16mg and 8mg/kg (100% & 67% respectively). Clinical findings such as tremor and paresis were observed in 4 and 8mg/kg groups. Food consumption decreased during the 1st week in all As treated groups. Pathological lesions were noted in the stomach, liver and brain. Liver weight increased in 4mg/kg and higher doses. There were decreased RBC and lymphocyte counts, hemoglobin, hematocrit, and albumin levels in 4 and 8 mg/kg groups. The neutrophil count increased in both 4 and 8mg/kg groups. The GGT level increased only in the 8mg/kg As group. Dieldrin data is as follows. There was 100% mortality in 16 and 8mg/kg groups and 57% in the 4mg/kg group. Hyperactivity and aggressiveness were observed in 4mg/kg and above. Food consumption decreased during the 1st week followed by an increase during the 3rd and 4th weeks in the 4mg/kg group. Pathological lesions were noted in the brain and stomach of 4mg/kg and above. Liver weight increased in the 2 and 4mg/kg groups. Levels of CYP450 1A1 and 2B1 increased in all Ded treated groups but were significantly higher in 1 and 4mg/kg group. In conclusion, the MTD will be less than 4mg/kg body weight in both arsenic and dieldrin groups. (Supported by MHPF/ATSDR Cooperative Agreement # U50/ ATU473408-01)

**2113**

CHARACTERIZATION OF ISCHEMIA-REPERFUSION EFFECTS IN RENAL CELLS — A SCREENING APPROACH.

A. Heussner, E. O'Brien and D. Dietrich. *Environmental Toxicology, University of Konstanz, Konstanz, Germany*.

Acute renal failure from ischemia-reperfusion (IR) injury remains a serious clinical problem. While various excellent animal models have been established in the last years, only few validated *in vitro* (human) models exist. Therefore, the aim of the presented study was to investigate the suitability of a human renal cell line (IHKE) and to compare the effects observed with the results from a well-established equivalent porcine renal cell line (LLC-PK1), which is frequently used for IR studies. For this comparison, the experiments with LLC-PK1 of various other authors were repeated under our standard conditions to eliminate confounding factors of the cell culture as handling differences, possible deviations from the original cell strain, etc. IR was simulated by adaptation of the mineral oil immersion method, described by Meldrum, K.K. et al., *J. Surg. Res.* 99 (2001). The effects of IR were investigated using a systematic screening approach according to DOE (design of experiment) recommendations for an inscribed central composite design, considering initial cell number, serum content, duration of ischemia and reperfusion and using several endpoints, i.e. cell number, Hoechst staining, TUNEL assay and MTT reduction assay. These data demonstrated that the IHKE cell line may be a suitable model for IR research.

**2114**

OCHRATOXIN A- INDUCED GENE EXPRESSION DEREGULATIONS IN THE KIDNEY OF EKER RATS ANALYZED ON AFFYMETRIX CHIPS.

K. Stemmer<sup>1</sup>, H. Ellinger<sup>2</sup>, T. Lampertsoerfer<sup>1</sup>, M. Thiel<sup>2</sup>, H. Ahr<sup>2</sup> and D. Dietrich<sup>1</sup>. <sup>1</sup>*University of Konstanz, Konstanz, Germany* and <sup>2</sup>*Molecular and Genetic Toxicology, Bayer Health Care AG, Germany, Germany*.

Hereditary renal cell carcinomas (RCC) in the Eker rat model are due to a dominant germline mutation in the tuberous sclerosis 2 (Tsc2) tumor suppressor gene. As Eker rats still harbour one normal copy of the Tsc2 gene, a second somatic mutation might be the rate limiting step for the development of RCC. As previous studies have shown a clear susceptibility of Tsc2 mutant rats to RCC induction by chemical carcinogens, the Eker rat may represent a useful model to study the action of renal carcinogens. As Ochratoxin A is suggested to be a human renal carcinogen based on sufficient evidence of carcinogenicity in experimental animals, Eker rats were used to assess novel early markers of OTA induced carcinogenesis. In order to examine these events, male rats were treated for up to 14 days with a daily oral dose of 210 µg OTA/kg BW shown previously to induce kidney tumors in chronic study. After 1, 3, 7 and 14 days, groups of three rats were sacrificed, RNA from the kidney cortex was isolated and gene expression patterns were analyzed on Affymetrix RAE-230A chips. Using statistical and clustering tools provided by GeneData Expressionist Analyst software, characteristically deregulated genes were extracted and then functionally annotated. Those genes with altered expression belonged, amongst others, to the functional categories of amino acid and protein metabolism, membrane transport and oxidative stress. At the dose used, DNA damage response genes were not found to be deregulated. In conclusion, even low doses of OTA have a clear influence on gene expression within the first two weeks of toxin exposure. Preliminary functional analysis of the deregulated genes suggests an epigenetic rather than a genotoxic mechanism of action at the low dose.

**2115**

CHARACTERIZATION OF OCHRATOXIN A- TRANSPORTING ORGANIC ANION TRANSPORTERS IN RENAL CELLS.

M. Biester, E. O'Brien, A. Heussner and D. Dietrich. *Environmental Toxicology, University of Konstanz, Konstanz, Germany*.

Ochratoxin A (OTA) is a toxic metabolite produced by several fungal species. It is found with disturbing regularity in foodstuffs and fodder, therefore OTA is consumed by humans and animals. OTA is associated with the development of kidney carcinomas in laboratory animals and with nephropathies in pigs, as well as with two human renal diseases, namely Balkan endemic nephropathy (BEN) and urothelial tumors. The mechanism underlying its toxicity is still unknown. One plausible explanation for the obvious renal specificity of OTA could be accumulation in proximal tubular cells during the course of excretion (transport and/or reabsorption) thereby reaching toxic concentration within the cells. Several functional expression studies with *Xenopus laevis* oocytes have indicated OTA to be transported by organic anion transporters (Oats). In the present study the expression of Oat1, Oat2 and Oat3 in proximal tubular cells were investigated. All three transporter isoforms could be detected in porcine renal cortical tissue at RNA-level via RT-PCR, using human OAT1/2/3 primers. Sequence analysis and comparison of human and pig Oat-sequences showed high similarity. However, the expression

of these transporters was lost during preparation/ passaging of primary porcine kidney cells (PKC). Optimization of preparation and culture conditions is currently being undertaken with the aim of maintaining stable expression and functionality of Oats in PKC.

**2116**

CYTOTOXICITY OF THE NEPHROTOXINS ARISTOLOCHIC ACID AND MAM-ACETATE ON HUMAN AND PORCINE KIDNEY CELL LINES AND PRIMARY KIDNEY CORTEX CELLS.

S. Huljic<sup>1</sup>, E. Dorr<sup>2</sup>, B. Brune<sup>2</sup> and D. Dietrich<sup>1</sup>. <sup>1</sup>*University of Konstanz, Konstanz, Germany* and <sup>2</sup>*University of Kaiserslautern, Kaiserslautern, Germany*.

The nitrophenanthrene derivatives aristolochic acid I and II (AA), are the major components of the plant extract of *Aristolochia* spp. In 1982 it was observed that AA is a potent carcinogen in rats, causing a high incidence of tumours in the forestomach as well as primary tumours in the renal cortex, renal pelvis and urinary bladder. AA-exposed humans presented with a rapidly progressive renal fibrosis followed by a high prevalence of urothelial cancer. Cycasin is contained in cycad plants used by some populations as food. It is carcinogenic in several animal species, inducing tumours in various organs including the kidney. However, little is known about the toxic effects in human kidney. Methylazoxymethanol (MAM), the aglycone of cycasin is assumed to be the metabolite responsible for toxicity. The closely related synthetic substance methylazoxymethanol acetate (MAM-Ac) is more stable and was therefore used in this study. The cytotoxic effects of AA and MAM-Ac on human and porcine cell lines (HEK293, IHKE, LLC-PK1) as well as on human and porcine primary kidney cortex cells (HKC, PKC) were investigated. Exposure times were 24, 48, and 72h and the endpoints chosen were MTT reduction and cell number. Differences in sensitivity between species, sex and cell type were investigated. Preliminary data suggest distinct differences in sensitivity between species and between primary cells and cell lines. For example pig primary cells were approximately 36 times more sensitive to AA than their human counterparts.

**2117**

EFFECT OF ETHYLENE GLYCOL METABOLITES ON VARIOUS CYTOTOXICITY PARAMETERS IN HUMAN PROXIMAL TUBULE CELLS.

C. Guo, Y. Li, B. Crenshaw and K. McMartin. *Pharmacology, LSU Health Sciences Center, Shreveport, LA*.

Ethylene glycol (EG) is nephrotoxic due to its metabolism. Most studies suggest that the toxicity is due to oxalate accumulation, but some have suggested that toxicity results from effects of metabolites such as glycoaldehyde (GLA) or glyoxylic acid (GXA) on proximal tubule cells. Initial studies showed that calcium oxalate monohydrate (COM), the form of oxalate *in vivo*, but not glycolic acid (GA) or GXA increases ethidium dimer uptake and decreases calcein AM fluorescence, suggesting cytotoxicity of COM. The present studies were designed to re-examine these results using other measures of cell death, such as lactate dehydrogenase (LDH) release and the conversion of the tetrazolium salt XTT to a colorimetric dye. Human proximal tubule cells in culture were incubated in physiologic buffers for 6 h at 37°C with COM (1-10 mM), GA (5-25 mM), GXA (0.2-5 mM) and GLA (0.2-2 mM). To assess effect of acidity on the cytotoxicity, all incubations were carried out at pH 6, 6.5, 7 or 7.4. The results show that COM dose-dependently increased LDH release, while GA, GXA and GLA did not increase the release. Conversely, COM had no effect on the XTT assay, while GA and GXA decreased XTT activity only at acidic pH. GLA decreased XTT activity at 1-2 mM and this effect was exacerbated at pH 6. The correlation between the uptake of ethidium monomer and the release of LDH suggest that COM is cytotoxic to human kidney cells in culture, while none of the other metabolites are toxic at relevant concentrations. The data also suggest that the XTT assay is not a valid measure of cytotoxicity in this system.

D. Anderson Cancer Center, Science Park-Research Division, Smithville, TX*.

2, 3, 5-Tris-(glutathion-S-yl)hydroquinone (TGHQ), a metabolite of hydroquinone, induces ROS-dependent DNA damage and cell death in renal proximal tubule epithelial cells (LLC-PK1). 2-D PAGE coupled to MALDI-TOF peptide mass mapping and post source decay revealed that TGHQ altered the relative intensity of three spots, each identified as peroxiredoxin 3 (Prx3), in LLC-PK1 cells.

After TGHQ treatment, the intensity of the spot with a more acidic pI increased, whereas intensity of the spot with more basic pI decreased. Non-denaturing western blot analysis using a specific antibody against Prx3, revealed an additional band after TGHQ treatment, migrating faster than the equivalent band in the untreated sample, possibly due to oxidation. Interestingly, Prxs behave as antioxidative enzymes to reduce peroxides, and regulate MAPK activation. Prxs can be hyperoxidized and are inactivated by oxidation of the reactive cysteine residue to either a sulfenic or sulfonic acid, in the presence of large amount of ROS. Because TGHQ induces ROS-dependent MAPK and histone H3 phosphorylation precede cell death, the post-translational modification of Prxs, especially as a consequence of oxidation, may play an important role in ROS-induced cell death. Attempts to identify the Prx3-associated proteins are under way in LLC-PK1 cells. Our data suggest that TGHQ generated ROS induce a post-translational modification within Prx3, which likely plays an important role in TGHQ-mediated renal cell death. Prx3 oxidation in ROS-treated renal cells is also highly reproducible, and can therefore be used as a biomarker for ROS-induced renal cell damage. (Grants: ES07784, DK59491, GM39338, P30ES-07784, P30ES-06694)

**2119** UP-REGULATION OF HEAT SHOCK PROTEIN 27 AND RETINOL BINDING PROTEIN CONTRIBUTES TO 11-DEOXY-16, 16-DIMETHYL PROSTAGLANDIN E2 MEDIATED CYTOPROTECTION.

J. L. Lord<sup>1</sup>, Z. Jia<sup>1</sup>, D. W. Cromey<sup>2</sup>, R. C. Lantz<sup>2</sup>, T. J. Monks<sup>1</sup> and S. S. Lau<sup>1</sup>.

<sup>1</sup>Department of Pharmacology & Toxicology, College of Pharmacy, University of Arizona, Tucson, AZ and <sup>2</sup>Cell Biol & Anat, College of Medicine, University of Arizona, Tucson, AZ.

11-Deoxy-16, 16-dimethyl prostaglandin E2 (DDM-PGE2) protects renal proximal tubular epithelial cells (LLC-PK1) against oncotic cell death via the activation of a thromboxane A2 (TP) receptor. Cytoprotection is associated with the up-regulation of several proteins, including ER stress proteins, elongation factors, and several cytoskeletal proteins. 2-D gel electrophoresis coupled with MALDI-TOF peptide mass mapping revealed heat shock protein 27 (HSP27) was also selectively induced by DDM-PGE2. HSP27 is known to regulate actin filament dynamics and to participate in the stabilization of the actin cytoskeleton. Consistent with this, DDM-PGE2 prevented actin depolymerization induced by Cytochalasin D (CD), an actin filament disrupting agent, and HSP27 co-localized with disrupted actin after CD treatment. Moreover, HSP27 translocated into the nucleus, and co-localized with actin in close proximity to the cell membrane following treatment with 2, 3, 5-(trisglutathion-S-yl)-hydroquinone (TGHQ). HSP27 is a molecular chaperone that is phosphorylated in response to reactive oxygen species. Following TGHQ treatment, 2-D PAGE and western blot confirmed the phosphorylation of HSP27, correlating with its role in compensatory cytoprotection. DDM-PGE2 also induced the synthesis of retinol binding protein (RBP). The TP agonist, U46619, recapitulated the effects of DDM-PGE2, and the TP antagonist, SQ29, 845, abolished the induction of RBP in parallel with a loss in cytoprotection. The retinoic acid nuclear receptor agonist, all-trans retinoic acid, induced RBP with similar kinetics as DDM-PGE2 and U46619, with maximum induction occurring at 12 hours. All-trans retinoic acid also recapitulated the cytoprotective effects of DDM-PGE2 in LLC-PK1 cells, suggesting the possible involvement of retinoid signaling in the cytoprotective response. (GM56321, ES06694).

**2120** ASSESSMENT OF *IN VITRO* TOXICITY OF SELECTED CHEMO-THERAPEUTIC DRUGS USING HUMAN PRIMARY RENAL CELLS.

W. Li, M. Lam, A. Birkeland, L. Warfe, D. Choy, J. Post and M. Sullivan. *Pharmacology, Berlex, Richmond, CA.*

Chemo-therapeutic drugs often cause organ toxicity due to non-specific effects on cancerous and normal cells. Improving safety or reducing toxicity presents a critical challenge for drug discovery. In the present study, effects of selected anti-cancer drugs (camptothecin, doxorubicin, colchicine, paclitaxel, cisplatin, and carboplatin) on cell function/viability and proliferation mechanisms were investigated. Potency or anti-proliferation activity of each drug on cancer cells (hepatoma HepG2) and human primary renal proximal tubule cells (hRPTECs) were determined with the [<sup>3</sup>H]thymidine incorporation assay and results indicated all six drugs blocked cell proliferation of both cell types. EC<sub>50</sub> values for anti-proliferation activity suggested that camptothecin is most potent, followed by doxorubicin, paclitaxel, colchicine, cisplatin and carboplatin in hRPTECs. Cytotoxicity to hRPTECs was assessed with the ATP bioluminescence assay that monitors changes in cellular ATP level. Camptothecin, doxorubicin and cisplatin induced cytotoxicity in hRPTECs with EC<sub>50</sub> for cytotoxicity at 0.4, 11.5 and 39.3  $\mu$ M, respectively. The tested drugs displayed wide dosage separation between potency threshold and cytotoxicity based on EC<sub>50</sub> ratios. These findings using hRPTECs correlated well

with reported human nephrotoxicity. Therefore *in vitro* hRPTEC system provides a useful tool for understanding drug properties and for future safety testing of new chemo-therapeutic drugs.

**2121** NEPHROTOXICITY OF N-(3, 5-DICHLOROPHENYL)-3-HYDROXYSUCCINAMIC ACID IN MALE AND FEMALE FISCHER 344 RATS.

G. O. Rankin, D. K. Anestis, K. R. Saunders and S. K. Hong. *Pharmacology, Marshall University, Huntington, WV.*

Previous studies demonstrated that heated solutions of N-(3, 5-dichlorophenyl)-3-hydroxysuccinamic acid (3-NDHSA), a metabolite of the agricultural fungicide N-(3, 5-dichlorophenyl)succinimide (NDPS), induced nephrotoxicity in rats. However, the possibility existed that warming 3-NDHSA cyclized it to the nephrotoxic metabolite N-(3, 5-dichlorophenyl)-2-hydroxysuccinimide. The purpose of this study was to examine the nephrotoxic potential of non-heated solutions of 3-NDHSA in male and female Fisher 344 rats to determine the effects of heating on nephrotoxic potential and gender differences in toxic potential. Rats (4/group) were administered a single injection of 3-NDHSA (0.1, 0.2 or 0.4 mmol/kg, ip) or vehicle, and renal function was monitored at 24 and 48 hr. In male rats, 3-NDHSA 0.2 mmol/kg induced mild nephrotoxicity seen as diuresis and transient, mild proteinuria. However, 3-NDHSA 0.4 mmol/kg induced marked nephrotoxicity. In female rats, 3-NDHSA 0.1 mmol/kg did not affect renal function, while 3-NDHSA 0.2 mmol/kg induced mild nephrotoxicity as evidenced by transient diuresis and proteinuria. As in males, 3-NDHSA 0.4 mmol/kg induced marked nephrotoxicity. These results indicate that 3-NDHSA is equipotent to NDPS in inducing nephrotoxicity, but unlike NDPS and other nephrotoxic NDPS metabolites, 3-NDHSA does not exhibit gender differences in nephrotoxic potential. Supported in part by NIH grant DK31210.

**2122** COMPARISON OF THE *IN VITRO* NEPHROTOXIC POTENTIAL OF DICLOFENAC AND ACETAMINOPHEN IN ISOLATED RENAL PROXIMAL TUBULES FROM MALE FISCHER 344 RATS.

S. L. Miles, J. G. Ball and G. O. Rankin. *Pharmacology, Marshall University, Huntington, WV.*

Acetaminophen (APAP) and diclofenac (DC) which are frequently used as analgesics have each been associated with causing adverse renal effects. While nephrotoxic events associated with APAP are generally due to drug overdose, diclofenac has been shown to cause nephrotoxicity at therapeutic doses. The purpose of this study was to assess and compare the nephrotoxic potential of low concentrations of APAP and DC. To assess nephrotoxicity, the effects of APAP and DC on cellular lactate dehydrogenase (LDH) release and nucleotide levels (ATP, ADP, AMP) were investigated in isolated renal proximal tubules (IRPT) from male Fischer 344 rats. IRPTs were incubated for 30 or 60 minutes in the presence of APAP (200 or 500  $\mu$ M), and for 15 or 30 minutes with DC (200 or 500  $\mu$ M). APAP was not nephrotoxic at the tested concentrations and time points in IRPTs. However, acute DC-induced toxicity in IRPTs as demonstrated by increased LDH release was preceded by a decrease in ATP levels. ATP levels were found to be significantly depressed by both concentrations of DC at 15 minutes, while LDH release was not increased. By 30 minutes, DC treatment caused a significant increase in LDH release, and ATP and ADP levels were both significantly decreased. This data indicates that while APAP does not appear to have any nephrotoxic potential at these low concentrations, early events in DC toxicity appear to result in the alteration of mitochondrial production of ATP, or, due to a toxic cellular reaction, the cellular needs for ATP exceeds the cells ability to produce ATP. This toxic event (alterations in ATP levels) occurs at an earlier time point than general cellular toxicity as demonstrated by LDH release and is in agreement with the potential for DC to induce nephrotoxicity at therapeutic doses.

**2123** *IN VITRO* GSH ADDUCT FORMATION: EVIDENCE FOR BIOACTIVATION OF THE NEPHROTOXICANT N-(3, 5-DICHLOROPHENYL)SUCCINIMIDE THROUGH ALCOHOL-O-GLUCURONIDATION AND SULFATION.

D. Cui<sup>1,2</sup>, G. O. Rankin<sup>3</sup> and P. J. Harvison<sup>1</sup>. <sup>1</sup>Department of Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA, <sup>2</sup>Department of Pharmaceutical Candidates Optimization, Bristol-Myers Squibb, Princeton, NJ and <sup>3</sup>Department of Pharmacology, Marshall University School of Medicine, Huntington, WV.

The agricultural fungicide, N-(3, 5-dichlorophenyl)succinimide (NDPS), is nephrotoxic in rats. Previous studies indicated that metabolism of NDPS (both Phase I and Phase II) contributes to the mechanism of toxicity. Small amounts of

Phase II metabolites, including alcohol-O-linked glucuronides and sulfates, have been identified *in vivo*. These conjugates were also produced *in vitro* from N-(3, 5-dichlorophenyl)-2-hydroxysuccinimide (NDHS) an oxidative metabolite of NDPS. In the current study, we investigated the chemical reactivity of the NDHS glucuronide and sulfate conjugates and compared their *in vitro* GSH adduct formation with NDHS. Reactivity of the synthetic NDHS-O-sulfate (NSC), a putative reactive metabolite, was also studied. NDHS (0.1 mM) was incubated with rat liver S9 in the presence or absence of co-factors for conjugations (UDPGA or PAPS). GSH (5 mM) was added in all the reactions, and the mixtures were incubated for 40 min at 37 °C. In a separate experiment, aliquots of the incubates were collected at different time point (5-160 min) after GSH addition. Samples were analyzed using LC-MS/MS. Six GSH adducts were formed in incubations where UDPGA/PAPS were added, and they were identified as three pairs of diastereomers of GS-NDHS, and 2-/3-GS-N-(3, 5-dichlorophenyl)-2-/3-hydroxysuccinamic acids (2-/3-GS-NDHSA). Compared to NDHS, NSC was ~500-fold more reactive towards GSH conjugation. Fortifying Phase II cofactors also increased the formation of GSH adducts by ~8-fold. Results from these experiments demonstrate that formation of the alcohol-O-glucuronide and O-sulfate conjugates in NDPS metabolism may represent bioactivation pathways, and may potentially contribute to the mechanism of nephrotoxicity.

## 2124

### EFFECT OF ENANTIOMER-BASED INHIBITORS OF $\text{Ca}^{2+}$ -INDEPENDENT PHOSPHOLIPASE A<sub>2</sub> ON RENAL AND CANCER CELL DEATH.

L. Zhang, W. Zhang and B. S. Cummings. *Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.*

Recent studies suggest that human embryonic kidney cells (HEK293), kidney (Caki-1), lung (A549), prostate (PC-3) carcinomas, and brain glioblastomas (A172) express both the cytosolic (iPLA<sub>2</sub>β) and microsomal (iPLA<sub>2</sub>γ) isoforms of  $\text{Ca}^{2+}$ -independent phospholipase A<sub>2</sub> (iPLA<sub>2</sub>), and that iPLA<sub>2</sub> inhibition decreased chemotherapeutic-induced apoptosis in rabbit renal proximal tubules cells (RPTC). However, the effect of iPLA<sub>2</sub> inhibitors on chemotherapeutic-induced cell death in human renal and cancer cells is unknown. Treatment of PC-3 and A172 cells with racemic BEL (0-5.0  $\mu\text{M}$ ) increased annexin V (apoptotic cell marker) and propidium iodide (PI, oncotic cell marker) staining. In contrast, treatment of RPTC, HEK293, Caki-1 or A549 cells with BEL for 24 h did not. BEL treatment prior to cisplatin (0-100  $\mu\text{M}$ ) or vincristine (0-2  $\mu\text{M}$ ) exposure reduced apoptosis 30-50% in all kidney cells tested (RPTC, HEK293 and Caki-1 cells). In contrast, BEL had no effect on cisplatin- or vincristine-induced cell death in PC-3 or A172 cells, or cisplatin-induced apoptosis in A549 cells. Interestingly, pre-treatment of A549 cells with BEL altered the mechanism of vincristine-induced cell death from apoptosis to oncosis. Because racemic BEL inhibits both cytosolic iPLA<sub>2</sub>β and microsomal iPLA<sub>2</sub>γ, more enantiomeric selective inhibitors were studied. R- and S-enantiomers of BEL were separated using high performance liquid chromatography and the selectivity of S-BEL for cytosolic iPLA<sub>2</sub>β and microsomal iPLA<sub>2</sub>γ was verified in RPTC. Following verification of selectivity the effect of the two enantiomers on cell death was studied in Caki-1, HEK293, PC-3, A172 and A549 cells using 3-(4, dimethylthiazolyl-2)-2, 5-diphenyltetrazolium bromide (MTT). Treatment with S-BEL alone caused greater decreases in MTT staining compared to cells treated with either R-BEL or racemic-BEL in all cell lines, suggesting that selective inhibition of iPLA<sub>2</sub>β may induce cell death. Collectively, these data suggest that iPLA<sub>2</sub> isoforms mediate the mechanisms of cell death in both human renal and cancer cells.

## 2125

### IDENTIFICATION AND CHARACTERIZATION OF iPLA<sub>2</sub>γ IN MITOCHONDRIA.

G. R. Kinsey<sup>1</sup>, J. McHowat<sup>2</sup> and R. G. Schnellmann<sup>1</sup>. <sup>1</sup>*Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC* and <sup>2</sup>*Pathology, St. Louis University, St. Louis, MO.*

We have shown that primary cultures of rabbit renal proximal tubular cells (RPTC) express  $\text{Ca}^{2+}$ -independent phospholipase A<sub>2</sub>γ (iPLA<sub>2</sub>γ) in the endoplasmic reticulum (ER). Inhibition of RPTC iPLA<sub>2</sub>γ with bromoenol lactone (BEL) potentiated lipid peroxidation and necrotic cell death induced by oxidants. While two recent reports described iPLA<sub>2</sub> activity in mitochondria, the specific isoform(s) of iPLA<sub>2</sub> responsible for this activity were not determined. The goals of the present study were to determine 1) whether RPTC possess mitochondrial iPLA<sub>2</sub> activity 2) the characteristics and identity of this iPLA<sub>2</sub> and 3) whether human kidney cells possess similar ER and mitochondrial activity. Mitochondria were isolated from rabbit kidney cortex, RPTC and human embryonic kidney (HEK293) cells and iPLA<sub>2</sub> activity measured as the cleavage of 16:0, [<sup>3</sup>H]18:1 phosphatidylcholine or plasmalogen substrates in the absence of  $\text{Ca}^{2+}$  (4 mM EGTA). iPLA<sub>2</sub> activity was detected in rabbit kidney and RPTC mitochondrial inner membranes. Three isoforms of iPLA<sub>2</sub> could be responsible for the mitochondrial activity, cPLA<sub>2</sub>γ, iPLA<sub>2</sub>β

or iPLA<sub>2</sub>γ. Using the differential sensitivity to iPLA<sub>2</sub> inhibitors among iPLA<sub>2</sub> isoforms, we determined that rabbit kidney mitochondrial iPLA<sub>2</sub> was inhibited by racemic BEL and R-BEL, but not methyl arachidonyl fluorophosphonate (MAFP) or S-BEL. Immunoblot analyses using an anti-peptide antibody to iPLA<sub>2</sub>γ revealed an 88 kDa immunoreactive protein in rabbit kidney ER and mitochondria. These results show that rabbit kidney mitochondrial iPLA<sub>2</sub> is iPLA<sub>2</sub>γ. We also identified iPLA<sub>2</sub>γ, but not cPLA<sub>2</sub>γ or iPLA<sub>2</sub>β, in the ER and mitochondria of HEK293 cells. In summary, iPLA<sub>2</sub>γ is found in two subcellular membranes that are subjected to oxidative stress and vital for cell function and survival. This is consistent with the hypothesis that iPLA<sub>2</sub>γ protects cells from oxidative stress by inhibiting and/or repairing lipid peroxidation.

### ISCHEMIA-INDUCED CLEAVAGE OF CADHERINS IN NRK CELLS: EVIDENCE FOR A ROLE OF MT1-MMP.

M. Pulido<sup>1</sup>, K. Bayless<sup>2</sup>, R. Burghardt<sup>3</sup>, G. Davis<sup>2</sup> and A. Parrish<sup>1</sup>.

<sup>1</sup>*Pharmacology and Toxicology, Texas A&M University System Health Science Center, College Station, TX*, <sup>2</sup>*Pathology, Texas A&M University System Health Science Center, College Station, TX* and <sup>3</sup>*Veterinary Anatomy, Texas A&M University, College Station, TX.*

Ischemia is the leading cause of acute renal failure (ARF), a disease associated with high morbidity and mortality. Disruption of intercellular adhesion in the proximal tubules is linked to ARF, although the molecular mechanism(s) remain unclear. In these studies, we adapted a model of ischemia to normal rat kidney (NRK) cells and examined the cadherin/catenin complex, the predominant regulator of cell-cell adhesion. Ischemia was induced by applying a thin layer of phosphate buffered saline (PBS) solution supplemented with calcium and magnesium and a layer of mineral oil, restricting exposure to oxygen. Hypoxia was detected by an increase in pimonidazole adducts, as well as an increase in GLUT-1 protein levels. Ischemia did not decrease cell number, but there was a decrease in ATP levels. In addition, there was no evidence of cleaved caspase 3 or 9 during 6 hr of ischemia. Ischemic cells exhibited an extracellular 80 kDa and intracellular 40 kDa E-cadherin fragment after 4-6 hr of ischemia. While no fragments of N-cadherin were observed at any time point, the detectable levels of this protein decreased during ischemia. E-cadherin cleavage and loss of N-cadherin was associated with decreased cadherin function as revealed by cell aggregation. The effects of ischemia on E- and N-cadherin were independent of mRNA and protein synthesis. The MMP inhibitors, GM6001 and TAPI-O, inhibited cleavage and/or loss of E- and N-cadherin protein expression. TIMP-3 and to a lesser extent TIMP-2, but not TIMP-1, inhibits ischemic cleavage and/or loss of E- and N-cadherin, suggesting the involvement of a membrane-bound MMP. Blocking MT1-MMP activity fully protects full-length E- and N-cadherin. These results demonstrate that ischemia induces activation of latent MT1-MMP and subsequent disruption of cadherin/catenin complexes, implying that MT1-MMP plays a role in ischemia-induced ARF.

## 2127

### ROLE OF HEAT SHOCK PROTEINS AND SIGNALING PATHWAYS IN DETERMINING RESPONSE OF HUMAN PROXIMAL TUBULAR CELLS TO S-(1, 2-DICHLOROVINYL)-L-CYSTEINE (DCVC).

D. A. Putt, L. H. Lash, S. E. Hueni and B. P. Horwitz. *Pharmacology, Wayne State University Sch. Med., Detroit, MI.*

Confluent, primary cultures of human proximal tubular (hPT) cells were used as a model system to determine time and dose dependence of toxic responses to DCVC, a nephrotoxic metabolite of the environmental contaminant and putative renal carcinogen trichloroethylene (TCE). Previous studies showed that DCVC causes cellular necrosis only at relatively high doses (> 100  $\mu\text{M}$ ) and long incubation times (> 24 hr) whereas both apoptosis and enhanced cellular proliferation occur at relatively low doses (10-100  $\mu\text{M}$ ) and early incubation times (2-8 hr). To investigate whether differential effects on expression of regulatory proteins were associated with these responses, we performed Western blots on hPT cells treated for up to 24 hr with a range of concentrations of DCVC. Exposure of hPT cells to concentrations of DCVC that are associated with apoptosis and enhanced cell proliferation caused marked increases (1.5- to 10-fold) in expression of several proteins that regulate apoptosis (Bcl-2, Bax, Apaf-1, caspase-9 and PARP cleavage products) and cellular growth and differentiation (c-Jun, p53, Hsp27). Effects on c-Jun, p53, and Hsp27 implicate function of the mitogen activated protein kinase pathway and changes in the cellular cytoskeleton in determining the response of the cell to DCVC exposure. DCVC exposure is also known to activate protein kinase C. Higher concentrations of DCVC caused an increase in expression of NF- $\kappa$ B p65 subunit, consistent with oxidative stress. Hence, we conclude that exposure of hPT cells to DCVC induces several proteins and activates multiple signaling pathways. Depending on dose and time of exposure, these signaling pathways can lead to either cell death by necrosis or apoptosis, repair, or enhanced cell proliferation. The precise pattern of expression of these and other proteins may serve as molecular

markers for TRI or DCVC exposure and effect in human kidney. Identification of these pathways may also suggest novel therapeutic approaches. (Supported by NIH Grant ES08828.)

## 2128

### IDENTIFICATION AND LOCALIZATION OF CALPAIN 10 TO MITOCHONDRIA.

D. Arrington and R. G. Schnellmann. *Pharmaceutical Sciences, MUSC, Charleston, SC.*

Calpains,  $\text{Ca}^{2+}$ -activated cysteine proteases, are a family of 14 proteases that can be sub-divided into two classes based on the presence (*typical*) or absence (*atypical*) of domain IV (the primary  $\text{Ca}^{2+}$ -binding domain). While calpains are largely cytosolic, we showed that the mitochondrial matrix contained calpain activity and that inhibition of this activity blocked  $\text{Ca}^{2+}$ -induced mitochondrial dysfunction. The goal of this study was to identify the mitochondrial matrix calpain. The calpain inhibitor PD150606 inhibits calpain activity by blocking  $\text{Ca}^{2+}$  binding in domain IV and, thus, can be used to differentiate between *typical* and *atypical* calpains. PD150606 did not inhibit matrix calpain activity. Subsequently, we examined all calpain sequences for a mitochondrial targeting sequence using the mitochondrial protein prediction algorithm MITOP2 (<http://ihg.gsf.de/mitop2/start.jsp>). Only calpain 10, an *atypical* calpain, received a positive score using this algorithm. Using immunoblot analysis and two different antibodies directed against calpain 10, a 75 kDa immunoreactive band was identified, consistent with the molecular weight predicted by the calpain 10 amino acid sequence. Finally, we expressed a calpain 10-GFP fusion construct in NIH-3T3 fibroblasts and determined that calpain 10 localized to the mitochondria. Thus, using a variety of approaches, we have shown that the mitochondrial matrix calpain is calpain isoform 10. The mitochondrial localization of calpain 10 has important implications for mitochondrial injury.

## 2129

### EPITHELIAL BARRIER CHARACTERISTICS AND EXPRESSION OF CELL ADHESION MOLECULES IN PROXIMAL TUBULE-DERIVED CELL LINES COMMONLY USED FOR *IN VITRO* NEPHROTOXICITY TESTING.

W. C. Prozialeck, P. C. Lamar and C. S. Smith. *Pharmacology, Midwestern University, Downers Grove, IL.*

During the course of studies examining the effects of nephrotoxic metals on proximal tubule derived cell lines in culture, we noticed that the cell lines seemed to vary markedly in their epithelial barrier characteristics. To examine this phenomenon in more detail, we monitored the development of transepithelial electrical resistance (TER) and the expression of a panel of cell adhesion molecules that are involved in maintaining epithelial barrier function in several proximal tubule-derived cell lines that have been commonly used as model systems for *in vitro* toxicity studies. The specific cell lines that were studied included: LLC-PK<sub>1</sub>, OK, NRK52E and HK-2, along with commercially available primary cultures of human proximal tubule epithelial cells (HTPE). The results showed that the LLC-PK1 cell line developed the highest TER (> 200 ohms $\bullet$ cm<sup>2</sup>) followed by the OK cell line (~50 ohms $\bullet$ cm<sup>2</sup>). All of the other cell lines failed to develop significant TER even after 2 weeks in culture. Immunofluorescence labeling studies showed that all of the cell lines, except HK-2 and OK, expressed high levels of the calcium-dependent cell adhesion molecule, E-cadherin; the OK cells expressed high levels of N-cadherin and the HK-2 cells expressed lower levels. All of the cell lines expressed moderate-high levels of the tight-junction scaffolding protein ZO-1. In addition, the LLC-PK<sub>1</sub> and OK cells expressed high levels of the tight-junction barrier protein occludin, which was co-localized with ZO-1. By contrast, the other cell lines exhibited only weak occludin labeling. These findings indicate that the OK cell line exhibits characteristics that most closely resemble those of proximal tubule epithelial cell *in vivo*, and they suggest that the differences in the barrier characteristics of renal epithelial cell lines may be related to differences in the expression of the tight-junction barrier protein occludin. Supported by NIH Grant R01 ES006478.

## 2130

### CYTOTOXICITY AND METABOLISM OF S-1, 2-DICHLOROVINYL-GLUTATHIONE (DCV-GSH) AND CHLORAL (CH) BY HUMAN PROXIMAL TUBULE CELLS (HPTC) IN CULTURE.

E. A. Lock, L. Tolliver-Ho and R. G. Schnellmann. *Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC.*

Trichloroethylene (TRI) is an important industrial solvent that causes toxic nephrosis in rats and mice following chronic exposure. TRI is metabolised by CYP 450 to CH, as a major pathway, and via GSH conjugation to DCV-GSH as a minor pathway. We have examined the effect of daily exposure to CH and DCV-GSH for 10

days on primary HPTC in culture from 4 different donors. Confluent cells, 8-10 days after seeding, were exposed daily to CH at 0.03 to 3mM or DCV-GSH at 0.05 to 5 $\mu$ M. Cytotoxicity was determined using MTT following 1, 3, 7 and 10 days exposure. Respiration in the presence and absence of FCCP (1 $\mu$ M) was measured after 10 days exposure to DCV-GSH. The extent of CH metabolism to trichloroethanol (TCE-OH) and trichloroacetic acid (TCA) was determined in the media by gas chromatography, while the presence of formic acid in the media was measured by 1H-NMR spectroscopy. DCV-GSH was cytotoxic to HPTC with an IC50 value of about 5  $\mu$ M/day after 10 days exposure with no effect at 0.5  $\mu$ M. Treatment with DCV-GSH inhibited both resting and uncoupled mitochondrial respiration after 10 daily exposures at concentrations > 0.5  $\mu$ M DCV-GSH. CH was not cytotoxic at doses up to 1mM/day for 10 days to HPTC. The cells readily metabolized CH at this dose to TCE-OH and TCA with about 50% being converted to TCE-OH and 2.5% to TCA each day for 10 days. Exposure to CH (3mM) also lead to a 3-fold increase in the concentration of formic acid in the media (control 0.065 $\pm$ 0.021mM; treated 0.18mM $\pm$ 0.037mM). Low daily doses of DCV-GSH lead to progressive cytotoxicity indicating that the enzymes metabolizing GSH conjugates and activating the cysteine conjugate ( $\beta$ -lyase) were present in these HPTC. CH was also readily metabolized over 10 days and we provide preliminary evidence for an increased excretion of formic acid. Microarray analysis is being conducted to look for gene changes in HPTC following subchronic exposure to non-cytotoxic doses of the GSH-derived metabolites of TRI.

### PROTEOMIC CHARACTERIZATION OF THE EFFECTS OF A KINASE INHIBITOR ON PROTEIN EXPRESSION IN RAT KIDNEY.

J. Leonard<sup>1</sup>, M. Courcol<sup>1</sup>, E. Boitier<sup>1</sup>, M. Duchesne<sup>2</sup>, F. Parker<sup>2</sup>, Z. Jayyosi<sup>3</sup>, R. A. Roberts<sup>1,4</sup> and J. Gautier<sup>1</sup>. <sup>1</sup>*Drug Safety Evaluation, Sanofi Aventis, Vitry-sur-Seine, France*, <sup>2</sup>*Functional Genomics, Sanofi Aventis, Vitry-sur-Seine, France*, <sup>3</sup>*Drug Safety Evaluation, Sanofi Aventis, Bridgewater, NJ* and <sup>4</sup>*Safety Assessment (current address), Astra Zeneca, Alderley Park, United Kingdom*.

In a 14-day oral toxicity study performed in male Sprague-Dawley rats, a kinase inhibitor compound X, that has been developed for the treatment of asthma, induced kidney toxicity at a dose of 200 mg/kg, but not at a pharmacological dose of 10 mg/kg. A proteomic study was initiated to elucidate the molecular mechanisms underlying the observed drug-induced nephrotoxicity. After protein extraction, 2D gel electrophoresis was performed using differential gel electrophoresis technology. Protein identification of the up- and down-regulated spots was performed by mass spectrometry. Results showed that compound X, at the low dose of 10 mg/kg, induced over-expression of 5 proteins and down-regulation of 8 proteins, whereas at 200 mg/kg it gave an up-regulation of 29 proteins and a down-regulation of 20 proteins. Data analysis showed that a number of biochemical pathways were modulated such as amino acid, urea cycle and protein metabolism, as well as carbohydrate metabolism. Proteins involved in anti-oxidant defence and xenobiotic metabolism were also found to be affected by treatment, giving clues to the mechanism of toxicity of compound X in kidney. Among the proteins of interest, kynurenine aminotransferase, glycine amidinotransferase and phosphotriesterase related protein, known to be involved in kidney impairment and/or xenobiotic detoxification, were also modulated and corroborated the histopathological observations. In addition, mass spectrometry results showed that proteins like ornithine aminotransferase and glycine amidinotransferase were detected in 2D gels as several spots corresponding to different isoelectric points or molecular weights; this suggests that drug-induced modulation of protein isoforms could be potentially used as a toxicity-specific signature of compound X in the kidney.

## 2132

### REGULATION OF GRP78 IN THE GLOMERULAR MESANGIAL CELL STRESS RESPONSE.

A. Nanez<sup>1,2</sup>, H. Falaharpisheh<sup>1,2</sup>, Y. Qian<sup>3</sup>, E. Tiffany-Castiglioni<sup>3</sup> and K. S. Ramos<sup>1,2</sup>. <sup>1</sup>*Biochemistry and Molecular Biology, University of Louisville, Louisville, KY*, <sup>2</sup>*Center for Genetics and Molecular Medicine, University of Louisville, Louisville, KY* and <sup>3</sup>*Department of Veterinary Anatomy & Public Health, Texas A&M University, College Station, TX*.

Chemical injury is associated with endoplasmic reticulum (ER) stress, a reaction characterized by activation of the unfolded protein response and proteasomal degradation of proteins expelled into the cytoplasm. The ER stress response may be caused by dysregulation of intra-ER  $\text{Ca}^{2+}$ , by oxidative stress, or buildup of misfolded proteins. Grp78 plays a central role in the ER stress response in various cell types, including neuronal and renal cells, and therefore, studies were conducted to evaluate mechanisms of the ER stress response in rat glomerular mesangial cells or kidney embryonic cells challenged with toxic metals (Mercury chloride ( $\text{HgCl}_2$ ) or lead ( $\text{Pb}$ ) acetate) or aromatic hydrocarbons (BaP), respectively. Challenge of mesangial cells with 1 or 10  $\mu\text{M}$   $\text{HgCl}_2$  or lead acetate was associated with concentration-dependent increases in grp78 mRNA and protein. CAT reporter assays

completed using constructs containing promoter sequences responsible for thapsigargin inducibility did not show trans-activation by either heavy metals or BaP. Co-treatment of metal-treated cells with actinomycin D (a transcriptional inhibitor) or cycloheximide (a protein synthesis inhibitor) ablated the induction response, suggesting that regulation of Grp78 by metals involves a transcriptional mechanism. Immunocytochemical analysis of kidney cells challenged with 3  $\mu$ M BaP revealed a 2-fold increase in Grp78 expression. Collectively, these data suggest that Grp78 is involved in the stress response of renal cells to different forms of chemical injury.

### 2133 REDUCTION OF CYCLOSPORIN A NEPHROTOXICITY BY GADOLINIUM CHLORIDE.

Z. Zhong and J. Sun. *Cell and Developmental Biology, University of North Carolina, Chapel Hill, NC*. Sponsor: J. Lemasters.

The immunosuppressant cyclosporin A (CsA) causes both hepato- and nephrotoxicity in patients. It is known that CsA activates Kupffer cells in the liver. In addition, liver regulation of renal function accounts for, at least partly, impaired urinary excretion in a variety of diseases. Therefore, these experiments investigated if gadolinium chloride ( $GdCl_3$ ), which selectively destroys Kupffer cells, would affect nephrotoxicity due to CsA. Rats were treated with CsA (25mg/kg, i.g.) or an equivalent volume of vehicle for 5 days. Intracellular calcium in Kupffer cells isolated from vehicle-treated rats was not altered by acute CsA addition (1  $\mu$  g/mL); however, in Kupffer cells isolated from CsA-treated rats, CsA addition increased intracellular calcium about 15-fold, indicating that CsA sensitizes and activates Kupffer cells. Kupffer cells isolated from the liver decreased about 70% after  $GdCl_3$  (20 mg/kg, i.v.) treatment. However,  $GdCl_3$  did not significantly alter monocytes/macrophages in the kidney as determined by ED1 and ED2 immunohistochemical staining. Glomerular filtration rates (GFR) and serum creatinine were about 0.6 ml/min/100 g body weight and 0.45 mg/dL, respectively, in vehicle-treated rats. CsA decreased GFR by 70% and doubled serum creatinine levels.  $GdCl_3$  blunted CsA-induced decreases in GFR and increases of serum creatinine by about 50%. Taken together, CsA inhibits renal function, at least in part, in a Kupffer cell-dependent manner. These results suggest that hepatic-renal interaction probably plays a role in CsA nephrotoxicity.

### 2134 THE EFFECT OF S-ADENOSYL-L-METHIONINE (SAMe) AND ASCORBIC ACID ON P-AMINOPHENOL TOXICITY IN RENAL SLICES.

M. Valentovic, R. Harmon and D. Hoover. *Pharmacology, Marshall University School of Medicine, Huntington, WV*.

p-Aminophenol is a known renal toxicant. The purpose of this study was to investigate the effect of the nutraceutical S-adenosyl-l-methionine (SAMe) and ascorbic acid on PAP *in vitro* nephrotoxicity. Renal cortical slices were prepared from kidneys obtained from Fischer 344 (F344) rats weighing 200-250 g. Renal slices were washed at 25°C in Krebs buffer. Renal slices were pretreated for 15 min with 2 mM ascorbic acid or 30-60 min with 0.2 mM SAMe. Slices were then incubated with 0, 0.1, or 0.25 5 mM PAP for up to 120 min at 37°C and constant oxygen. Renal slices exposed to 0.25 mM PAP showed toxicity as measured by increased lactate dehydrogenase (LDH) leakage and decreased pyruvate-stimulated gluconeogenesis. PAP decreased ( $p<0.05$ ) both total glutathione (GSH) and glutathione disulfide (GSSG) within 30 min when compared to vehicle controls. SAMe pretreatment did not reduce PAP toxicity as indicated by a comparable rise in LDH leakage. Pretreatment with ascorbic acid reduced PAP toxicity. Further studies examined the effect of ascorbic acid pretreatment on PAP associated depletion of glutathione. Pretreatment with ascorbic acid prevented PAP depletion of total glutathione. Total glutathione levels were diminished to 53% and 6% of control values following exposure to 0.1 and 0.25 mM PAP, resp. Tissues treated with 0.1 and 0.25 mM PAP pretreated with ascorbic acid had glutathione levels that were 111% and 91%, resp., of control. These data show that SAMe did not alter PAP toxicity. Furthermore, ascorbic acid pretreatment reduced toxicity of PAP in renal slices and this attenuation may be mediated by preventing glutathione depletion.

### 2135 HUMAN PRECISION-CUT KIDNEY-CORTEX SLICES AS A TOXICOLOGY MODEL FOR EVALUATING THE HYPERAMMONEMIC EFFECT OF VALPROATE: A CARBON 13 NMR STUDY.

G. Baverel, A. Vittorelli, C. Gauthier, C. Michoulet and G. Martin. *Metabolic and Renal Pathophysiology, INSERM U499, Lyon Cedex 08, France*. Sponsor: J. Descotes.

The aim of the present study was to evaluate the suitability of human precision-cut kidney-cortex slices as a model to study the mechanism whereby valproate stimulates renal ammoniogenesis and leads to hyperammonemia. The metabolism of ei-

ther unlabeled or 13C-labeled glutamine was studied in human kidney-cortex slices incubated either in Krebs-Henseleit medium for 4 hours or in William's medium E for up to 48 hours. After incubation, substrate removal and product formation were measured by enzymatic and NMR spectroscopy methods. Glutamate accumulation tended to plateau but glutamine removal and ammonia, alanine and lactate accumulation as well as flux through glutamate dehydrogenase increased to various extents with time for up to 4 hours of incubation indicating the metabolic viability of the slices. Valproate, a widely used antiepileptic drug and a hyperammonemic compound, markedly and in a dose-dependent manner stimulated ammonia production. With 3-13C-glutamine as substrate, and in the absence and the presence of valproate, 13C-glutamate, 13C-alanine and 13C-lactate accounted for 81% and 96%, 34% and 63%, 30% and 46% of the glutamate, alanine and lactate accumulations measured enzymatically, respectively. Combination of the 13C NMR results obtained with a mathematical model of the metabolic pathways involved revealed that valproate markedly stimulated fluxes through the ammoniagenic enzymes (glutaminase and glutamate dehydrogenase) and through alanine aminotransferase, phosphoenolpyruvate carboxykinase, pyruvate kinase and lactate dehydrogenase. The slices also metabolized glutamine and retained their reactivity to valproate during incubations lasting for up to 48 hours. These results demonstrate that, although endogenous metabolism substantially operates in the presence of glutamine, human precision-cut kidney-cortex slices are metabolically viable and respond to the ammoniagenic effect of valproate. Thus, this model is suitable for metabolic and pharmacological studies.

### 2136 UTILITY OF A SUBCLINICAL RENAL INJURY MODEL IN RATS FOR DETECTION OF INCREASED SENSITIVITY TO SITE-SPECIFIC NEPHROTOXIC METALS.

E. F. Madden, R. P. Brown and P. L. Goering. *Center for Devices and Radiological Health, USFDA, Silver Spring, MD*.

Subclinical renal injury (SRI) can predispose individuals to adverse effects of nephrotoxic metals. The objective of this study was to determine if kidneys in rats with SRI are more sensitive than healthy control animals to nephrotoxic metals that exert their effect on different segments of the nephron. To induce SRI, male Sprague-Dawley rats were dosed (sc) daily for 3 days with 250 mg/kg gentamicin, an aminoglycoside that primarily injures the proximal convoluted tubules ( $S_1/S_2$  segments). Twenty-four hr after the third injection, SRI- and saline-pretreated rats were injected with either saline or  $K_2Cr_2O_7$  (5.0 mg Cr/kg, sc).  $HgCl_2$  (0.25 mg Hg/kg, iv), or  $LiCl_2$  (5.0 mEq Li/kg, ip), compounds generally believed to exert effects primarily on the proximal convoluted tubule ( $S_1/S_2$  segments), proximal straight tubule ( $S_3$  segment), and distal tubule, respectively. Blood urea nitrogen (BUN) and creatinine, and urinary N-acetyl- $\beta$ -glucosaminidase/creatinine ratio (NAG/Cr), specific gravity (SG) and total protein (TP) were assessed 24 hours after metal injection. BUN levels were increased by 1.5-, 1.4-, 1.7-fold and NAG/Cr levels were elevated by 3.4-, 5.7-, and 2.2-fold in SRI rats challenged with Cr, Hg, and Li, respectively, compared to saline-pretreated rats challenged with metals. Similar fold-increases in BUN and NAG/Cr levels were observed in SRI rats challenged with metals compared to SRI rats challenged with saline. Slight increases in blood creatinine were observed in SRI rats challenged with metals compared to all other treatment groups. Urine specific gravity decreased in SRI rats challenged metals compared to metal treatment alone, but values were similar to SRI rats challenged with saline. Urinary TP was not altered in any treatment group. These results suggest that the gentamicin-induced model of SRI is sensitive to the effects of compounds that exert effects on specific nephron sites, thereby increasing the utility of the model for preclinical screening of compounds that may injure various nephron segments.

### 2137 PREPLACED RENAL CELL DIVISION IS THE CRITICAL MECHANISM OF PROTECTION IN MICE AGAINST S-1, 2-DICHLOROVINYL-L-CYSTEINE-INDUCED ACUTE RENAL FAILURE AND DEATH.

M. C. Korrapati<sup>1</sup>, J. Chilakapati<sup>1</sup>, E. A. Lock<sup>2</sup>, J. Latendresse<sup>3</sup>, A. Warbritton<sup>3</sup> and H. M. Mehendale<sup>1</sup>. <sup>1</sup>ULM, Monroe, LA, <sup>2</sup>MUSC, Charleston, SC and <sup>3</sup>NCTR, Jefferson, AR.

We have shown that mice pretreated with a low dose of S-1, 2-dichlorovinyl-L-cysteine (DCVC) protects them from death caused by a normally lethal dose of DCVC (autoprotection). Priming with low dose of DCVC increases sustained  $G_1$  to S-phase clearance due to the upregulated expression of phospho- retinoblastoma protein (pRB) that persists even after the lethal dose. Objective of the study was to test if the administration of colchicine (CLC), abolishes protection via down regulation of pRB leading to progression of injury in the absence of newly dividing/divided cells. First group of mice received a priming dose of DCVC (15 mg/kg) at 0

h followed by vehicle treatment (distilled water, 10 ml/kg) at 42 & 66 h prior to receiving a lethal dose (75 mg/kg) at 72 h. The second group of mice received CLC (1.5 mg/kg ip) instead of distilled water at 42 & 66 h, all other treatments remaining the same. Mice receiving low dose + CLC, DW + CLC and DW alone were maintained as the controls. CLC intervention abolished autoprotection and resulted in progression of injury leading to death. CLC abolished the promotogenic effect of the low dose of DCVC by down regulating cyclin D1/cdk4-mediated phosphorylation of retinoblastoma protein. S-phase stimulation was markedly inhibited as assessed by BrdU pulse and PCNA labeling. These mice suffered severe renal damage as assessed by light microscopy of H&E stained kidney sections. Plasma BUN and creatinine were significantly increased after CLC intervention. These findings suggest the protective dose-stimulated renal tissue repair and recovery from acute renal failure. Higher G<sub>1</sub> to S phase clearance by increased pRB is the key mechanism behind sustained stimulation of renal tissue repair in autoprotection. These findings raise the possibility that pRB-mediated mechanism may be availed for potential pharmacotherapeutic modulation to restore lost proximal tubular structure and function. (Supported by DK 61650).

INHIBITION OF TISSUE REPAIR LEADS TO PROGRESSION OF INJURY, ACUTE RENAL FAILURE AND DEATH IN MICE.

**R. N. Reddy** and **H. M. Mehendale**. *Toxicology, University of Louisiana Monroe, Monroe, LA.*

The objective of the present study was to test the hypothesis that inhibition of tissue repair by colchicine (CLC), an antimitotic agent, leads to progression of injury and animal death after exposure to a nonlethal dose of DCVC. Male Swiss Webster (SW) mice were administered a normally nonlethal dose of DCVC (30 mg/kg, i.p.) on day 0 and CLC (2 mg/kg, i.p.) at 42 h and 66 h after administration of DCVC and observed for mortality. BUN, serum creatinine, urinary volume, pH, specific gravity, glucose, protein, creatinine, N-acetyl  $\beta$ -D-glucosaminidase (NAG), calpain immunohistochemistry were assessed as markers of injury during a time course of 0 to 14 days. Immunohistochemistry and Western blotting for aquaporin 1 was also carried out. Tissue repair was assessed by <sup>3</sup>H-thymidine pulse labeling and PCNA immunohistochemistry. There was 100 % mortality by 120 h in the group of mice receiving CLC after DCVC as against 0 % mortality in mice receiving either DCVC or CLC alone. BUN and serum creatinine elevations peaked on days 2 and 3 in the group receiving DCVC and CLC but on days 5 and 6 in mice receiving DCVC alone which decreased later. Polyuria on days 1 and 2 in DCVC mice and oliguria occurred on days 4, 5 and 6 in the CLC control group. Urinary pH increased to 8 by day 1 in DCVC treated groups and to 9 in CLC treated group and remained so during 14 days in all the treated groups. Urinary glucose and NAG:creatinine ratio increased on day 1 in both the DCVC groups and was found unaltered in CLC treated group. CLC intervention decreased S phase stimulation by DCVC indicating inhibition of tissue repair. Calpain immunohistochemistry revealed higher extracellular calpain co-incident with progression of injury in the DCVC treated mice receiving CLC intervention. Neither DCVC with or without CLC nor CLC alone affected aquaporin 1 expression in the descending thin limbs of loops of Henle of the kidneys. The results from the present study indicate that tissue repair is essential for the survival of the mice (DK 61650).

**2139**

ROLE OF LOWER PROGRESSION OF DCVC-INITIATED RENAL INJURY IN DIABETES-INDUCED PROTECTION FROM NEPHROTOXICITY.

Our previous work showed that streptozotocin (STZ)-induced type 1 diabetic (DB) mice exhibit significantly lower progression of renal injury and higher survival induced by augmented nephrogenic tissue repair after challenge with a normally LD<sub>90</sub> dose (75 mg/kg, i.p.) of S-1, 2-dichlorovinyl-L-cysteine (DCVC). Objective of the present work is to investigate the mechanisms of lower progression of DCVC-initiated renal injury in diabetes. Progression of renal injury is thought to be mediated via the destructive actions of cysteine protease calpain, which leaks out of dying cells. Formalin fixed kidney sections from DB and nondiabetic (NDB) mice were immunohistochemically stained for localization of calpain following treatment with the lethal dose of DCVC. Significantly higher number of necrotic proximal tubules stained positive for calpain and these cases were associated with acute renal failure (ARF) in NDB kidneys from 12 to 36 h after DCVC treatment. In stark contrast, the DB kidneys revealed fewer calpain-positive tubules commensurate with the lower progression of DCVC-initiated tubular necrosis (12 to 72 h) in these mice. Calpastatin, the endogenous inhibitor of calpain is known to be over-

expressed in dividing/newly divided cells, thereby making them resistant to the progression of injury. Since DB kidneys have 4-fold higher number of cells advancing in S-phase even before DCVC treatment, we hypothesized that overexpression of calpastatin in DB kidney may explain the lower progression of DCVC-initiated renal injury. Immunohistochemistry revealed higher expression of calpastatin in DB kidney as compared to the NDB kidney before DCVC treatment. These data suggest that overexpression of calpastatin in cells advancing to S-phase in DB kidney imparts resistance to destruction by calpain, thereby explaining the markedly lower progression of DCVC-initiated renal injury, recovery from ARF-bound injury, and survival in DB mice. TISSUE DISTRIBUTION AND RENAL ONTOGENY OF ORGANIC CATION TRANSPORTERS IN MICE.

**Y. M. Alnouti, J. S. Petrick, T. R. Knight and C. D. Klaassen**. *University of Kansas Medical Center, Kansas City, KS.*

Organic cation transporters (Octs) are primarily responsible for the elimination of cationic endobiotics and xenobiotics from the body. Organic carnitine transporters (Octns) represent a subfamily of Octs that are responsible for carnitine disposition. Understanding the tissue distribution of Octs may be important in elucidating their role in absorption, distribution, elimination and organ-specific toxicity of xenobiotics. Similarly, ontogenetic expression may indicate a role for Octs in age-specific sensitivity to xenobiotic toxicity. Therefore, the purpose of this study was to characterize the tissue distribution and renal ontogenetic expression of Oct1, Oct2, Oct3, Octn1, Octn2 and Octn3 mRNA in male and female mice. mRNA expression was determined using the branched DNA signal amplification assay (bDNA). The tissues examined were liver, kidney, stomach, duodenum, jejunum, ileum, large intestine, heart, brain, lung, testes, ovary, placenta and uterus. Oct1, Oct2, Octn1 and Octn2 mRNA expression was highest in kidney. Oct1 was also moderately expressed in liver. Octn1 and Octn2 were also moderately expressed in duodenum, jejunum and ileum. Oct3 mRNA levels were highest in placenta and ovary, whereas Octn3 was exclusively expressed in testes. Renal expression of Oct2 mRNA was female-predominant. However, this gender difference in Oct2 kidney expression was not observed until 30 days after birth. Expression of Oct1, Oct2, Octn1 and Octn2 in kidney increased gradually from prenatal day -2 through day 45 in both genders. The kidney-predominant expression of Octs implicates Octs as key mediators in renal excretion of cationic xenobiotics. Furthermore, the elevated expression of Oct3 in ovary and placenta and the exclusive expression of Octn3 in testes might suggest a critical functional role for these transporters in the sex organs. (Supported by NIH Grants ES09649, ES-09716 and ES-07079).

DIETARY MODULATION OF THE RENAL TOXICITY OF P-NONYLPHENOL (NP) IN SPRAGUE-DAWLEY RATS.

**S. Cooper<sup>1</sup>, X. Fu<sup>1</sup>, J. R. Latendresse<sup>2</sup> and K. B. Delclos<sup>1</sup>.** <sup>1</sup>*NCTR, Jefferson, AR* and <sup>2</sup>*Charles River Laboratories, Jefferson, AR.*

We previously demonstrated that NP at 1000 and 2000 ppm fed in a soy- and alfalfa-free diet (5K96) from gestation day (GD) 7 to postnatal day (PND) 50 induced polycystic kidney disease in male and female rats (Latendresse et al., *Toxicol. Sciences*. 62: 140, 2001). To test our hypothesis that the soy-free diet had exacerbated this toxicity, male and female weanling rats were assigned to one of four diets, two of which were soy free (5K-96 and AIN-93G) and two of which contained soy (Purina 5001 and AIN-93G with soy protein isolate as the protein source (AIN-SPI)). Rats were mated within diet groups at approximately 11 weeks of age. On GD7, half of the vaginal plug-positive dams in each diet group were placed on the same diet containing 2000 ppm NP while the other half continued on control diet. Exposure continued through gestation and lactation, and pups were continued on the same diet as their dam until termination at PND 50. Neither diet nor NP treatment had significant effects on the proportion of dams producing litters, litter size or weight. Body, liver, and kidney weights were collected at necropsy of male and female pups on PND 2, 14, and 21, male pups at PND 50, and dams. Portions of the kidneys were fixed for later microscopic evaluation and frozen for biochemical assays. Body weights were generally significantly higher in animals fed Purina 5001 than those fed the other diets. In the PND 50 animals, NP significantly lowered terminal body weight in all diet groups. Liver to body weight ratios were significantly elevated by NP in all diet groups except 5K96. Kidney to body weight ratios were significantly elevated by approximately 2-fold by NP in the 5K96 and AIN-93G diet groups, but not in the Purina 5001 group. Relative kidney weight was slightly elevated (approximately 30%) in the AIN-SPI diet group. These organ weight differences were not observed in pups at other ages or in dams. While histological evaluation of the kidneys remains to be completed, these results confirm a significant effect of diet on the renal effects of NP.

## ETIOLOGY OF HYDRONEPHROSIS WITHOUT OBSTRUCTION IN THE MOUSE KIDNEY BY LACTATIONAL EXPOSURE TO DIOXIN.

N. Nishimura<sup>1</sup>, J. Yonemoto<sup>1</sup>, Y. Takeuchi<sup>1</sup>, C. Yokoi<sup>1</sup>, H. Nishimura<sup>3</sup> and C. Tohyama<sup>2</sup>. <sup>1</sup>*Endocrine Disruptors and Dioxin Project, National Institute for Environmental Studies and Dioxin Project, Tsukuba, Japan*, <sup>2</sup>*Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Japan and* <sup>3</sup>*Aichi Mizuho University, Toyota, Japan.*

The hydronephrosis is defined as a disease that has dilatation of the pelvis and calices proximal to the point of obstruction due to backpressure following the accumulation of urine. Prenatal exposure to teratogenic dose of 2, 3, 7, 8- tetrachlorodibenzo-p-dioxin (TCDD) has been established to cause this malformation in mice with hyperplasia of the ureteral epithelium. To elucidate the etiology of hydronephrosis by TCDD exposure, C57Bl/6 dams were given a single oral dose of 10g TCDD/kg on postnatal day (PND) 1 after the normal delivery, and pups were euthanized on specified times for pathophysiological and molecular analyses. Histopathological examinations on the hydronephrotic kidney from pups on PNDs 7, 14 and 21 showed that there is no apparent obstruction due to hyperplasia, and that immunostaining for cytochrome P450(CYP)1A1 is confined to the distal tubular epithelium. Pups that developed hydronephrosis manifested polyuria with elevated levels of Na and K in urine, and decreased concentrations of Na and K in the blood circulation. Microarray analysis with subsequent analysis by real-time RT-PCR on kidney tissues from pups showed gene expression of Na, K channel transporter genes are altered at least as early as PND7. The present results not only demonstrate a new finding on hydronephrosis without morphological obstruction, but also suggest a novel molecular mechanism to explain the etiology of this malformation that may be driven in an XRE-dependent fashion.

## EFFECTS OF CONAZOLE FUNGICIDES ON DEVELOPMENT AND PARTURITION IN THE RAT.

M. G. Narotsky<sup>1</sup>, J. C. Rockett<sup>1</sup>, C. R. Blystone<sup>2</sup>, A. K. Goetz<sup>2</sup>, H. Ren<sup>1</sup>, D. S. Best<sup>1</sup>, H. P. Nichols<sup>1</sup>, J. E. Schmid<sup>1</sup> and D. J. Dix<sup>1</sup>. <sup>1</sup>*Reproductive Toxicology Division, USEPA, ORD, NHEERL, Research Triangle Park, NC* and <sup>2</sup>*Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.*

Conazoles are fungicides used extensively in agriculture and as pharmaceuticals. As part of an effort to evaluate the changes in gene expression corresponding to reproductive toxicity, we examined the effects of three conazoles on pregnancy and neonates. Wistar Han rats were exposed via feed from gestation day 6 to the weaning of their litters to propiconazole (P) at 100, 500, or 2500 ppm; myclobutanil (M) at 100, 500, or 2000 ppm; triadimefon (T) at 100, 500, or 1800 ppm; or vehicle control. Litters were examined on postnatal days 0 and 8. The highest concentration of each of the three chemicals caused delayed parturition. T1800 had particularly severe effects, with 19% of the dams unable to successfully deliver live pups; in some cases dystocia led to maternal death. Increased pre- and postnatal mortality at M2000 and T1800 were attributed to effects on parturition. In addition, prenatal loss at P2500 was marginally increased. Pup weights were increased at M100 on day 0. Marginal increases in pup weight were noted on day 0 at M2000 and P2500, and on day 8 at M500 and P500. In contrast, T1800 pup weights were decreased on days 0 and 8. Anogenital distance (on day 0), analyzed with pup weight as a covariate, was increased in females at M2000, and in males at M2000, P2500, and T1800. We conclude that exposure to the highest concentrations of M, P, and T adversely affected parturition and consequently impacted perinatal survival. The effects on parturition and anogenital distance may be related to aromatase inhibition, a known property of conazole compounds. [This abstract does not necessarily reflect EPA policy.]

## TRIADIMEFON INDUCES RAT THYROID TUMORS THROUGH A NON-TSH MEDIATED MODE OF ACTION.

Nesnow<sup>1</sup>. <sup>1</sup>*Environmental Carcinogenesis Division, USEPA, Research Triangle Park, NC* and <sup>2</sup>*Reproductive Toxicology Division, USEPA, Research Triangle Park, NC.*

Conazoles are a class of fungicides used as agricultural and pharmaceutical products which inhibit ergosterol biosynthesis. Members of this class are hepatotoxic and cause mouse hepatocellular tumors and/or rat thyroid follicular cell tumors. Triadimefon-induced rat thyroid tumors may arise through increased TSH secretion after induction of thyroxine metabolizing enzymes. Male Wistar rats treated with triadimefon (TRID, 100, 500, 1800 ppm), propiconazole (PROP, 100, 500, 2500 ppm), or myclobutanil (MYCL, 100, 500, 2000 ppm) in feed for 4, 30, or

90d were evaluated for clinical signs, body and liver wt, histopathology of thyroid and liver, metabolizing enzyme activity, and serum T3, T4, and TSH levels. There was a dose-dependent increase in liver wt but body wts were not different from control for all treatments. Pentoxyresorufin O-dealkylation (PROD) activities had a dose-related increase at all time points for all conazoles. UGT activities were induced to the same extent after 30 and 90d for all three conazoles. Livers from all high dose treated rats had centrilobular hepatocyte hypertrophy after 4d, while only TRID and PROP treated rats had hepatocyte hypertrophy after 30d, and only TRID treated rats had hepatocyte hypertrophy after 90d. Thyroid follicular cell hypertrophy and colloid depletion was present only after 30d TRID treatment. A dose-dependent decrease in T4 was present after 4d with all 3 compounds but only the high doses of PROP and TRID after 30d. T3 was decreased in the high dose group of TRID after 4d and in a dose-dependent manner for all compounds after 30d. Thyroid hormone levels did not differ from control values after 90d and TSH was not different from control in any exposure group. Although this group of conazoles does transiently perturb thyroid function, these data suggest that thyroid tumors arising after TRID treatment are not a result of persistent increases in TSH. [This abstract does not reflect EPA policy.]

## MYCLOBUTANIL AND TRIADIMEFON METABOLISM BY RAT CYP ISOFORMS AND LIVER MICROSONES.

J. Tang<sup>1</sup>, Y. Sey<sup>2</sup>, R. Murrel<sup>3</sup>, J. Rockett<sup>4</sup>, D. Dix<sup>4</sup> and H. Barton<sup>2</sup>. <sup>1</sup>*Curriculum in Toxicology, UNC-Chapel Hill, Chapel Hill, NC*, <sup>2</sup>*Experimental Toxicology Division, USEPA NHEERL, Research Triangle Park, NC*, <sup>3</sup>*Department of Environmental and Molecular Toxicology, NC State University, Raleigh, NC* and <sup>4</sup>*Reproductive Toxicology Division, USEPA NHEERL, Research Triangle Park, NC.*

The mode of action of conazole fungicides is to inhibit cytochrome P450 (CYP) 51 activity and thus the biosynthesis of ergosterol by fungi. Conazoles can also modulate other CYP activities in vertebrate species including humans. Myclobutanil (MCL) and triadimefon (TRD) are agricultural conazoles with similar chemical structures. Laboratory animal studies have shown MCL and TRD have reproductive toxicity and carcinogenic activity, respectively. It has been proposed that modulation of CYP activity may be the common mechanism underlying their toxic effects. This study was designed to investigate 1) whether MCL and TRD modulated rat CYP activities that results in changes to conazole metabolism, and 2) which rat CYP isoforms were responsible for conazole metabolism. Liver microsomes were prepared from adult male Sprague-Dawley rats exposed orally to vehicle, MCL (10 or 150 mg/kg), or TRD (5 or 115 mg/kg) for 14 days. Total P450 concentrations in both high dosage groups were significantly higher ( $P < 0.01$ ) than vehicle control. The rate of MCL disappearance when incubated with microsomes was much more rapid than for TRD, and the disappearance rate for both chemicals increased with microsomes from rats exposed to higher dose of either chemical versus control. Incubation of MCL with recombinant rat CYP isoforms indicated that CYP2C6, 2C11, 3A1, and 3A2 had metabolized myclobutanil, but not CYP2B1, 1A1, 1A2, 2A1, 2A2, 2C12, 2C13, 2D1, 2D2, and 2E1. CYP2C6 and 3A1 were the only isoforms responsible for TRD metabolism but at a much lower rate. These results indicate that both MCL and TRD induce CYP activities that led to modest increases in their own metabolism. (This abstract does not reflect EPA policy. ## COMPARATIVE LIVER P450 ENZYME ACTIVITY AND HISTOPATHOLOGY IN MICE TREATED WITH THE CONAZOLE FUNGICIDES: MYCLOBUTANIL, PROPICONAZOLE AND TRIADIMEFON.

J. Allen, D. C. Wolf, M. George, S. D. Hester, G. Sun, S. Thai, D. Delker, G. Nelson, E. Winkfield, B. Roop, S. Leavitt, W. Ward and S. C. Nesnow. *Environmental Carcinogenesis Division, USEPA, Research Triangle Park, NC.*

Conazoles are fungicides used in agriculture and pharmaceutical products and comprise a class of chemicals which inhibit ergosterol biosynthesis. Both propiconazole and triadimefon are hepatotoxic and hepatotumorigenic in mice, while myclobutanil is not a mouse liver tumorigen. The tumorigenic activities of these conazoles are thought to be mediated through increased liver cytochrome P450 enzyme activity leading to oxidative stress, mitogenesis and altered foci development. We have assessed how P450 enzyme activity and liver pathology correlate with known hepatotumorigenic responses to conazoles. Male CD-1 mice were treated in the feed for 4, 30 and 90 days with triadimefon (0, 100, 500 or 1800 ppm), propiconazole (0, 100, 500 or 2500 ppm) or myclobutanil (0, 100, 500 or 2000 ppm). Alkoxyresorufin O-dealkylation assays indicated that all 3 chemicals induced similar patterns of dose-related increases in pentoxyresorufin O-dealkylation (PROD), and to a lesser extent, ethoxyresorufin O-dealkylation and/or methoxyresorufin O-dealkylation. Propiconazole high-dose exposures over 30 and 90 days induced 36 to 38-fold higher levels of PROD. Myclobutanil and triadimefon at high dose exposures also induced PROD 10 to 15-fold over controls at all time points. All treatments gave dose-dependent increases in liver weights. Liver histopathology revealed

similar dose-dependent hypertrophy following exposure to all 3 conazoles. There were no significant treatment effects on body weight. Overall, with the exception of some high dose effects observed for propiconazole, a similar induction pattern for these specific AROD-assayed liver enzymes and histopathologies was observed for the 3 conazoles, regardless of their tumorigenic potential. [This abstract does not necessarily reflect EPA policy.]

**2147** COMPARISON OF HEPATIC GENE EXPRESSION PROFILES FROM MICE EXPOSED TO THREE TOXICOLOGICALLY DIFFERENT CONAZOLES.

W. Ward, S. D. Hester, S. Thai, J. Allen, C. Jones, D. C. Wolf and S. Nesnow. *Environmental Carcinogenesis Division, USEPA, Research Triangle Park, NC.*

Conazoles comprise a chemical class of fungicides used as agricultural and pharmaceutical products. Both propiconazole and triadimefon are hepatotoxic and hepatotumorigenic in mice, while myclobutanil is not a mouse liver tumorigen. The tumorigenic activities of these conazoles are thought to be mediated through increased liver cytochrome P450 enzyme activity leading to oxidative stress, mitogenesis, and altered foci development. Our goal was to assess correlations of global gene expression in liver with the hepatocarcinogenic responses in mice. Male CD-1 mice were treated for 4 days with feed incorporated with triadimefon (0, 500 or 1800 ppm), propiconazole (0, 500 or 2500 ppm) or myclobutanil (0, 500 or 2000 ppm). At high dose exposures, propiconazole induced more than twice the number of differentially expressed genes (Affymetrix 430 2.0 gene array) compared to triadimefon or myclobutanil. 121 genes were upregulated by 50% or more in liver tissue from mice treated with any of the three conazoles; 87 genes were upregulated in both triadimefon and propiconazole; 102 genes were upregulated exclusively in triadimefon and 328 genes were upregulated exclusively in propiconazole. All three conazoles increased the gene expression of a series of cytochrome P450s including, cyp2b20, cyp2c37, and cyp2c55. These P450 increases were dose responsive with more than twenty-fold induction at the high dose in some cases. Effects of global gene expression at the lower doses are also being investigated. [This abstract does not necessarily reflect EPA policy.]

**2148** REPRODUCTIVE EFFECTS OF EXPOSURE TO CONAZOLE FUNGICIDES IN THE MALE RAT.

A. K. Goetz<sup>1</sup>, C. Blystone<sup>1</sup>, H. Ren<sup>2</sup>, J. E. Schmid<sup>2</sup>, H. P. Nichols<sup>2</sup>, W. Bao<sup>2</sup>, D. S. Best<sup>2</sup>, M. G. Narotsky<sup>2</sup>, D. C. Wolf<sup>2</sup>, J. C. Rockett<sup>2</sup> and D. J. Dix<sup>2</sup>.

<sup>1</sup>Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC and <sup>2</sup>NHEERL, Office of Research and Development, USEPA, Research Triangle Park, NC.

Conazoles are a class of fungicides used in pharmaceutical and agricultural applications. Three agricultural conazoles were selected, representing a range of reported cancer and reproductive effects, for a study exposing litters (16-20 per dose group) from gestation day 6 to postnatal day (PND) 99. Wistar Han rats were exposed via feed to vehicle, myclobutanil (M, 100, 500, or 2000 ppm), propiconazole (P, 100, 500, or 2500 ppm), or triadimefon (T, 100, 500, or 1800 ppm). One male per litter was sacrificed at PND 1, 22, 50, 92 or 99. Measurements included anogenital distance (AGD) at PND 0, body weight (BW), organ weights, serum hormone levels, and age at preputial separation (PPS). Mating assays were conducted with adult males and untreated females. AGD was increased by the high concentration of all 3 conazoles. T1800 delayed PPS. Liver weights increased at PND50 by M2000 and P2500, and at PND92 by P2500 and T1800. Testis weights increased at PND22 by M2000, at PND50 by M2000 and T500, and at PND92-99 by T1800. Epididymal weights increased at PND92-99 by T1800, and ventral prostate weights increased at PND92 by M500, M2000 and T500. Serum testosterone increased at PND92-99 by M2000, P2500, T500 and T1800. Thyroid weights increased at PND92 by T1800, and total serum thyroxine levels decreased at PND92 by T1800. Mating assays identified impaired fertility by M2000 and T1800, apparently due to ejaculation failure. Effects on AGD, PPS, testis and accessory sex gland weights, serum hormones and fertility represent adverse reproductive outcomes following long-term exposures to conazoles. Future efforts will focus on elucidating mechanisms underlying these effects. [Funded by USEPA Cooperative Research Agreement No. CT826512010 with North Carolina State University. This abstract does not necessarily reflect EPA policy.]

**2149** COMPARISON OF GENE EXPRESSION PROFILES FROM RATS FED THREE TOXICOLOGICALLY DIFFERENT CONAZOLES.

S. Hester, S. Thai, D. C. Wolf, W. Ward and S. C. Nesnow. *Environmental Carcinogenesis Division, USEPA, Research Triangle Park, NC.*

Conazoles are a class of fungicides used as pharmaceutical and agricultural products. In chronic bioassays, triadimefon was hepatotoxic and induced transitional cell adenomas in the thyroid gland. Both propiconazole and myclobutanil were he-

patotoxic but had no effect on the thyroid gland. It has been proposed that triadimefon induces thyroid tumors by altering the levels of thyroid hormone and TSH as a result of induction of xenobiotic metabolizing enzymes. Genomic profiling was utilized to investigate whether transcriptional alterations were associated with their toxic mode of action. Male Wistar rats (3 per group) were exposed to conazoles in the feed for 4 days: triadimefon (1800 ppm), propiconazole (2500 ppm), myclobutanil (2000 ppm). Hepatic gene expression was performed using Affymetrix GeneChips (Rat 230\_2). Differential gene expression was assessed at the probe level using Robust Multichip Average Analysis (RMA). De Novo gene expression between treatment groups was analyzed using hierarchical clustering, K-Nearest Neighbor, and PCA. All 3 conazoles could be discriminated from controls with propiconazole and myclobutanil clustering together and distinct from triadimefon. Statistical analyses showed 150 genes were in common among the 3 conazoles including several cytochromes P450s, GSTs, and one UDP-glucuronosyltransferase. In contrast, 500 genes were unique to triadimefon. These genes were mapped to several gene networks including steroid biosynthesis, cell proliferation, and DNA repair pathways. Future analyses will focus on associating these alterations with triadimefon's toxicological effects. [This abstract does not necessarily reflect EPA policy.]

**2150** PROFILING GENE EXPRESSION IN HUMAN H295R ADRENOCORTICAL CARCINOMA CELLS AND RAT TESTES TO IDENTIFY PATHWAYS OF TOXICITY FOR CONAZOLE FUNGICIDES.

H. Ren<sup>1</sup>, J. E. Schmid<sup>1</sup>, J. Retief<sup>2</sup>, Y. Turpaz<sup>2</sup>, X. Zhang<sup>3</sup>, P. D. Jones<sup>3</sup>, J. L. Newsted<sup>4</sup>, J. P. Giesy<sup>3</sup>, D. C. Wolf<sup>1</sup>, C. R. Wood<sup>1</sup>, W. Bao<sup>1</sup> and D. J. Dix<sup>1</sup>.

<sup>1</sup>NHEERL/ORD, USEPA, Research Triangle Park, NC, <sup>2</sup>Affymetrix Inc., Santa Clara, CA, <sup>3</sup>Department of Zoology, Michigan State University, East Lansing, MI and <sup>4</sup>ENTRIX Inc., East Lansing, MI.

Conazoles are widely used agricultural and pharmaceutical fungicides which inhibit sterol and steroid biosynthesis. Studies with 3 agricultural conazoles were conducted by *in vitro* exposure of H295R cells and *in vivo* exposure of Wistar-Han rats. H295R cells express key steroidogenic enzymes and represent an alternative to the rat testis for assessing endocrine disruption. We used quantitative PCR (qPCR) and DNA microarrays to profile gene expression and identify common effects and toxicity pathways. H295R cells were cultured with 1, 3, 10, 30 or 100  $\mu$ M of each conazole for 48-72 hours. Adult rats were fed myclobutanil (100, 500, 2000 ppm), triadimefon (100, 500, 1800 ppm), propiconazole (100, 500, 2500 ppm), or vehicle-added rodent chow for four days. Expression of 11 steroidogenic genes was measured by qPCR for all H295R dose groups. In addition, Affymetrix Human U133plus2.0 GeneChips were used to profile gene expression for the 3 higher doses of each conazole. Rat testis gene expression for all dose groups was profiled using Affymetrix Rat 230 2.0 GeneChips. Resulting data were log-transformed and analyzed by multi-way ANOVA to determine interactions between the chemicals and the *in vitro* and *in vivo* systems. Comparison of results for steroidogenic genes between the H295R cells and rat testis, and between qPCR and microarray are underway. Microarray results in H295R cells and rat testis identified many orthologous genes and common biological pathways, including programmed cell death, cell cycle, lipid metabolism and steroid metabolism. [This abstract does not necessarily reflect EPA policy]

**2151** REPRODUCTIVE TOXICITY OF EXPOSURE TO CONAZOLE FUNGICIDES IN THE FEMALE RAT.

J. C. Rockett<sup>1</sup>, M. G. Narotsky<sup>1</sup>, I. Thillainadarajah<sup>1</sup>, C. R. Blystone<sup>2,1</sup>, A. K. Goetz<sup>2,1</sup>, H. Ren<sup>1</sup>, D. S. Best<sup>1</sup>, R. N. Murrell<sup>2,1</sup>, H. P. Nichols<sup>1</sup>, J. E. Schmid<sup>1</sup>, K. E. Thompson<sup>3</sup> and D. J. Dix<sup>1</sup>. <sup>1</sup>RTD/NHEERL/ORD, USEPA, Research Triangle Park, NC, <sup>2</sup>Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC and <sup>3</sup>Reproductive Toxicology, Pharmaceutical Research Institute, Bristol-Myers Squibb Company, New Brunswick, NJ.

Conazole fungicides are used widely in pharmaceutical and agricultural applications. Although some conazoles have been investigated extensively for toxicological effects, there is little published information on the reproductive toxicity of many of the agriculturally important conazoles. In this study, three agricultural conazoles were evaluated for effects on female reproductive development. Wistar-Han rats were exposed via feed to vehicle control, propiconazole (P) (100, 500, or 2500 ppm), myclobutanil (M) (100, 500, or 2000 ppm), or triadimefon (T) (100, 500, or 1800 ppm) from gestation day 6 to the first proestrus after post natal day (PND) 98. Body weight (BW) and anogenital distance (AGD) at PND0, age and BW at vaginal opening (VO), and BW and organ weight at termination were measured. Histological examination of ovaries was conducted. Female pup weights at PND0 were unaffected by treatment. AGD at PND0 was increased by M2000. Age of puberty (VO) was delayed by T1800 independent of BW. At PND99 there was a decrease in BW by T1800, an increase in relative liver weight by P2500 and

T1800, and an increase in relative ovarian weight by M2000 and T1800. All ovaries contained follicles at all stages of development and had normal appearing corpora lutea. We conclude that exposure to the high concentrations of M and T adversely impacted female reproductive development. The observed changes suggest a mechanism involving inhibition of estrogen synthesis or function. Ongoing analysis of estrous cyclicity, serum hormone levels, and ovarian pathology will serve to further characterize the effects of these exposures and help clarify mechanism. This abstract does not necessarily reflect EPA policy.

## 2152 A RISK ASSESSMENT OF THE TRIAZINE HERBICIDE ATRAZINE.

D. W. Gammon, C. N. Aldous, W. C. Carr, J. R. Sanborn and K. F. Pfeifer, *Department of Pesticide Regulation, California EPA, Sacramento, CA.*

Toxicity was assessed in animal studies and exposure estimated from occupational and dietary sources. The endpoints were: rabbit developmental toxicity (acute NOEL 5 mg/kg/day); dog cardiotoxicity (chronic NOEL 0.5 mg/kg/day); mammary tumors resulted from lifetime exposure. These occurred only in female SD rats, were malignant, dose-dependent and were also observed with other, related triazines. Evidence for a genotoxic basis for these tumors was either equivocal or negative. An endocrine basis for the mammary tumors, involving premature aging of the female SD rat reproductive system, has been proposed. There is evidence for the mechanism including one or more of the following: the induction of aromatase (CYP19) and/or other P450 oxygenases, an (antagonist) action at the estrogen feedback receptor in the hypothalamus, an (agonist) action at the mammary gland estrogen receptor or an effect on adrenergic neurons in the hypothalamic-pituitary pathway. The potential occupational exposure to atrazine was assessed during mixing, loading, and application. ADD values were 1.8 to 6.1  $\mu\text{g}/\text{kg}/\text{day}$ . The MOS values for short-term exposure were 820 to 2,800. Theoretical calculations of acute dietary exposure used tolerance levels, along with secondary residues, and water. Atrazine plus the (3) main chlorotriazine metabolites were combined. MOS values were above 2000, for all population subgroups. Dietary exposure to atrazine is therefore extremely unlikely to result in human health hazard. Possible ecotoxicity includes the feminization of frogs/toads, measured in laboratory and field studies. In the latter, the water bodies with the greatest numbers of deformed frogs sometimes had the lowest concentrations of atrazine. Other studies have also cast doubt on the feminization theory, except perhaps at very high levels of atrazine. Epidemiology studies have investigated atrazine's ability to cause adverse effects in humans. Although some studies suggest that atrazine elevates the risk of prostate cancer, the published literature is inconclusive with respect to cancer incidence.

## 2153 METHOXYCHLOR INHIBITS EXPRESSION OF ANTIOXIDANT ENZYMES IN THE MOUSE OVARY.

R. K. Gupta, K. P. Miller, D. Tomic and J. A. Flaws, *Toxicology, University of Maryland at Baltimore, Baltimore, MD.*

Females are born with a finite number of primordial follicles, of which a small fraction reaches the antral stage. Antral follicles are responsible for releasing an egg for fertilization and maintaining cyclicity. *In vivo* studies with the organochlorine pesticide methoxychlor (MXC) have shown that antral follicles are the primary targets of MXC exposure. Specifically, MXC exposure decreases the number of antral follicles and increases the percentage of antral follicles undergoing atresia (cell death via apoptosis). While different pathways lead to toxicant-induced cell death, oxidative stress is known to cause apoptosis in non-reproductive and reproductive tissues. Certain toxicants produce reactive oxygen species, which are detoxified by antioxidant enzymes such as superoxide dismutase (SOD), glutathione peroxidase (GPX), and catalase (CAT). Thus, this work tested the hypothesis that MXC inhibits the expression of selected antioxidant enzymes in antral follicles. To test this hypothesis, 39-day old CD-1 mice were dosed with either sesame oil (control) or MXC (32 or 64 mg/kg/day) for 20 days. After treatment, ovaries were collected and antral follicles were isolated from the ovaries and subjected to real time polymerase chain reaction for measurement of mRNA levels of SOD, GPX, and CAT. The results indicate that MXC significantly decreases mRNA expression as compared to controls of SOD (control=2.98  $\pm$  0.30 genomic equivalents (ge); MXC 32 mg/kg/day=0.94  $\pm$  0.08 ge; MXC 64 mg/kg/day=1.28  $\pm$  0.16 ge; n=3; p  $\leq$  0.003), GPX (control=2.36  $\pm$  0.48 ge; MXC 32 mg/kg/day=0.90  $\pm$  0.03 ge; MXC 64 mg/kg/day=1.09  $\pm$  0.10 ge; n=3; p  $\leq$  0.05), and CAT (control=2.02  $\pm$  0.24 ge; MXC 32 mg/kg/day=0.98  $\pm$  0.05 ge; MXC 64 mg/kg/day=1.13  $\pm$  0.07 ge; n=3; p  $\leq$  0.01). Collectively, these data indicate that MXC inhibits the expression of SOD, GPX, and CAT in antral follicles. Therefore, it is possible that MXC may cause atresia of ovarian antral follicles by inducing oxidative stress through inhibition of SOD, GPX, and CAT detoxifying pathways. (Supported by NIH HD38955, T32 ES07263, and Colgate Palmolive Fellowship)

## 2154 TRANSIENT ACTIVATION OF ACETYLCHOLINESTERASE BY PARAOXON.

C. A. Rosenfeld<sup>1</sup> and L. G. Sultatos<sup>2</sup>. <sup>1</sup>*Drug Metabolism and Pharmacokinetics, Schering-Plough Research Institute, Lafayette, NJ* and <sup>2</sup>*Pharmacology & Physiology, UMD New Jersey Medical School, Newark, NJ.*

Previous studies with certain organophosphates such as paraoxon (*O, O*-diethyl *O*-(*p*-nitrophenyl) phosphate) and chlorpyrifos oxon (*O, O*-diethyl *O*-(3, 5, 6-trichloro-2-pyridyl) phosphate), have shown that their interactions with acetylcholinesterase are more complex than originally thought. The present study extends these observations by documenting conditions under which paraoxon causes a transient increase in hydrolysis of acetylthiocholine by human recombinant acetylcholinesterase that precedes the phosphorylation of Ser-203 of the catalytic triad. Co-incubation of 10 nM paraoxon with 0.4 mM acetylthiocholine and 0.4 pM enzyme active site yielded an initial velocity of  $0.0721 \pm 0.0242$  (mean  $\pm$  SD) OD units per min, compared to  $0.0165 \pm 0.004$  OD units per minute without paraoxon. The increased hydrolysis was apparent for up to about 3 min, after which time activity decreased as phosphorylation of the active site proceeded. Higher concentrations of paraoxon produced less measurable enhanced activity for shorter periods of time, as the phosphorylation reaction proceeded at a faster rate, until 100 nM paraoxon only inhibited activity. These results confirm that the interactions of some organophosphates with acetylcholinesterase are more complex than is often thought. Secondly, these studies suggest that paraoxon might bind to a site on acetylcholinesterase distinct from the active site, and that binding can modulate catalytic activity.

## 2155 EVALUATION FOR THE ADDITIVE TOXIC INFLUENCE OF ORGANOPHOSPHORUS PESTICIDES.

M. Tahara<sup>1,2</sup>, R. Kubota<sup>1</sup>, H. Nakazawa<sup>2</sup>, A. Hirose<sup>3</sup>, M. Ema<sup>3</sup>, H. Tokunaga<sup>1</sup> and T. Nishimura<sup>1</sup>. <sup>1</sup>*Division of Environmental Chemistry, National Institute of Health Sciences, Tokyo, Japan*, <sup>2</sup>*Department of Analytical Chemistry, Hoshi University, Tokyo, Japan* and <sup>3</sup>*Division of Risk Assessment, Biological, Safety Research Center, National Institute of Health Sciences, Tokyo, Japan.*

Organophosphorus pesticides (OPs) are abundantly produced and used widely all over the world. OPs have been detected from samples prepared from food and the environmental materials. Although it has been concluded each OP hardly shows the adverse effect in the detected concentration level, the co-effect of multiple OP is not sufficiently considered. It is necessary to evaluate hazard assessment of multiple coexisted OPs, which may especially occur in the environment. Therefore, it is important to establish the testing method to evaluate the toxicity for multiple OPs. It is known that its and its oxide have the toxicity by the inhibition of acetylcholinesterase activity, an enzyme is received the crucial problem to nerve transmission. We established the testing method by measuring of cholinesterase (ChE) activity using 5-methyl-2-thienylthiocholine-iodide as substrate. We examined the inhibition of ChE activity for fifteen OPs by this *in vitro* method. Consequently, these OPs were classified into three groups according to the degree of inhibition, the OPs which inhibit ChE activity strongly at low concentration, the OPs which inhibit slightly, and the others. From comparison between the degree of inhibition and the value of acceptable daily intake, there was a relationship. It is indicated that the toxicity of OPs was simply evaluated by the degree of inhibition of ChE activity with this *in vitro* method. As results under coexisting condition of a few OPs in the combination of three groups, the additive action of the inhibition was found. In the present work, we could demonstrate the simple *in vitro* method to evaluate for the toxicity of coexisted OPs by degree of inhibition of ChE activity at low levels. Using this method, it is possible to evaluate the adverse load by coexisted OPs in the environment.

## 2156 BIOLOGICAL MONITORING OF EXPOSURE TO ORGANOPHOSPHORUS INSECTICIDES IN GREENHOUSE WORKERS.

M. Bouchard<sup>1,3</sup>, G. Carrier<sup>1</sup>, R. C. Brunet<sup>2</sup>, N. Noisel<sup>1</sup>, G. Labarre<sup>1</sup>, P. Dumas<sup>3</sup> and J. Weber<sup>3</sup>. <sup>1</sup>*Environmental and Occupational Health, University of Montreal, Montreal, QC, Canada*, <sup>2</sup>*Mathematics and statistics, University of Montreal, Montreal, QC, Canada* and <sup>3</sup>*Risques biologiques, environnementaux et occupationnels, Institut national de santé publique du Québec, Montreal, QC, Canada.*

Exposure to selected organophosphorus insecticides (OPs), malathion, diazinon and acephate, was evaluated in greenhouse workers through measurements of the urinary excretion time courses of specific and non-specific biomarkers. For the study of each OP, the participation of eight individuals was obtained: two applicators, five workers manipulating treated plants and one office worker. Each participant provided all micturitions (in separate bottles) during a 24-h period following

the onset of an exposure episode to either malathion, diazinon or acephate. For several workers, the urinary excretion of malathion specific metabolites, mono- and di-carboxylic acids (MCA and DCA), increased following the onset of an exposure to malathion. Maximum values of MCA and DCA were observed between 8 and 12 h but concentrations had returned to baseline values by 24 h following the onset of exposure. Excretion patterns of methyl phosphoric derivatives (the sum of DMTP, DMTP and DMP) usually differed from that of MCA and DCA and concentration values were in general much higher than those of MCA and DCA. The 24-h cumulative excretion values of malathion biomarkers were however far below biological reference values proposed in a previous work. In all of the urine samples provided by the participants, urinary concentrations of 2-isopropyl-4-methyl-6-hydroxypyrimidine, a specific metabolite of diazinon, as well as acephate and methamidophos were below or equal to the analytical limit of detection (1, 0.8 and 0.2  $\mu$ g/L, respectively) except for acephate in one individual (concentrations between 1.4 and 3.5  $\mu$ g/L). There was also no marked increase in the urinary excretion of the non-specific metabolites of diazinon, ethyl phosphoric derivatives (the sum of DETP and DEP), following the onset of an exposure to diazinon. These results show that the greenhouse workers under study were poorly exposed to OPs.

KINETIC DATA ON PESTICIDE METABOLISM IN HUMANS TO ALLOW PBPK/PD MODELS FOR PARATHION AND CHLORPYRIFOS TO PREDICT SUSCEPTIBILITY.

J. R. Olson, J. B. Knaak, B. P. McGarrigle, K. M. Kransler, R. J. Foxenberg and P. J. Kostyniak. *Pharmacology and Toxicology, SUNY at Buffalo, Buffalo, NY.*

The ultimate utility of any physiologically based pharmacokinetic (PBPK) model is limited by the availability of accurate kinetic parameters that reflect the rate of biotransformation of xenobiotics in the population of interest. The primary objective of this study was to obtain kinetic parameters (Vmax, Km values) for the metabolism of model organophosphate pesticides (parathion and chlorpyrifos) in liver from humans of various ages. A sensitive and specific HPLC method was developed to quantify the products of biotransformation resulting from incubations of pesticides with human liver microsomal specimens and recombinant human CYPs. The kinetics of parathion metabolism (1 to 100  $\mu$ M) was initially assessed in six specimens of CYP characterized human liver microsomes from males and females of 19 to 54 years of age. The Km for the formation of paraoxon and p-nitrophenol ranged from 8.7 to 39.1 and from 15.2 to 55.9  $\mu$ M, respectively, while the Vmax values ranged from 589 to 1495 and from 588 to 1232 pmol/min/mg, respectively. These results support the need to include a range of kinetic parameters to reflect the inherent interindividual variability in biotransformation. The Vmax for transformation of parathion to paraoxon in the six human liver microsomal specimens correlates with the formation of 6-beta hydroxytestosterone from testosterone, a marker for CYP3A4 activity ( $r^2 = 0.96$ ). Studies with recombinant CYPs also indicate that CYP1A2 and CYP2B6 contribute substantially to paraoxon formation, while CYP1A2 also effectively catalyzes the formation of p-nitrophenol. Additional studies will provide estimates of the age-specific kinetics of biotransformation of selected pesticides. These data will then be utilized in the multi-route, multi-chemical PBPK/ pharmacodynamic (PD) model (ERDEM, Exposure Related Dose Estimating Model) (Blancato et al., 2000; Knaak et al., 2001) to estimate the sensitivity of individuals within various age groups. (Supported by USEPA STAR grant R-83068301)

ORGANOPHOSPHORUS PESTICIDES INHIBIT PRENYLATED METHYLATED PROTEIN METHYL ESTERASE.

N. S. Lamango. *College of Pharmacy and Pharmaceutical Sciences, Florida A&M University, Tallahassee, FL. Sponsor: A. Ndifor.*

Prenylation and subsequent S-adenosyl-L-methionine-dependent methylation are essential secondary modifications for the biological activity of a significant number of eucaryotic proteins. Prenylated proteins such as the G- $\gamma$  subunits of G-protein coupled receptors, nuclear lamins, guanine nucleotide binding proteins such as Ras and Rab are prenylated and undergo methylation. Prenylated methylated protein methyl esterase (PMPMEase) readily hydrolyses the prenylated protein methyl esters thus making this step reversible and possibly regulatory. Organophosphorus (OPs) are known to cause conditions such as Parkinsonism and neurodegeneration. Mutations of the gene for paraoxonase, a liver esterase, are a risk factor for Parkinson's disease. The effect of OPs on PMPMEase was thus investigated. Benzoyl-glycyl-farnesyl-cysteine methyl ester (BzGFCM) was developed as a specific PMPMEase substrate and characterized by electron-spray ionization mass spectrometry to be of the calculated molecular mass. Rat liver supernatant and brain membrane extracts hydrolyzed BzGFCM forming benzoyl-glycyl-farnesyl-

cysteine (BzGFC) in a time- and concentration-dependent manner. The liver and brain enzymes cleaved BzGFCM with Km values of  $4.58 \pm 0.30$  and  $25.57 \pm 2.36$   $\mu$ M and Vmax values of  $2.21 \pm 0.03$  and  $0.17 \pm 0.003$  nmol/min/mg, respectively. The liver enzyme eluted from a Sephadryl 200 HR gel-filtration column as a single peak with an apparent size of 89 kDa. The brain enzyme eluted as two peaks of 53 and 890 kDa. OPs inhibited the liver enzyme with IC50 values from 4.77  $\mu$ M for parathion to 0.04  $\mu$ M for paraoxon, respectively. Only about 50% of the brain activity was inhibited by 0.4 to 1 mM solutions of paraoxon. Mipafox did not significantly inhibit the brain enzyme. BzGFCM was not hydrolyzed by various cholinesterases indicating its specificity for PMPMEase. Perturbations in prenylated protein metabolism may play a role in non-cholinergic OPs-induced toxicity since prenylated proteins play such important roles in cell signaling, proliferation, differentiation and apoptosis.

ASSESSING EXPOSURES TO FLEA CONTROL INSECTICIDES FROM THE FUR OF DOGS TREATED WITH FLEA COLLARS.

K. Davis<sup>1</sup>, J. Chambers<sup>1</sup>, J. Moran<sup>1</sup>, N. Holifield<sup>1</sup> and S. Boone<sup>2</sup>. <sup>1</sup>*Basic Science, Mississippi State University, Mississippi State, MS* and <sup>2</sup>*USEPA, Stennis Space Center, MS.*

There are reported insecticide residues present in food, water, and on surfaces such as carpets treated for flea control. However, no studies have quantified dislodgable flea control insecticide residues on pets that could be transferred to children. Previous studies conducted in our laboratory have indicated that these dislodgable residues may be in the ng range. This study involved the treatment of pet dogs with over-the-counter flea collars containing the insecticides chlorpyrifos or tetrachlorvinphos. Insecticide residues on cotton gloves used to pet the dogs for 5 minutes and cotton t-shirts worn by a child for a 4-hour period were obtained. First morning urine samples were obtained from one adult and one child for urinary metabolite quantification. Transferable residues of both insecticides to the gloves were highest on and near the collar and were lowest in areas distant from the collar. The 14 day mean residues for chlorpyrifos over the collar and in the tail region were  $503 \pm 84$  ng/glove and  $10 \pm 2$  ng/glove, respectively. Chlorpyrifos residues observed at 20 days post application were  $434 \pm 78$  ng/glove and  $7 \pm 2$  ng/glove, respectively. Tetrachlorvinphos residues at 14 days post treatment were 22,  $413 \pm 3042$  ng/glove over the collar and  $81 \pm 20$  ng/glove in the tail region. The mean residues at 20 days post treatment were 15,  $788 \pm 2195$  ng/glove and  $82 \pm 34$  ng/glove, respectively. Chlorpyrifos t-shirt residue levels varied from 121 ug/g to 201 ug/g and tetrachlorvinphos t-shirt residue levels were in a range from 923 ug/g to 3098 ug/g. There were no significant differences in the levels of 3, 5, 6-trichloropyridinol, the urinary metabolite of chlorpyrifos, in adults or children after the placement of the collar. However, children had higher levels of the metabolite than adults, 15-20 ng/ml compared to 5-10 ng/ml. (Supported by EPA Grant R828017)

EFFECT OF PYRETHRINS ON CYTOCHROME P450 FORMS IN CULTURED RAT AND HUMAN HEPATOCYTES.

B. G. Lake<sup>1</sup>, R. J. Price<sup>1</sup>, A. M. Giddings<sup>1</sup>, C. Meredith<sup>1</sup> and T. G. Osimitz<sup>2</sup>. <sup>1</sup>*Molecular Sciences, BIBRA International Ltd., Carshalton, Surrey, United Kingdom* and <sup>2</sup>*Science Strategies LLC, Charlottesville, VA.*

High doses of Pyrethrins (PY) have been shown to produce liver and thyroid tumors in rats by a mode of action involving the induction of hepatic xenobiotic metabolising enzymes. The aim of this study was to compare the effects of PY with those of the rat liver and thyroid tumor promoter sodium phenobarbital (NaPB) on some cytochrome P450 (CYP) forms in cultured rat and human hepatocytes. Female Sprague-Dawley rat and human (both male and female) hepatocytes were cultured for 3 days with 0-1000  $\mu$ M PY or NaPB. Over this concentration range PY and NaPB were not markedly cytotoxic to either rat or human hepatocytes. Levels of CYP mRNAs were determined by real-time quantitative reverse transcription-polymerase chain reaction methodology. Enzyme activities were determined in intact monolayers. In rat hepatocytes, treatment with PY and NaPB increased levels of CYP2B1 mRNA up to 8 and 28 fold, respectively, and levels of CYP2B1/2 mRNA up to 5 and 30 fold, respectively. PY and NaPB increased 7-benzyloxy-4-trifluoromethylcoumarin O-debenzylase activity (a CYP1A/2B marker) up to 3 and 5 fold, respectively. Both PY and NaPB also increased CYP2B-dependent 7-pentoxyresorufin O-depetylase and CYP3A-dependent testosterone 6 $\beta$ -hydroxylase activities. In human hepatocytes, treatment with PY and NaPB increased levels of CYP3A4 mRNA up to 15 and 17 fold, respectively, and testosterone 6 $\beta$ -hydroxylase activity up to 2.4 and 4.2 fold, respectively. The effects of PY and NaPB were concentration-dependent and exhibited a threshold, with low concentrations hav-

ing no effect on the markers of hepatic xenobiotic metabolism studied. These results demonstrate that both PY and NaPB induce CYP2B and to a lesser extent CYP3A forms in cultured rat hepatocytes. Like NaPB, PY can also induce CYP forms in cultured human hepatocytes. (Supported by the Pyrethrin Joint Venture).

## 2161

### RELATIVE POTENCIES FOR ACUTE EFFECTS OF PYRETHROIDS ON MOTOR FUNCTION IN RATS.

M. J. Wolansky<sup>1</sup>, M. J. DeVito<sup>2</sup>, C. Gennings<sup>3</sup>, W. Carter<sup>3</sup>, R. A. Carchman<sup>3</sup> and K. M. Crofton<sup>2</sup>. <sup>1</sup>National Research Council, Research Triangle Park, NC, <sup>2</sup>NTD and ETD, USEPA, Research Triangle Park, NC and <sup>3</sup>Solveritas, LLC, Richmond, VA.

A proposed common mode-of-action for pyrethroid insecticides, includes alterations in sodium channel dynamics in nervous system tissues, consequent disturbance of neuronal membrane polarization, abnormal discharge in targeted neurons, and changes in nervous system function. The present work provides *in vivo* functional data for use in the cumulative risk assessment of pyrethroids. This work characterized dose-response curves and calculated relative potencies for motor dysfunction produced by 11 commonly used pyrethroids. Five Type I (bifenthrin, s-bioallethrin, permethrin, resmethrin, tefluthrin) and six Type II compounds (beta-cyfluthrin, lambda-cyhalothrin, cypermethrin, deltamethrin, esfenvalerate, fenpropathrin) were tested in adult male Long Evans rats. Acute oral dose-response curves for motor function were characterized for each chemical [n=7-12 per dose, 6-8 dose levels per chemical, 1 ml/kg corn oil vehicle]. Motor function was measured using figure-8 mazes. Animals were tested for one hr during the period of peak effects (between 1 and 4 hour after dosing, as determined in pilot studies). All pyrethroids, regardless of structural class, produced dosage-dependent decreases in motor activity. Individual chemical ED30s were calculated using a flexible single-chemicals-required method of analysis applicable to chemicals with differing maximum-effect asymptotes (Gennings et al., 2004). Relative potencies were calculated based as the ratio of each chemical's ED30 to the ED30 of the index chemical, deltamethrin (ED30 ~3 mg/kg). Preliminary data analyses revealed ED30s that ranged from 1.4 to 210 mg/kg and estimations of the relative potency ratios for the pyrethroids ranged from 0.5 to 70. These data suggest a common toxicity endpoint for effects on general motor function in rats that can be used for assessing cumulative risk. Future work will test the ability of this common endpoint to predict additivity of pyrethroid mixtures. (This is abstract does not necessarily reflect USEPA policy)

## 2162

### USING ARRAY TECHNOLOGY TO IDENTIFY POTENTIAL BIOMARKERS FOR PYRETHROID INSECTICIDES.

J. Harrill<sup>1</sup>, M. J. Wolansky<sup>2</sup>, S. Hester<sup>3</sup>, J. M. Hedge<sup>4</sup> and K. M. Crofton<sup>4,1</sup>.

<sup>1</sup>Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, <sup>2</sup>National Research Council, Research Triangle Park, NC, <sup>3</sup>ETD, NHEERL, ORD, USEPA, Research Triangle Park, NC and <sup>4</sup>NTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.

Pyrethroid insecticides affect nervous system function by disruption of sodium channels in nerve membranes. FQPA requirements for assessing cumulative risk have increased the need for rapid and sensitive biomarkers of effect. This project aims to develop biochemical markers of neurotoxicity following acute exposure to pyrethroids. Gene arrays were used to determine candidate proteins to serve as biomarkers. Male rats were orally exposed to deltamethrin (1-6 mg/kg, DLT) or permethrin (50-200 mg/kg, PER) in corn oil vehicle. Tissue was collected at 2, 6, or 24 hr after exposure. Total RNA was isolated from whole brain or frontal cortex. RNA was analyzed using either ClonTech Rat Toxicology 1.2 arrays (whole brain) or Affymetrix Rat 230 2.0 arrays (frontal cortex). Data analyses revealed relatively few genes that were altered in both PER and DLT treated tissue. For PER, 115 transcripts responded in a dose-related manner (including at least a 3-fold increase at highest dose). For DLT, 126 genes responded in a dose-related manner. From these two sets, 13 transcripts were identified as responding similarly for both pyrethroids, including 7 genes with known identities: e.g. carboxylesterase 1, recoverin, phenylalanine hydroxylase, leucyl-specific aminopeptidase PILS. For DLT treatment using the ClonTech Rat Toxicology 1.2 array, 29 genes responded in a dose-dependent manner. Of the 13 transcripts common to the two pyrethroids in the Affymetrix array, 2 were up-regulated >3-fold in the ClonTech Rat Toxicology 1.2 array with the same dose of DLT at 24 hours. These differences may be due to the use of frontal cortex versus whole brain or variation in treatment times. Future work will involve confirming candidate genes from both technologies using qRT-PCR or protein activity assays. (This is abstract does not necessarily reflect USEPA policy)

## 2163

### ACTIVATION OF MITOGEN-ACTIVATED PROTEIN KINASE AND TRANSCRIPTIONAL FACTORS PRECEDES CYCLOOXYGENASE-2 GENE EXPRESSION IN MACROPHAGES EXPOSED TO THE O, P- DDT.

J. Kim<sup>1,2</sup>, E. Han<sup>1,2</sup> and H. Jeong<sup>1,2</sup>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.

Dichlorodiphenyltrichloroethane (DDT) is used as an insecticide and prevents many people in the tropical zone from devastating malaria. On the other hand, a number of reports have indicated that it may act as an endocrine disruptor and also has possible carcinogenic effects. The purpose of this study was to test the hypothesis that o, p-DDT induces cyclooxygenase-2 (COX-2) gene expression in macrophages and that this is regulated at the level of mitogen-activated protein kinases (MAPKs). Exposure of the murine macrophage cell line RAW 264.7 to o, p-DDT for 24 h markedly enhanced the production of prostaglandin E2 (PGE2), a major COX-2 metabolite. PGE2 elevation was preceded by increases in COX-2 mRNA and COX-2 protein in o, p-DDT-treated cells. o, p-DDT induced rapid phosphorylation of extracellular signal regulated protein kinases 1 and 2 (ERK1/2), p38 and c-Jun N-terminal kinases 1 and 2 (JNK1/2) phosphorylation. To investigate the significant cis-acting regions which COX-2 promoter, transient transfection experiments were carried out using reporter vectors harboring deleted COX-2 promoters. The transcriptional factor binding sites for activator protein 1 (AP-1) and NF- $\kappa$ B could be important for the induction of COX-2 by o, p-DDT. The results of these studies suggest that induction of transcriptional activation of COX-2 by o, p-DDT might be mediated through the AP-1 and NF- $\kappa$ B activation.

## 2164

### SUCCESSFUL ELIMINATION OF PARAQUAT BY HEMOPERFUSION USING PULSATILE EXTRACORPOREAL CIRCULATION.

E. Hwang<sup>1</sup>, S. Lee<sup>2</sup>, J. Hwang<sup>2</sup>, J. Lee<sup>3</sup>, C. Lee<sup>4</sup> and Y. Kim<sup>1</sup>. <sup>1</sup>Department of Thoracic and Cardiovascular Surgery, Konkuk University Chungju Hospital, Chungju, South Korea, <sup>2</sup>Department of Thoracic and Cardiovascular Surgery, Konkuk University Hospital, Seoul, South Korea, <sup>3</sup>Department of Emergency Medicine, Konkuk University Chungju Hospital, Chungju, South Korea and <sup>4</sup>Department of Diagnostic and Experimental Medicine, Konkuk University Chungju Hospital, Chungju, South Korea.

A 42-years old female was admitted to our emergency department for ingestion of paraquat as suicide attempt. She had no previous medical history or operation history. She ingested paraquat (Gramoxone<sup>®</sup>) and alcohol 3 hours before. She had a shallow ulceration on tongue. We began gastric lavage with distilled water via orogastric tube as much as 20, 000 ml. Then, we poured activated charcoal powder into her stomach via orogastric tube for reduction of paraquat absorption. Using qualification method, paraquat was identified in her urine. Qualification method that is 2N Sodium hydroxide 1ml was mixed with Sodium hydrosulfite 10mg, and mixed reagent was mixed with the patient's urine 10ml during 30 seconds. After 2 minutes, the color of urine was identified. The positive result was bluish or blue greenish change. Her vital sign was stable. Hemoperfusion with charcoal filter (Adsorba300<sup>®</sup>, Gambro) was initiated after insertion of double lumen central vein catheter with pulsatile extracorporeal circulation unit (T-PLS<sup>®</sup> New Heartbio, Korea) in intensive care unit. She was covered with Vinyl curtain for prevention of oxidation of already absorbed paraquat. After 90 minutes of hemoperfusion, qualification of urine and serum converted to negative. Then, after 3hrs of hemoperfusion, the same qualification shown to be negative. Hemoperfusion was stopped. She was received diuretics and antiemetics. After 2 days later, she was moved to general ward and started regular diet. At that times, qualification test was negative. We recommended the being consultation of psychiatrics for suicide attempt but, she refused. She was discharged on 5th hospital day without complication and was prescribed methylprednisolone for prevention of pulmonary fibrosis. She was observed at our patient department without any complications.

## 2165

### DDT-INDUCED AROMATASE AND CYCLOOXYGENASE-2 GENE EXPRESSION IN TESTICULAR LEYDIG R2C CELLS.

D. Oh<sup>1,2</sup> and H. Jeong<sup>1,2</sup>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.

Dichlorodiphenyltrichloroethane (DDT) is a widespread environmental pollutant. Aromatase (estrogen synthase) is the cytochrome P450 enzyme complex that converts C19 androgens to C18 estrogens. In this study, we investigated the effect of DDT on aromatase gene expression through cyclooxygenase-2 (COX-2) in testicular Leydig R2C cells. Exposure of the R2C cells to DDT markedly enhanced COX-2 gene expression. Enhanced COX-2 enzyme levels by DDT treatment results in

increased production of prostaglandin E2 (PGE2), a major COX-2 metabolite. COX-2 inhibitors decreased DDT-induced PGE2 production. Furthermore, PGE2 increased aromatase activity in leydig R2C cells. In addition, DDT was found to increase aromatase gene expression in R2C cell in a dose dependent manner. Our results indicated that the increase of aromatase gene expression by DDT in R2C cell is mediated through increased PGE2 production by DDT-induced COX-2 gene expression. Overall, elevated levels of these factors in R2C cells microenvironment can result in increased aromatase activity via autocrine mechanisms in R2C cells.

## 2166 INDUCTION OF CYP3A4 BY O, P'-DDT IN HEPG2 CELLS.

I. M. Medina and G. Elizondo-Azuela. *Toxicology, CINVESTAV-IPN, Mexico City, D.F., Mexico.* Sponsor: B. Quintanilla-Vega.

For almost 50 years, million of Mexicans have been directly or indirectly exposed to DDT (1, 1, 1-trichloro-2, 2-bis(4-chlorophenyl) ethane). DDT a well known endocrine disruptor agent is an organochlorine pesticide still used in many developing countries for the control of vector-transmitted diseases. Although DDT was banned in many countries, is still present in the environment due to its resistant to degradation. Among DDT effects, it has been reported its capacity to induce rodent cytochrome P450 (CYP) 2B and 3A subfamilies. However, little information is available of its effects on the regulation of human CYPs. Technical grade DDT contains 80% of the *o*, *p*'-DDT and 20 % of the *o*, *p*-DDT isomers. The *o*, *p*'-DDT isomer exhibits estrogenic activity through its binding to the estrogen receptor (ER). The ER is a ligand-inducible transcription factor that modulates the expression of several genes including CYP3A4, which is the predominant CYP expressed in human liver. CYP3A4 contributes to the metabolism of approximately half the drugs in use today, and catalyzes the 6 $\beta$ -hydroxylation of a number of steroids including cortisol, testosterone and progesterone. The aim this study was to analyze the effects of *o*, *p*'-DDT on CYP3A4 gene expression in HepG2 cell cultures. HepG2 cells were exposed to up to 10  $\mu$ M of *o*, *p*'-DDT during 12 and 24 hours. After treatment, cells were harvested and cellular contents were extracted for mRNA and immunoreactive protein analysis. Treatment with *o*, *p*'-DDT resulted in a significantly increase in CYP3A4 mRNA and immunoreactive protein in a dose-dependent response, up to 13-fold and 3.8 fold, respectively with the highest dose compared to untreated cultures. Our results indicate that *o*, *p*'-DDT was able to activate transcriptionally CYP3A4 gene since treatment with actinomycin D blocked the CYP3A4 mRNA increase induced by *o*, *p*'-DDT. Finally, studies are in progress to define the mechanisms by which *o*, *p*'-DDT induce the expression of CYP3A4.

## 2167 N-DEALKYLATION IS A KEY DETERMINANT IN THE HEPATOTOXICITY OF CHLOROACETANILIDE HERBICIDE ALACHLOR.

V. M. Kale and S. A. Meyer. *Toxicology, University of Louisiana at Monroe, Monroe, LA.*

Chloroacetanilides alachlor, acetochlor, and metolachlor (*N*-methoxymethyl-, -ethoxymethyl-, and -methoxyisopropyl-, resp.) are widely used pre-emergent herbicides. Coleman et al. (Env. Hlth. Persp, 108: 1151, 2000) have shown rates of *N*-dealkylation of alachlor  $\gg$  acetochlor  $\gg$  metolachlor  $\sim$  0 with human and rat liver microsomes and alachlor *N*-dealkylation to 2-chloro-*N*(2, 6-diethylphenyl)acetamide (CDEPA) by CYP3A4. In our previous studies in SD rats, hepatotoxicity was alachlor  $\gg$  metolachlor (Miranda et al., Toxicol. Sciences, 66: 321, 2002). These results support the hypothesis that *N*-dealkylation by CYP3A1/2, rat ortholog of CYP3A4, plays a critical role in chloroacetanilide hepatotoxicity. The objectives of the present investigations were 1) to compare and evaluate hepatotoxicity of alachlor, acetochlor vs non-toxic metolachlor in isolated rat hepatocytes, and 2) to identify the possible role of the *N*-dealkylated CDEPA and CYP3A in the alachlor bioactivation pathway. Results of the present investigation indicate that indeed *N*-dealkylation is a determinant of hepatotoxicity of the chloroacetanilide herbicides in isolated rat hepatocytes as supported by EC50 values for alachlor (486 $\pm$ 43  $\mu$ M), acetochlor (465 $\pm$ 91  $\mu$ M) and metolachlor (708 $\pm$ 68  $\mu$ M). Rat hepatocytes catalyzed *N*-dealkylation of alachlor to CDEPA, and CDEPA (EC50 = 224  $\mu$ M) was much more toxic than parent compound in isolated rat hepatocytes. We also found that further metabolism of the CDEPA to DEA is a detoxification pathway as DEA EC50 is  $\gg$ 1600  $\mu$ M. However, our observation that CDEPA was still produced in the presence of CYP3A inhibitor clorotrimazole, which did not prevent alachlor cytotoxicity, implicates an enzyme other than CYP3A1/2. Preliminary studies on alachlor suggest the relevance of rat hepatocyte results with cryopreserved human hepatocytes (BD Gentest, Lot # 65, CYP3A4 activity 140 pmol/min/10e6 cells, EC50 ~700  $\mu$ M). Collectively these results support a critical role for *N*-dealkylation in chloroacetanilide hepatotoxicity catalyzed by an enzyme other than CYP3A. Support: LA Board of Regents.

### TRIBUTYLtin REGULATED STEROIDOGENIC ENZYME GENES EXPRESSION AND CHANGES SEXUAL HORMONE IN MOUSE TESTICULAR LEYDIG CELLS.

H. Kim<sup>1, 2</sup>, K. Lee<sup>1</sup>, K. Jung<sup>1, 2</sup>, D. Oh<sup>1, 2</sup>, K. Oh<sup>1, 2</sup>, J. Choi<sup>1, 2</sup> and H. Jeong<sup>1</sup>,  
<sup>1</sup>*Pharmacy, Chosun University, Kwangju, Kwangju, South Korea* and <sup>2</sup>*Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.*

Tributyltin (TBT) is a widespread environmental pollutant and distributed hormonal functions in reproductive organs. In this study, we investigated that the regulation of steroidogenesis genes induced by TBT in the rat leydig cell line, R2C. As the results, TBT treatment stimulated testosterone synthesis gradually up in does dependent manner. Moreover, to confirm TBT-mediated testosterone synthesis, we investigated several kinds of steroidogenic enzyme expression in R2C cells. RT-PCR analysis revealed that TBT increased the level of aromatase mRNA in does dependent manner. In addition, TBT increased 3beta-hydroxysteroid dehydrogenase mRNA in does dependent manner. However, TBT did not significant effects on 17beta-hydroxysteroid dehydrogenase and cholesterol side chain cleavage enzyme (P450SCC) mRNA level. In the present study, we have demonstrated that TBT induces testosterone contents via inducing steroidogenic genes expression in rat testicular Leydig cells. Taken together, these results suggest that TBT may disrupt endocrine homeostasis not only by directly binding to aromatase as previously suggested but also by inducing expression of steroidogenic enzyme genes.

## 2169

### TRIBUTYLtin INDUCE CELL CYCLE ARREST IN RAT TESTICULAR LEYDIG CELLS.

D. Kim<sup>3</sup>, K. Lee<sup>1, 2</sup>, D. Oh<sup>1, 2</sup>, J. Kim<sup>1, 2</sup>, H. Kim<sup>1, 2</sup>, D. Shin<sup>1, 2</sup> and H. Jeong<sup>1</sup>,  
<sup>1</sup>*Pharmacy, Chosun University, Kwangju, Kwangju, South Korea*, <sup>2</sup>*Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea* and <sup>3</sup>*Pathology, College of Oriental Medicine, Daejeon University, Daejeon, South Korea.*

Tributyltin used world-wide in antifouling paints for ships is a widespread environmental pollutant and cause reproductive organs atrophy in rodents. We investigated the effects of tributyltin on rat testicular leydig cells cycle arrest to establishing induction of growth arrest and apoptosis of R2C, rat leydig cells. Our data show that the induction of cell apoptosis and cell cycle arrest at G0/G1 phase by tributyltin might be associated with the induction of p53 and p21, and mediated via the apoptosis-related bcl-2 family proteins. In this report, we further investigated the mechanism involved in the cell cycle arrest induced by tributyltin in R2C cells. The inhibitory effect of tributyltin on the cell cycle progression of R2C cells which arrested cells at the G0/G1 phase was associated with a marked decrease in the protein expression of p53 and an induction in the content of cyclin-dependent kinase (cdk) inhibitor p21 protein. Moreover, this effect was correlated with the elevation in Cyclin D/Cdk 4 complex declined, preventing the phosphorylation of retinoblastoma (Rb) and the subsequent dissociation of Rb/E2F complex. This provides strong evidence that the apoptotic effect of tributyltin, arresting cells at the G0/G1 phase, was exerted by inducing the expression of p21 that, in turn, repressed the activity of cyclin D1/cdk 2 and the phosphorylation of Rb.

## 2170

### THE BIPYRIDYL HERBICIDE PARAQUAT CAUSES OXIDATIVE STRESS-MEDIATED TOXICITY IN HUMAN NEUROBLASTOMA SH-SY5Y CELLS: RELEVANCE TO PARKINSON'S DISEASE.

W. Yang and E. Tiffany-Castiglioni. *Veterinary Integrative Biosciences, Texas A&M University, College Station, TX.*

Paraquat (PQ) is a cationic non-selective bipyridyl herbicide widely used to control weeds and grasses in agriculture. Epidemiologic studies indicate that exposure to pesticides can be a risk factor in the incidence of Parkinson's disease (PD). A strong correlation has been reported between exposure to paraquat and PD incidence in Canada, Taiwan, and the United States. This correlation is supported by animal studies showing that paraquat causes toxicity in dopaminergic neurons of the rat and mouse brain. However, it is unclear how paraquat triggers toxicity in dopaminergic neurons. Based on the prooxidant properties of paraquat, we hypothesized that paraquat may cause oxidative stress-mediated toxicity in dopaminergic neurons. To explore this possibility, dopaminergic SH-SY5Y cells were treated with paraquat, and several biomarkers of oxidative stress were measured. First, paraquat increased intracellular levels of reactive oxygen species, but decreased the levels of glutathione. Second, paraquat inhibited glutathione peroxidase activity, but did not affect glutathione reductase activity. On the other hand, paraquat increased GST activity by 24 h, after which GST activity returned to the control value at 48 h. Third, paraquat dissipated mitochondrial membrane potential (MTP). Fourth, paraquat caused increases of malondialdehyde (MDA) and protein carbonyls, as well as DNA fragmentation, indicating oxidative damage to major cellular components. Taken together, current data verify our hypothesis that paraquat induces ox-

idative stress-mediated toxicity in dopaminergic SH-SY5Y cells. Thus, these results suggest that paraquat may cause oxidative stress in dopaminergic neurons of human brain, and support the hypothesis that paraquat is an environmental risk factor implicated in the incidence of PD.

DIFFERENTIAL INDUCTION OF CYCLOOXYGENASE-2 (COX-2) AND HEME OXYGENASE-1 (HO-1) BY UVB LIGHT IN GROWING AND CALCIUM-DIFFERENTIATED PRIMARY CULTURES OF MOUSE KERATINOCYTES.

A. T. Black<sup>1</sup>, M. P. Shakarjian<sup>2</sup>, D. R. Gerecke<sup>1,3</sup>, A. M. Vetrano<sup>3</sup>, D. E. Heck<sup>1,3</sup> and J. D. Laskin<sup>1,4</sup>. <sup>1</sup>Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ, <sup>2</sup>Department of Medicine, UMDNJ-Robert W Johnson Med. Sch, Piscataway, NJ, <sup>3</sup>Pharmacology and Toxicology, Rutgers University, Piscataway, NJ and <sup>4</sup>Environmental and Occupational Medicine, UMDNJ-Robert W Johnson Med. Sch, Piscataway, NJ.

Exposure to ultraviolet light as a component of sunlight has been demonstrated to be a major factor in the development of skin cancer. The high energy wavelengths of the ultraviolet B (UVB) spectra (290-320 nm) can cause damage to DNA and also initiate an inflammatory response as well as intracellular oxidative stress. Numerous studies have shown that the presence of inflammatory mediators and reactive oxygen species contribute to the development of cancer. COX-2, responsible for the formation of prostaglandins, is known to be induced by UVB in human skin. HO-1, known to be induced by reactive oxygen species, is an effective cellular antioxidant. In the present studies, we compared the effect of UVB on the expression of COX-2 and HO-1 in undifferentiated and calcium-differentiated primary mouse keratinocytes. Both cell types constitutively express small amounts of COX-2 and HO-1 mRNA as measured by real-time PCR. Differentiated cells, however, express 2-fold more HO-1 than undifferentiated cells. UVB light (2.5 to 25 mJ/cm<sup>2</sup>) caused a dose-dependent increase in expression of both COX-2 and HO-1 mRNA and protein as measured western blotting. Undifferentiated cells showed a greater response to UVB light than differentiated cells in expression of both COX-2 and HO-1, with approximately twice the induction at the maximal UVB dose. In contrast, the differentiated cells exhibited higher absolute induction at every UVB dose. Taken together, these data indicate that not only the dose of UVB but also the differentiation state of the keratinocytes is critical to expression of either a pro-inflammatory enzyme, COX-2, or an antioxidant and protective enzyme, HO-1. DECREASING MALATHION APPLICATION TIME FOR LICE TREATMENT REDUCES TRANSDERMAL ABSORPTION.

R. Brand<sup>1,2</sup>, A. Charron<sup>1</sup> and R. Brand<sup>1,2</sup>. <sup>1</sup>Internal Medicine, Evanston Northwestern Healthcare, Evanston, IL and <sup>2</sup>Internal Medicine, Feinberg School of Medicine at Northwestern University, Chicago, IL. Sponsor: P. Iversen.

Background: Head lice are the most common parasitic infestation in the United States and Europe. Children are commonly infected with head lice requiring topical treatment with pediculicides. The instructions for the Ovide® 0.5% malathion formulation include placing formulation on dry hair and leaving it on for eight to twelve hours. Ovide®, however is effective at killing 100% of both lice and nits in ten minutes. Our concern of over exposing children to malathion has led us to examine whether significantly more malathion will penetrate transdermally when applied for the recommended eight hours than for a shorter but apparently equally effective period. Methods: *In vitro* absorption studies were performed to determine if reducing malathion application time decreases skin absorption. Ovide® was placed on either full thickness haired rat skin or human abdominal skin for 0.5, 2, 4, or 8 hours before removal, skin was thoroughly washed with shampoo and penetration was allowed to continue for either 24 (rat and human), 48 (rat) or 72 (rat) hours. Results: A 0.5 hour exposure caused 0.36 + 0.14 % of the donor malathion to penetrate through human skin after 24 hours and 2.1 + 0.6% remained in the skin after washing with shampoo. After 8 hours of topical applications penetration was approximately 3 fold greater (1.02 + 0.41) and 3.4 + 0.5% remained in the skin ( $p < 0.05$  vs 0.5 hr). The relationship between absorption and exposure time also occurred for haired rat skin ( $p < 0.05$ ) although the magnitude was smaller than for human skin. This differential continued for the full 72 hours studied. Conclusions: Reducing Ovide® application from the suggested 8-12 hours to 30 minutes can significantly reduce transdermal absorption of malathion, without decreasing the product's efficacy. Further clinical studies in children are warranted to confirm the efficacy of this shortened application time.

DERMAL PENETRATION OF SODIUM LAURYL SULPHATE AND ITS EFFECT UPON THE ABSORPTION OF OTHER CHEMICALS *IN VITRO*.

J. Wakefield<sup>1</sup>, D. Lockley<sup>2</sup>, R. Pendlington<sup>2</sup> and F. Williams<sup>1</sup>. <sup>1</sup>Environmental Medicine, University of Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom and <sup>2</sup>SEAC, Unilever Colworth, Sharnbrook, Bedfordshire, United Kingdom.

Sodium Lauryl Sulphate (SLS) (an anionic surfactant) is a known skin irritant. The irritation caused by SLS produces reversible changes in the barrier function of the skin. The objective was to investigate the dermal penetration and localisation of SLS through full-thickness and dermatomed human skin *in vitro* and its effect upon the dermal penetration of testosterone and water. Human breast skin was mounted in flow-through diffusion cells. Receptor fluid (MEM + 2%w/v BSA) was pumped at 1.5ml/hr (pH 7.4, 32°C). 2%w/v <sup>14</sup>C-SLS in water (25μl) was applied to the surface (0.64cm<sup>2</sup>) of full thickness (~1mm) and dermatomed (280μm) skin for 1hr, removed, and the distribution determined at 0, 3, 6, 12 and 24hrs after removal of the SLS. SLS (0, 1, 2, 4 and 10%w/v [100μl]) was applied to full-thickness skin for 1hr then rinsed off. <sup>3</sup>H-water (100μl) was applied to the treated surface for 11hrs. In a further study, <sup>14</sup>C-testosterone (10μl) was applied for 24hrs to full-thickness and dermatomed skin pre-treated with SLS. Following a 1hr application of SLS (2%w/v), 4-5% of the applied dose was absorbed into full-thickness skin, and 1-1.5% into dermatomed skin, with no significant change in distribution over time. SLS did not readily pass into the receptor fluid, remaining within the stratum corneum and dermis after 24hrs. The total amount of water penetrating to the receptor fluid increased with concentration of SLS pre-treatment. However, with increasing concentration of SLS, testosterone penetration into the receptor fluid, decreased through both full-thickness and dermatomed skin, remaining within the skin instead. It appears that SLS localisation affected the skin such, that the passage of a hydrophilic compound (water) into the receptor fluid was increased, whilst the penetration of a lipophilic compound (testosterone) was reduced. It is believed that SLS forms micelles within the stratum corneum and dermis, preventing lipophilic chemicals from passing into the receptor fluid *in vitro*.

INVESTIGATION OF SKIN BARRIER CREAMS FOR LOWERING PENETRATION OF JP-8 JET FUEL THROUGH *IN VITRO* PIG SKIN.

J. J. Schlager<sup>1</sup>, D. L. Pollard<sup>2</sup>, T. A. Minnick<sup>1</sup>, A. J. Guilfoil<sup>1</sup> and S. C. Stevens<sup>1</sup>. <sup>1</sup>HEPB, Applied Biotechnology Branch, Air Force Research Laboratory, Dayton, OH and <sup>2</sup>ManTech Environmental Technologies, Inc., Dayton, OH.

Skin irritation remains a concern for Air Force personnel exposed to JP-8 jet fuel. One manner to lower or eliminate skin and systemic JP-8 exposure is to use a skin-enhancement barrier cream. To determine inhibition of JP-8 penetration for a number of existing marketed products, we applied an even coverage of each barrier cream on a 10 cm<sup>2</sup> section of harvested dorsal pig skin (dermatome avg. 0.6mm). After application of even coverage of a barrier cream at room temp onto pig skin, and the skin was weighed, placed in static penetration cell at 37°C for 45 min, and exposed to JP-8 (2mL) for 4 hr. JP-8 chemical component penetration was captured in VOLPO-saline (20 mL) into the lower chamber. Samples (20μl) were withdrawn from the lower chamber sidearm and heated (140°C) to stable vapor phase using a headspace sampler for component separation on a non-polar SPB-1 column with FID detection. Total average area of eluted hydrocarbon vapor from samples (n=3) was compared between the coated and non-coated pig skin after the 4hr penetration study. Generally, products tested ranged from no barrier properties, to a 35% rate of the control. Also, after completion of the 4hr penetration experiment, the pig skin was wiped with water and paper towels, and skin punch samples (4mm diameter) were taken with a dermal biopsy punch for vapor headspace analysis. These skin punch results showed the best barrier creams for both barrier maintenance as well as those aiding surface removal of JP-8 from skin. The results varied from no benefit to 15% of the JP-8 amount in unprotected skin. The best barriers creams to JP-8 were pr88, Ply No. 9, Chimal, SERPACWA and Prolin skin guard. These results show that not all creams promoting non-polar barrier qualities would create a barrier to JP-8 penetration in this model. Further work will test the degree of protection against JP-8 irritation each cream offers with regards to skin exposure of JP-8 to New Zealand white rabbits.

2175

EFFECT OF ACUTE AND CHRONIC EXPOSURE TO THE CLEANSER, TRICHLOROETHYLENE, ON THE DERMAL ABSORPTION OF THE BIOCIDE TRIAZINE.

J. L. Yeatts, R. E. Baynes, J. D. Brooks, B. M. Barlow and J. E. Riviere. Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.

Triazine is often added to cutting-fluid formulations in the metal machining industry as a preservative that inhibits the growth of biological material. Unfortunately, triazine has been shown to cause contact dermatitis in exposed workers.

Trichloroethylene, TCE, is a solvent used for cleaning and rinsing. The purpose of this study was to examine the effect of TCE on the dermal absorption of the biocide triazine. A porcine skin *in vitro* flow-through diffusion cell system was used for these studies. In one set of experiments, the diffusion cells were dosed topically with <sup>14</sup>C-Triazine mixtures containing TCE and the 3 most common cutting-fluid components as aqueous mineral oil (MO) or polyethylene glycol (PEG) mixtures. The cutting-fluid components were 5% linear alkylbenzene sulfonate (LAS), 5% triethanolamine (TEA), and 5% sulfated ricinoleic acid (SRA). In another set of experiments, the diffusion cells were dosed with <sup>14</sup>C-Triazine mixtures containing the cutting-fluid components in aqueous MO or PEG-based mixtures after having been pre-exposed *in situ* to TCE for 96 hours. In the MO-based formulations, the absorption of <sup>14</sup>C-Triazine ranged from 3.05 to 3.65% dose. In the PEG-based formulations, the absorption of <sup>14</sup>C-Triazine ranged from 2.70 to 4.06% dose. In both sets of experiments, the porcine skin that was pre-exposed *in situ* to TCE showed greater absorption of <sup>14</sup>C-Triazine. The chronic effects of TCE appear to be more important in the PEG-based mixtures than in the MO-based mixtures. Supported by NIOSH Grant R01-OH-03669

EFFECT OF *IN VIVO* JET FUEL EXPOSURE ON SUBSEQUENT *IN VITRO* DERMAL ABSORPTION OF AROMATIC AND ALIPHATIC HYDROCARBONS.

F. Muhammad<sup>1</sup>, N. A. Monteiro-Riviere<sup>2</sup>, R. E. Baynes<sup>2</sup> and J. E. Riviere<sup>2</sup>.

<sup>1</sup>University of Agriculture, Faisalabad, Pakistan and <sup>2</sup>Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.

The percutaneous absorption of topically applied jet fuel hydrocarbons (HC) through skin previously exposed to fuel has not been studied, although this exposure is the occupational norm. Pigs were exposed to JP-8 fuel soaked cotton for 1 and 4 days with repeated daily exposures. Pre-exposed and unexposed skin was dermatomed and placed in *in-vitro* diffusion cells. Five cells with exposed and four cells with unexposed skin were dosed with a mixture of 14 HC consisting of nonane, decane, undecane, dodecane, tridecane, tetradecane, pentadecane, hexadecane, ethyl benzene, o-xylene, trimethyl benzene (TMB), cyclohexyl benzene (CHB), naphthalene, and dimethyl naphthalene (DMN) in water + ethanol (50:50) as diluent. Five cells containing JP-8 exposed skin were dosed solely with diluent to determine skin HC retention. Flux, diffusivity and permeability were calculated. There was a 2- and 4-fold increase in absorption of specific aromatic HC like ethyl benzene, o-xylene and TMB through 1 and 4-day JP-8 pre-exposed skin, respectively. Similarly, dodecane and tridecane were absorbed more in 4-day than 1-day JP-8 pre-exposed skin. Absorption of naphthalene and DMN was 1.5 times greater than controls in 1 and 4-day pre-exposures. CHB, naphthalene and DMN had significant skin retention in 4-day pre-exposures as compared to 1-day exposures that might be capable of further absorption days post exposure. The possible mechanism of an increase in HC absorption in fuel pre-exposed skin may be via lipid extraction from the stratum corneum as indicated by Fourier Transform Infrared (FTIR) spectroscopy. This study suggests that pre-exposure of skin to jet fuel enhances the subsequent *in vitro* absorption of HC. Single dose absorption data from naive skin may not be optimal to predict the toxic potential for repeated exposures. For certain compounds, persistent absorption may occur days after the initial exposure. Supported by USAFOSR F49620-01-1-0080

**2177**

ABSORPTION OF LAWSONE THROUGH HUMAN SKIN.

M. E. Kraeling<sup>1</sup>, C. T. Jung<sup>2</sup> and R. L. Bronaugh<sup>1</sup>. <sup>1</sup>Office of Cosmetics and Colors, USFDA, Laurel, MD and <sup>2</sup>Office of Pharmaceutical Science, USFDA, Rockville, MD.

Lawson (2-hydroxy-1, 4-naphthoquinone) is the principal color ingredient in henna, a color additive approved with limitations for coloring hair by the Food and Drug Administration under 21 CFR 73.2190. The safety of lawson as a coloring agent in hair dye products has recently been evaluated by the Scientific Committee on Cosmetics and Non-Food Products (SCCNFP) of the EU. The SCCNFP concluded that lawson was mutagenic and not suitable for use as a hair coloring agent. Studies were conducted to measure the extent of lawson absorption through human skin. Lawson skin absorption was determined from two hair coloring products and two shampoo products, all containing henna. [<sup>14</sup>C]-Lawson (Sp. Ac. 22.9 mCi/mmol) was added to each commercial product and applied to excised, non-viable human skin (approx. 240 microns thick) mounted in flow-through diffusion cells perfused with a physiological buffer (HEPES-buffered Hanks' balanced salt solution, pH 7.4). Products remained on the skin for 5 min (shampoos) and 1 h (hair color paste). For the henna hair paste products, 0.29 and 1.4% of the applied dose was absorbed into the receptor fluid in 24 h while 2.2 and 3.7% remained in the skin. For the henna shampoo products, 0.32 and 0.34% of the applied dose was absorbed into the receptor fluid at 24 h while 3.6 and 6.8% remained in the skin. For all products, most of the lawson applied was washed from the surface of the skin (83 - 102%) at the end of the exposure period.

Extended absorption studies were conducted for 72 h to determine if skin levels of lawson in the 24 h studies might eventually be percutaneously absorbed. These studies determined that the majority of the lawson remained in the skin with little diffusing out into the receptor fluid. For example, the 72 h receptor fluid values following administration of henna paste products were only 0.48 and 1.61%. Since most of the receptor fluid values did not increase significantly during the extended studies, the receptor fluid values at 24 h should be used in a subsequent exposure assessment.

**2178**

SKIN PENETRATION OF BREAK-FREE CLP IN THREE SPECIES; SPRAGUE DAWLEY RAT, CD-1 MOUSE, AND YORKSHIRE PIG.

C. M. Garrett and J. N. McDougal. *Pharmacology/Toxicology, Wright State University, Dayton, OH.*

Break-Free CLP (a complex mixture of polyalphaolephin oil, proprietary ingredients and other hydrocarbons) is used by the US and some European military, police departments and private citizens to clean, lubricate and protect firearms. Skin exposures from this widespread use are likely, although it is unknown whether systemic toxicity can result from skin contact. The purpose of this study was to determine the penetration of Break-Free in laboratory animal skin so that the hazards to humans can be estimated. We used static diffusion cells and GC/MS headspace analysis of receptor and skin samples to estimate the flux of liquid Break-Free across the skin for up to six hours. The sum of the concentrations of six major constituents of Break-Free was used as a surrogate for the concentration of the mixture. The constituents were decane (RT = 2.86 min), butanedioic acid dimethyl ester (RT = 3.2 min), undecane (RT = 4.25 min), dodecane (RT = 6.9 min), hexanedioic acid dimethyl ester (RT = 8.8 min), and tridecane (RT = 11.4 min). Average total flux values were 9.78 ug/cm<sup>2</sup>/h for pig, 43.2 ug/cm<sup>2</sup>/h for rat, and 131 ug/cm<sup>2</sup>/h for mouse. Concentration of chemical in the skin following a 6 hour exposure was 0.949 ug/mg skin in pig, 9.78 ug/mg skin in rat, and 31.6 ug/mg skin in the mouse. As expected, different components of Break-Free were found in the receptor solution than were found in the skin following exposure. The major Break Free components found in the receptor solution of all three species were decane and undecane, while the skin had highest concentrations of butanedioic acid dimethyl ester and dodecane. All six measured components were present to some extent in both receptor solution and skin of all species examined. We conclude that penetration of Break-Free is measurable but low in these species. The potential for systemic toxicity from this mixture can be evaluated based on toxicity of the individual components. (Funded by Naval Health Research Center Detachment Environmental Effects Laboratory)

**2179**

CHANGES IN GENE EXPRESSION IN RAT EPIDERMIS AFTER JET FUEL (JP-8) EXPOSURE TO THE SKIN.

C. M. Amato, C. M. Garrett and J. N. McDougal. *Pharmacology/Toxicology, Wright State University, Dayton, OH.*

An estimated 13 million US workers are potentially exposed to chemicals and as a result irritant contact dermatitis is a common occupational disease. Understanding the molecular mechanisms behind skin irritation may establish prophylactic and therapeutic interventions for jet fuel-induced skin disease. No previous studies have shown how JP-8 fuel affects gene expression of skin cells located in the epidermal layer. The purpose of our study was to identify genomic changes in rat epidermis resulting from jet fuel-induced skin irritation. Five hundred microliters of JP-8 was placed in a Hill Top Chamber and secured with a Lomir rodent jacket onto the shaved mid-scapular region of male Fisher 344 rats. Exposure time was one hour, and the skin was collected and observed at 1, 4, and 8 hours after the beginning of the exposure. Skin samples were compared with samples from sham-treated rats. At the conclusion of the experiment, skin was excised, and the epidermis was removed in 5 micron sections using a cryotome. Total RNA was isolated from the epidermal layer. We measured changes in gene expression using the Affymetrix gene array (Rat Genome U34A chip). This experiment showed that changes in gene transcripts occur as early as one hour and become progressively greater after initiation of treatment with JP-8. At one hour, 116 genes were up regulated and 14 were down regulated. At four hours, 175 gene transcripts were up regulated and 100 were down regulated. At eight hours, 327 transcripts were up regulated and 473 were down regulated. When transcripts showing the greatest changes were cross-referenced within the Simplified Gene Ontology database (GeneSpring), the molecular function categories associated with these transcripts differed over time. After one hour, the nucleic acid binding genes were up-regulated the most. Enzymes were the most changed category of genes at the two later time points. These studies illustrate the rapid response of gene expression and the sequence of gene induction immediately after JP-8 exposures to the skin. (Funded by Air Force Office of Scientific Research)

## PROTEOMIC ANALYSIS OF JP-8 JET FUEL EXPOSURE IN HUMAN KERATINOCYTE CELL CULTURE.

F. Witzmann<sup>1</sup>, N. Monteiro-Riviere<sup>2</sup>, A. Inman<sup>2</sup>, N. Pedrick<sup>1</sup>, H. Ringham<sup>1</sup> and J. Riviere<sup>2</sup>. <sup>1</sup>*Cellular & Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN* and <sup>2</sup>*Center for Chemical Toxicology Research & Pharmacokinetics, College of Veterinary Medicine, North Carolina State University, Raleigh, NC.*

Dermal exposure to jet fuel is a significant occupational hazard. Previous studies have investigated its absorption and disposition in skin, and the systemic biochemical and immunotoxicological sequelae to exposure. Despite studies of JP-8 jet fuel components in murine, porcine or human keratinocyte cell cultures, proteomic analysis of JP-8 exposure has not been investigated. This study was conducted to examine the effect of JP-8 administration on the human epidermal keratinocyte (HEK) proteome. Using a two-dimensional electrophoretic approach combined with mass spectrometric-based protein identification, we analyzed protein (2DE) expression in HEK exposed to 0.1% JP-8 in culture medium for 24 h. Using 1 mL medium, HEK reached 65% confluence, while in 2 mL they achieved 95% confluence. Nearly 1, 200 protein spots were resolved by 2DE and image analysis. In the 95% confluent group, 0.1% JP-8 exposure resulted in significant expression differences ( $P < .01$ ) in 32 proteins of the 929 proteins matched and analyzed. In the slow growing cells, 45 proteins were differentially expressed ( $P < .01$ ). In both groups, roughly a third of these alterations were increases in protein expression, two-thirds were declines with JP-8 exposure. 2-way ANOVA was unable to demonstrate any interaction between confluence and JP-8 effects. Although 13 more proteins were altered ( $P < .01$ ) by JP-8 in the 65% slow-growing group, all proteins common to both groups responded similarly to JP-8. Peptide mass fingerprint identification of effected proteins revealed a variety of functional implications. In general, up-regulated proteins involved endocytotic/exocytotic mechanisms, their cytoskeletal components, and cell stress. Down-regulated proteins generally included those involved in vesicular function. Supported by AFOSR Grants # F49620-03-1-0089 (FAW) & F49620-01-1-0080 (JER).

## EXPRESSION PROFILING OF HUMAN EPIDERMAL KERATINOCYTE RESPONSE FOLLOWING JP-8 EXPOSURE.

C. Chou<sup>1</sup>, J. Yang<sup>2</sup>, N. A. Monteiro-Riviere<sup>3</sup> and J. J. Chen<sup>4</sup>. <sup>1</sup>*Department of Veterinary Medicine, National Chung-Hsing University, Taichung, Taiwan*, <sup>2</sup>*Department of Dermatology, Chung-Shan Medical University Hospital, Taichung, Taiwan*, <sup>3</sup>*Center for Cutaneous Toxicology and Research Pharmacokinetics, North Carolina State University, Raleigh, NC* and <sup>4</sup>*Institute of Molecular Biology, National Chung-Hsing University, Taichung, Taiwan*.

Jet fuel exposure initiates and promotes many biological and toxicological changes in human epidermal keratinocytes (HEK). In order to elucidate the molecular mechanisms involved in jet fuel toxicity, cDNA microarray was performed to examine the changes in gene expression in HEK after neat JP-8 exposure. Total RNA of controlled HEK and HEK cells harvested at 12 and 24 h after dosing were extracted for microarray analysis of 9600 expressed sequence tags (EST) including cancer, apoptosis, inflammation and metabolism-related genes. One-way ANOVA was employed to identify statistically significant ( $p < 0.05$ ) genes. The results showed that a total of 150 genes (1.6%) were identified as JP-8 responsive and their expression profiles were classified into 9 clusters by self-organizing map (SOM). Among the significantly regulated genes, those involved in basal transcription and translation were up-regulated while genes related to DNA repair, metabolism and keratinization were mostly down-regulated. Genes encoded for growth factors, apoptosis, signal transduction and adhesion were also altered. These results indicate that HEK responds to a single dose of JP-8 insult. A cascade of change in gene expression follows and demonstrated a complex expression profile. The data also describes several cellular processes previously not associated with jet fuel exposure. Taken together, this initial microarray analysis could advance the understanding of HEK responses to jet fuel exposure and provides a platform from which further studies concerning mechanisms and pathways of jet fuel toxicity could be approached. ## JP-8 JET FUEL EXPOSURE INDUCES INFLAMMATORY CYTOKINES IN RAT SKIN.

R. Gallucci<sup>1</sup>, S. K. O'Dell<sup>1</sup>, D. Faulkner<sup>1</sup> and L. D. Fechter<sup>2</sup>. <sup>1</sup>*Pharmaceutical Sciences, OU Health Sciences Center, Oklahoma City, OK* and <sup>2</sup>*Jerry Pettis Memorial Veterans Medical Center, Loma Linda, CA.*

The DoD has identified that one of the main complaints of personnel exposed to JP-8 jet fuel is irritant dermatitis. The purpose of this investigation is to describe the JP-8 induced inflammatory cytokine response in skin. JP-8 jet fuel or acetone

control was applied to the denuded skin of rats once a day for seven days. Skin samples from the exposed area were collected 2 and 24 hours after the final exposure. Histological examination of skin biopsies showed neutrophilic inflammatory infiltrate. RT-PCR was performed utilizing skin total RNA to examine the expression of various inflammatory cytokines. The CXC chemokine GRO-alpha was significantly upregulated at both time points, whereas GRO-beta was only increased 2 hours post final exposure. The CC chemokines MCP-1, Mip-1alpha, and Eotaxin were induced at both time points, whereas Mip-1beta was induced only 24 hours post exposure. IL-1beta, and IL-6 mRNA were significantly induced at both time points, while TNF-alpha was not significantly different from control. ELISA of skin protein confirmed that MCP-1, TNF-alpha, and IL-1beta were modulated as indicated by PCR analysis. However, skin IL-6 protein content was not increased at either time point. Data from the present study indicates that repeated (seven day) JP-8 exposure induces numerous proinflammatory cytokines in skin. The increased expression of these cytokines and chemokines may lead to increased inflammatory infiltrate in exposed skin, resulting in JP-8 induced irritant dermatitis.

## PROTEOMIC ANALYSIS OF NANOPARTICLE EXPOSURE IN HUMAN KERATINOCYTE CELL CULTURE.

There has been explosive growth in engineering disciplines using nanoparticles, structures with characteristic dimensions between 1 and 100nm. These range from applications in the fields of ceramics to microelectronics as well as many areas of drug delivery. Nanomaterials have shown that they can be incorporated into human keratinocytes (HEK) in cell culture. There is no information available on the protein expression in cultured HEKs exposed to nanomaterials. This study was conducted to determine the effect of multi-walled carbon nanotubes (MWCNT) on the HEK cell proteome. Using a two-dimensional electrophoresis-based proteomics approach, we analyzed protein expression in HEKs exposed to 0.4mg/ml of MWCNT in culture medium for 24 h. Approximately 970 protein spots were resolved by two-dimensional electrophoresis and their relative abundance compared using image analysis. The expression of 32 proteins was significantly altered ( $p < 0.05$ ) by the MWCNT. Peptide mass fingerprint identification of the effected proteins revealed the identities of 22 proteins, 15 of which were upregulated while 7 decreased in expression. The protein alterations suggest dysregulation of intermediate filament expression, cell cycle inhibition, effects on metabolism, increased lysosome/melosome biogenesis, altered vesicular trafficking/exocytosis, and membrane scaffold protein down-regulation. Supported by AFOSR Grant F49620-03-1-0089 (FAW) and Center for Chemical Toxicology Research and Pharmacokinetics (NAMR).

## NANOTUBE DISPERSAL IN HUMAN KERATINOCYTE CELL CULTURE USING SURFACTANTS.

A. O. Inman<sup>1</sup>, Y. Y. Wang<sup>2</sup>, R. J. Nemanich<sup>2</sup>, J. E. Riviere<sup>1</sup> and N. A. Monteiro-Riviere<sup>1</sup>. <sup>1</sup>*Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC* and <sup>2</sup>*Department of Physics, North Carolina State University, Raleigh, NC.*

Nanoparticles exhibit a variety of unique chemical and physical properties. These unique properties have placed these particles in the forefront of emerging technologies and may result in similarly unique biological effects. We are currently studying the interactions of multi-walled carbon nanotubes (MWCNT) in cultured human keratinocytes. Many of these particles cannot enter the cell since substantial van der Waals attractions cause them to readily aggregate in the aqueous culture medium. Surfactants may be used to disperse these aggregates to increase the effective MWCNT concentration. However, these surfactants must not be toxic to the cells. HEKs were exposed to serial dilutions (10%, 5%, 1%, 0.5%, and 0.1%) of Pluronic® (L61, L92, and F127) and Tween (20 and 60) surfactants in media for 24 h in a humidified 5% CO<sub>2</sub> atmosphere at 37°C. HEK viability (neutral red uptake), proportional to surfactant concentration, ranged from 27.1% to 98.5% with Pluronic® F127; cell viability with the remaining surfactants was less than 10%. MWCNT (0.4mg/ml), vortexed and sonicated in media containing 5% or 1% Pluronic® F127, were incubated with HEKs under culture conditions for 24 h. Media was harvested at 1, 2, 4, 8, 12, and 24 h post exposure, quickly frozen, and stored at -80°C until IL-8 assay. The 24 h viability of HEKs exposed to both 5% F127 + MWCNT and 1% F127 + MWCNT was significantly less ( $p < 0.05$ ) than the corresponding media and surfactant controls. Normalized IL-8 release from the F127 and F127 + MWCNT treatments was significantly higher ( $p < 0.05$ ) than the

corresponding media controls. Preliminary data indicates that the surfactant Pluronic® F127 does reduce MWCNT aggregates in the aqueous medium without causing a significant decrease in HEK viability.

The *in vivo* disposition of nanoscale materials is of interest due to their potential inclusion in a large number of products. As part of a project to determine the dermal penetration of nanoscale material, we examined the disposition of nanoscale material injected in the dermis of mice. Quantum dots (QD) consisting of CdSe nanocrystals, encased in a ZnS shell and PEG outer coating were injected intradermally (ID) in female SKH-1 hairless mice and their disappearance from the injection site and disposition were determined using digital macrophotography and fluorescence microscopy. Mice were injected in each flank with 5  $\mu$ l of 5.5  $\mu$ M red QD (655 nm emission; 6 x 12 nm rods) and 7.5  $\mu$ M yellow QD (565 nm emission; 6 nm spheres), or sterile saline, imaged under UV illumination, and sacrificed at 0, 6, 12, 18, 24, and 48 hrs. Under UV illumination, the highly fluorescent QD could be observed and digitally imaged moving from the injection sites via subcutaneous lymphatic ducts to regional lymph nodes. The tracking of fluorescence in subcutaneous lymphatic ducts with accumulation in lymph nodes occurred minutes after injection in some animals and was no longer apparent after 6 hrs. Residual fluorescent QD remained at the site of injection until necropsy. Lymph nodes from QD injected animals exhibited fluorescence that was localized in subcapsular and trabecular lymphatic sinuses. QD fluorescence in lymph nodes was most abundant at 0 hr and 6 hr, but was detected at all time points. In conclusion, intradermally injected nanoscaled QD remained as a depot in skin, penetrated the surrounding viable subcutis and were visibly distributed to draining lymph nodes via subcutaneous lymphatics. These results are consistent with the previously reported use of near infrared emitting nanoscale particles for imaging sentinel lymph nodes.

IMAGING THE PENETRATION OF RUBPY-DOPED SILICA NANOPARTICLES INTO HUMAN AND MOUSE SKIN WITH FLUORESCENT MICROSCOPY.

S. C. Wasdo, S. M. Roberts, S. Santra, J. Munson and Y. Song. *University of Florida, Gainesville, FL*.

Nano-sized particles have the potential to enter body through routes that are inaccessible to larger particulates. One such route is dermal absorption. To study the penetration of nano-particulates into mammalian skin, we exposed whole-thickness mouse and dermatomed (600  $\mu$ m) human skin *in vitro* to suspensions of RubPy doped 50-nm silica particles under static and dynamic conditions. For static samples, 100 x 300 mm skin sections were placed flat with the epidermis side up and a 5  $\mu$ L aliquot of a 20 mg/mL suspension of the dye doped silica particles was placed on the center of a section. Static samples were left undisturbed for 2 h. Dynamic samples were treated similarly, but placed upon a single-hinged flexing device, which flexed the upper half of the section between 0 and 45° above horizontal 30x/min for two hours. After the 2-h incubation, the skin sections were rinsed with PBS and gently blotted to remove excess particles. After fixing in formaldehyde, samples were cut from dermis side out in 20- $\mu$ m sections and examined by fluorescent microscopy. The silica particles were found to penetrate into the stratum corneum and epidermis of both skin types and under both treatments with a higher concentration of particles occurring in the tissues of flexed samples. Particle count in the epidermis was low compared to the stratum corneum and higher in the mouse than the human; presumably a result of the thinner stratum corneum of the mouse.

MODULATORY EFFECTS OF SUBCHRONIC EXPOSURE TO SIMULATED SOLAR LIGHT ON TATTOOED SKIN IN SKH-1 MICE.

N. V. Gopee<sup>1,2</sup>, Y. Cui<sup>1,2</sup>, G. R. Olson<sup>3</sup>, A. R. Warbrinton<sup>3</sup>, B. J. Miller<sup>1,2</sup>, L. H. Couch<sup>1,2</sup>, W. G. Wamer<sup>4</sup> and P. C. Howard<sup>1,2</sup>. <sup>1</sup>*NCTR, USFDA, Jefferson, AR*, <sup>2</sup>*NTP Center for Phototoxicology, NCTR, USFDA, Jefferson, AR*, <sup>3</sup>*Charles River Co., Jefferson, AR* and <sup>4</sup>*CFSAN, USFDA, College Park, MD*.

Tattooing is the process of depositing pigment into the dermis of the skin with a needle producing an indelible decorative pattern. In an attempt to determine the phototoxicity of tattoo pigments, we have shown that tattooing induces an acute

inflammatory response in the skin with recovery within 13 days. The present study examines the effect of subchronic exposure of tattooed mice to simulated solar light (SSL). Female SKH-1(*br/br*) hairless mice were tattooed longitudinally on the dorsal side. The test mixtures consisted of vehicle (10% glycerol in water) or vehicle containing cadmium sulfide (CdS) or Pigment Red 22 (PR22). After 2 weeks to allow skin recovery, half of the mice were exposed to 1.4 Standard Erythema Dose/day SSL for 13 weeks and then euthanized. Minimal dermal inflammation was present in one-third of the non-tattooed and vehicle-tattooed skin not exposed to SSL. The incidence of dermal inflammation increased to 67% and 56%, respectively, upon exposure to SSL. In contrast, exposure to SSL did not increase the incidence of dermal inflammation in the CdS (100%) and PR22 (67%) tattooed skin. Acanthosis was present in all SSL-exposed animals except the CdS-tattooed group. Dermal necrosis and fibrosis, and epidermal hyperplasia were present exclusively in CdS-tattooed animals (100%) with or without SSL. Dermal histiocytic infiltration was noted only in the PR22-tattooed skin and increased in incidence from 33% to 100% in the presence of SSL. Western blotting and immunohistochemistry showed cutaneous COX-1, COX-2 and ODC proteins were significantly different in animals exposed to SSL when compared to non-exposed mice, notably in the CdS group. Real time PCR demonstrated differential expression of cyclin D1, HIF-1 $\alpha$  and cMyc in response to SSL in tattooed and non-tattooed mice. The results demonstrate the modulatory effects of subchronic exposure to SSL in the skin of tattooed mice.

ROLE OF VITAMIN E IN THE ANTIOXIDANT DEFENSE SYSTEM OF SKIN IN YOUNG AND OLD MICE EXPOSED TO CUMENE HYDROPEROXIDE.

A. R. Murray<sup>1</sup>, E. Kisin<sup>2</sup>, K. Kawai<sup>3</sup>, V. E. Kagan<sup>3</sup>, C. Kommineni<sup>2</sup>, V. Castranova<sup>1,2</sup> and A. A. Shvedova<sup>1,2</sup>. <sup>1</sup>*Physiology and Pharmacology, WVU, Morgantown, WV*, <sup>2</sup>*PPRB, NIOSH, Morgantown, WV* and <sup>3</sup>*University of Pittsburgh, Pittsburgh, PA*.

The skin is exposed to numerous environmental, chemical, and physical stressors (UV-irradiation) whose injurious action is often associated with the development of oxidative stress. While the skin possesses an elaborate antioxidant (AO) defense system to prevent oxidative stress, excessive exposure to occupational and environmental insults can overwhelm the cutaneous AO capacity. Age-related decline of AO protection may further enhance sensitivity of skin to chemically induced oxidative damage. To evaluate whether aging affected the AO capabilities of the skin, we studied changes in vitamin E, glutathione (GSH), ascorbate, and total AO reserve levels in the skin of female mice from 4 to 32 weeks of age. Among studied AO, we observed the most significant and rapid reduction occurred in the vitamin E content. To study how topical exposure to cumene hydroperoxide (Cum-OOH) affected the AO status of the skin of young/old mice, two models were used: 1) mice given a diet deficient in vitamin E and 2) mice with a genetic deletion of the tocopherol transporter protein (Ttpa knockout). We found that oxidative DNA damage (8-oxo-2'-deoxyguanosine) in skin of old mice (32 weeks) occurred independently of vitamin E status while DNA damage in skin of young animals (13 weeks) exposed to Cum-OOH was dependent upon vitamin E. Cum-OOH induced oxidative stress in old mice as assessed by depletion of GSH, ascorbate, and total AO reserve. Cum-OOH induced morphological changes to a greater extent in the skin of old vitamin E deficient animals compared to young mice. Similar results were found in the Ttpa knockout mice exposed to Cum-OOH; however, the mice only had a 40% reduction in their vitamin E levels and the resulting changes were not as profound as in the mice given the vitamin E deficient diet. In conclusion, AO, in particular vitamin E, play a prominent role in the protection of skin against oxidative injury induced by Cum-OOH exposure *in vivo*.

**2189**

DETECTION OF BENZO(A)PYRENE-INDUCED DNA DAMAGE IN THE SKIN OF CD-1 MICE USING THE COMET ASSAY.

J. W. Parton, Y. Xu and J. K. Kerzee. *MicaGenix, Inc., Greenfield, IN*.

The single cell gel electrophoresis assay (SCGE or "comet" assay) is a rapid, sensitive method used to detect DNA damage *in vivo* and *in vitro*. The principle of the assay is based on the ability of denatured, cleaved and unwound DNA to migrate out of the nucleus when an electric current is applied to the cell, whereas intact, undamaged DNA remains within the confines of the nucleus. While this assay has been successful in studies to predict potential clastogenic agents, there is little data published on the use of the comet assay to analyze these agents in intact mammalian skin. Since DNA strand breaks result in the formation of micronuclei, we hypothesized that the comet assay would provide a sensitive method for detecting DNA damage in the skin of CD-1 mice challenged topically with benzo(a)pyrene (BaP), a prototypical carcinogen and potent electrophilic agent. To test this hypothesis, BaP (2mg/ml), or acetone (vehicle), was painted onto the shaved back of CD-1 mice daily for 3, 6, and 10 days. At each time point, two mice were sacrificed

and skin samples were collected and processed for the comet assay. DNA single strand breaks were quantified by the differences observed in comet moment, percent (%) tail DNA, and comet tail length. These parameters were significantly increased by BaP compared to vehicle in all animals. When the level of DNA damage was analyzed using comet moment to compare the distribution of the skin cells in BaP- and vehicle-treated animals, BaP treatment resulted in a significant increase in the number of cells with DNA damage. This response elicited by BaP did not increase in severity beyond day 3. These findings indicate that a net balance of DNA damage and repair is likely achieved in the skin of BaP-treated animals over the course of 10 days of exposure. Furthermore, chemically-induced DNA damage can be detected using the comet assay in a short-term exposure model.

## 2190 EFFECT OF METHYL SUBSTITUTION OF BENZENE ON THE PERCUTANEOUS ABSORPTION AND SKIN IRRITATION HAIRLESS RATS.

J. Ramapuram<sup>1</sup>, E. AHAGHOTU<sup>1</sup> and M. SINGH<sup>1</sup>. <sup>1</sup>Florida A&M University, Tallahassee, FL and <sup>2</sup>SOT, ETEST, AL.

To study the structure activity relationship (SAR) between the methyl substitution of benzene and 1) permeation or retention in skin layers 2) their irritation potential in hairless rats after dermal exposures. Methods: The skin permeation or retention studies were carried out on freshly excised hairless rat skin mounted on Franz diffusion cells filled with 6% Brij 98 in normal saline. Benzene, dimethyl benzene (xylene) and tetramethyl benzene (isodurene) spiked with respective <sup>3</sup>H radiolabeled chemicals were applied to the epidermal surface. After defined exposure period, the receptor samples were collected; the exposed skin area was tape stripped for SC, and sectioned into epidermis and dermis with a cryotome. The permeation rate and retention in stratum corneum (SC), epidermis and dermis were determined by scintillation counting of the samples. The skin irritation of the chemicals was studied in hairless rats by occlusive (230  $\mu$ l for 1 h using Hill top chambers®) and unocclusive (15  $\mu$ l every 2 h for 8 h a day for 4 days) dermal exposures. The transepidermal water loss (TEWL) and erythema were measured at different time intervals after dermal exposures. Results: The permeation of benzene decreases with increase in methyl groups of benzene (2.5 and 80 times higher flux by xylene and isodurene). The retention of chemicals in SC showed a direct correlation between amount retained in SC and methyl substitution or log P of the chemical. The retention in epidermis and dermis of different chemicals were approximately 10-15 times higher than SC. The skin irritation (TEWL and Erythema) increases with methyl substitution of benzene (isodurene > xylene > benzene). The TEWL data correlated "very well with erythema scores of the chemicals. Conclusion: A clear relationship between the flux or skin retention and methyl substitution of the chemical was established. The skin irritation increases with methyl substitution of benzene under the experimental conditions of present study.

## 2191 LONG TERM REPRODUCIBILITY OF EPIDERM<sup>TM</sup>, AN EPIDERMAL MODEL FOR DERMAL TESTING AND RESEARCH.

M. Klausner, J. Kubilus, J. E. Sheasgreen and P. J. Hayden. MatTek Corporation, Ashland, MA.

An *in vitro* model of human epidermis, EpiDerm (EPI-200), cultured from neonatal, normal human epidermal keratinocytes has been sold commercially by MatTek Corporation since 1993. Using serum free medium, weekly lots of EpiDerm are produced and shipped for dermal irritancy, product efficacy, percutaneous absorption, pharmacological, and basic skin research studies. In 2000 and 2002, respectively, European and US regulators approved the use of EpiDerm to assess the skin corrosivity of chemicals. Validation studies utilizing EpiDerm for phototoxicity and skin irritation are currently underway. For commercial and regulatory purposes, it is crucial that the model is reproducible both within a given lot and between lots, especially over extended periods. To address tissue reproducibility, quality control testing of each EpiDerm lot involves exposure to the surfactant, 1% Triton X-100 (TX), and a negative control, ultrapure water. Using the MTT assay, which historically has been the *in vitro* endpoint of choice for European and US regulators, a dose response curve is constructed and an exposure time which reduces the tissue viability to 50% (ET-50) is interpolated. The yearly average ET-50 since 1996 has varied from 6.5 hr (2000) to 7.5 hr (1998). The coefficients of variation (CV) for the negative control have averaged under 7% for every year since 1997 and the average CV for all tissues has never exceeded 13.2%. Using light microscopy, histological H&E cross-sections show an epidermis-like morphology that is reproducible both within and between lots. Hence, over the past 10+ years of commercial production, EpiDerm has remained a highly reproducible, stable toxicological model that is ideally suited for industrial and regulatory toxicology and other skin related studies.

## 2192 DETERMINING SKIN IRRITATION POTENTIAL OF INDUSTRIAL FLUIDS IN HUMANS USING TRANS-EPIDERMAL WATER LOSS (TEWL).

M. Wragg<sup>1</sup> and S. Signs<sup>2</sup>. <sup>1</sup>Lubrizol Limited, Derby, United Kingdom and <sup>2</sup>The Lubrizol Corporation, Wickliffe, OH.

Evaluating the skin irritation potential of industrial fluids is becoming increasingly important for downstream lubricant users. In the absence of validated alternative methods, animal models (eg. OECD method guideline 404) have been relied upon to provide a prediction of the irritant potential of a fluid in the workplace. It is suggested that evaluating the irritant potential of industrial fluids in human volunteers using trans-epidermal water loss (TEWL) and colorimetry measurements could offer a scientifically-valid alternative to established animal models, and provide greater predictive accuracy for estimating potential skin reactions in workers following occupational exposure. Several industrial fluids were evaluated for skin irritation potential using a 4-hour semi-occluded exposure in rabbits (OECD method 404). These same fluids; in addition to 0.2% SLS as a positive control, and negative control treatments including water, highly refined lubricant base oil and an untreated site; were also examined in a panel of 30 human volunteers using a 24-hour occluded exposure. Irritation was quantitatively scored using  $\Delta$ TEWL, colorimetry, and estimation of erythema/edema by a trained dermatologist. RESULTS: Three of the supplied fluids produced Primary Irritation Index (PII) scores in rabbits of >3.0 (erythema and edema values met the EU criteria for a skin irritant, R38), but were found to be unsuitable for investigation in volunteers based upon initial observations of severe irritation that exceeded ethical limits for testing in humans. Other fluids produced PII = 1.0 when tested in rabbits (did not meet the EU skin irritant criteria) were found using the TEWL model to have a slightly higher potential to cause skin irritation in the workplace than that of non-additized, highly-refined mineral oil. The results show that measurement of  $\Delta$ TEWL following 24-hour occluded exposure in human volunteers is sufficiently sensitive to identify industrial fluids that have the potential to cause an adverse skin reaction in the workplace under unprotected exposure conditions.

## 2193 EVALUATION OF HISTORICAL POSITIVE CONTROL DATA FOR RESPONSE CONSISTENCY AND REDUCTION IN ANIMAL USE IN PHOTOTOXICITY AND PHOTOALLERGY ASSESSMENTS.

D. B. Learn, C. P. Sambuco, M. Arocena, M. L. Davis, T. S. Coston, P. D. Forbes and A. M. Hoberman. Center for Photobiology, Charles River Discovery and Development Services, Argus Division, Horsham, PA.

In phototoxicology, positive control agents (PCA) have been included in animal studies when assessing potential adverse effects of pharmaceuticals and chemicals. Whether to use PCA groups in all such assays is a decision based on regulatory requirements, the effort to reduce animal use and confidence in the consistency of the required response. In acute phototoxicity (PT) assays performed in our laboratory, 8-methoxysoralen (8-MOP) and lomefloxacin (LOM) are commonly used PCA as is 3, 3', 4', 5'-tetrachlorosalicylanilide (TCSA) for contact hypersensitivity (CH) and photoallergy (PA) assessments. Historical control data (HCD) were compiled from studies over the past 7 years for cutaneous PT induced by 8-MOP in hairless mice, haired (Long-Evans) rats, haired guinea pigs and hairless guinea pigs, by LOM in hairless mice and CH and PA induced by TCSA in guinea pigs. Ocular PT HCD using Long-Evans rats were also compiled. The routes of administration for PT included topical, oral (gavage) and intravenous while the topical route of administration was evaluated for CH and PA. In all studies, the light source was a filtered xenon arc solar simulator emitting environmentally-relevant ultraviolet, visible and infrared radiation. Review of the HCD revealed that erythema, edema and flaking assessed by visual observation were the most common signs of cutaneous PT, CH and PA. Corneal opacity and/or edema detected by ophthalmologic examination and substantiated by histopathological evaluation were the hallmarks of ocular PT. The incidences of the cutaneous and ocular findings were consistent and reproducible across studies and over time. Therefore, the HCD revealed that the *in vivo* phototoxicology assays are robust and these data, rather than positive control animals, can be used to demonstrate the validity of the assays and appropriately reduce the use of animals in these assessments.

## 2194 QUANTIFICATION OF MIXTURE INTERACTIONS ON DERMAL PERMEABILITY-A SOLVATOCHROMATIC APPROACH.

R. E. Baynes, B. M. Barlow, X. R. Xia, J. L. Yeatts, J. D. Brooks and J. E. Riviere. Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.

The influences of mixture-mixture interactions, differing solvent systems, and surfactants on permeability and dermal absorption have not been well studied. Past research has focused on the toxicity of a single solute dosed in an organic solvent; unfortunately, these conditions do not generally represent real world scenarios of

occupational use. The scope of our study is to identify and quantify physicochemical interactions that drive dermal permeability using Linear Solvation Energy Relationships (Log permeability =  $c + r^*R_2 + s^*\pi_2^H + a^*\sum\alpha_2^H + b^*\sum\beta_2^H + v^*V_x$ ) during complex mixture exposure. Seven solutes (propylbenzene, biphenyl, naphthalene, methyl benzoate, 4-nitrotoluene, phenol, and 3-methyl phenol) with a wide range of known physicochemical properties (Log p, solubility, molecular weights, etc.) and LSER solvatochromatic parameters ( $R_2, \pi_2^H, \alpha_2^H, \beta_2^H, V_x$ ) were prepared in various mixtures (0-100% aqueous or ethanol solutions and/or 0.1%, 1% and 10% SLS), and applied to a porcine skin flow thru diffusion cell system. Dermal permeability was then calculated using the resultant perfusate and SPME GC/MS or GC/FID detection. The LSER system coefficients ( $r, s, a, b, v$ ) were compared to derive an interaction coefficient value ( $\Delta r, \Delta s, \Delta a, \Delta b, \Delta v$ ). Preliminarily results indicate that ethanol at 50% strength decreased both hydrogen bond acceptor activity ( $\Delta r - 2.010$ ) and McGowan molecular volume ( $\Delta v - 0.729$ ), while the presence of surfactants increased both hydrogen bond acceptor activity ( $\Delta b + 1.979$ ), and McGowan molecular volume ( $\Delta v + 1.305$ ). These results indicated that system basicity and lipophilicity play a significant role in dermal permeability of solutes after exposure to complex solvent and surfactant mixtures. Further studies are aimed at discerning quantitatively the biological and chemical contributions of these interactions. Supported by NIOSH Grant R01-OH-03669

### PREDICTING HUMAN SKIN ABSORPTION OF CHEMICALS: DEVELOPMENT OF A NOVEL QUANTITATIVE STRUCTURE ACTIVITY RELATIONSHIP.

W. Luo<sup>1</sup>, S. Medrek<sup>2</sup>, H. Nguyen<sup>1</sup> and W. Fung<sup>1</sup>. <sup>1</sup>Toxicology, L'Oréal USA, Clark, NJ and <sup>2</sup>Department of Chemical Engineering, Princeton University, Princeton, NJ.

The objective of this study was to construct and validate a simple model using over 340 chemicals of diverse structure for the quantitative prediction of percutaneous absorption based on their physicochemical properties. Such a model is a valuable tool for screening and prioritization in safety evaluation and risk assessment of chemicals. A number of models will be presented. Of particular interest is a simple three-parameter QSAR model to predict the permeability coefficient,  $K_p$ , with a training set of 306 chemicals and their physicochemical descriptors. In addition to the experimental  $K_{ow}$  values, over 300 2D and 3D atomic and molecular descriptors were analyzed using MDLs QSAR computer program (MDL Information Systems, Inc., San Leandro, CA 94577). All  $K_p$  values used in training and validation were experimental data obtained from various sources. Using the stepwise regression analysis, three molecular descriptors were determined to have significant statistical correlation with  $K_p$  ( $R^2 = 0.8225$ ):  $\log K_{ow}$ ,  $x_0$  (quantification of both molecular size and the degree of skeletal branching), and  $S_{SSS}CH$  (count of aromatic carbon groups). Subsequently, the model was validated using both internal (leave-one-out) and external validation (90/10 random split) procedures. The  $R^2$  from internal validation is 0.8108, and that from external validation is 0.5829,  $\log K_p$  ( $\text{cm}/\text{hr}$ ) =  $0.5892 * \log K_{ow} - 0.1006 * x_0 - 0.1617 * S_{SSS}CH - 2.62353$  ( $R^2 = 0.8225$ ) In conclusion, an algorithm to estimate human skin absorption was derived based on physicochemical properties of over 300 compounds. Compared to other skin absorption QSAR models in the literature, our model has incorporated more chemicals and explored more descriptors in addition to the commonly used MW and  $K_{ow}$ . Additionally, our model is reasonably predictive and has stood up to both internal and external statistical validations.

### A NOVEL SYSTEM COEFFICIENT APPROACH FOR QUANTITATIVE ASSESSMENT OF DERMAL ABSORPTION FROM CHEMICAL MIXTURES BY USING THE MEMBRANE-COATED FIBER TECHNIQUE.

X. R. Xia, R. E. Baynes, N. A. Monteiro-Riviere and J. E. Riviere. Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.

Chemical exposure in most environmental and occupational settings involves complicated chemical mixtures, not individual chemicals. However, current health risk assessment of dermal absorption is based on permeation data for individual chemicals due to lack of available quantitative methods or experimental data from chemical mixtures. In the system coefficient approach, a set of solute descriptors, [ $R, \pi, \alpha, \beta, V$ ], represents the molecular interaction strengths of a chemical of interest, while a set of system coefficients, [ $r, s, a, b, v$ ], represents those of the skin/medium system. The permeation coefficient or partition coefficient ( $\log K$ ) is correlated with the system coefficients and the solute descriptors via Abraham's linear free energy relationship. The major components of the mixture determine the system coefficients. When the major components change in composition or proportion, the system coefficients will be changed. Therefore, the changes in the system coefficients can be used to study the changes of the chemical mixtures:  $\log K = c + (r + \delta r)R +$

$(s + \delta s)\pi + (a + \delta a)\alpha + (b + \delta b)\beta + (v + \delta v)V$ . When 25% of ethanol was added to the water solution of the 32 calibration compounds, the system coefficient changes of the polyacrylate/water system [ $\delta r, \delta s, \delta a, \delta b, \delta v$ ] were [-0.12, 0.17, 0.23, 0.33, -0.42], respectively. When 1% of sodium lauryl sulfate was added to the water solution, the system coefficient changes [ $\delta r, \delta s, \delta a, \delta b, \delta v$ ] were [-0.41, 0.34, 0.23, 0.74, -1.53], respectively. In practical risk assessments, the changes in system coefficients can be treated as sufficiently similar mixtures. If the system coefficients of the mixture of concern and the system coefficients of the sufficiently similar mixtures are determined, the permeability or partition coefficient of any chemical can be obtained by using the system coefficient approach. ## 2197

### PREDICTION OF DERMAL ABSORPTION OF CHEMICAL MIXTURES USING BOTH PENETRANT AND MIXTURE COMPONENT PROPERTIES IN A HYBRID QUANTITATIVE STRUCTURE PERMEABILITY RELATIONSHIP (QSPR).

J. E. Riviere and J. D. Brooks. Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.

Occupational and environmental exposure to topical chemicals is usually in the form of complex chemical mixtures, yet risk assessment is based on experimentally derived data from individual chemical exposures or computed physicochemical properties. We present an approach using modified QSPR models where absorption through two systems (porcine skin flow-through diffusion cells-PSFT and isolated perfused porcine skin flaps-IPPSF) are well predicted using a QSPR model describing the individual penetrants, coupled with a mixture/vehicle factor (MF) that accounts for physicochemical properties of the vehicle/mixture components. The baseline equation is  $\log K_p = c + mMF + rR + s\pi + a\alpha + b\beta + vV$  where  $R$  is molar refractivity,  $\pi$  is polarizability constant,  $\alpha$  is H-bonding acidity,  $\beta$  is H-bonding basicity and  $V$  the McGowan molecular volume of the penetrants of interest;  $c, m, r, s, a, b$  and  $v$  are strength coefficients coupling these descriptors to skin permeability ( $K_p$ ) in PSFT (12 penetrants in 24 mixtures) or to AUC of the absorption flux profile in IPPSF (8 penetrants in 4 mixtures). Mixtures consisted of different combinations of vehicles (water, ethanol, propylene glycol) and additives (sodium lauryl sulfate, methyl nicotinate). Across all exposures with no MF,  $R^2$  for absorption was 0.68 in IPPSF and 0.58 in PSFT. With the MF, correlations increased to 0.74 for IPPSF and 0.85 for PSFT. The initial MF is a function of the Henry Constant for the mixture components, although other factors are presently being investigated. The importance of these findings is that there is an approach whereby the effects of a mixture on absorption of a penetrant of interest can be quantitated in a standard QSPR model if physicochemical properties of the mixture are also taken into account. The good correlations obtained in the IPPSF, which has previously shown to be predictive of *in vivo* human absorption, suggests that this approach merits attention. Supported by NIOSH R01-OH-07555

### COMPUTER-CONTROLLED SYSTEM FOR GENERATION OF CHEMICAL VAPORS IN *IN VITRO* DERMAL UPTAKE STUDIES.

M. Rauma and G. Johansson. Work Environment Toxicology, Karolinska Institutet, Stockholm, Sweden.

Recent work in our laboratory shows that dermal uptake of chemicals may be assessed *in vitro* by thermogravimetric analysis (TGA), i.e. by passing chemical vapor over a piece of skin while recording the weight increase under carefully controlled temperature and humidity conditions. This technique requires (1) a high-precision TGA balance and (2) a stable generation and supply of water and chemical vapors at known concentrations. For the latter purpose, we have developed a high precision computer-controlled exposure system. Clean, dry air flows at controlled rates (45 ml/min) through stainless steel gas impinger bottles containing the chemicals of interest. The impingers reside in a water bath maintained at exactly 25°C. To prevent retention and condensation of chemical vapor downstream, all tubing and connectors are made of stainless steel and insulated and kept at 30°C with a heat cable. Two parallel impinger systems with separate mass flow regulators allow for different exposure sequences, for example: 50% water + 50% chemical A for 1 hour, followed by 50% water only for 3 hours then 50% water + 50% chemical B etc. The airflow is redirected to the impingers by computer-controlled magnetic valves. A dedicated computer software allows execution of exposure sequences with millisecond precision. Measurements of dry air leaving an impinger containing cyclohexanone showed that the concentration in outlet air (measured by photoionization detection) rapidly reached a plateau (90% response in approx. 8 sec) and remained stable at a level corresponding to the theoretical saturation concentration. Cyclohexanone has a low vapor pressure compared to many other solvents, and we expect that chemicals with a higher vapor pressure behave similarly. In conclusion, this computerized system with automated, high-precision generation of sequences

of chemical vapour allows measurements of dermal uptake of chemical vapor with little manual effort. The system is closed, facilitating studies of toxic substances. This study was supported by the Swedish Council for Working Life and Social Research (FAS).

CAN CHRONIC SKIN IRRITATION BE PREDICTED BY AN ACUTE TEST?

C. M. de Jongh, J. J. Jacobs, S. Kezic and M. M. Verberk. *Coronel Institute for Occupational and Environmental Health, AMC, University of Amsterdam, Amsterdam, Netherlands. Sponsor: P. Boogaard.*

A repeated sodium lauryl sulfate (SLS) exposure test is a model for chronic skin irritation. However this test is too time-consuming to be used as a screening tool for individual susceptibility. Our objective was to investigate whether an acute 24-h SLS patch test predicts the outcome of a repeated SLS patch test. Twenty healthy volunteers were exposed to SLS on the volar forearm. On one site 1% SLS (200 µl) for 24 h (acute patch test) was applied, on another site 0.1% SLS for 6 h, 4 days a week, during 3 weeks (repeated patch test). Skin barrier function (transepidermal water loss, TEWL) and skin redness (measured with an erythema meter) were measured at day 2 for the acute and at day 17 for the repeated SLS application. Exposure to SLS resulted in an increase of TEWL and erythema after both the acute and the repeated test. Large inter-individual differences in these responses were observed. A relation was found between the increase in skin redness after the acute and the repeated test ( $r = 0.72$ ,  $p = 0.001$ ). However, no correlation was found between skin barrier function in both tests ( $r = 0.06$ ). Skin barrier function and skin redness were significantly correlated after the acute test ( $r = 0.68$ ,  $p = 0.001$ ), but no correlation was found after the repeated test ( $r = -0.00$ ). Higher erythema values at day 10 correlated ( $r = -0.58$ ,  $p = 0.011$ ) with a stronger decrease in TEWL values from day 10 to day 17. For screening purposes in occupational medicine, skin redness after a single 24-h exposure to SLS still has insufficient predictive value for redness after a repeated exposure. The lack of predictive value of an acute test might be due to differences in barrier repair between subjects during repeated exposure. Additionally, our data suggests that the extent of erythema during the second week may predict the improvement of the skin barrier (skin hardening).

ANTI-PSORIASIS MODEL IN THE MOUSE.

S. Rowton and P. Long. *Covance Laboratories Ltd., Harrogate, United Kingdom. Sponsor: D. Everett.*

Psoriasis is a chronic cutaneous disease affecting approximately 1-3% of the population. It is a relapsing / remitting disease of variable severity and in the absence of a cure, current treatments are aimed towards reducing the severity of the lesions. Although there are several animal models available for psoriasis research, no one model imitates the disease completely. One such model is the mouse tail model, which simplistic in its approach, can be useful in identifying potential anti-psoriasis compounds, which target the cell differentiation aspect of the disease. The mouse tail is considered to be histologically and biochemically similar to psoriatic skin found in humans. It is composed of parakeratotic (PK) scales (a common feature of the abnormal epidermis in psoriasis), with orthokeratotic (OK) differentiation at the neck of the hair follicle. Many anti-psoriasis drugs alleviate the condition by inhibiting parakertosis and restoring the granular (OK) cell layer of the epidermis. For validation purposes, 0.1mL of control, dithranol, calcipotriol or betamethasone valerate were applied topically to the tail of male CD-1 mice. Animals were treated once daily, five times per week, for two weeks. Approximately two hours following the final treatment the animals were killed and their tails prepared for histopathological assessment. Using the Seescan Image Analysis System the percentage of OK was determined and epidermal thickness measured. Dithranol produced a significant increase in OK and epidermal thickness when compared to the control group. The increase in epidermal thickness was considered to be due to the known irritant effect of dithranol. Calcipotriol produced a significant increase in OK and slight decrease epidermal thickness. Betamethasone valerate had little effect on OK restoration, but did cause significant thinning of the epidermis. In conclusion, the potential of compounds to restore the granular layer as an indicator of anti-psoriasis activity can be assessed using the mouse tail model, providing that the compounds target cell differentiation rather than the inflammatory aspect of the disease.

EVALUATION OF THE TOXICITY OF MEDICAL COUNTERMEASURES FOR SULFUR MUSTARD.

D. M. Moore<sup>1</sup>, R. C. Kiser<sup>1</sup>, N. A. Niemuth<sup>1</sup>, B. M. Biddle<sup>1</sup>, M. C. Babin<sup>1</sup>, I. Koplovitz<sup>2</sup> and W. J. Smith<sup>2</sup>. <sup>1</sup>*Battelle Memorial Institute, Columbus, OH and* <sup>2</sup>*US Army Medical Research Institute of Chemical Defense, Aberdeen, MD.*

Since 1997, Battelle's Medical Research and Evaluation Facility has supported the US Army Medical Research Institute of Chemical Defense program in evaluating candidate drugs for protection from sulfur mustard (SM) injury using the mouse

ear vesicant model (MEVM). Several compounds have proven to reduce tissue damage from SM when tested as pre- and/or post-treatments. In order to gain information on the toxicity potential of four of these compounds, a study was conducted applying various doses of each compound to both ears and observing the mice for 14 days. Clinical observations and body weights over time were recorded. A simple motor incapacitation test also was administered. The motor incapacitation test consisted of placing a mouse on the top of a 5"x 5" screen that was subsequently inverted. Mice climbing back to the top of the screen grid within 1 minute of inversion passed the performance test. Mice which fell or remained on the bottom of the grid for the one minute test period failed. The four compounds tested were 4-methyl-2-mercaptopuridine-1-oxide (ICD# 1308), indomethacin (ICD# 2086), BAL (ICD# 2525), and 8-methyl-N-vanillyl-6-nonenamide or capsaicin (ICD# 3537). Motor incapacitation testing demonstrated no evidence of gross behavioral deficit for any of the compounds tested. Minor clinical signs resolved within a few days for ICD# 2525 and #3537. ICD #2086 proved highly toxic in the range of doses tested and only a dose-related reduction in body weight gains from days 0 to 14 was observed for the other three compounds. This work was supported by the US Army Medical Research and Materiel Command under Contract DAMD17-99-D-0010, Task Order 0002.

**2202**

MOUSE EAR VESICANT MODEL (MEVM) EVALUATION OF TREATMENT COMBINATIONS AGAINST TOPICAL SULFUR MUSTARD CHALLENGE.

R. C. Kiser<sup>1</sup>, D. M. Moore<sup>1</sup>, N. A. Niemuth<sup>1</sup>, B. M. Biddle<sup>1</sup>, M. C. Babin<sup>1</sup>, R. P. Casillas<sup>1</sup>, I. Koplovitz<sup>2</sup> and W. J. Smith<sup>2</sup>. <sup>1</sup>*Battelle Memorial Institute, Columbus, OH and* <sup>2</sup>*US Army Medical Research Institute of Chemical Defense, Aberdeen, MD.*

The mouse ear vesicant model (MEVM) has been used as a screening tool at Battelle to identify compounds that protect skin from sulfur mustard (SM)-induced injury. The original MEVM provided a quantitative edema response and histopathologic endpoints as measurements of inflammation and tissue damage at 24 h following topical exposure to SM (0.16 mg). Compound effectiveness was defined as a reduction in these endpoints. To further evaluate lead candidate compounds, the MEVM has been modified for use as a 7-day model and a modified Draize scoring system of 0-4 (no damage to extensive necrosis) was incorporated as the primary endpoint to quickly and easily evaluate the extent of ear tissue damage up to day 7 and/or day 14. Nine lead candidate compounds were selected to be evaluated as single 10 min post-treatments after a 0.08 mg SM challenge. These compounds were tested alone and in combination and ear tissue was scored on days 7 and 14. Compounds and/or combinations of compounds either passed or failed based on Draize ear tissue scores being statistically decreased from the SM no-compound treatment group. Draize scores were significantly reduced when 4 compounds (4-methyl-2-mercaptopuridine-1-oxide (ICD# 1308), BAL (ICD# 2525), octyl homovanillamide (ICD# 2980), and 8-methyl-N-vanillyl-6-nonenamide or capsaicin (ICD# 3537) were tested alone or in combination with 7 or 8 other compounds. For ICD# 1308, 2980 and 3537, none of the combination therapies provided significantly greater reduction in SM injury than did the compound alone. No compound or combination tested appeared more effective than #1308 alone. No combination therapy provided significantly greater reduction in SM injury than both individual components. This work was supported by the US Army Medical Research and Materiel Command under Contract DAMD17-99-D-0010, Task Order 0002.

90-DAY SUBCHRONIC DERMAL TOXICITY OF INSECT REPELLENT SS-220i IN RATS.

J. T. Houpt and G. J. Leach. *US Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD.*

John T. Houpt, Glenn J. Leach, U. S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD, USA. A 90-day subchronic toxicity study was conducted to determine the dermal toxicity of the candidate insect repellents SS-220i (CAS# 69462-43-7). Entomological studies have demonstrated SS-220i to be as effective or better than N, N-diethyl-m-toluamide (DEET) in repelling various species of mosquitoes and biting flies. The entomological data supports continued development of SS-220i as a topical insect repellent. Information generated from this study, along with results from other laboratory animal toxicity studies, will be utilized to predict the potential risk to human health upon exposure to this compound. SS-220i was administered via the dermal route to young adult Sprague-Dawley rats five days per week for ninety days at dose levels of 0, 60, 175 or 350 mg/kg for females. Male dose levels were 0, 60, 250 or 500 mg/kg. The 21-day range-finding study, as well as the subsequent subchronic study, indicated that SS-220i demonstrated no systemic toxic effects. Skin irritation was evident in all exposure groups and lower body weights were present in mid and high dose groups of both sexes. These changes were all resolved following the 7 week recovery period. Female rats were more susceptible to the dermal irritating effects of

SS-220i than males. The No-Observed Effect Level (NOEL) for subchronic dermal exposure to SS-220i as determined from this study, is 60 mg/kg/day. (Abstract does not reflect US Army Policy)

**2204**

**DATABASE CONSOLIDATION BASED ON TOXML OF GENETIC TOXICITY DATA SUBMITTED TO CFSAN/OFAS AND CDER.**

J. Mayer<sup>1</sup>, M. Cheeseman<sup>1</sup>, C. Nelson<sup>1</sup>, R. Benz<sup>2</sup>, E. Matthews<sup>2</sup>, N. Kruhlak<sup>2</sup>, J. Contrera<sup>2</sup>, M. Twaroski<sup>1</sup>, K. Arvidson<sup>1</sup> and C. Yang<sup>3</sup>. <sup>1</sup>CFSAN/OFAS, USFDA, College Park, MD, <sup>2</sup>CDER/OPS/ICSAS, USFDA, Rockville, MD and <sup>3</sup>Leadscape, Inc., Columbus, OH.

Structure searchable electronic databases are a valuable new tool that will assist the FDA in its mission to promptly and efficiently review incoming submissions. CFSAN/OFAS, in collaboration with Leadscape, Inc., is consolidating genetic toxicity data submitted in petitions from the 1960s to the present day. CDER/OPS/ICSAS is separately gathering similar information. Presently these data are distributed in various locations as paper files, microfiche, and non-standardized toxicology memoranda. The organization of the data into a consistent, searchable format should reduce paperwork, expedite the toxicology review process, and provide valuable information to industry that is currently available only to the FDA. Furthermore, by incorporating chemical structures with genetic toxicity information, biologically active moieties can be identified and used to develop QSAR modeling and testing guidelines. Additionally, chemicals devoid of data can be compared to known structures, allowing for improved safety review through the identification of analogs. Four database frameworks have been created: bacterial mutagenesis, *in vitro* chromosome aberration, *in vitro* mammalian mutagenesis, and *in vivo* micronucleus. Controlled vocabulary for these databases has been established. The separate databases are all tied together into an overall genetic toxicity database for standardization and easy accessibility. Beyond the genetic toxicity databases described here, additional databases for subchronic, chronic, and teratogenicity studies are in preparation.

**2205**

**INTER-LABORATORY EVALUATION OF BIOLUMINESCENT SALMONELLA REVERSE MUTATION ASSAY USING TEN (10) MODEL CHEMICALS.**

J. I. Ackerman<sup>1</sup>, T. Hayashi<sup>2</sup>, J. Hitchcock<sup>3</sup>, L. Li<sup>4</sup>, S. Lu<sup>4</sup>, Y. Nagai<sup>2</sup>, F. Spence<sup>3</sup> and J. Aubrech<sup>1</sup>. <sup>1</sup>Safety Sciences, Pfizer Inc., Groton, CT, <sup>2</sup>Safety Sciences, Pfizer Inc., Nagoya, Japan, <sup>3</sup>Safety Sciences, Pfizer Inc., Sandwich, United Kingdom, <sup>4</sup>Safety Sciences, Pfizer Inc., La Jolla, CA, <sup>5</sup>Safety Sciences, Pfizer Inc., La Jolla, CA, <sup>6</sup>Safety Sciences, Pfizer Inc., Nagoya, Japan, <sup>7</sup>Safety Sciences, Pfizer Inc., Sandwich, United Kingdom and <sup>8</sup>Safety Sciences, Pfizer Inc., Groton, CT.

We have developed the Bioluminescent Salmonella Reverse Mutation Assay as a tool for detecting mutagenicity applicable for high throughput screening of new chemicals. In this study, we report the inter-laboratory evaluation of the assay using 10 model chemicals in three independent laboratories located in the US and Japan. The chemicals were tested in at least three independent experiments using strains TA98-lux and TA100-lux in presence and absence of metabolic activation (rat S9). The results were statistically evaluated and compared to published results (NTP). Seven of ten compounds tested were positive to either TA98-lux and/or TA100-lux in presence or absence of S9 (nitrofurazone, o-dianisidine dihydrochloride, benzo-<a>pyrene, 1, 4-benzoquinone dioxime, 2-amino-5-nitrophenol, 2-bromo-4, 6-dinitroaniline, busulfan) and remaining 3 of 10 compounds were negative (anthracene, crystal violet, benzyl chloride). Final results of all three inter-laboratory evaluations yielded 100% concordance to published data. Results of all three inter-laboratory evaluations specifically from each 40 different condition (e.g. 98 +S9 for busulfan) obtained almost perfect concordance. We conclude that the Bioluminescent Salmonella reverse mutation assay is a robust, accurate and economical high throughput assay applicable for mutagenicity screening.

**2206**

**MEASUREMENT OF MUTANT FREQUENCY IN T-CELL RECEPTOR GENE BY FLOW CYTOMETRY ON EL-4 MOUSE LYMPHOMA CELLS.**

N. Kunugita<sup>1</sup>, N. Mei<sup>2,3</sup>, T. Goncharova<sup>2</sup> and T. Norimura<sup>2</sup>. <sup>1</sup>School of Health Sciences, University of Occupational and Environmental Health, Kitakyushu, Japan, <sup>2</sup>Department of Radiation Biology & Health, University of Occupational and Environmental Health, Kitakyushu and <sup>3</sup>NCTR, Jefferson, AR.

It is well known that somatic mutations are induced by ionizing irradiation. Peripheral CD4<sup>+</sup> lymphocytes deficient in the expression of TCR/CD3 complex on the cell surface show CD3<sup>4+</sup> due to a somatic mutation at the T-cell receptor

(TCR) genes. We have previously reported the measurement of mutant frequency on the TCR gene of mice T-lymphocytes after irradiation by flow cytometry. In this study, we developed an *in vitro* experiment system using murine EL-4 lymphoma cells and observed mutant frequency of EL-4 cells defective in the TCR gene expression after irradiation by flow cytometry using an Epics XL. EL-4 cells were stained with fluorescein-labeled anti-CD4 and phycoerythrin-labeled anti-CD3 antibodies. They were analyzed with a flow cytometer to detect mutant EL-4 cells lacking surface expression of TCR/CD3 complexes which showed CD3<sup>4+</sup> T cells. Mutant T cells could be observed at 2 days after 3 Gy irradiation. Frequency of mutant EL-4 cells was  $4.0 \times 10^{-4}$  for 0Gy and the value increased to the maximum level of  $38 \times 10^{-4}$  between 4 and 8 days after 3 Gy irradiation and these data were found to be best fitted by a linear-quadratic dose-response model. After the peak value the TCR mutant frequency gradually decreased with a half-life of approximately 3.2 days. We also examined the hprt (hypoxanthine phosphoribosyltransferase) mutation assay at seven days after irradiation and the cytogenesis-blocked micronucleus assay at 20 hours after irradiation. The frequencies of hprt mutation and micronuclei were found to be best fitted by a linear-quadratic dose-response model and a linear dose-response model, respectively. The method to detect mutation on TCR gene is quick and easy in comparison with other methods and is considered useful for the mutagenicity test.

**2207**

**A HIGH-THROUGHPUT UNSCHEDULED DNA SYNTHESIS (UDS) ASSAY USING FLOW CYTOMETRY.**

C. A. Kirk, D. R. Cerven and G. L. DeGeorge. *MB Research Laboratories, Spinnerstown, PA.*

There is a growing need in industry and regulatory agencies for an inexpensive screening assay that can reliably determine the genotoxic potential of the large number of new chemical compounds synthesized each year. The Unscheduled DNA Synthesis (UDS) Assay is a proven method to identify and characterize genotoxic chemicals. It is based on the ability of damaged DNA to incorporate radiolabeled thymidine during the repair of various types of genetic lesions, which are subsequently detected by standard autoradiographic methods. However, several technical aspects of the standard UDS assay, including its use of radioactivity, have greatly limited its more widespread application. We have made modifications to the standard UDS assay through incorporation of BrdU incorporation and flow cytometry as a detection method. In addition, this is an *in vitro*, non-animal based test, using human hepatocyte cultures or avian embryonic hepatocytes, as well as less metabolically active human keratinocytes as the test system, therefore addressing all of the 3Rs of animal testing. We have also demonstrated the accuracy and sensitivity of this version of UDS, termed 'FLUDS', which allows higher throughput and much shorter study times (a few days versus weeks for the standard UDS assay). This new assay can discriminate between innate and biotransformed genotoxins, and is fully quantitative. It has reliably detected and characterized the UDS induced by ethylnitrosourea, aphidicolin, 2-acetylaminofluorene, and fluorene. Due to its high-throughput capability and other improvements over the standard UDS assay, the FLUDS assay now adds an important and humane tool of considerable value to regulatory agencies, academia as well as scientists in the pharmaceutical, chemical, cosmetic and consumer products industries.

**2208**

**MODIFIED BACTERIAL MUTATION TEST PROCEDURES FOR EVALUATION OF PEPTIDES AND AMINO ACID-CONTAINING MATERIAL.**

C. Thompson. *Toxicology, CTBR, Senneville, QC, Canada.* Sponsor: C. Banks.

Biological materials such as peptides can release amino acids either spontaneously or as a result of enzymatic degradation by S9 during the course of bacterial mutation testing. Low levels of released amino acids from soluble materials can cause moderate increases in the number of revertant (mutated) bacterial colonies on the plate, while higher levels lead to overgrowth of non-mutated bacteria, making counting of mutant colonies impossible. In the case of poorly soluble material, the released amino acids can be present at high levels in localized spots on the plate, which leads to growth of 'pseudo-revertant colonies'. The 'treat and wash' modified pre-incubation method is an adaptation of the treat and plate method used for evaluation of antibiotics and involves washing the bacteria free of test compound after a 90-minute exposure prior to plating out on agar plates. The MC overlay method is a modified version of the plate incorporation assay in which a top overlay containing 4% high viscosity methyl cellulose in place of agar is used to stabilize peptide in solution. Both modified methods have shown expected increases in revertant colony counts with standard positive control materials. Peptides that produced false positive results or could not be evaluated due to overgrowth of non-mutant bacteria using standard methods, showed no evidence of genotoxicity using the modified methods. The mean revertant colony counts of the untreated controls for both methods were within the laboratory historical control range. It is concluded that

the treat and wash and MC overlay methods are valid versions of the bacterial mutation test for avoiding complications associated with feeding effects due to released amino acids.

## 2209

### DEVELOPMENT OF A NOVEL MICRONUCLEUS ASSAY USING THE HUMAN 3-D SKIN MODEL, EPIDERM™

R. D. Curren<sup>1</sup>, G. Mun<sup>1</sup>, D. P. Gibson<sup>2</sup> and M. J. Aardema<sup>2</sup>. <sup>1</sup>*Institute for In Vitro Sciences, Inc., Gaithersburg, MD* and <sup>2</sup>*Procter & Gamble Co., Cincinnati, OH*. The rodent *in vivo* micronucleus assay is an important part of a tiered testing strategy in genetic toxicology. However, this assay, in general, only provides information about materials available systemically, not at the point of contact, e.g. skin. Although *in vivo* rodent skin micronucleus assays are being developed, the results will still require extrapolation to the human. Furthermore, to fully comply with recent European legislation such as the 7<sup>th</sup> Amendment to the Cosmetics Directive, non-animal test methods will be needed to assess new chemicals and ingredients. Therefore we have begun development of a micronucleus assay using a commercially available 3-D engineered skin model of human origin, EpiDerm™ (MatTek Corp, Ashland, MA). We first evaluated whether a population of binucleated cells sufficient for a micronucleus assay could be obtained by exposing the tissue to 1-3  $\mu$ g/ml cytochalasin B (Cyt B). The frequency of binucleated cells increased both with time (to at least 120 h) and with increasing concentration of Cyt B. Three  $\mu$ g/ml Cyt B allowed us to reliably obtain 40-50% binucleated cells at 48h. Mitomycin C (MMC) was then used (in the presence of 3  $\mu$ g/ml Cyt B) to investigate toxicity and micronuclei formation in EpiDerm™. Exposing the tissue directly through the growth medium for 48h gave a dose response for toxicity between 0.03 and 0.6  $\mu$ g/ml. Maximum micronuclei induction (~5%) occurred at 0.06-0.6  $\mu$ g/ml MMC. Experiments conducted with and without Cyt B indicated higher frequencies in the presence of Cyt B as expected. A topical application protocol was then developed using two 10  $\mu$ l (per 0.64  $\text{cm}^2$  tissue) applications of MMC in ethanol 24 and 48h prior to harvest. Maximum micronucleus response (~8%) and toxicity occurred with applications of 6-60  $\mu$ g/ml MMC. The background frequency of micronuclei was very low (~0.1%). These studies show that micronuclei can be reproducibly induced in a 3-D skin model and are the first steps in developing a routine “*in vivo*-like” assay for chromosomal damage in human tissue.

### INCREASED MICRONUCLEI FOLLOWING OXYMORPHONE ADMINISTRATION ARE SECONDARY TO INCREASED BODY TEMPERATURE.

D. Shuey<sup>1</sup>, R. Gudi<sup>2</sup>, L. Krsmanovic<sup>2</sup> and R. Gerson<sup>1</sup>. <sup>1</sup>*Endo Pharmaceuticals Inc., Chadds Ford, PA* and <sup>2</sup>*BioReliance, Rockville, MD*.

Oxymorphone is a potent opioid analgesic. Oral administration of oxymorphone to rats at doses  $\geq$ 20 mg/kg and mice at 500 mg/kg produces an increase in bone marrow micronucleated polychromatic erythrocytes (MPCEs). Oxymorphone does not produce chromosome aberrations *in vitro*, suggesting that the increase in MPCEs may involve indirect mechanisms. Opioids are known to affect thermoregulatory mechanisms. Environmentally- or chemically-induced changes in body temperature can increase the incidence of MPCEs in rodents. Studies were conducted to examine the relationship between increased MPCEs in rats given oxymorphone and changes in body temperature. Single oral doses of oxymorphone previously shown to increase MPCEs (20, 40 mg/kg) also produced a marked, rapid increase in body temperature. Pretreatment of animals with sodium salicylate was effective in preventing the increase in body temperature after oxymorphone administration. MPCEs were evaluated in rats after administration of oxymorphone (40 mg/kg, PO) alone or preceded by an oral dose of sodium salicylate (300 mg/kg, 60 min or 500 mg/kg, 30 min). When animals were pretreated with sodium salicylate, peak body temperature was lower, and body temperature returned to baseline more quickly than when oxymorphone was given alone. Administration of oxymorphone alone produced a statistically significant increase in the incidence of MPCEs (3.6 per 1000 PCEs vs. 0.4 in controls). The number of MPCEs in animals pretreated with sodium salicylate was similar to the vehicle control group. Sodium salicylate alone had no effect on the number of MPCEs. Systemic oxymorphone exposure was not significantly impacted by sodium salicylate pretreatment; Cmax and AUC values were similar when oxymorphone was given alone or preceded by sodium salicylate. These results indicate that the increased incidence of MPCEs following oxymorphone administration is directly related to increased body temperature.

## 2211

### THE CONTRIBUTION OF NON-CHEMICALLY INDUCED HYPOTHERMIA IN THE FORMATION OF MICRONUCLEI (MN) IN THE MOUSE BONE MARROW MICRONUCLEUS TEST (MNT).

P. J. Spencer, J. G. Grundy, J. M. Waechter and B. Gollapudi. *Toxicology & Environmental Research and Consulting, The Dow Chemical Company, Midland, MI*.

Previous studies indicated certain chemicals induce substantial and prolonged body temperature (BT) changes accompanied by an increased incidence of micronuclei (MN). The contribution of hypothermia alone vis-à-vis direct effects of the chemi-

cal/its metabolites in the etiology of MN formation is unknown. The present study reports effects of non-chemically induced hypothermia on MN formation in CD-1 mice. Six males/group were restrained in plastic cone-type devices and housed at normal room temperature (RT = 21°C) or in an incubator maintained at a temperature of 12°C for 7h. Preliminary studies indicated restraint was necessary to induce hypothermia in mice maintained at lower ambient temperatures. BT of all mice was monitored at baseline and multiple times throughout the 7h cold exposure period using subcutaneous digital transponders. Bone marrow samples were evaluated for MN formation 24h after the 7h exposure period. Restrained mice housed at 12°C for 7h experienced a significant and prolonged hypothermia (~12°C decrease in BT) but recovered to near normal BT 1 hr after returning to standard housing. No changes in BT occurred in mice restrained but housed at RT. A small, but statistically significant increase in MN was observed in bone marrow of mice receiving a 7h cold exposure treatment (RT = 0.67 MN/1000 PCE vs. 12°C/7h = 2.17 MN/1000 PCE,  $\alpha \leq 0.05$ ). These results suggest a potentially confounding role for hypothermia in the mouse bone marrow MNT and the need to exercise caution in interpreting the biological significance of marginal increases in MN at doses inducing hypothermia.

### IN VITRO MICRONUCLEUS SCORING BY FLOW CYTOMETRY: DIFFERENTIAL STAINING OF MICRONUCLEI AND APOPTOTIC CHROMATIN ENHANCES ASSAY RELIABILITY.

S. D. Dertinger, S. Avlasevich, S. Cairns and D. K. Torous. *Litron Laboratories, Rochester, NY*.

The *in vitro* micronucleus test has received considerable attention in the areas of drug safety assessment and toxicological research. The less tedious nature of the assay relative to chromosome aberration analyses is a driving force, and explains why many drug screening programs have adopted the endpoint. High-throughput scoring of micronuclei (MN) would further enhance the utility of the assay for lead optimization and other early drug development work. Although a flow cytometric (FCM) method for scoring cell culture-derived MN has been described in the literature, it lacks the ability to distinguish these events from apoptotic chromatin (Nusse and Marx (1997) *Mutat. Res.* 392, 109-115). Here, we report advances to the previously described method whereby a sequential staining procedure is used to differentially label these two types of sub-2n particles. With this method, apoptotic cells are labeled with ethidium monoazide (EMA). After a photoactivation step which binds EMA to apoptotic chromatin, cells are stripped of their cytoplasmic membranes and incubated with RNase plus a pan-nucleic acid dye (SYTOX Green). This process provides a suspension of free nuclei and MN which are differentially stained relative to chromatin associated with dead/dying cells. Studies with mouse L5178Y cells demonstrate that: 1) EMA labels apoptotic and necrotic cells, and 2) the sequential labeling procedure provides reliable MN enumeration, even when cultures contain high percentages of dead cells. Data from FCM-based analysis following treatment with hydroxyurea, methyl methanesulfonate, benzo(a)pyrene, and etoposide are presented, and are shown to correspond closely with microscopy-based measurements. Collectively, these data suggest that this EMA/SYTOX staining procedure provides reliable, high-throughput enumeration of *in vitro* MN. Further collaborative investigations with additional cell lines and genotoxins are planned to test the robustness of this methodology. This work was supported by a grant from the National Cancer Institute, No. R44CA094493.

### ESTABLISHMENT OF HUMANIZED IN VITRO GENOTOXICITY TEST SYSTEM.

M. Honma<sup>1</sup>, A. Hakura<sup>2</sup>, H. Oka<sup>3</sup>, W. Takasaki<sup>4</sup>, Y. F. Sasaki<sup>5</sup>, S. Suzuki<sup>6</sup> and T. Sato<sup>6</sup>. <sup>1</sup>*National Institute of Health Sciences, Tokyo, Japan*, <sup>2</sup>*Eisai Co.Ltd., Gifu, Japan*, <sup>3</sup>*Taiboh Pharmacology Co.Ltd., Tokushima, Japan*, <sup>4</sup>*Sankyo Co.Ltd., Shizuoka, Japan*, <sup>5</sup>*Hachinohe NCT, Aomori, Japan* and <sup>6</sup>*HAB Bio Res Inst, Chiba, Japan*.

Genotoxicity tests have been generally used as hazard identification for mutagens or possible carcinogens. To pursue the possibility whether the genotoxicity tests can be applied for evaluating genetic (cancer) risk for human, we established a humanized *in vitro* genotoxicity test system comprised of human cells and human metabolic system. Human lymphoblastoid cell line WTK-1 and human liver S9, which is supplied from Human and Animal Bridge (HAB) Research Organization in Japan through National Disease Research Interchange (NDRI) in the USA, were used in this study. We optimized the protocol for micronuclei test (MN) and TK-gene mutation assay (TK). Carcinogens as well as non-carcinogens required for metabolic activation were examined by this system and their results were compared to those examined under rat S9 and other existing genotoxicity data. Human carcinogens (class 1 by IARC), benzidine, cyclophosphamide, and 2-naphthylamine clearly showed genotoxicity under human S9 as well as rat S9. Rodent carcinogens (2A or

2B), benzo(a)[a]pyrene, IQ, and N-nitroso-di-n-butylamine exhibited no or very weak responses under human S9 although they were extremely genotoxic under rat S9. On the other hand, 2-aminoanthracene, which is non-classified in IARC, yielded stronger genotoxicity under human S9 than under rat S9, suggesting that special attention should be taken for evaluating its human carcinogenicity. The humanized genotoxicity tests must be more advantageous to evaluate genotoxicity for human than other genotoxicity tests, and the data would be helpful for estimating human risk of carcinogens or non-carcinogens if the epidemiological evidence is not available.

## 2214

### DIFFERENTIAL S-9 ACTIVATION OF HYDROCODONE BITARTRATE AND NALTREXONE HYDROCHLORIDE WITH HUMAN LIVER S-9 AND RAT LIVER S-9 IN THE MOUSE LYMPHOMA FORWARD MUTATION ASSAY.

K. W. Hew<sup>1</sup>, M. A. Cifone<sup>2</sup> and T. Lawal<sup>2</sup>. <sup>1</sup>Purdue Pharmacology L.P., Ardsley, NY and <sup>2</sup>Covance Laboratories Inc., Vienna, VA.

*In vitro* genotoxicity assays routinely include induced rat liver S-9 as part of a metabolic activation system. However, the rat liver system may not accurately predict the risk for human exposure since P450 gene expression and enzyme activity profiles can differ dramatically between the two species. Hydrocodone bitartrate and naltrexone hydrochloride were both assayed in the mouse lymphoma forward mutation assay with and without rat liver activation or a human S-9 activation system. In the absence of rat liver S-9 activation, hydrocodone bitartrate and naltrexone hydrochloride were negative for mutagenicity over a wide range of cytotoxicity. When hydrocodone bitartrate was analyzed for mutant induction at concentrations from 9.85 to 375 µg/mL in the presence of induced rat liver S-9, dose related increases in mutant frequency were observed from 62.5 to 375 µg/mL. When naltrexone hydrochloride was analyzed for mutant induction at concentrations from 75 to 550 µg/mL in the presence of induced rat liver S-9, dose related increases in mutant frequency were observed from 300 to 550 µg/mL. In order to determine the human relevance of these results, both hydrocodone bitartrate and naltrexone hydrochloride were tested in the presence of a human S-9 activation system. Hydrocodone bitartrate and naltrexone hydrochloride were tested in the presence of a pooled human S-9 metabolic activation system with concentrations ranging from 9.85 to 1600 µg/mL and 31.3 to 1200 µg/mL, respectively. In each of these tests, no dose-related increases in mutant frequency were observed in two trials over a wide range of cytotoxicity. These data demonstrate that the positive responses observed with hydrocodone bitartrate and naltrexone hydrochloride in the presence of induced rat liver S-9 metabolic activation could not be repeated with a human S-9 system, suggesting that the *in vitro* genotoxicity assay using the rat liver S-9 activation may not be predictive of genotoxicity in humans.

## 2215

### APPLICATION OF HUMAN EXOGENOUS METABOLIC SYSTEM IN GENOTOXICITY EVALUATION.

A. P. Li<sup>1, 2, 3</sup>, S. K. Roy<sup>3</sup>, C. Bode<sup>4</sup>, P. Kirby<sup>2, 3</sup> and A. Thilagar<sup>2, 3</sup>. <sup>1</sup>Advanced Pharmaceutical Sciences, Columbia, MD, <sup>2</sup>The ADMET Group LLC, Rockville, MD, <sup>3</sup>Sitek Laboratories Inc., Rockville, MD and <sup>4</sup>Tissue Transformation Technologies, Inc., Edison, NJ.

Species-differences in drug metabolism is a well-established phenomenon, believed to be a key determinant of species-differences in drug toxicity. However, current genotoxicity assay involves mainly exogenous activating systems derived from rodents, with the most commonly used being Aroclor 1254-induced rat liver postmitochondrial supernatant (S-9). A drawback with the use of rat liver S-9 is that genotoxicity involving human metabolites would be missed, thereby leading to false negative results. Conversely, genotoxicity involving rat-specific metabolites would lead to false positive results. We believe that genotoxicity studies should also involve human liver-derived exogenous metabolic activation systems. Using Chinese hamster ovary cells (CHO) and measuring cytotoxicity and genotoxicity, we evaluated the ability of two human liver-derived exogenous activating systems: human hepatocytes and human liver S-9, in the activation of promutagens cyclophosphamide (CP), dimethylnitrosamine (DMN) and dimethylbenzanthracene (DMBA). Our results show that all three promutagens were genotoxic in the presence of the human exogenous activating systems, with human S9 apparently more potent than human hepatocytes. Results with human S9 is comparable to that obtained with rat liver S9, except that with rat S9, DMBA was the most mutagenic of the three promutagens, while DMN was the most mutagenic with human S9. Results of the study suggest that human liver-derived exogenous metabolic systems such as human hepatocytes and human S9 can be applied in routine *in vitro* genotoxicity assays and may provide results more relevant to human than that obtained with nonhuman systems.

## 2216

### MOLECULAR ANALYSIS OF SPONTANEOUS AND 3'-AZIDO-3'-DEOXYTHYMIDINE-INDUCED L5178Y *TK*<sup>+/−</sup> MOUSE LYMPHOMA CELL MUTANTS.

J. Wang<sup>1, 2</sup>, L. Chen<sup>1, 3</sup>, T. Chen<sup>1</sup> and M. M. Moore<sup>1, 2</sup>. <sup>1</sup>DGRT, NCTR, Jefferson, AR, <sup>2</sup>Department of Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR and <sup>3</sup>College of Life Science and Technology, Shanghai Jiao Tong University, Shanghai, China.

The aim of this study was to investigate the types of mutational damage induced by the clastogen 3'-Azido-3'-deoxythymidine (AZT). AZT induced a significant dose-related increase in the thymidine kinase (*Tk*) mutant frequency (MF) in L5178Y/ *Tk*<sup>+/−</sup> 3.7.2C mouse lymphoma cells. At the highest dose (1 mg/ml), AZT induced approximately a 5-fold increase in MF over that of the control. 65% of the mutants were small colonies whereas 40% of the mutants in the control were small colonies. 150 AZT-induced mutants and 69 spontaneous mutants were isolated and analyzed. Loss of heterozygosity (LOH) analysis using a heteromorphic microsatellite locus within the *Tk* gene was performed to determine the status of the *Tk*<sup>+</sup> allele. In addition, gene dosage analysis was conducted using a Real-time PCR method to elucidate the number of *Tk* alleles in the mutants showed LOH at the *Tk* locus. One *Tk* allele would indicate deletion while two alleles would be consistent with a recombination event. Among the AZT-induced *Tk* mutants, the percentage of point mutation, deletion and recombination events were 0%, 43% and 57% in the small colonies and 25%, 24% and 51% in the large colonies, respectively. Among the spontaneous mutants, they were 3%, 30% and 67% in the small colonies and 58%, 0% and 42% in the large colonies. These results indicate that more deletions and fewer point mutations occurred in the small colonies than large colonies, both in AZT-induced and spontaneous mutants. More deletions and fewer point mutations were observed in the AZT-induced mutants than the spontaneous mutants. These results are consistent with the fact that AZT induces mutations via a clastogenic mechanism.

## 2217

### GENOTOXIC EFFECTS OF 4-HYDROXYNONENAL TRIACETATE, A CHEMICALLY PROTECTED FORM OF THE LIPID PEROXIDATION PRODUCT 4-HYDROXYNONENAL, AS ASSAYED IN L5178Y MOUSE LYMPHOMA CELLS.

S. P. Singh<sup>1</sup>, L. Chen<sup>3</sup>, N. Mei<sup>2</sup>, T. Chen<sup>2</sup>, E. McLain<sup>1</sup>, V. Samokyszn<sup>1</sup>, M. Moore<sup>2</sup> and P. Zimniak<sup>1</sup>. <sup>1</sup>Toxicology, UAMS, Little Rock, AR, <sup>2</sup>Genetic and Reproductive Toxicology, NCTR, Jefferson, AR and <sup>3</sup>College of Life Sciences, Shanghai Jiao Tong University, Shanghai, China.

The lipid peroxidation product 4-hydroxy-2-enal (4-HNE) is cytotoxic and mutagenic at superphysiological concentrations. To characterize the mechanism of action of 4-HNE, we assessed genomic damage using the mouse lymphoma assay (MLA) which measures the frequency of mutations in the *Tk* gene. As a strong electrophile, 4-HNE reacts readily with nucleophilic centers on cellular components. When added extracellularly, it may therefore react preferentially with proteins close to the cell surface and not reach deeper targets such as DNA in the cell nucleus. We therefore tested the hypothesis that 4-HNE triacetate (4-HNE(Ac)3), a protected form of 4-HNE which is metabolically converted to 4-HNE (Neely, M.D., et al., J. Neurochem. 72: 2323-2333, 1999) is a more effective mutagen than 4-HNE. When added in serum-containing medium which simulates extracellular generation in an organism, 4-HNE was not mutagenic in the MLA system up to 38 mM. In contrast, exposure to 4-HNE(Ac)3, which mimics intracellular formation of 4-HNE, resulted in dose-dependent mutagenesis. At 17 mM 4-HNE(Ac)3, the mutant frequency was  $7.2 \times 10^{-4}$  which was >7-fold higher than the spontaneous mutant frequency in mouse lymphoma cells. The majority of mutations induced by 4-HNE(Ac)3 were clastogenic events affecting a large segment of the chromosome (up to at least 40 cM from the *Tk* gene). The results indicate that, in the presence of serum which approximates physiological conditions, intracellularly generated but not external 4-HNE is strongly genotoxic at concentrations which may occur during oxidative stress.

## 2218

### PHOTOMUTAGENICITY OF RETINYL PALMITATE AND ANHYDRORETINOL IN MOUSE LYMPHOMA CELLS.

N. Mei<sup>1</sup>, Q. Xia<sup>2</sup>, L. Chen<sup>1</sup>, P. P. Fu<sup>2</sup>, M. M. Moore<sup>1</sup> and T. Chen<sup>1</sup>. <sup>1</sup>Division of Genetic and Reproductive Toxicology, NCTR/FDA, Jefferson, AR and <sup>2</sup>Division of Biochemical Toxicology, NCTR/FDA, Jefferson, AR.

Retinyl palmitate (RP), a storage form of Vitamin A, is frequently used as an active cosmetic ingredient. However, when exposed to sunlight, RP is facilely decomposed to photodecomposition products, including anhydroretinol (AR). In this study, we evaluated the mutagenicity of RP and AR in mouse lymphoma cells when concomitantly exposed to UVA light irradiation. The L5178Y/ *Tk*<sup>+/−</sup> mouse lymphoma cells were treated with different doses of RP and AR alone/or under UVA

light (320-400 nm). While exposure of cells to UVA light alone at 0.122 J/cm<sup>2</sup>/min for 5-45 min displayed a dose-response for mutation induction in the Tk gene, with a induced mutant frequency (MF) of 136 10-6 after 30 min of light irradiation, cells received RP alone at 25-250  $\mu$ g/ml for 4 hrs did not increase MF. Treatment of cells with 0.5-25  $\mu$ g/ml RP under UVA light for 30 min produced a synergistic mutagenicity effect. At 25  $\mu$ g/ml RP with UVA exposure (12% of relative total growth), the induced MF was about 3-fold higher than that for UVA exposure alone. Similar results were obtained from AR treatment. While AR itself was not mutagenic, it induced mutation induction in the cells when exposed concomitantly to UVA light. To elucidate the underlying photomutagenic mechanism of RP, we determined the loss of heterozygosity (LOH) at four microsatellite loci spanning the entire chromosome 11 for RP/UVA-induced mutants. Ninety three percent of the mutants lost the Tk+ allele at Tk locus, and 84% of the damage extended to 6cM in chromosome length. These results suggest that RP and AR are photomutagenic in mouse lymphoma cells through a clastogenic action.

## 2219 GENETIC TOXICOLOGICAL STUDIES FOR LUPINUS TERMIS ALCOHOLIC EXTRACT.

M. R. Santiago<sup>1</sup>, Z. Ramos<sup>2</sup>, I. Oquendo<sup>2</sup>, M. Antoun<sup>2</sup> and D. Herreno-Saenz<sup>1</sup>.

<sup>1</sup>Pharmacology and Toxicology, School of Medicine, University of Puerto Rico, San Juan, Puerto Rico and <sup>2</sup>School of Pharmacy, University of Puerto Rico, San Juan, Puerto Rico.

Lupin species have been widely cultivated for human consumption and used in traditional medicine. The Lupin species, Lupinus termis has been widely cultivated in Sudan and used as an aqueous extract to treat a variety of dermatological disorders. Lupinus termis seeds also have been used as a skin softener and in a variety of cosmetic preparations. Previous studies have shown the effectiveness of the alcoholic extract of Lupinus termis seeds in the treatment of chronic eczema. In the current study, the mutagenic and/or clastogenic potential of the alcoholic extract of Lupinus termis seeds was investigated using the Mouse Lymphoma Assay and the Micronucleus Test. In Mouse Lymphoma assay, L5178Y TK+/- cells were treated for 4 hrs with a range of concentrations of the alcoholic extract, in the presence and absence of S9. Benzo(a)pyrene and 4-Nitro-quinoline-1-oxide were the positive controls. In Micronucleus test, Balb/C male mice were treated with the 50% LD50 of the alcoholic extract. Mitomycin C (2 mg/Kg) was used as the positive. Mice were sacrificed 24 hrs and 48 hrs after treatment, the bone marrow was flushed and cell suspensions were prepared to determine the incidence of micronucleated polychromatic erythrocytes. The results obtained in these genetic toxicological assays showed that there were no differences between experimental and negative control samples. These results corroborate and complement the previously obtained results for the *Salmonella typhimurium* Reverse Mutation Assay. This genetic toxicological study suggests that under the experimental conditions, the alcoholic extract of Lupinus termis seeds does not have either mutagenic nor clastogenic potential.

## 2220 TAXOL INDUCES MUTATIONS IN THE TK GENE OF L5178Y/TK+/- MOUSE LYMPHOMA CELLS THROUGH A MITOTIC NON-DISJUNCTION MECHANISM.

M. M. Moore, N. Mei, L. Chen and T. Chen. Division of Genetic and Reproductive Toxicology, NCTR/FDA, Jefferson, AR.

Taxol (paclitaxel) is a potent anti-cancer drug that binds to tubulin and inhibits cell division. Taxol has been shown to induce chromosome aberrations in human lymphocytes *in vitro* and to induce micronuclei in mice. However, Taxol is not mutagenic in the Ames test or the CHO/Hprt gene mutation assay. In this study, we evaluated the mutagenicity of taxol in the Tk+/- 3.7.2C mouse lymphoma assay (MLA). Three independent experiments were performed using 4-hour treatment. Taxol induced a dose-related increase in mutant frequency. The results were similar in the three experiments with a 0.75  $\mu$ g/ml Taxol-induced mutant frequency of 163 x 10<sup>-6</sup> at 30% relative total growth in one experiment. Forty two percent of the mutants from this treatment were small colony mutants. Loss of heterozygosity (LOH) analysis of 73 mutants from control cultures and 160 mutants (both small and large colony) from taxol-treated cultures was conducted using four microsatellite loci spanning the entire chromosome 11. Almost all (99%) of the taxol-induced mutants lost all 4 microsatellite markers, indicating the loss of the entire chromosome 11b containing the Tk+ allele. Only 22% of the mutants from untreated control cultures showed the same microsatellite pattern. These data suggest that taxol induces mutations in the MLA via a mitotic non-disjunction mechanism. This adds to the weight of evidence that the MLA can detect aneuploids.

## 2221 INCREASED GERMLINE MUTATION FREQUENCIES INDUCED BY ETHYLENE DICHLORIDE IN MALE MICE.

H. J. Daigle and V. L. Wilson. Biological Science, Louisiana State University, Baton Rouge, LA.

The ability of genotoxic agents to disrupt or cause cessation of spermatogenesis in mammalian species including the human has been known for many years. This was generally the prediction (and diagnosis) of males undergoing vigorous chemotherapy and/or radiation therapy for cancer. However, in recent years it has become recognized that many of these individuals may become fertile again. The return to fertility after a genotoxic agent induced sterile period has not been well studied. We have developed animal models for the study of the sterilizing effects of ethylene dichloride (EDC) in male C57BL/6 mice. If a sterile period is produced in males by the killing of stem germ cells, then spermatogenesis cannot continue until a critical mass of stem germ cells is reached by the "clonal" expansion of the surviving stem germ cells. Based on this theory mutant clusters, sporadic clusters mutated stem cells, should be formed upon re-initiation of spermatogenesis. The formation of mutant clusters has been demonstrated in sperm from treated Drosophila, however due to limitations in methodologies, mutant clusters in the sperm of mammalian species, i.e. mice, has not been shown as of this date. To address this problem we used the ultra-sensitive molecular intragenic mutation assay (Needle-in-a-haystack PCR/RE/LCR assay) which is capable of one-in-a-million sensitivity. Sexually mature male C57BL/6 mice received EDC i.p. injections with dosages ranging from 5 to 40 mg/kg or vehicle and subsequently held for 45 days to allow for complete turn over of spermatogenesis. Males were then paired with females to determine fertility. Mice were sacrificed after siring two litters or determining that there was permanent sterility. The 5mg/kg male mice recovered to fertility and sired litters of pups after a sterile period of up to 5 weeks. Our results showed that there was an expansion of Bmp5 short ear mutant clusters following the return to fertility, to a frequency of one-in-ten thousand in mature sperm.

2222 MICROARRAY GENE EXPRESSION ANALYSIS REVEALS DIFFERENCES BETWEEN LARGE AND SMALL COLONY THYMIDINE KINASE MUTANTS OF L5178Y MOUSE LYMPHOMA CELLS.

T. Han<sup>1,2</sup>, J. Wang<sup>3</sup>, T. Chen<sup>3</sup>, J. C. Fuscoe<sup>1,2</sup> and M. M. Martha<sup>3</sup>. <sup>1</sup>Center for Functional Genomics, NCTR/USFDA, Jefferson, AR, <sup>2</sup>Division of Systems Toxicology, NCTR/USFDA, Jefferson, AR and <sup>3</sup>Division of Genetic and Reproductive Toxicology, NCTR/USFDA, Jefferson, AR.

The L5178Y mouse lymphoma assay (MLA) is widely used to evaluate chemicals for their ability to induce mutation. The thymidine kinase (Tk) mutants detected in the assay fall into two categories: small colony and large colony Tk mutants. Small colony mutants grow slowly and their induction is associated with clastogenicity. Large colony mutants grow at normal rates and their induction is associated with point mutations. In order to investigate the molecular basis for differences between the large and small colony Tk mutants, microarray gene expression analysis was conducted on 4 small and 4 large colony Tk mutants. Long-oligonucleotide microarrays of 20, 000 mouse genes were used in 2-color hybridizations using a reference design. Correlation (R value) within the small and large colony groups ranged from 0.90 to 0.97. The raw data was normalized using locally weighted linear regression (LOWESS) in ArrayTrack, a database with software tools developed at the NCTR. Based on cluster analysis of the gene expression changes, the large colony mutants could be distinguished from the small colony mutants. In addition, the gene expression patterns in the large colony group of mutants were very homogeneous while the patterns from the small colony group of mutants were highly heterogeneous. The Significance Analysis of Microarray (SAM) program was then used for analysis of significant gene expression changes between the two groups (1.4-fold and false discovery rate <0.05). Genes whose expression was significantly different were mapped onto the mouse karyotype using ArrayTrack. Approximately 30% of the genes whose expression was significantly increased in the small colony mutants mapped to chromosome 11, where the Tk gene resides. These results suggest that altered expression of genes near the Tk gene is associated with the small colony phenotype.

## 2223 MICRONUCLEUS INDUCTION AND DNA DAMAGE IN V 79 CELLS *IN VITRO* BY DUSTS FROM HARD METAL SINTERING AND DETONATION COATING PROCESSES.

M. J. Keane and W. E. Wallace. Health Eff. Lab. Division, NIOSH, Morgantown, WV.

ABSTRACT Hard metal bulk dusts from a molding-sintering process and from a detonation-coating process were characterized for their ability to induce micronuclei and DNA damage in cultured V 79 Chinese hamster lung fibroblast cells. The study included the precoating mixture and overspray material from a detonation coating process, an unsintered material from a molding-sintering operation, and the tungsten carbide and cobalt ingredients from the sintering process. Doses were selected after viability testing and ranged from 0 to 200  $\mu$ g/cm<sup>2</sup>. Results indicate that the unsintered sample and pre- and post-coating detonation coating mixtures showed a positive dose-response relationship for micronucleus induction; WC alone was weakly positive for a single dose only. The overspray material from the detonation-coating process showed greater micronucleus induction than any of the other materials. Results from the DNA damage assay indicate that the three hard

metal mixtures are all capable of DNA damage, with similar dose-response curves. The addition of 10 or 20 mM N-acetyl cysteine, a general antioxidant, significantly attenuated DNA damage by all three samples. The results indicate that materials from either conventional or detonation-coating processes are capable of genotoxicity in V 79 cells *in vitro*, including DNA damage and micronucleus induction, and DNA damage is at least partially through oxidative mechanisms. The post-detonation material is a more potent inducer of micronuclei than are the predetonation and unsintered dusts, but the DNA damage potential of all three dusts are quantitatively similar.

**2224**

TRICHLOROETHYLENE (TCE) INHALATION DID NOT INDUCE CYTOGENETIC DAMAGE IN THE RAT BONE MARROW MICRONUCLEUS TEST (MNT).

J. W. Wilmer, P. J. Spencer, J. G. Grundy, V. A. Linscombe, S. M. Krieger and B. Gollapudi. *Toxicology & Environmental Research and Consulting, The Dow Chemical Company, Midland, MI.*

TCE was previously reported to induce a small increase (2-3 fold) in micronucleated polychromatic erythrocytes (MN-PCEs) in the bone marrow of CD rats following a single 6h inhalation exposure. The current study attempted to replicate these findings and to correlate them to potential TCE-induced hypothermia. Male CD rats were exposed by inhalation to targeted concentrations 0, 50, 500 2500 or 5000 ppm TCE for 6h on a single day. Chamber concentrations of TCE were measured once/h. Relative body temperatures (BT) of 6 rats/group were measured pre-exposure and at 3, 19 & 48h post exposure using programmable transponders. BT was monitored at 5-min intervals 22h pre-exposure, during exposure and 19 h post-exposure in a single rat/group using radio-telemetry. Bone marrow samples were evaluated for MN formation at 19h & 48h post-exposure. Rats treated with cyclophosphamide monohydrate and sacrificed 19 hrs later served as positive controls. Actual mean chamber concentrations were 0, 53, 521, 2579 and 4677 ppm. A single 6h inhalation exposure to 5000 ppm TCE caused marked toxicity and deaths in male rats. A small, but notable drop in BT was identified via radio-telemetry at 5000 ppm during exposure but was considered inconsequential to the interpretation of the test results. No increase in MN-PCE or decrease in the relative proportion of PCE was observed in any of the TCE treatment groups. The positive control rats had significant increases in MN-PCE. In conclusion, results from the current study indicated that inhalation exposure of rats to TCE up to a maximum tolerated concentration did not induce cytogenetic damage in the bone marrow.

Sponsor: E. Nelson.

Organometals, such as tin derivatives are distributed in the environment. Human exposure to these chemicals can lead to acute and chronic intoxication. Following uptake de-/alkylation occurs that changes the bioavailability and toxicity of the tin species. In this study, the tin de-/alkylation products monomethyltin chloride (MMT), dimethyltin dichloride (DMT), trimethyltin chloride (TMT), and tetramethyltin (TetraMT) were investigated for cyto- and genotoxic effects in relation to the cellular uptake. To identify genotoxic effects micronucleus (MN) assay, chromosome analysis (CA) and sister chromatid exchange (SCE) test were used. The cellular uptake was assessed using ICP-MS analysis. The toxicity of DMT and TMT was evaluated also after forced uptake by electroporation. Our results show that the ability of organotin compounds to penetrate cell membranes modulates their genotoxicity. DMT and TMT did not induce elevated numbers of MN up to a concentration of 1 mM. Chromosome analysis and SCE revealed that DMT induced significantly elevated numbers of CA and SCE at concentration of > 1 mM. The cellular uptake of the organotin compounds was dose dependent whereas the percentage of the exposure substrate found intracellularly was always < 1%. The order of cellular uptake for the organotin compounds was: DMT > TMT > MMT > TetraMT. After forced uptake by electroporation DMT and TMT induced significantly elevated numbers of MN at concentrations of 5 and 50  $\mu$ M, respectively. Altogether, our results show that the methylated tin compounds have just weak genotoxic potential. This can be explained by the poor membrane permeability of the compounds. After forced uptake of DMT and TMT, the genotoxic effects are increased. These findings suggest that methylated tin compounds are able to induce genomic damage if the membrane permeability is increased.

**2226**

RAT ERYTHROCYTE MICRONUCLEUS TEST: ROLE OF ERYTHROPOESIS AND EFFECT OF CIGARETTE MAINSTREAM SMOKE.

E. Van Miert and P. Vanscheeuwijk. *PHILIP MORRIS Research Laboratories bvba, Leuven, Belgium.* Sponsor: H. Haussmann.

The genotoxicity of cigarette mainstream smoke (MS) has been investigated using the *in vivo* micronucleus test. According to guidelines (OECD 474), the highest dose at which chemicals are to be tested should be sublethal. Since MS from filter cigarettes at sublethal doses contains significant amounts of CO, and CO may enhance erythropoiesis, its effect on micronucleus formation was investigated. Erythropoiesis was also stimulated using erythropoietin (EPO). The MicroFlow kit (Litron Laboratories) was used for quantification of CD-71-positive reticulocytes (proportion of reticulocytes among total erythrocytes: RET) and micronucleated reticulocytes (proportion of micronucleated reticulocytes among total reticulocytes: MnRET) from rat blood. Sprague-Dawley rats (8/group) were nose-only exposed to MS from the Reference Cigarette 2R4F at concentrations up to 1250  $\mu$ g TPM/l (1400 ppm CO) for 2 x 1 h/day, 4 days. RET increased from 1.2% to 2.5% ( $p<0.05$ ) and MnRET from 0.12% to 0.28% ( $p<0.05$ ). The non-filter Reference Cigarette 2R1 failed to increase the RET and MnRET at 1250  $\mu$ g TPM/l (700 ppm CO), but supplementing this smoke with CO to 1400 ppm increased RET and MnRET ( $p<0.05$ ). CO alone (1400 ppm) increased RET ( $p<0.01$ ), but not the MnRET. When rats were treated with 0, 30, or 100 U/kg EPO in combination with 0-1200  $\mu$ g TPM/l from the 2R4F, the EPO-treatment increased the RET from 1.1% to 6.2%. MS exposure did not increase the MnRET, whereas the EPO-treatment did (to 0.38%). The RET and MnRET were increased after treatment with a non-cytotoxic dose of cyclophosphamide (1.5 mg/kg) in combination with EPO-treatment at 30 and 100 U/kg ( $p<0.05$ ). We have demonstrated that the proportion of MnRET correlates with the proportion of RET in rat blood, indicating that enhanced erythropoiesis influences the proportion of MnRET after exposure to MS. It is thus important to carefully examine the proportion of RET in the micronucleus test with MS. The MS-induced increase in RET (as a result of CO) may yield confounded genotoxicity results.

**2227**

THE EFFECT OF BREVENAL ON DNA DAMAGE IN HUMAN LYMPHOCYTES INDUCED BY BREVETOXINS 2 AND 3 (PBTX-2 OR 3).

J. E. Gibson<sup>1,4</sup>, A. N. Sayer<sup>4,1</sup>, A. J. Bourdelais<sup>2</sup> and D. G. Baden<sup>2,3</sup>.

<sup>1</sup>*Pharmacology and Toxicology, The Brody School of Medicine at East Carolina University, Greenville, NC,* <sup>2</sup>*Center for Marine Science, University of North Carolina at Wilmington, Wilmington, NC,* <sup>3</sup>*Chemistry, University of North Carolina at Wilmington, Wilmington, NC and* <sup>4</sup>*Biology, East Carolina University, Greenville, OR.*

Brevinal is a nontoxic polyether that competes with brevetoxin for the active site on the voltage-sensitive sodium channel. Brevetoxins are polyether toxins from blooms of marine dinoflagellates and activate voltage-sensitive sodium channels and may induce fish kills, marine mammal poisoning and adverse human health effects such as respiratory irritation and airway constriction. The purpose here was to determine if brevetoxins could induce DNA damage in human lymphocytes, and if the damage could be antagonized by brevenal. Unrepaired or erroneously repaired DNA damage may result in gene mutation, chromosome aberration, and modulation of gene regulation, which have been associated with immunotoxicity and carcinogenesis. The single-cell gel electrophoresis assay, or comet assay, was used to determine and compare DNA damage following various treatments. The data shown is the tail moment which is the percentage of DNA in the tail multiplied by the length between the center of the head and tail (units of measure are arbitrary). The negative control tail moment was 28.4 (S.E.=1.5), whereas the positive control(hydrogen peroxide) was 71.8 (2.2). PbTx-2, 10-8 M was 49.4 (9.9) and PbTx-3, 10-8 M was 71.8 (11.9). Brevenal, 1  $\mu$ g/ml 1 hour before the brevetoxins protected the lymphocytes from DNA damage (PbTx-2; 33.9 (1.4) and PbTx-3; 42.4 (0.8)). The tail moment for brevenal alone was 30.8 (2.6). PbTx-2 and 3 are potent inducers of DNA damage in normal human lymphocytes, which is fully antagonized by brevenal. Brevenal also competitively displaces tritiated brevetoxin in a synaptosome receptor-binding assay. Similarly, brevetoxin-induced DNA damage at 10-8 M in human lymphocytes was antagonized by brevenal. (Supported by the North Carolina Agromedicine Center and USDA/CSREES; The brevetoxins and the brevenal were provided under NIEHS grant P01 ES10594).

BISPHENOL A-INDUCED DNA DAMAGE IN C57BL/6N MICE: PRACTICAL *IN VIVO* APPLICATIONS OF THE COMET ASSAY.

Y. Xu, J. W. Parton and J. K. Kerzee. *MicaGenix, Inc., Greenfield, IN.*

Bisphenol A (4, 4'-isopropylidene-2-diphenol; BPA) is an industrial monomer used for the synthesis of polycarbonate plastics and epoxy resins. Although there is no evidence that BPA poses any known health risk to humans, animal studies suggest that

BPA exposure may lead to chromosomal abnormalities. Previous studies in our laboratory found that BPA-induced DNA damage was detectable using the comet assay, however BPA exposure did not result in chromosomal aberrations or the formation of micronuclei in Chinese hamster ovary (CHO) cells. The current study was conducted to investigate the potential of BPA to induce DNA damage in male C57BL/6N mice using the comet assay, as well as determine the feasibility of screening chemicals using the comet assay *in vivo*. Animals were orally gavaged with a single dose of BPA (100mg/kg) or water. At 1, 3 and 6 hours post treatment, the animals were sacrificed and the testis, liver, lung, and brain were collected, flash frozen in liquid nitrogen, and stored at -80°C until processed for the comet assay. In addition, the comet assay was also performed using fresh organs collected at the time of harvest. BPA challenge resulted in a time-dependent effect on DNA damage in the testis, but not in other organs examined, which was comparable in both fresh and frozen tissue. Comet moment, tail length and %DNA in the comet tail, were not affected after 1 hour of BPA exposure, but significantly increased after 3 hours. This response was subsequently decreased by 6 hours post BPA-challenge. An increase in the number of cells with elevated DNA damage was also observed in testis after 3 hours of BPA administration. These results indicate that BPA exposure might result in transient DNA damage that is rapidly repaired in the testis, but not in other organs. This is consistent with reported findings of decreased sperm counts and increased oxidative stress in the testis of BPA-treated animals. These data also indicate that frozen tissue, in lieu of fresh tissue, may be used in the comet assay, providing a practical application for screening compounds with the comet assay *in vivo*.

THE EFFECT OF PUFF VOLUME ON THE SPECIFIC ACTIVITY OF CIGARETTE SMOKE CONDENSATE AS MEASURED IN THE AMES ASSAY.

R. Leverette, M. B. Bennett, J. T. Hamm, M. Misra, S. V. Vulimiri and S. F. Yee. *Lorillard, Greensboro, NC.*

Previous studies have shown that identical cigarettes smoked under different smoking regimes (i.e. standard ISO/FTC versus Massachusetts/Canadian intense smoking protocols) resulted in lower specific activities (revertants/mg condensate) in the Ames assay as smoking intensity increased. The smoking regimes specified by some regulatory authorities differ in more than one smoking parameter (e.g. puff volume, puff interval, ventilation blocking). Therefore, to examine the effects of only puff volume on specific activity we smoked PMM16 industry-monitor cigarettes (un-ventilated) under identical conditions of temperature and humidity with a 2 second draw and 1 minute puff interval at 5 different puff volumes (10, 25, 35, 45, 55 ml). Condensates from each puff volume were collected on Cambridge filter pads, extracted in DMSO and tested in the Ames (preincubation) assay using *Salmonella* strains TA98 and TA100 under S9+ conditions. The delivery of Wet Total Particulate Matter (WTPM) increased from 3.7 to 33.0 mg/cigarette as puff volume increased. Additionally, the water content of the WTPM increased from 0.3 to 9.0 mg/cigarette as puff volume increased. The specific activities for WTPM in strains TA98 and TA100 showed a decreasing trend as puff volume increased. However, this trend of decreasing specific activity was eliminated in strain TA98 when calculated for Dry Particulate Matter (DPM: WTPM minus water) and FTC Tar (WTPM minus water and nicotine). Interestingly, the trend of decreasing specific activity with increasing puff volume remained in strain TA100 when calculated for DPM and FTC Tar. In conclusion, it appears that the trend of decreasing specific activity measured in TA98 may be the result of the water in WTPM acting as a diluent.

GENOTOXICITY PROFILES OF COMMON ALKYL HALIDES AND ALKYL ESTERS.

J. J. Osowski<sup>1</sup>, M. E. Masucci<sup>1</sup>, Z. Kirpnick<sup>2</sup>, E. E. Rubitski<sup>1</sup>, J. K. Cheung<sup>1</sup>, J. I. Ackerman<sup>1</sup>, W. W. Ku<sup>1</sup>, R. H. Schiestl<sup>2</sup> and J. Aubrecht<sup>1</sup>. <sup>1</sup>*Safety Sciences, Pfizer, Inc., Groton, CT* and <sup>2</sup>*Departments of Pathology, Environmental Health and Radiation Oncology, Geffen School of Medicine and School of Public Health, UCLA, Los Angeles, CA.*

Genotoxic impurities could be generated during the synthesis and/or formulation of drugs. For instance, alkylating agents such as alkyl halides and alkyl esters of alkyl sulfonic acids might occur as products of strong acid/alcohol interactions during the process of drug salt formation. Although the genotoxicity of classic alkylating agents such as methyl and ethyl methanesulfonate has been well characterized, the majority of compounds from this class has been tested only to assess their mutagenicity using the *Salmonella* reversion assay. Therefore, we set out to investigate genotoxic profiles of 22 halogenated alkanes and alkylesters of sulfuric and alkane-aryl-sulfonic acids using a battery of cellular and molecular assays. The mutagenic potential was evaluated using the Spiral modification of the *Salmonella* reversion assay in TA98 and TA100 tester strains. Clastogenicity was measured using the *in-vitro* micronucleus assay in CHO cells. The deletion recombination (DEL) assay in *Saccharomyces cerevisiae* was used to further investigate the potential of selected

compounds to cause DNA breaks and chromosome instability. The tested esters of alkyl- and aryl-sulfonic acids produced mutagenic and clastogenic responses. In contrast, the esters of sulfuric acid displayed mostly clastogenic activity. The majority of alkyl halides were not genotoxic. In summary, our study contributes to better understanding of the genotoxic properties of common alkyl halides and alkyl esters and might provide guidance to managing risk of genotoxic process-related impurities of drug substances and products.

DETECTING ANTHRACYCLINE-INDUCED INTRACHROMOSOMAL RECOMBINBINATION IN *SACCHAROMYCES CEREVISIAE* USING A DEL ASSAY.

J. Aramagost and W. J. Mackay. *Biology, Edinboro University, Edinboro, PA.*

For more than thirty years, anthracyclines (initially daunomycin and adriamycin and, more recently, idarubicin and epirubicin) have represented one of the most commonly used classes of anticancer drugs. It is known that anthracyclines interact with DNA in a very complex manner. Studies in our lab have shown that anthracyclines can induce base-substitution and frameshift mutations in the bacterium *Salmonella typhimurium*. Furthermore, our lab has demonstrated that these mutations can be recognized by the DNA repair protein O<sup>6</sup> methylguanine DNA repair methyltransferase (MGMT). The objective of this study is to accurately access the recombinogenic potential of anthracyclines in a unicellular eukaryotic organism. In the yeast deletion (DEL) assay, recombination is induced by the formation of DNA strand breaks which are a substrate for initiation of genetic repair in this organism. Using the DEL assay, our lab has examined the role of DNA recombination pathways in the recognition and removal of anthracycline-induced DNA adducts. Specifically, daunomycin (79-fold induction), adriamycin (491-fold induction), idarubicin (88-fold induction), and epirubicin (325-fold induction) tested positive in this assay. These results indicate that anthracyclines can act as genotoxins in eukaryotes.

**2232**

CARCINOGENIC CR(VI) AND THE NUTRITIONAL SUPPLEMENT CR(III) INDUCE DNA DELETIONS IN YEAST AND MICE.

Z. Kirpnick, R. Reliene, N. Carls and R. H. Schiestl. *Pathology, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

The high levels of Cr(VI) contamination in drinking water across the country has led to concerns as to whether or not Cr(VI) ingestion from drinking water can lead to cancer. An argument against the role of Cr(VI) as an oral carcinogen is that it is reduced to Cr(III) in biological systems. Cr(III) is a popular nutritional supplement. In order to establish effective regulatory measures that protect the general public, the potential of Cr(VI) and Cr(III) to cause cancer via ingestion must be examined. There exists a large body of evidence, which confirms that chromosomal rearrangements such as DNA deletions are an important intermediate step in carcinogenesis. In this study, two systems screening for DNA deletions were used to compare the ability of Cr(VI) and Cr(III) to induce chromosomal rearrangements in the yeast *S. cerevisiae* and *in vivo* in the C57BL/6J pun/un mice. The mice were exposed to Cr(VI) and Cr(III) via drinking water during gestation and 70 kb DNA deletions at the pink-eyed unstable (pun) allele were determined in the resulting offspring. Induction of DNA deletion in yeast was measured by growth on selective media. Both Cr(VI) and Cr(III) significantly induced DNA deletions in mice and yeast as compared to the spontaneous level of deletions. Quantification of intracellular concentrations of Cr after exposure of yeast cells to either Cr(III) or Cr(VI) revealed that Cr(III) is more genotoxic than Cr(VI) once it is inside the cell. The quantification of tissue Cr concentration in mice confirms this trend. Therefore, this study concludes that both, the environmental contaminant Cr(VI) and the nutritional supplement Cr(III), when ingested via drinking water, lead to a genotoxic endpoint which is an intermediate in the process of carcinogenesis.

**2233**

YEAST DEL ASSAY DETECTS CLASTOGENS.

E. E. Rubitski<sup>1</sup>, Z. Kirpnick<sup>2</sup>, M. Homiski<sup>1</sup>, M. Repnevskaya<sup>2</sup>, N. Howlett<sup>3</sup>, R. H. Schiestl<sup>2</sup> and J. Aubrecht<sup>1</sup>. <sup>1</sup>*Safety Sciences, Pfizer, Inc., Groton, CT*,

<sup>2</sup>*Departments of Pathology, Environmental Health and Radiation Oncology, Geffen School of Medicine and School of Public Health, UCLA, Los Angeles, CA* and

<sup>3</sup>*Department of Pediatric Oncology, Dana-Farber Cancer Institute, Boston, MA.*

The DEL Assay for chromosomal rearrangement in the yeast *S. cerevisiae* is able to detect a wide range of carcinogens. In a study with approximately 60 compounds of known carcinogenic activity, the DEL assays detected 86% correctly whereas the Ames *Salmonella* assay detected only 30% correctly<sup>1</sup>. Since the DEL assay is highly inducible by DNA double strand breaks, this study examined the utility of the DEL assay for detecting clastogens. Ten model compounds, with varied genotoxic activity, were examined for their effect on the frequency of DNA deletions with the

DEL assay. The *in vitro* micronucleus assay in CHO cells, a commonly used tool for detection of clastogens, was performed on the same compounds and the results of the two assays were compared. The compounds tested were: Actinomycin D, Camptothecin, Methotrexate and 5-Fluorodeoxyuridine, which are anticancer agents, Noscapine and Furosemide are therapeutics, Acridine, Methyl Acrylate and Resorcinol are industrial chemicals and Diazinon is an insecticide. Our data indicate that the DEL assay provides highly concordant data with the standard *in vitro* MN assay. The DEL assay might have a potential application as a robust, fast, and economical screen for detecting clastogens *in vitro*.

**2234**

NUCLEAR LOCALISATION AND DNA REPAIR CAPACITY OF HOGG1 VARIANTS POLYMORPHIC AT RESIDUE 326 FOLLOWING TRANSFECTION OF OGG1<sup>-/-</sup> NULL MOUSE FIBROBLASTS.

D. Smart, N. Hodges and K. Chipman. *School of Biosciences, The University of Birmingham, Birmingham, United Kingdom.* Sponsor: T. Hammond.

Cells are continuously exposed to damaging reactive oxygen species (ROS), which are produced from both endogenous and exogenous sources. 8-oxodeoxyguanosine (8-oxodG) is an abundant base lesion formed during oxidative stress which, if not repaired, can give rise to G:C → T:A transversion mutations in DNA. The DNA repair enzyme human 8-oxoguanine DNA glycosylase-1 (hOGG1) catalyses the removal of 8-oxodG from DNA and therefore acts to promote genome stability. hOGG1 deletion, mutation and polymorphism may result in a hypermutator phenotype and individual susceptibility to oxidative pathologies including cancer, diabetes and ageing. Limited and conflicting evidence exists regarding the repair capacity of a prevalent (approximately 40% of population) hOGG1 polymorphism, the Cys326-hOGG1 variant. In the current study, an *in vitro* cell culture model was developed to investigate the cellular localisation and DNA repair capacity of Ser326 (wild-type), Cys326- and Gly326 (artificial)-hOGG1 variants. mOGG1<sup>-/-</sup> null mouse embryonic fibroblasts were transiently transfected with mammalian expression vectors containing either Ser326-, Cys326- or Gly326-hOGG1 cDNA and treated with the glutathione (GSH)-depleting agent DL-buthionine-[S, R]-sulfoximine (BSO) (1 mM) for 24 hours as a means of oxidative stress. GFP-tagged hOGG1 variants were all shown by fluorescence microscopy to be of nuclear localisation irrespective of GSH status. All variants also detected and repaired 8-oxodG with similar activity in an oligonucleotide incision assay. Again, this was irrespective of the GSH status of the cells. These results indicate that the variant forms have normal nuclear location and are functional under the conditions employed. Current studies are aimed at assessing relative intracellular repair activities following treatment with DNA oxidants.

**2235**

A COMPARATIVE STUDY OF UVB AND UVC MUTAGENESIS IN DNA REPAIR PROFICIENT AND MISMATCH REPAIR DEFICIENT (*PMS2*) MOUSE CELLS.

A. Skinner<sup>1,2</sup>, C. Shin-Darlak<sup>1,2</sup> and M. Turker<sup>1,2</sup>. <sup>1</sup>*Center for Research on Occupational and Environmental Toxicology, Oregon Health and Sciences University, Portland, OR* and <sup>2</sup>*Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR*.

Ultraviolet light is a potent environmental mutagen via the production of both cyclobutane pyrimidine dimers (CPD) and 6-4 photoproducts (6-4 PP). UVC radiation (200-280 nm) is readily absorbed by DNA which makes it a convenient tool for studying UV mutagenesis. However, UVB (280-315 nm) is a better tool to use when considering mutagens of environmental concern because, unlike UVC, UVB rays are not deflected by ozone and are capable of reaching the earth's surface. We therefore performed a comparative study of UVB and UVC mutagenesis in both DNA repair proficient and mismatch repair deficient (*Pms2*) backgrounds. Using an *Apri* reversion assay designed to detect both C→T and CC→TT mutations, mutation frequencies and the spectrum of mutations induced by both wavelengths were compared. These mutations are considered the 'signatures' of UV mutagenesis. For this assay, a phenylalanine codon (TTC) in mouse *Apri* was changed to proline (CCC) and reversion mutations were detected by acquisition of *Apri* function. An advantageous feature of this reversion assay is that both C→T and CC→TT substitutions restore *Apri* function. Interestingly, more tandem mutations were induced in mismatch repair-deficient cells by both UVC and UVB than in wild type cells. Also, there was profound difference in which base was altered in wild type cells treated with UVB or UVC. UVB induced single base changes at both target cytosines (CCC, CCC), whereas UVC induced single base mutations at only the internal cytosine (CCC). Two conclusions may be made from this study: mismatch repair protects against tandem CC→TT mutations, and UVB induces DNA lesions that are processed differently than UVC in wild type cells.

MODULATION OF NNK-INDUCED GENETIC DAMAGE BY POLYMORPHISM IN THE BASE EXCISION REPAIR GENE APE1 IN SMOKERS.

K. Wolfe, A. A. Affatato, C. E. Hill, J. K. Wickliffe and S. Z. Abdel-Rahman. *University of Texas Medical Branch, Galveston, TX*.

Tobacco contains many potent carcinogens, including the tobacco-specific nitrosamine NNK. Metabolism of NNK generates methylating and free radical species that can methylate DNA and cause oxidative DNA damage. The base excision repair (BER) pathway is designed to remove non-bulky adducts, such as those produced by NNK. The AP endonuclease APE1 plays a critical role in the BER process by initiating the repair of the AP sites generated by the excision of damaged bases in the DNA. Polymorphisms in several DNA repair genes have been identified, and many have been associated with cancer risk. In the current study we tested the hypothesis that the inheritance of the Asp148Glu polymorphism in APE1 influences the level of genetic damage resulting from exposure to nitrosamines found in tobacco smoke. We used the mutagen sensitivity assay, with NNK as a model mutagen, to test this hypothesis. Lymphocytes from 106 healthy volunteers were exposed *in vitro* to NNK, and the genotoxic response was measured by assessing the increase in chromosome aberration (CA) frequency. Our data indicate that the inheritance of the variant Glu allele is protective against NNK-induced genetic damage. A significant (P=0.005) decrease in NNK-induced CA (total breaks/100 cells) was observed in cells from smokers with the Glu allele (2.65) compared to cells from smokers homozygous for the wild-type Asp allele (4.71). The protective effect was significantly (P=0.009) more pronounced in males (1.85) compared to females (3.38). These data suggest that the 148Glu allele may affect the repair efficiency of NNK-induced genetic damage and consequently, may play a significant role as a risk factor for smoking-related cancers (Supported by an External Research Program grant from Philip Morris Inc. and NIEHS T32ES07254).

THE MECHANISMS OF DITHIOCARBAMATE DEVELOPMENTAL TOXICITY.

F. Tilton<sup>1,2,3</sup> and R. L. Tanguay<sup>1,2,3</sup>. <sup>1</sup>*Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR*, <sup>2</sup>*Marine & Freshwater Biomedical Sciences Center, Oregon State University, Corvallis, OR* and <sup>3</sup>*Environmental Health Sciences Center, Oregon State University, Corvallis, OR*.

We have previously reported that the dithiocarbamate pesticide, sodium metan (NaM), and its active ingredient, methylisothiocyanate (MITC) cause notochord malformations in the developing zebrafish during a sensitive developmental window which occurs > 6 hours before the visual manifestation of the malformation. Several dithiocarbamates (DTC), isothiocyanates (ITC) and carbon disulfide were investigated to determine the ultimate *in vivo* toxicant perturbing the pathway(s) leading to a deformed notochord. Among other observations, all the DTC and carbon disulfide elicited notochord malformations similar to those previously observed with NaM and MITC. Of the ITC tested only MITC exposure led to notochord malformations. It appears that in development DTC and/or carbon disulfide interact with the target leading to a malformed notochord. The potential involvement of cellular oxidative stress pathways and the role of metals were also investigated. Reduced glutathione (GSH) suppressed DTC induced notochord malformation with toxicant co-exposures however; differences in GSH protection/recovery were evident when the exposure windows were manipulated. Surprisingly, GSH failed to diminish MITC-induced malformations. Studies using Cu and Zn as well as their respective membrane permeable and impermeable chelators indicate a potential contribution from Cu. In order to identify the target causing perturbed notochord development; preliminary microarray experiments were undertaken encompassing the critical window of sensitivity to identify primary gene expression changes in response to chemical exposure. In conclusion, the underlying mechanism of DTC developmental toxicity appears to require *in vivo* glutathione depletion prior to DTC-target interaction. Furthermore, metals may play a role in the notochord response to DTC. Supported by NIEHS #ES00210, #ES03850, and #ES07060.

TCDD ALTERS GENE EXPRESSION IN ZEBRAFISH OVARY: INSIGHT INTO THE MECHANISMS BY WHICH TCDD IMPACTS REPRODUCTION IN FISH.

T. King Heiden<sup>1,2</sup>, M. Riss<sup>1</sup>, M. Hessner<sup>3</sup>, R. Hutz<sup>1,2</sup> and M. J. Carvan<sup>1</sup>. <sup>1</sup>*UW-Milwaukee Great Lakes WATER Inst, Milwaukee, WI*, <sup>2</sup>*Biological Sciences, UW-Milwaukee, Milwaukee, WI* and <sup>3</sup>*Pediatrics, Medical College of Wisconsin, Milwaukee, WI*.

TCDD (2, 3, 7, 8-tetrachlorodibenzo-p-dioxin) is a reproductive toxicant and endocrine disruptor in nearly all vertebrates. Fish are among the most sensitive vertebrates to the toxic effects of TCDD, and exposure to TCDD modulates their reproductive success by inhibiting ovarian development and estradiol production,

and ultimately reducing egg production. The molecular mechanisms by which TCDD induces these reproductive alterations have not been fully characterized. The ovary is a major target organ for TCDD toxicity, and estrogens are required for normal growth and development of the ovary. Therefore, TCDD-induced effects on reproduction may reflect AHR mediated alterations in ovarian gene expression with specific impacts on steroidogenesis. This study was designed to investigate the impact of TCDD exposure on gene expression as they relate to the suppression of estradiol biosynthesis or the alteration of oogenesis or vitellogenesis. Adult female zebrafish were exposed to different concentrations of TCDD in the diet for a period of four weeks, after which total RNA was isolated from the ovary. We have previously shown that adult female zebrafish show a significant decrease in the ovosomatic index following chronic dietary exposure to TCDD and, at high doses, exhibit severe ovarian necrosis and decreased egg production. Genes and pathways whose expression in the ovary was affected by TCDD were identified by microarray analysis using a common reference experimental design. Several genes were identified as being dysregulated at least 2-fold following dietary TCDD exposure (approximately 4% of genes surveyed were upregulated and 1.4% downregulated) and on-going analyses will provide additional information regarding the cellular pathways that are affected. Identifying potential molecular targets of TCDD constitutes the first step in understanding the mechanisms that underlie the toxic effects of TCDD on the female reproductive system.

**2239**

MATRIX METALLOPROTEINASE INHIBITION DURING ZEBRAFISH EMBRYOGENESIS FOLLOWING EXPOSURE TO HYDROCORTISONE AND DEXAMETHASONE.

J. M. Hillegass, C. M. Villano, L. A. White and K. R. Cooper. *Biochemistry & Microbiology, Rutgers, The State University of New Jersey, New Brunswick, NJ.*

Matrix metalloproteinases (MMPs) are a family of enzymes capable of digesting various components of the extracellular matrix (ECM). These degradative processes are essential for a number of biological and pathological processes, including embryogenesis, where MMPs participate in the normal ECM remodeling that occurs during tissue morphogenesis and development. Studies have demonstrated that MMP gene expression is inhibited by the action of glucocorticoids through mechanisms involving the glucocorticoid receptor. Further, glucocorticoids have been shown to alter developmental processes in several species, including mice and humans. Therefore, we propose that glucocorticoids alter normal development through inhibition of MMPs. Zebrafish (*Danio rerio*) were used as a model to study the effects of MMP-13 (Collagenase-3) inhibition during embryogenesis following acute exposure to the glucocorticoids hydrocortisone (HC) and dexamethasone (DX). Zebrafish eggs approximately 3 hours post-fertilization were exposed to 1, 10, or 100 ppm HC or DX for 24 hours. Total RNA was isolated from developing eggs and reverse transcription was performed to produce cDNA for quantitative PCR. Normalization of quantitative PCR data to  $\beta$ -actin revealed an inhibition of MMP-13 gene expression at 100 ppm when compared to negative and solvent controls. This effect was observed for both glucocorticoids, although DX was a more potent inhibitor of MMP-13 gene expression than HC. These results suggest that exposure to glucocorticoids during embryogenesis has the potential to affect normal development by preventing MMPs from performing essential ECM remodeling processes.

EARLY EMBRYONIC RESPONSES OF ZEBRAFISH TO DIESEL PARTICULATE MATTER.

M. D. Smith, S. J. D'Surrey, V. Tillis, E. Johnson and E. Eiland. *Biology, University of Mississippi, University, MS.*

Exposure to diesel particulate matter is reasonably anticipated to be a human carcinogen. An increased risk of lung cancer is found in the majority of human studies. Different toxicity tests have been conducted on carcinogens and the toxic effects they have on humans as well as other living organisms. Fish embryo assays have been conducted because they are more effective compared to short-term assays using juvenile and adult fish, and they offer more diverse endpoints for the evaluation of teratogenic effects (Sutter, 1987). Additionally, fish models serve as useful for the assessment of water-borne and sediment-deposited toxins because they provide advanced warnings of the potential danger of new chemicals and the possibility of environmental pollution. This study was conducted to determine the impact of diesel particulate matter (DPM) on the embryonic development of zebrafish from 12-240 hours post fertilization (hpf). Zebrafish (*Danio rerio*) embryos were exposed to different concentrations of DPM and early life stages were assessed for mortality, average time to hatch, and other endpoints. DPM did not increase mortality from (0-48 hpf), nor did it affect time to hatch (48-96 hpf). DPM doses of 25 $\mu$ g elicited toxic responses in zebrafish larvae. Pericardial edema and craniofacial malformations were first observed at 72 hpf, followed by an onset of spinal deformity (96hpf) and mortality (132 hpf). At 48, 72, 96, 120, and 144 hpf, the aver-

age heart rate decreased slightly with increased DPM concentration. At 24 and 48 hpf, spontaneous movement was reduced in DPM-treated zebrafish. This demonstration of zebrafish responsiveness to DPM early life toxicity coupled with the considerable information on developmental biology and genetics of zebrafish provides a foundation for future investigations into the mechanism of diesel particulate matter toxicity.

ARYL HYDROCARBON RECEPTOR (AHR) ACTIVATION INHIBITS ZEBRAFISH EARLY LIFE STAGE CAUDAL FIN REGENERATION.

L. K. Mathew, E. A. Andreasen and R. L. Tanguay. *Environmental and Molecular Toxicology, The Environmental Health Sciences Center, and The Marine and Freshwater Biomedical Sciences Center, Oregon State University, Corvallis, OR.*

Adult zebrafish have the remarkable ability to completely regenerate their caudal fins within two weeks following surgical amputation by a process that involves reactivation of early developmental signal transduction pathways. We have previously established the adult caudal fin regeneration model to investigate the molecular mechanism(s) of TCDD toxicity. When adult zebrafish are injected with TCDD, fin regeneration is significantly impaired at multiple regenerative stages, suggesting that outgrowth rather than re-differentiation is specifically disrupted by TCDD-mediated aryl hydrocarbon receptor (AHR) activation. Mechanistically, we propose that inappropriate activation of AHR by high affinity ligands such as TCDD interfere with growth-promoting signal transduction pathways. The key is to identify these pathways, and their down stream targets, in a whole animal model amenable to molecular and genetic manipulations. Because the true advantage of the zebrafish model is the numerous molecular and genetic tools available to manipulate and monitor development during early life stages, and because there are many technical limitations of the adult regeneration model, we sought to develop an embryonic model to test the hypothesis that AHR activation interferes with fibroblast growth factor (FGF) signaling *in vivo*. Here we report that when the embryonic caudal fin is surgically amputated at 2 days post fertilization, complete regeneration occurs by 5 days. However, when zebrafish embryos are waterborne exposed to TCDD for two hours immediately following amputation, larva fin regeneration is completely blocked. Importantly, the molecular responses to TCDD in the fin are similar to the responses following direct FGF receptor inactivation, suggesting commonality. This embryonic model will allow mechanistic identification of the interactions between FGF and AHR signal transduction pathways *in vivo*. Supported by NIEHS grants ES10820, ES00210, and #ES03850.

TCDD IMPAIRS EXTRACELLULAR MATRIX REMODELING IN THE REGENERATING ZEBRAFISH CAUDAL FIN.

E. A. Andreasen, J. M. Zodrow, L. K. Mathew, R. Hasson and R. L. Tanguay. *Environmental and Molecular Toxicology, The Environmental Health Sciences Center, and The Marine and Freshwater Biomedical Sciences Center, Oregon State University, Corvallis, OR.*

Adult zebrafish can completely regenerate their caudal fin following amputation. Exposure to 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) inhibits this regenerative process at several stages. Proper regulation of transcription, nerve innervation and extracellular matrix composition is essential for complete fin regeneration. The process is initiated by the formation of an epithelial wound cap over the amputation site by 12 hours post amputation (hpa). Once the cap is formed, mesenchymal cells proliferate and migrate from sites distal to the wound plane and accumulate under the epithelial cap forming the blastemal structure within 48 hpa. Blastemal cells differentiate and proliferate, and the regenerate becomes innervated with nerves and blood vessels during the regenerative outgrowth phase which is completed at about 14 days post amputation (dpa). Regenerative outgrowth does not occur in TCDD-exposed zebrafish. To test the hypothesis that TCDD blocks regeneration by impairing extracellular matrix remodeling, male zebrafish were i.p. injected with 50 ng/g TCDD or vehicle and caudal fins were amputated. Collagen metabolism was impaired by TCDD exposure. Histological staining demonstrates that TCDD exposure leads to an accumulation of collagen just posterior to the amputation site by 3 dpa. Transgenic fish expressing green fluorescent protein in vascular endothelium were also used to visualize revascularization. By 3 dpa, the vascular network in the regenerating fin of TCDD-exposed fish is disorganized compared to vehicle exposed animals. Furthermore, immunohistochemical analysis revealed that axonal outgrowth and innervation was impacted by TCDD as early as 3 dpa. Quantitative real time PCR studies revealed that the aryl hydrocarbon pathway is active and that matrix remodeling genes are expressed in the regenerate following TCDD exposure. Supported by NIEHS grants ES10820, ES00210, and #ES03850.

ETHANOL- AND ACETALDEHYDE-MEDIATED DEVELOPMENTAL TOXICITY IN ZEBRAFISH.

M. Reimers, J. La Du, A. Flockton and R. Tanguay. Department of Environmental and Molecular Toxicology, The Environmental Health Sciences Center, and The Marine/Freshwater Biomedical Sciences Center, Oregon State University, Corvallis, OR.

Ethanol is a well-established developmental toxicant. However, the mechanism(s) of toxicity remains unclear. Zebrafish are becoming an important model system for the evaluation of chemical and drug toxicity. In this study zebrafish embryos were utilized to compare the developmental toxicity resulting from ethanol and acetaldehyde exposure. Embryos were exposed to waterborne ethanol and acetaldehyde concentrations at two different intervals up to 48 hours post-fertilization, encompassing the earliest stages of embryogenesis. The waterborne ethanol concentration that causes 50% mortality ( $LC_{50}$ ) and 50% malformations ( $EC_{50}$ ) following a 45-hour ethanol exposure was approximately 340 mM (1.98% v/v) and 138 mM (0.80% v/v), respectively. Reducing the exposure window to the first 24 hours of embryogenesis, similar signs of toxicity, such as pericardial edema and craniofacial malformations, were produced at nearly identical ethanol concentrations. The  $LC_{50}$  for acetaldehyde was 0.54 mM and the acetaldehyde exposed embryos developed similar, but not identical responses as those induced by ethanol. Ethanol associated craniofacial abnormalities observed in mammals have been suggested to be partly due to apoptotic cell death of neural crest cells that are critical for craniofacial morphogenesis. Using acridine orange and TUNEL assays to distinguish between necrotic and apoptotic cell death, we observed a marked increase in apoptotic cells in the brain of ethanol exposed embryos. To test the hypothesis that oxidative stress plays a role in ethanol toxicity, several antioxidants were used to alter ethanol-dependent responses. These results demonstrate that the zebrafish model will provide an opportunity to further evaluate the role of oxidative stress in mediating the action(s) of ethanol on vertebrate development. Supported by NIH grants AA12783, ES03850, and ES00210.

EFFECTS OF ETOPOSIDE ON HUMAN FETAL HEMATOPOIETIC STEM CELLS.

C. G. Moneypenny, P. L. Stapleton and E. P. Gallagher. Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.

During fetal development, the liver serves as the primary hematopoietic organ in which hematopoietic stem cells (HSC) comprise a large proportion of hepatic cell populations. As HSC are pluripotent and are capable of initiating long-term hematopoiesis, injury to these cells during pregnancy may have ramifications with regard to the subsequent development of infant acute leukemias. In the current study, we used fetal HSC as a model to examine the effects of etoposide, a chemotherapeutic agent used in adults that can cause secondary leukemias containing genetic translocations similar to those in the infant acute leukemias. Exposure of HSC to a range of etoposide doses from 23 nM-5  $\mu$ M resulted in a dose-dependent inhibition of proliferation, with effects observed at as low as 23 nM. DNA damage, as detected by the COMET assay, was observed at 138 nM etoposide exposure, but not at lower concentrations. Exposure to 138 nM etoposide also stimulated an increase in the CD33 early myeloid and CD38 lymphoid lineages within HSC, but did not stimulate apoptosis in total HSC populations. Collectively, our data indicate that human fetal HSC are highly sensitive to physiological relevant concentrations of etoposide, as evidenced by a loss of proliferative capacity of the overall cell populations, alterations in differentiation, and induction of DNA damage. Supported by NIH ES09427 and USEPA STAR R827441.

DOSE-DEPENDENT SURVIVAL DIFFERENCES IN CHICKENS DEVELOPMENTALLY CO-EXPOSED TO NEAR-INFRARED LIGHT THERAPY AND DIOXIN.

R. L. Yeager<sup>1</sup>, J. A. Franzosa<sup>1</sup>, D. S. Millsap<sup>1</sup>, J. T. Eells<sup>2</sup>, H. T. Whelan<sup>3</sup> and D. S. Henshel<sup>1</sup>. <sup>1</sup>School of Public and Environmental Affairs, Indiana University, Bloomington, IN, <sup>2</sup>Department of Health Science, University of Wisconsin-Milwaukee, Milwaukee, WI and <sup>3</sup>Department of Neurology, Medical College of Wisconsin, Milwaukee, WI.

Photobiomodulation by red to near-infrared (630—1000 nm) light has been shown to stimulate mitochondrial energy (ATP) production, accelerate wound healing, and promote cellular survival following a toxic insult. 2, 3, 7, 8 Tetrachlorodibenzo-p-dioxin (TCDD) increases late embryo mortality in chickens by causing biochemical changes that culminate in decreased available energy. We tested the hypothesis that *in ovo* treatment with a red light-emitting diode (LED) array would attenuate TCDD-related embryo mortality. Domestic chicken eggs (*Gallus gallus*) were divided into ten treatment groups (no-inject, safflower oil vehicle, and 2, 20, 200 ppt TCDD), all with or without LED treatment (670 nm at a fluence of 2 J/cm<sup>2</sup> at 24 h intervals). Surprisingly, we observed an LED-induced in-

crease in mortality in the vehicle control and 2 ppt treatment groups. In contrast, LED treatment decreased mortality in the 200 ppt dioxin treated group (36% decrease in mortality rate). When week-three mortality was analyzed by correcting for the death occurring within the first two weeks of incubation, there remained a 22% decrease in mortality rate for the LED versus non-light treated chicks exposed to 200 ppt dioxin. By comparison, there was an equivalent week-3 mortality rate in the LED treated and non-light treated chicks in the vehicle control and 2 ppt dose groups. Thus an oil-NIR light interaction appears to contribute to early death at sub-lethal doses of TCDD. However, at higher doses of TCDD, LED treatment significantly attenuates TCDD toxicity. We speculate that 670 nm LED treatment may act directly on the oil vehicle and generate reactive oxygen species or alternatively may activate enzymes which metabolize the vehicle to an epoxide. ALTERATION OF NORMAL CARDIAC DEVELOPMENT BY TRICHLOROETHYLENE AND ITS METABOLITE TRICHLOROACETIC ACID.

V. J. Drake<sup>1</sup>, S. L. Kropowski<sup>2</sup>, J. W. Lough<sup>2</sup> and S. M. Smith<sup>1</sup>. <sup>1</sup>Nutritional Sciences, University of Wisconsin-Madison, Madison, WI and <sup>2</sup>Cell Biology, Anatomy and Neurobiology, Medical College of Wisconsin, Milwaukee, WI. Sponsor: R. Hines.

Congenital heart defects (CHD) are common birth anomalies, yet little is known regarding the specific mechanisms that induce these developmental malformations. Epidemiological and animal model studies have established an association between CHD and gestational exposure to trichloroethylene (TCE) and trichloroacetic acid (TCA), a metabolite of TCE. Both of these halogenated hydrocarbons are common drinking water contaminants in the US. The reported cardiac defects consistently emphasize malformations of the valves and septa; however, next to nothing is known regarding the molecular and cellular basis for the cardiac teratogenicity caused by TCE or TCA. To study this, we developed a chick embryo model in which exposure to these halogenated hydrocarbons reproducibly alters heart development. We found that TCE exposure at various levels of 0.2, 4, and 200 nanomoles/egg during cardiac cushion (early valve) formation decreases embryonic survival and triggers a U-shaped dose response curve. The most potent TCE exposure of 4 nanomoles/egg was associated with a significantly increased proliferative index (as measured by bromodeoxyuridine incorporation) within the cells of the atrioventricular canal and outflow tract cushions; cardiac cushions ultimately form the mature heart valvuloseptal structures. Moreover, direct comparison of equimolar exposures (4 nanomoles/egg) of TCE, trichloroethanol (TCOH) and TCA resulted in the metabolite TCA increasing cushion cell proliferation to a similar level as the parent compound. Correspondingly, we found that TCA was the most potent at decreasing survival of all the TCE metabolites examined. Studies investigating the effect of TCE and TCA on molecular signals obligatory for cushion formation are in progress. Overall, our results show that the halogenated hydrocarbons TCE and TCA are cardiac teratogens at environmentally relevant exposure levels. (Supported by ES11738)

TOXICOGENOMICS IN MALFORMATIONS INDUCED BY FUNGICIDE FLUCONAZOLE.

C. L. Galli<sup>1</sup>, E. Menegola<sup>2</sup>, E. Giavini<sup>2</sup>, E. Corsini<sup>1</sup> and M. Marinovich<sup>1</sup>. <sup>1</sup>Department of Pharmacological Sciences, University of Milan, Milan, Italy and <sup>2</sup>Department of Biology, University of Milan, Milan, Italy.

Some case-reports associate the use of fluconazole (an antifungal triazole for human mycosis treatment) early before or during pregnancy with birth defects in conceptuses. Also other triazoles, used in agriculture as fungicides, showed a teratogenic effect in embryos developed *in vitro*. For triazoles, in addition of the induction of a pattern of malformations overlapping those induced by an excess of RA, it has been shown the inhibition of the metabolism of all-trans-retinoic acid as well as alterations of the hindbrain and of the migration of hindbrain neural crest cells (NCC), basic process for the craniofacial morphogenesis. The aim of the present study was to identify and characterise the composite changes in gene/protein expression that may occur at selected critical periods of development. CD:Crl rat embryos (9.5 d.p.c.) were exposed *in vitro* at the teratogenic concentration of Fluconazole (500 microM) dissolved in ethanol. After 20 hours in culture (WEC) the embryos were morphologically examined and processed for histologic and biochemical analysis. Total RNA was isolated from hindbrain of control and exposed embryos cultured for 20 h, which is critical in NCC migration from hindbrain to the embryonic cranio-facial primordia, using a single-step isolation. The identification of genes differentially expressed was performed using a commercially available rat cDNA expression macro-array. Of the 1200 genes analysed only 46 resulted expressed in embryo cultures. Of particular interest was the upregulation of integrin 1 alpha, neuro specific enolase, TIMP 1 and the down-regulation of several potassium channels, alcohol dehydrogenase, RET1 and 2, VEGFR1. We are currently evaluating the role of such genes in the embryonic processes giving rise to the ob-

served malformations. Overall, the use of genomic allows to disentangle mechanistic aspects of teratogenic relevance. Acknowledgement. This work was partially funded by MIUR (COFIN 2003)

RELATIVE POTENCIES OF SELECTED DIHALOACETIC ACIDS AND THEIR MAJOR METABOLITES IN MOUSE WHOLE EMBRYO CULTURE.

S. Hunter, M. Blanton and E. Rogers. *RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.* Sponsor: J. Rogers.

Haloacetic acids (HAA) are produced by disinfection and present in tap water. Several HAAs produce developmental effects when administered to rodents. To better understand the causes of HAA-induced effects *in vivo* we compared the time and concentration dependent effects of three developmentally toxic HAAs (bromo-chloro-(BCA), dibromo-(DBA), dichloro-(DCA) acetate) and their major metabolites (glyoxylate(GO), glycolate(G), oxalate(O)) in whole embryo culture. CD-1 mouse conceptuses (3-6 somite stage, GD8) were exposed to parent or metabolite for 1, 3, 6 or 24H and morphological development evaluated at 24H. A 24H exposure to each of the compounds produced dysmorphogenesis. To compare the potencies of these compounds an ED05 benchmark concentration (BMC) was calculated for induction of dysmorphogenesis. The relative potencies and BMC of these compounds are BCA(52 $\mu$ M) = DBA(69 $\mu$ M) > GO(442 $\mu$ M) > G(645 $\mu$ M) > O(792 $\mu$ M) > DCA(1792 $\mu$ M). Conceptuses were then exposed to these compounds for 1, 3 or 6H at concentrations that produced high rates of dysmorphogenesis with a 24H exposure. A 3 or 6H exposure to 300 $\mu$ M BCA produced prosencephalic and pharyngeal arch defects. A 6H exposure to 11000 $\mu$ M DCA produced severely malformed embryos. A 6H exposure to 300 $\mu$ M DBA altered somitogenesis but not morphogenesis. A 6H exposure to 1500 $\mu$ M GO, 3500 $\mu$ M G or 3500 $\mu$ M O did not produce defects. Therefore, BCA could be the proximate toxicant because it disrupts development with short-term exposures and at concentrations lower than the metabolites. DBA requires exposures longer than 6H to disrupt morphogenesis but is more potent than the metabolites. Exposure to DCA disrupts development, but much lower concentrations of the metabolites are sufficient to produce those effects. Therefore when administered *in vivo*, BCA is likely the proximate toxicant, and the metabolites are the likely toxicants when DCA is administered. More information relating time and concentration will be needed to determine if the effects of DBA administration are the result of DBA and/or its metabolites. This abstract does not represent EPA policy

EVALUATION OF GLYCOLIC ACID IN RABBIT WHOLE EMBRYO CULTURE.

E. W. Carney, B. Tornesi and N. Moore. *Toxicology & Environmental Research and Consulting, The Dow Chemical Company, Midland, MI.*

The purpose of this study was to evaluate the development of rabbit post-implantation embryos exposed *in vitro* to glycolic acid (GA), the developmentally toxic metabolite of ethylene glycol (EG) in rodent species. This study was part of a larger effort to understand why high doses of EG are teratogenic in rodents, but not in rabbits, and to understand the relevance of the animal data to humans. Rabbit conceptuses were explanted from untreated pregnant New Zealand White rabbits on gestation day 9. The conceptuses were then exposed in culture to 0, 2.5, 6.0, or 12.5 mM of GA, or to the positive control, 5.0 mM methoxyacetic acid (MAA). The two highest GA concentrations had previously been shown to cause a high incidence of craniofacial and somite defects in rat whole embryo cultures (Carney *et al.*, *Teratology* 53:38-46, 1996; Klug *et al.*, *Toxicology in Vitro* 15:635-642, 2001). After approximately 48 hours in culture the rabbit embryos were evaluated for viability (heart beat), growth (somite number, head length, yolk sac protein content) and morphological development (quantitative morphology score, percent malformed embryos). There were no effects of GA on any parameter of development. This lack of embryotoxicity contrasted sharply with the teratogenic effects of MAA, which induced malformations in 83% of the embryos. These data suggest a fundamental difference in the sensitivity of rat and rabbit embryos to GA, but the relevance of this finding to humans is as yet unclear. Funded by the Ethylene Oxide and Derivatives Sector Group of CEFIC (Brussels, Belgium).

ENDOGENOUS EMBRYONIC CATALASE ACTIVITY DURING ORGANOGENESIS IN EMBRYO CULTURE, *IN VIVO* AND AFTER EXPOSURE TO PHENYTOIN-ENHANCED OXIDATIVE STRESS.

J. Perstin<sup>1</sup> and P. G. Wells<sup>1,2</sup>. <sup>1</sup>*Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada* and <sup>2</sup>*Department of Pharmacology, University of Toronto, Toronto, ON, Canada*.

Reactive oxygen species (ROS) including hydrogen peroxide ( $H_2O_2$ ) have been implicated in the mechanism of birth defects, and the developing embryo is uniquely susceptible due to its low levels of most antioxidative enzymes. Exogenous adminis-

tration of the antioxidative enzyme catalase, which detoxifies  $H_2O_2$ , is known to be embryoprotective, but little is known about the embryonic expression, inter-individual variability or protective importance of the endogenous enzyme. Herein, we determined the endogenous activity of catalase in embryos in culture and *in vivo* during organogenesis. CD-1 mouse embryos were explanted on gestational day (GD) 9.5 (plug = GD 1) and cultured for 24 hr at 37°C in medium containing the ROS-initiating teratogen phenytoin (20  $\mu$ g/ml, 80  $\mu$ M) or its vehicle (0.002 N NaOH), followed by analysis of sonicated homogenates for catalase activity, which was compared to *in vivo* embryonic activities on GDs 9.5, 10.5 and 12.5. The mean catalase activity was similar in embryos *in vivo* and in culture (range: 30-55 U/mg protein), constituting about 6% of maternal hepatic activity, and was not increased by exposure in culture to phenytoin. Sonication revealed higher embryonic activity than previously reported, without altering its activity relative to maternal levels. Catalase activity among individual littermates on GD 12.5 varied at least 4-fold, suggesting that inter-individual differences may contribute to embryopathic risk. (Support: Canadian Institutes of Health Research)

IN VITRO STUDY ON THE EMBRYOTOXIC POTENTIAL OF N-METHYL-PYRROLIDONE (NMP) AND ITS METABOLITES.

B. Flick<sup>1</sup>, R. Jaeckh<sup>2</sup> and S. Klug<sup>1</sup>. <sup>1</sup>*Institute of Clinical Pharmacology and Toxicology, Berlin, Germany* and <sup>2</sup>*BASF AG, Ludwigshafen, Germany*. Sponsor: L. Sherman.

INTRODUCTION: N-methyl-2-pyrrolidone (NMP) and its metabolites, 5-hydroxy-methyl-pyrrolidone (5H-NMP), N-methylsuccinimide (MSI) and 2 hydroxy-methyl-succinimide (2H-MSI), were compared *in vitro* for their embryotoxic potential in order to identify the agent(s) relevant to embryotoxicity under *in vivo* conditions. METHODS: Two *in vitro* test systems were used: 1. the whole embryo culture embryotoxicity test (WEC) using postimplantation embryos and 2. the balb/c 3T3 cytotoxicity test (CT) (balb/c 3T3 fibroblasts). In the WEC system the test substances were ranked according to growth and differentiation parameters, especially the frequency of dysmorphogenes. The NOEC WEC was defined as the maximum tested concentration showing no adverse effect on the total morphological score whereas ICMax WEC was the lowest tested concentration that showed a maximum rate of malformation. In the CT system IC50 3T3 was defined as the concentration leading to 50% growth inhibition. RESULTS: The rankings obtained in the WEC system (in terms of decreasing embryotoxicity) were: NMP (2, 500 and 6, 000  $\mu$ mol/l) > 5H-NMP (8, 000 and 12, 000  $\mu$ mol/l) > 2H-MSI (12, 000 and 24, 000  $\mu$ mol/l) > MSI (16, 000 and 44, 000  $\mu$ mol/l); (NOEC WEC and ICMax WEC). In the CT system the ranking of decreasing cytotoxicity was: MSI (4, 800  $\mu$ mol/l) > NMP (7, 300  $\mu$ mol/l) > 2H-MSI (8, 000  $\mu$ mol/l) > 5H-NMP (29, 000  $\mu$ mol/l); (IC50 3T3). Specific dysmorphogenes induced by NMP and 5H-NMP were observed in the head region of the embryos, abnormal development of the second visceral arches and open neural pores. CONCLUSIONS: Using the prediction model developed by the European Centre for the Validation of Alternative Methods (ECVAM) which is based on NOEC WEC, ICMax WEC and IC50 3T3, NMP and 5H-NMP were classified as weakly embryotoxic; MSI and 2H-MSI as non-embryotoxic. This *in vitro* study indicates that embryotoxicity previously observed after NMP administration to experimental animals is predominantly caused by the parent compound, NMP. + This work has been sponsored by the NMP Producers Group Inc. Washington/DC.

IN VITRO STUDY ON THE EMBRYOTOXIC POTENTIAL OF BRANCHED-CHAIN CARBOXYLIC ACIDS.

B. Flick<sup>1</sup>, R. Jaeckh<sup>2</sup> and S. Klug<sup>1</sup>. <sup>1</sup>*Institute of Clinical Pharmacology and Toxicology, Berlin, Germany* and <sup>2</sup>*BASF AG, Ludwigshafen, Germany*. Sponsor: L. Sherman.

INTRODUCTION: Several branched-chain alcohols are important industrial products and may be regarded as metabolic precursors of corresponding branched-chain carboxylic acids. The developmental toxicity of certain branched-chain carboxylic acids such as valproic acid (VPA) or 2-ethylhexanoic acid (EHA) has been confirmed *in vivo*. 2-Propylheptanol (PHOH) is a branched-chain alcohol which is developmentally inactive in rats, but until now nothing is known about the embryotoxicity of the presumptive metabolite 2-propylheptanoic acid (PHA) and the metabolite of the major impurity in the commercial PHOH, 2-propyl-4-methylhexanoic acid (PMHA). Therefore, the embryotoxic potentials of these two carboxylic acids as compared to VPA and EHA as reference substances were determined *in vitro*. METHODS: Two *in vitro* test systems were used: 1. the whole embryo culture embryotoxicity test (WEC) using postimplantation rat embryos and 2. the balb/c 3T3 cytotoxicity test (CT). In the WEC system the test substances were ranked according to growth and differentiation parameters. RESULTS: The rankings obtained in the WEC system (in terms of decreasing embryotoxicity) were: PHA (17 and 150  $\mu$ g/ml) > VPA (17 and 150  $\mu$ g/ml) > EHA (100

and 300  $\mu$ g/ml) > PMHA (100 and 500  $\mu$ g/ml). In the CT system the ranking of decreasing cytotoxicity was: PHA (450  $\mu$ g/ml) > PMHA (1, 570  $\mu$ g/ml) > VPA (2, 010  $\mu$ g/ml) > EHA (3, 020  $\mu$ mol/l). Concentration given correspond to the NOECWEC, ICMMax WEC and IC50 3T3 of the WEC and CT, respectively. All test substances induced dysmorphogenes in the neural tube, otic and optic system. CONCLUSIONS: Using the prediction model developed by the European Centre for the Validation of Alternative Methods (ECVAM) which is based on NOECWEC and ICMMax-WEC and IC50-3T3, all tested chemicals were classified as weakly embryotoxic. In order to assess the relevance of these *in vitro* data for the situation *in vivo*, corresponding pharmacokinetic modelling is needed.

## 2253 CHARACTERIZATION OF ALCOHOL METABOLIZING ENZYMES IN JAPANESE MEDAKA.

X. Wang<sup>2,1</sup>, E. S. Williams<sup>2,1</sup>, M. L. Haasch<sup>1,2</sup> and A. K. Dasmahapatra<sup>1,2</sup>.

<sup>1</sup>Environmental Toxicology Research Program, NCNPR, RIPS, University of Mississippi, University, MS and <sup>2</sup>Department of Pharmacology, University of Mississippi, University, MS.

Cardiovascular defects in developmental ethanol exposure have been identified in both human and animal models and used as a phenotypic feature of fetal alcohol syndrome (FAS). The molecular mechanism of FAS has not yet been fully characterized. We used the Japanese medaka developmental model to evaluate FAS produced by acute ethanol exposure. Viable medaka eggs within 1h of fertilization were exposed to ethanol (0-400mM) in hatching solution for 48 h. Cardiovascular development was observed from 1-7 dpf. The embryos exposed to low ethanol concentrations (0-100mM) exhibited blood circulation at 2 dpf but active circulation was significantly delayed at higher ethanol doses (200-400mM). Moreover, embryos exposed to these ethanol concentrations (200-400mM) developed tube heart and blood clots in the Blood Island and in the circulatory vessels. We hypothesized that the cardiovascular abnormalities seen in developing medaka were due to one or more metabolites of ethanol metabolism. To examine this possibility, we have begun to characterize the genes for alcohol metabolizing enzymes in medaka. By applying PCR-based technologies, we previously cloned and characterized two alcohol dehydrogenase (ADH) enzyme cDNAs from the liver tissue of medaka. Additional work has yielded partial clones of two subtypes of aldehyde dehydrogenase cDNA (ALDH $\alpha$  and ALDH $\beta$ ) in adult medaka liver. ALDH $\alpha$  mRNA showed tissue specific expression, however ALDH $\beta$  was ubiquitously expressed (brain, eye, GI, Gill, heart, kidney, liver, muscle, skin, spleen and ovary). The expression patterns of ALDH $\alpha$  and  $\beta$  mRNA were different during development. ALDH $\alpha$  was first expressed at 2 dpf, but in contrast ALDH $\beta$  was expressed from fertilization onward. Our results indicate that ALDH $\beta$  is the major enzyme expressed during the early part of embryonic development and likely plays a significant role in the generation of ethanol- metabolites and the subsequent development of cardiovascular defects.

## 2254 VISUALIZATION OF TISSUE DISTRIBUTION AND METABOLISM OF BENZO(A)PYRENE IN EMBRYONIC MEDAKA (*ORYZIAS LATIPES*).

M. W. Hornung, R. D. Johnson, P. M. Cook and J. W. Nichols. NHEERL, MED, USEPA, Duluth, MN.

The tissue distribution of chemical during critical developmental stages is one factor that can contribute to the sensitivity of fish early life stages to the toxic effects of persistent bioaccumulative toxicants (PBTs). A new tool to monitor the tissue distribution of fluorescent PBTs in small organisms is multiphoton laser scanning microscopy (MPLSM). Imaging fluorescent PBTs that are not metabolized is straightforward because the location of fluorescence indicates the distribution of the PBT. However, a PBT such as benzo[a]pyrene (BaP) presents challenges because of the formation of metabolites with similar emission spectra. In this study, differences in the excitation of BaP and metabolites at four diagnostic multiphoton excitation wavelengths were used to investigate the tissue distribution of BaP during fish early development. Within 2h of fertilization, medaka eggs were exposed for 6h to BaP, then rinsed and transferred to clean media from which they were sampled throughout embryonic stages and through 3d post-hatch. At 1d post-fertilization there was strong fluorescence in the coalesced oil globules in the yolk and moderate fluorescence in the yolk itself. Images, along with chemical analysis of whole embryo extracts, indicated that BaP was metabolized early in development. Metabolism occurred well before liver formation and changes in fluorescence suggested a conversion from hydroxylated BaP to a BaP-glucuronide. Metabolism appeared as an initial loss of fluorescence from the oil globule with a sequential increase in fluorescence in the yolk, gall bladder, and intestine. The increased fluorescence was due to the formation of more highly fluorescent BaP metabolites. These metabolites were rapidly eliminated soon after the embryos hatched. The ability to image the metabolism and redistribution of chemical provides insight into the early metabolic

competency of embryos and indicates that fish embryos can metabolize xenobiotics much earlier than previously demonstrated. This abstract does not necessarily reflect EPA policy.

## 2255 PFOA INDUCES DYSMORPHOGENESIS IN MOUSE WHOLE EMBRYO CULTURE.

M. R. Blanton<sup>1</sup>, J. M. Padowski<sup>2</sup>, S. S. Hunter<sup>1</sup>, J. M. Rogers<sup>1</sup> and C. Lau<sup>1</sup>.

<sup>1</sup>RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC and <sup>2</sup>Curriculum in Toxicology, UNC, Chapel Hill, NC.

Perfluorooctanoate (PFOA) is a perfluoroalkyl acid (PFAA) found in numerous industrial and consumer products. Many PFAAs persist in the environment and are found in humans and animal tissues throughout the world. PFOA is a developmental toxicant *in vivo* producing embryonic, fetal and postnatal lethality, and altered fetal and neonatal growth. In order to determine if direct exposure of conceptuses to PFOA disrupts development, CD-1 mouse conceptuses (3-6 somite stage, GD8) were exposed to PFOA in whole embryo culture. At the end of a 24H culture period embryonic morphology was assessed and scored using a scoring system developed by our laboratory. Scores ranged from 0, for morphologically normal, to a maximum of 58 for severely affected embryos. In control medium, 82% of embryos (18/22) grew normally and the mean score was  $0.4 \pm 0.2$ . Exposure to 0.1 or 0.2mg/ml PFOA did not alter development (4/4 and 11/17, normal embryos respectively). However, dysmorphogenesis was induced by PFOA at 0.4 (82%), 0.6 (92%), 0.75 (100%) and 1.0 (100%) mg/ml. Exposure to 1.25mg/ml produced 100% embryo lethality. Prosencephalic and pharyngeal arch hypoplasia and abnormal heart outflow tract development were induced by  $>0.4$ mg/ml PFOA. Embryonic scores were increased at PFOA concentrations  $>0.4$ mg/ml and were  $0.0 \pm 0.0$ (0.1),  $1.7 \pm 0.7$ (0.2),  $11.3 \pm 2.2$ (0.4),  $11.3 \pm 2.0$ (0.6),  $23.5 \pm 1.5$ (0.75) and  $31.1 \pm 3.9$ (1.0). The benchmark concentration for a 5% increase in dysmorphic embryos by PFOA was  $0.04 \pm 0.01$ mg/ml. These studies demonstrate that a direct exposure to PFOA for 24H disrupts development and induces embryo lethality. This abstract does not represent EPA policy.

## 2256 THALIDOMIDE DEPLETES GLUTATHIONE AND INITIATES OXIDATIVE STRESS IN RAT NEURAL CREST CELLS.

C. Harris and P. A. Paximadis. Environmental Health Sciences, University of Michigan, Ann Arbor, MI.

Thalidomide is believed to be bioactivated to free radicals and initiate oxidative stress in teratogen-sensitive and insensitive embryos. Thalidomide and other teratogens that produce reactive oxygen species may exert their teratogenic effects by mechanisms that involve glutathione (GSH) oxidation and alteration of redox-sensitive regulatory systems. Cultured rat neural crest cells, important for their roles in sensory and structural embryogenesis *in vivo*, were used as a model system to characterize alterations and responses caused by thalidomide. Neural crest cells were isolated from thalidomide-resistant Sprague-Dawley rats on gestational day 11 and grown in culture. Total reduced GSH and oxidized glutathione (GSSG) concentrations were measured using HPLC. Untreated rat neural crest cells were found to contain very low concentrations of GSH (1.3 pmol/ $\mu$ g protein) and GSSG (0.017 pmol/ $\mu$ g protein, even in the presence of measurable amounts of GCLc and GCLm; enzymes responsible for GSH synthesis. Treatment with 10  $\mu$ M or 50  $\mu$ M thalidomide for 1, 3, 6, or 24 hr produced time and dose-dependent decreases in GSH to 0.52 pmol/ $\mu$ g protein and increased GSSG to 0.23 pmol/ $\mu$ g protein. Based on these changes, 50  $\mu$ M thalidomide produced a positive shift in intracellular redox potential from -219 mv to -161 mv after 24 hr, creating an environment where most cells become susceptible to misregulation of transcription factors and apoptosis. Qualitative assessment of GSH depletion in neural crest cells using CMFDA fluorescence staining and confocal microscopy confirmed the loss of GSH during the first 6 hr of exposure to thalidomide. Our results indicate that thalidomide produces a significant depletion of GSH and an increase in GSSG, resulting in a shift of cellular redox potential towards a more oxidative environment. These observations confirm that thalidomide is capable of initiating oxidative stress in neural crest cells obtained from an insensitive rodent species and may be useful in characterizing specific redox-sensitive regulatory pathways that regulate differentiation and proliferation.

## 2257 EXAMINATION OF METAL-INDUCED CELL CYCLE ALTERATIONS AND APOPTOSIS IN C57BL/6 AND SWV MOUSE EMBRYONIC FIBROBLASTS.

J. F. Robinson, X. Yu, J. S. Sidhu, S. Hong, E. Kim and E. M. Faustman. Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.

Neural tube defects (NTDs) are the most common of all serious human birth defects. Studies have identified genetic components that may confer increased susceptibility to environmentally-induced NTDs. The SWV and C57BL/6 mice strains

have shown a large disparity in sensitivity to environmentally-induced NTDs. Due to its complex status of proliferation, differentiation, and cell turnover, the developing embryo is highly susceptible to metal-induced cell cycle alterations and apoptosis. We hypothesize that differential metal-induced impacts within cell cycle and apoptosis pathways at the molecular level contribute to observed differing sensitivities between these two strains. A primary *in vitro* model was established by isolating murine embryonic fibroblasts (MEFs) at gestational day 14. Using the neutral red assay, a cytotoxicity profile was generated after a 24hr exposure to environmentally relevant concentrations of cadmium (Cd) and methyl mercury (MeHg). To characterize metal induced-alterations within cell cycle pathways, cell cycle kinetics were assessed using BrdU/Hoechst/PI and transcriptional changes of cyclin b1 were measured using RTPCR. Finally, to examine changes in apoptotic pathways, caspase 3/7 and 8 activities were measured. The SWV exhibited slightly higher sensitivity to Cd-induced cytotoxicity. For both metals, we observed inhibition of cell cycle progression, G2/M accumulation, and repressed cyclin b1 expression, but no differences were evident between strains. The C57BL/6 displayed a higher increase in caspase 3/7 and caspase 8 activity compared to the SWV with 10uM Cd. In summary, SWV and C57BL/6 MEFs exhibited dose dependent metal-induced alterations in cell cycle and apoptotic pathways. Since we found no differences in metal-induced cell cycle alterations, this suggests that differential sensitivity to metals between the SWV and C57BL/6 are possibly due to unique metal-induced cell death mechanisms. IDENTIFICATION OF GENE CLUSTERS AND SIGNALLING PATHWAYS AFFECTED BY DIBUTYL PHTHALATE - NUCLEAR RECEPTOR INTERACTIONS IN FOETAL RAT TESTES.

S. Plummer<sup>1</sup>, N. Hallmark<sup>2</sup>, R. Sharpe<sup>2</sup> and C. Elcombe<sup>1</sup>. <sup>1</sup>CXR Biosciences Ltd, Dundee, United Kingdom and <sup>2</sup>MRC Human Reproductive Sciences Unit, Edinburgh, United Kingdom.

Transcriptional profiling and immunohistochemical analysis in foetal testes of Wistar rats exposed *in utero* to di(n-butyl)phthalate (DBP) 500 mg/Kg were performed in order to identify signalling pathways associated with DBP-induced testicular dysgenesis. High density microarray analysis (22K array) in foetal testes at gestational days (GD) 15, 17 and 19 indicated DBP altered the expression of three functionally distinct gene clusters. A battery of genes involved in the synthesis of testosterone [including steroidogenic factor 1 (SF-1), steroidogenic acute regulatory protein (StAR), cytochrome P450 side chain cleavage (Cyp11a) and 17 $\alpha$ hydroxylase-17, 20-lyase (Cyp C17)] were down-regulated. This correlated with a 70% reduction in foetal testes testosterone levels. Insulin-like factor 3 (Insl3) and genes associated with cellular protection against oxidative stress were also down-regulated. SF-1 RNA levels in DBP-exposed foetal testes in individual litters measured by TaqMan correlated with changes in expression of the SF-1-regulated genes Insl3, StAR and Cyp11a. Immunohistochemical analysis of foetal testes indicated that down-regulation of the SF-1-regulated gene inhibin alpha was found in Leydig cells but not Sertoli cells, thus suggesting a cell type-specific effect. In adulthood, 65% of rats exposed *in utero* to DBP had either bilateral or unilateral cryptorchidism whereas there was no cryptorchidism in control animals. These results suggest that DBP-induced testicular dysgenesis involves effects on several different signalling pathways and is mediated in part through down-regulation of SF-1 together with a battery of genes regulated by this orphan nuclear receptor in a cell type specific manner. This studies were funded by the European Council for Plasticisers and Intermediates.

VALPROIC ACID INCREASES CONSERVATIVE HOMOLOGOUS RECOMBINATION FREQUENCY: IMPLICATIONS FOR A MECHANISM OF VALPROIC ACID-INDUCED NEURAL TUBE DEFECTS.

E. Defoort<sup>1</sup>, P. M. Kim<sup>1</sup> and L. M. Winn<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada and <sup>2</sup>School of Environmental Studies, Queen's University, Kingston, ON, Canada.

Valproic acid (VPA), a commonly used antiepileptic agent, is associated with a 1-2% incidence of neural tube defects (NTDs) when taken during pregnancy. However, the molecular mechanism by which VPA causes NTDs has not been elucidated. Previous research has shown that other teratogens exert their detrimental effects through oxidative stress, and an imbalance in the cellular redox state has also been noted after VPA exposure. Reactive oxygen species (ROS) can either directly cause DNA double strand breaks (DSBs) or oxidize DNA which can then lead to DSBs during repair. DSBs can be repaired through homologous recombination (HR), however HR is not error free and can result in detrimental genetic changes. Because the embryo requires tight regulation of gene expression in order to develop properly, we propose that the loss or dysfunction of critical genes involved in em-

bryonic development through aberrant HR may ultimately cause teratogenesis. To test our hypothesis that VPA causes an increase in DSBs that are repaired through HR, CHO 3-6 cells, which contain a neomycin direct repeat recombination substrate, were exposed to VPA (0.5, 1.0, 5.0 and 10.0 mM) for either 4 or 24 hours. A dose dependant increase in HR frequency was observed at 24 hours. Using the ROS sensitive dye 5-(and-6)-chloromethyl-2', 7'- dichlorodihydrofluorescein diacetate (CM-H2DCF), we have shown that exposure to VPA (5 and 10 mM) significantly increases intracellular ROS levels, suggesting that ROS may play a role in the increased HR frequency observed. HR can either occur with or without a loss of DNA. Through southern blot analysis, using neo cDNA as the probe, we have shown that VPA-induced (5 and 10 mM) HR occurs without a loss of DNA. This suggests that a loss of heterozygosity of genes critical to neural tube development may be a significant factor leading to NTDs. (Supported by CIHR)

TERATOGENIC EFFECTS OF FORSKOLIN, CYCLOPAMINE AND ETHANOL ON EARLY BRAIN AND EYE DEVELOPMENT.

E. Loucks and S. Ahlgren. Childrens Memorial Research Center, Chicago, IL.

Exposure of developing zebrafish (*Danio rerio*) to forskolin, cyclopamine, and ethanol has been shown to induce teratogenic effects affecting the patterning and formation of the brain and eyes. Many of these abnormalities are similar to some common human birth defects. Here, we compare and contrast the effects of these three toxins on developing embryos. Forskolin, cyclopamine and ethanol, all to differing extents, inhibit Sonic Hedgehog (Shh), a secreted protein with a signaling pathway essential for multiple events during embryogenesis, including the development of the brain and eyes. Shh protein and its receptors are also involved with signaling cascades that, when disrupted, cause developmental abnormalities. Cyclopia is a common phenotype seen in developing zebrafish embryos exposed to these three toxins, and resembles human SHH mutations. While these three toxins all act upon Shh, they differentially affect other genes important for brain formation. In our study, we have investigated several brain and eye patterning genes suspected to be affected by forskolin, cyclopamine and ethanol in developing zebrafish embryos. Zebrafish make an excellent animal model because of their high fecundity, external developmental growth, and extensive known genetic background. Embryos were exposed to each chemical starting at 30% epiboly (just prior to gastrulation) until they reached key developmental time points. Whole mount *in situ* hybridization for one forebrain gene, six3b, revealed dose-dependent effects with forskolin and ethanol which were not seen with cyclopamine. Morphological observation of body shape abnormalities demonstrated similarities between ethanol and forskolin but not cyclopamine. However, embryos exposed to cyclopamine had similar abnormalities to those seen with Smooth muscle omitted (smu) homozygous zebrafish, a smoothened (Shh receptor) mutant. A greater understanding of the mechanisms involved with forskolin, cyclopamine and ethanol treatments may shed some light on several human diseases that demonstrate similar malformations.

PROTECTION AGAINST MNU-INDUCED FETAL MALFORMATIONS AND PLACENTAL MALDEVELOPMENT WITH DIETARY BUTYLATED HYDROXYTOLUENE SUPPLEMENTATION.

M. R. Prater<sup>1,2</sup>, L. Pinn<sup>2</sup>, J. Keay<sup>2</sup> and S. D. Holladay<sup>2</sup>. <sup>1</sup>Biomedical Sciences, Edward Via Virginia College of Osteopathic Medicine, Blacksburg, VA and <sup>2</sup>Biomedical Sciences and Pathobiology, Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.

Methylnitrosourea (MNU) is a multisystem carcinogen and teratogen formed in protein metabolism in the presence of nitrites and gastric acid. MNU damages proliferating tissues by generating reactive oxygen species (ROS). Murine dams given MNU mid-gestation produce fetuses with distal limb defects. Disrupted placental integrity by excessive ROS is thought to be a major contributing factor. Daily dam diet supplemented with antioxidant (butylated hydroxytoluene, BHT) may protect against development of fetal anomalies by abrogation of ROS activity in rapidly developing tissues. This study correlated placental integrity with fetal distal limb defects in MNU-exposed CD-1 mice fed BHT. BHT dams had no changed food preference over controls. MNU increased fetal resorptions, decreased fetal size, and increased fetal distal limb anomalies (syndactyly, oligodactyly, polydactyly, clubbing and webbing). BHT counteracted negative effects of MNU on fetal loss and development of distal limb defects (syndactyly in all limbs, oligodactyly and clubbing in hind limbs). However, MNU and MNU+BHT fetuses were smaller than control fetuses and demonstrated increased webbing in all limbs, suggesting maturation delay and placental disruption (cell death, inflammation); limb shortening was proportional to fetal size. MNU+BHT resulted in partial protection against placental toxicity of MNU, an effect that may relate to diminished fetal distal limb defects. Results suggest that: 1. damage to placenta by MNU is in part ROS-mediated and can be reduced by antioxidant therapy; and 2. reduced distal limb defects in

MNU+BHT fetal mice is likely related to improved placental integrity and function. These results provide a basis for future studies of cellular and molecular mechanisms involved in the therapeutic use of antioxidants in reproductive medicine. Supported by NIH #5K01-RR-17018-3

*N*1- AND *N*7-DEOXYGUANOSINE ADDUCTS OF DIEPOXYBUTANE EXHIBIT DIFFERENT STABILITIES AND DECOMPOSITION PATTERNS UNDER PHYSIOLOGICAL CONDITIONS.

X. Zhang and A. A. Elfarra. *Department of Comparative Biosciences, University of Wisconsin-Madison, Madison, WI.*

1, 2, 3, 4-Diepoxybutane (DEB), an *in vivo* metabolite of 1, 3-butadiene, is a carcinogen and a potent mutagen. Previously, we have shown that DEB readily reacts with 2'-deoxyguanosine (dG) under physiological conditions to produce seven major nucleoside adducts resulting from alkylation at the *N*1- (P8, P9), *N*7- (P5, P5') and both the *N*1- and *N*2-positions of dG to form six- and seven-membered fused ring systems (P4-1, P4-2 and P6), respectively (Zhang and Elfarra, *Chem. Res. Toxicol.* 2003, 16, 1606; *ibid.* 2004, 17, 521). Because these adducts exhibited different stabilities and rates of formation under the reaction conditions, the goal of the present study was to characterize the stabilities and decomposition products of purified P8, P9, P5, P5', P4-1, P4-2 and P6 under *in vitro* physiological conditions (pH 7.4, 37 °C). The results show that whereas P4-1, P4-2 and P6 were stable for at least three weeks, P5, P5', P8 and P9 were labile with half-lives of 2.6, 2.7, 16 and 16 h, respectively. P5 and P5' decomposed initially by the loss of the sugar moiety to yield the corresponding guanine adducts, which exhibited a half-life of 33 h and decomposed by the addition of either water or HCl into the remaining oxirane ring. The decomposition of P8 and P9 yielded the stable nucleoside adducts P4-1, P4-2 and P6, in addition to nucleoside products resulting from the addition of water or HCl to the remaining oxirane ring. These results explain the formation of P4-1, P4-2 and P6 and provide a better understanding of the reaction of DEB with dG. The results also demonstrate significant differences in the stabilities and decomposition patterns of the dG-DEB adducts, which may facilitate the development of useful biomarkers of exposure to DEB (Supported by NIH Grant ES06841).

DEPURINATION OF NUCLEOSIDES INDUCED BY HALOGENATED ALKANES IN THE PHYSIOLOGICAL CONDITION.

J. Kim, J. Sherchan, B. Arjun, B. Choi, E. Kim, Y. Jahng, T. Jeong and E. Lee. *College of Pharmacy, Yeungnam University, Kyongsan, Kyongbuk, South Korea.*

2-Bromopropane,  $\text{CH}_3\text{CHBrCH}_3$ , is widely utilized as a cleansing solvent in electronic factories. It has been reported that a number of female workers, exposed occupationally to 2-bromopropane, were diagnosed with amenorrhea and male workers with oligospermia in Korea. 1-Bromopropane,  $\text{CH}_3\text{CH}_2\text{CH}_2\text{Br}$ , known as an alternative to ozone depleting solvents, which has structural similarity to 2-bromopropane, has been reported to be neurotoxic to rats in long-term inhalation exposure. 1- and 2-bromopropane were also reported as the causative agents for reproductive toxicity and immunotoxicity. We have been previously reported that the guanine adducts of 1-and 2-bromopropane was detected and quantitated by the treatment of 1- and 2-bromopropane to 2'-deoxyguanosine and calf thymus DNA at the physiological condition (pH 7.4, 37°C), as well as *in vivo* experiments, which indicated the possible mechanism of toxicity of 1- and 2-bromopropane. In this study, we observed the depurination of nucleosides by the treatment of 2-bromopropane and other halogenated alkanes at the physiological condition using HPLC and ESI LC/MS/MS. In addition, time-response and dose-response effects of depurination of nucleosides induced by halogenated alkanes at the physiological condition were investigated. The present results might explain the toxic effects of 2-bromopropane could be from the depurination of nucleosides as well as the adducts formation of the DNA.

EXPOSURE-BASED SAFETY ASSESSMENT OF THE NATURALLY OCCURRING FLAVOURING METHYL EUGENOL.

J. Ellis<sup>1</sup>, P. L. Carmichael<sup>2,1</sup> and N. J. Gooperham<sup>1</sup>. <sup>1</sup>*Biological Chemistry, Imperial College London, London, United Kingdom and*<sup>2</sup>*SEAC - Safety and Environmental Assurance, Unilever, Sharnbrook, United Kingdom.*

Methyl eugenol is a naturally occurring allylalkoxybenzene found in fruits, spices and essential oils that has been used as a food additive. It has structural similarities to the carcinogens safrole and estragole. Although high doses of methyl eugenol form DNA adducts and are hepatocarcinogenic in rodents (Abdo et al.

2001;Phillips et al. 1984;Randerath et al. 1984), it is generally regarded as safe (GRAS) at levels below 50ppm (Hall 1965). To investigate the potential toxicity of methyleugenol at doses more representative of human exposure, a 28 day feeding study with F344 rats was undertaken (1, 5 & 50mg/kg bw/day, 20 rats per group). Animals were monitored for signs of overt toxicity and necropsied at the end of the treatment period. Tissue samples were assessed for hepatic Proliferating Cell Nuclear Antigen (PCNA, a marker for increased cellular proliferation) serum gastrin (a marker of gastric damage) and DNA adducts (genotoxicity) using Nuclease P1 enhanced 32P-Postlabelling. Oral administration of methyl eugenol (daily gavage or continuous dietary admixture) for a period of 28 consecutive days did not induce signs of overt toxicity nor adversely affect weight gain or terminal liver weight. There was no dose-related macroscopic evidence of toxicity at necropsy, nor alteration of hepatic PCNA or serum gastrin. However, methyl eugenol-DNA adducts were detected in hepatic DNA from both male and female rats fed the dietary admixture ( $2.85 \pm 1.19$  adducts per  $10^8$  nucleotides) in the 50 mg/kg/day group. These data indicate that dietary exposure to methyl eugenol at doses of up to 50 mg/kg per day does not appear to induce overt toxicity, but is genotoxic. References Abdo, K. DETECTION OF ELEVATED 8-HYDROXYDEOXYGUANOSINE IN FRESHLY ISOLATED MOUSE LUNG CELLS FOLLOWING *IN VIVO* TREATMENT WITH AFLATOXIN B<sub>1</sub>

K. A. Guindon, S. L. Graham, L. L. Bedard and T. E. Massey. *Pharmacology and Toxicology, Queen, Kingston, ON, Canada.*

Aflatoxin B<sub>1</sub> (AFB<sub>1</sub>) is a mycotoxin produced by some strains of *Aspergillus*, and is a recognized pulmonary and hepatic carcinogen. A well established mechanism of the carcinogenicity of AFB<sub>1</sub> is bioactivation to the AFB<sub>1</sub>-8, 9-exo-epoxide and binding to DNA to form AFB<sub>1</sub>-N<sup>7</sup>-Guanine. Another important mechanism may be the formation of reactive oxygen species during AFB<sub>1</sub> metabolism, leading to oxidative DNA damage. The objective of this study was to determine the ability of AFB<sub>1</sub> to cause oxidative DNA damage in different mouse lung cell types. The formation of 8OHdG in freshly isolated mouse lung cell digest, alveolar macrophages, alveolar type II cells, and Clara cells, resulting from *in vivo* AFB<sub>1</sub> treatment at various time points was assessed using HPLC with electrochemical detection. These cell fractions prepared by centrifugal elutriation were chosen as they have demonstrated involvement in the metabolism of AFB<sub>1</sub>. An ~6 fold increase in 8OHdG formation was demonstrated in alveolar macrophages isolated from mice treated with a single tumourigenic dose of 50 mg/kg AFB<sub>1</sub> ip and euthanized 2 h post-treatment (n=3, p<0.05). The trend observed (n=3) is an ~5 fold increase in 8OHdG formation in Clara cells and an ~4 fold increase in both alveolar type II cells and cell digest. No increase in 8OHdG formation was demonstrated at 12 h (n=3, p>0.05), 24 h (n=1), or at 48 h (n=1) post-treatment as compared to controls. These results suggest that oxidative DNA damage in mouse lung cells may contribute to the carcinogenicity of AFB<sub>1</sub>. (Supported by the Canadian Institutes of Health Research Grant No. MOP-10382)

LIPID HYDROPEROXIDE-DERIVED DNA ADDUCTS GENERATED THROUGH REDOX CYCLING OF BENZO(A)PYRENE QUINONE.

J. Xu, S. Lee and I. A. Blair. *Department of Pharmacology, University of Pennsylvania, Philadelphia, PA. Sponsor: S. Burchiel.*

Polycyclic aromatic hydrocarbons(PAHs) are ubiquitous environmental pollutants found in tobacco smoke and car exhaust. PAHs are metabolized by cytochrome P-450s(CYPs) and epoxide hydrolases to catechols, which undergo further aldo/keto reductase-mediated oxidation to quinones such as benzo[a]pyrene quinone(BPQ). BPQ can enter a futile redox-cycle in the presence of NAD(P)H. Reactive oxygen species(ROS) including H<sub>2</sub>O<sub>2</sub> and superoxide are produced and amplified through the redox cycling. We hypothesized that in the presence of transition metal ions such as Cu<sup>2+</sup>, hydroxyl radicals would be generated from H<sub>2</sub>O<sub>2</sub> through Fenton chemistry. The hydroxyl radicals could then initiate lipid peroxidation of polyunsaturated fatty acids(PUFAs). Lipid-hydroperoxides undergo homolytic decomposition to give rise to bifunctional electrophiles including malondialdehyde(MDA), 4-hydroxy-2-nonenal(4-HNE), 4-oxo-2-nonenal(4-ONE) and 4, 5-epoxy-2(E)-decenal(4, 5-EDE). These endogenous bifunctional electrophiles can modify DNA bases such as 2'-deoxyguanosine(dGuo) to form M1G-2'-deoxyribose, 1, N<sup>2</sup>-propano-dGuo, heptanone-etheno-dGuo and etheno-dGuo, respectively. We have developed stable isotope dilution liquid chromatography(LC)/mass spectrometry(MS) to quantify these adducts in the selected reaction-monitoring(SRM) mode. These experiments demonstrated that redox cycling of BPQ in the presence of arachidonic acid promoted lipid peroxidation and elevated lipid hydroperoxide

derived dGuo adducts such as etheno-dGuo and heptanone-etheno-dGuo at low to moderate concentrations of BPQ(1-10  $\mu$ M). Adduct levels declined when a high concentration of BPQ(100  $\mu$ M) was used, which suggested that further oxidation of the initially formed adducts had occurred. Etheno-dGuo is mutagenic in mammalian cells and so this study raises the possibility that mutations can result through lipid hydroperoxide-mediated damage as well as through direct BPQ adduct formation or oxidative DNA damage. Therefore, it will be important in the future to assess the relative importance of these three pathways of DNA damage. Supported by NIH CA 92537.

METABOLISM OF 7H-DIBENZO[C, G]CARBAZOLE (DBC) OR BENZO[*A*]PYRENE (BaP) IN *CYP1A2* OR *AHR* GENE KNOCKOUTS: IMPLICATIONS FOR CARCINOGENICITY.

D. Ginsburg, G. Talaska, K. LaDow, B. Schumann, A. Puga and D. Warshawsky. *Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH*.

N-heterocyclic aromatics (NHA) are a subgroup of polycyclic aromatic hydrocarbons (PAH), which are environmentally important pollutants. *Cyp1a2* is one of several genes coding for metabolic enzymes that are regulated by the aryl hydrocarbon receptor (AHR). CYP1A2 is a major constitutive enzyme in the liver and possibly skin, capable of activating both NHA and PAH. The aim of this work is to elucidate the roles of the *Ahr* and *Cyp1a2* genes in the metabolism of the NHA DBC or the PAH BaP by studying how genetic damage is affected when *Cyp1a2* or *Ahr* is inactivated in mice treated with low doses of these carcinogens. Knockout mice (*Ahr*-/- and *Cyp1a2*-/-) were bred into a C57BL/6J (*wt*) genetic background for nine generations. Twenty-four hours after their backs were shaved, mice of the three strains were treated topically with DBC 8 mg/kg or BaP 33.3 mg/kg body weight (both in 25  $\mu$ l acetone), or acetone alone. The mice were euthanized 24 hours later and skin, liver and lung tissues were excised and stored at -80°C for DNA isolation.  $^{32}$ P-postlabeling was utilized to determine DNA adducts and to compare relative adduct levels. *Cyp1a2*-/- mice showed a 50% reduction of skin BaP-DNA adduct levels compared to *wt* controls. *Ahr*-/- mice had a 90% reduction of skin BaP-DNA adduct levels. These data suggest that CYP1A2 contributes significantly to the activation of BaP to a DNA-binding species in skin, and suggest that activation genes are rapidly induced in the skin and play a significant role in the metabolism of absorbed xenobiotics shortly after exposure. These phenomena were not observed in liver, where there was a 3-fold higher constitutive level of BaP-DNA adducts in *Ahr*-/- than in *wt* or *Cyp1a2*-/- mice. There was no significant effect of either gene knockout on the levels of DBC-DNA adducts in any of the tissues. These data indicate that metabolic activation of DBC occurs independently of either the *Cyp1a2* or *Ahr* gene. [NIH R01 ES04203-16A1, Warshawsky PI]

**2268**

CHARACTERIZATION OF STABLE BENZO[*A*]PYRENE-7, 8-QUINONE-DNA ADDUCTS IN CALF THYMUS DNA.

J. A. Ross, G. Nelson, W. T. Padgett, N. Balu, G. R. Lambert and S. Nesnow. *Environmental Carcinogenesis Division, USEPA, Research Triangle Park, NC*. Sponsor: D. Wolf.

Benzo[*a*]pyrene-7, 8-dione (BPQ) is a reactive aldo-keto reductase-mediated product of B[*a*]P-7, 8-diol, a major P450/epoxide hydrolase metabolite of the multi-species carcinogen, B[*a*]P. The role of BPQ in B[*a*]P's genotoxicity and carcinogenesis is evolving. Toxicity pathways involving BPQ include the formation of both stable and unstable DNA adducts and the generation of ROS via redox cycling. To investigate the stable DNA adduct pathway, we have synthesized nucleotide-3'-phosphate-BPQ DNA adduct standards and applied these to the characterization of BPQ-DNA adducts in calf thymus DNA (CT-DNA) using  $^{32}$ P-postlabeling analyses. Previously, we reported the full characterization of four BPQ-dGuo and two BPQ-dAdo nucleoside adducts [Balu *et al.* (2004) *Chem. Res. Toxicology*, 17, 827-838]. Using similar methods of syntheses and analyses, we prepared the analogous BPQ-nucleotide adducts. BPQ was incubated with CT-DNA for 24 h at 37°C.  $^{32}$ P-Postlabeling analysis showed the formation of 5 major and 7 minor DNA adducts. Adducts were also observed following the postlabeling of synthesized 3'-dGMP-BPQ and 3'-dAMP-BPQ standards. The 3'-dGMP-BPQ1, 2 standard exhibited 2 major adducts. The 3'-dGMP-BPQ3, 4 standard exhibited 2 major and one minor adduct. One major and one minor adduct were observed in both the 3'-dAMP-BPQ1 and the 3'-dAMP-BPQ2 standards. One adduct from the 3'-dGMP-BPQ3, 4 standard co-chromatographed with a major CT-DNA adduct. Adducts from the 3'-dAMP-BPQ1 and 3'-dAMP-BPQ2 standards appear to co-chromatograph with several of the minor CT-DNA adducts. This is the first reported example of the characterization of stable BPQ-DNA adducts in mammalian DNA and will serve as the foundation for future BPQ-DNA adduct studies *in vivo*. [This abstract does not necessarily reflect EPA policy.]

INDUCTION AND PERSISTENCE OF BENZO(A)PYRENE- AND DIBENZO[*A, L*]PYRENE-DNA ADDUCTS IN DNA REPAIR-PROFICIENT AND DEFICIENT CELLS.

W. A. Spencer and D. K. Orren. *Toxicology, University of Kentucky, Lexington, KY*. Sponsor: M. Vore.

Polycyclic aromatic hydrocarbons (PAHs), ubiquitous environmental contaminants found in automobile exhaust and tobacco smoke, are implicated in the etiology of lung and other human cancers. Benzo[*a*]pyrene (BP) and dibenzo[*a, l*]pyrene (DBP) are PAHs present in tobacco smoke and have been directly linked to skin, lung and mammary gland tumorigenesis in animal models. The ultimate carcinogens, the BP- and DBP-diol epoxides, are metabolites (generated by CYP1A1/CYP1B1 and epoxide hydrolase) that subsequently react with DNA to form guanine and adenine adducts. Ongoing metabolic activation, detoxification, adduct formation and removal by repair pathways affect DNA adduct levels. PAH adducts are generally removed by nucleotide excision repair (NER). To understand the dynamics of adduct formation and removal, BP- and DBP-DNA adduct levels were compared in NER-proficient (normal) and -deficient (xeroderma pigmentosum complementation group A) human fibroblasts designed with an inducible CYP1A1 gene.  $^{32}$ P-postlabeling experiments revealed formation of 1 major/2 minor and 3 major/several minor DNA adducts by BP- and DBP-dihydrodiols, respectively, in both cell lines. These adducts were only formed when CYP1A1 was induced and were chromatographically similar to those formed by direct treatment of dG and dA with BP- and DBP-diol epoxides. DNA adduct levels following DBP-dihydrodiol treatments (1-500 nM) increased in a dose-dependent manner, ranging from 42 to 1943 adducts/109 nucleotides and were significantly higher in NER-deficient cells, suggesting some adduct removal in NER-proficient cells during the 2 hr treatment interval. DBP- and BP-dihydrodiol treatments (at 100 nM) yielded similar total adduct levels. Following carcinogen removal, DBP adducts persisted in both cell lines while BP adducts decreased with time in the NER-proficient cells. Our results suggest that the strong carcinogenicity of DBP is due to poor repair of a subset of DBP adducts ultimately leading to mutations that increase the rate of cellular transformation.

COMPARISON OF DNA ADDUCT FORMATION BETWEEN TISSUES FROM MICE TREATED WITH COMPLEX PAH MIXTURES.

T. D. Phillips, A. M. Gillespie, L. Cizmas, G. Zhou, T. J. McDonald, Y. Qian and K. C. Donnelly. *Texas A&M University, College Station, TX*.

Contaminated wood preserving waste (WPW) facilities are found throughout the United States. Common contaminants at these sites include polycyclic aromatic hydrocarbons (PAHs) and pentachlorophenol (PCP). The purpose of this study was to compare DNA adduct formation from a complex mixture (CM) with those of chemical fractions isolated from the CM. The CM was isolated from oil collected as a non-aqueous phase liquid from a contaminated aquifer at an abandoned WPW facility. An aliquot of oil was fractionated using the EPA 3650B Method, liquid-liquid extraction, to obtain acid (AF), base (BF) and neutral (NF) fractions. The NF was enriched for chlorinated dioxins (PCDDs) and polycyclic aromatic hydrocarbons (PAHs) using a mixed bed silica column, and an alumina column, respectively, followed by a carbon column. A reconstituted mixture (RM) was prepared to mimic the levels of the 7 carcinogenic PAHs (cPAHs) and PCP found in the NF. All fractions were analyzed for chemical content using a GC/MS. The results indicate the AF contained mostly phenols, the BF contained a mixture of PAHs and phenols, the NF contained PAHs and PCDDs, the PCDD fraction contained hepta and octa PCDDs along with lower molecular weight PAHs, and the PAH fraction contained higher molecular weight PAHs. The fractions were applied topically to ICR female mice for a 24 hour exposure. DNA from harvested tissues were postlabeled with  $^{32}$ P to determine bulky adduct formation. The highest level of total DNA (tDNA) adducts was observed in skin, while the lung and liver tDNA adducts were not significantly different within treatment groups. Relatively low levels of DNA adducts were observed in tissues treated with the CM, while the PAH fraction produced the highest level of adducts. The data indicate that isolation of genotoxic components from complex mixtures allows for a more complete expression of component genotoxicity.

METABOLIC ACTIVATION AND PAH-DNA ADDUCT FORMATION FROM URBAN DUST PARTICULATE MATTER (SRM 1649A) IN HUMAN MAMMARY EPITHELIAL CELLS IN CULTURE.

L. A. Courter and W. M. Baird. *Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR*.

Complex mixtures in the environment are the primary source in which humans are exposed to polycyclic aromatic hydrocarbons (PAH). It is well established that PAH such as benzo[*a*]pyrene (B[*a*]P), upon metabolic activation by cytochrome P450

(CYP) enzymes, bind to DNA and form covalent PAH-DNA adducts. These adducts can lead to mutations, which may ultimately result in cancer. In our study, the effect of complex PAH mixtures on the activation of carcinogenic PAH to DNA-binding derivatives was investigated in human mammary epithelial cells (MCF-10A). MCF-10A cells were treated for 24 and 48 h with Standard Reference Material (SRM) 1649a, a complex mixture derived from urban dust particulate matter obtained from the National Institute of Standards and Technology. Simultaneously, the cells were treated with two carcinogenic PAH, B[a]P, dibenzo[a, l]pyrene (DB[a, l]P) and an appropriate amounts of B[a]P\* (mg/ml, B[a]P present in 1 mg SRM). In addition, the individual carcinogenic PAH mentioned above were co-treated with SRM 1649a. CYP enzyme activity capable of activating B[a]P, DB[a, l]P and SRM 1649a to their reactive DNA binding derivatives were observed as measured by ethoxyresorufin-O-deethylase assay. CYP1A1 and CYP1B1 expression was confirmed by Western blot analysis. PAH-DNA adduct analysis by 33P-postlabeling and reversed-phase high-performance liquid chromatography revealed DNA adduct formation on exposure to all treatment groups. MCF-10A cells treated with SRM 1649a exhibited lower, but detectable DNA adducts in comparison with BP or BP\* at both 24 and 48h after exposure. An additive increase in DNA binding was evident with co-treatments of SRM 1649a with B[a]P, B[a]P\* or DB[a, l]P. These results suggest that components in environmental PAH mixtures can either promote or inhibit metabolic activation and DNA adduct formation, a finding relevant to assessing human cancer risk. This research was funded by NIH grant CA28825.

DIESEL EXHAUST PARTICLES CAUSE INCREASED LEVELS OF DNA DELETIONS AND DNA ADDUCT FORMATION AFTER TRANSPLACENTAL EXPOSURE IN MICE.

R. Reliene<sup>1</sup>, A. Hlavacova<sup>1</sup>, B. Mahadevan<sup>2</sup>, W. M. Baird<sup>2</sup> and R. H. Schiestl<sup>1</sup>.  
<sup>1</sup>Pathology, Environmental Health and Radiation Oncology, UCLA, Los Angeles, CA and <sup>2</sup>Environmental Molecular Toxicology, Oregon State University, Corvallis, OR.

Diesel exhaust particles (DEP) are a major source of air-borne pollution and are linked to increased risk of lung cancer. Ambient air pollution to which the increasing use of diesel-powered engines contributes significantly has been linked to adverse pregnancy outcomes. Here we investigated genotoxic effects of DEP exposure, such as DNA deletions, oxidative DNA damage and DNA adduct formation, during embryonic development in mice. Pregnant dams were orally exposed to various doses of DEP (500, 250, 125, 62.5, 31.25 mg/kg/day) at embryonic days 10.5-15.5. In the offspring, the frequency of 70 kb DNA deletions spanning exons 6-18 at the pun allele that results in black-pigmented spots in the unpigmented retinal pigment epithelium of the eye of pun/pun mice was determined. A significant increase in the frequency of DNA deletions was observed in a dose-dependent manner. Levels of 8-OH deoxyguanosine indicating oxidative DNA damage were within the limits of the unexposed mouse embryos. 33P post-labeling analysis revealed low, but detectable levels of DNA adducts in the embryo tissue. The results from this study showed that transplacental exposure to DEP leading to DNA adduct formation resulted in a significant increase in the frequency of DNA deletions to the mouse fetus and such genetic alterations in the offspring may have pathological consequences later in life.

MLH1-DEFICIENT MICE ARE HYPERSENSITIVE TO PHIP-INDUCED MUTATION AND ABERRANT CRYPT FOCI: EVIDENCE FOR DIFFERENTIAL PROCESSING OF PHIP ADDUCT MISMATCHES BY THE MISMATCH REPAIR PATHWAY.

S. Smith-Roe, S. S. Crain and A. B. Buermeyer. *Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR.* Sponsor: L. Curtiss.

Disruption of the DNA mismatch repair (MMR) pathway results in elevated mutation rates and inappropriate survival of cells bearing DNA damage. Hereditary nonpolyposis colorectal cancer is an early onset predisposition for internal cancers caused by deficiency for one of several MMR genes. MMR-deficiency is also associated with sporadic cancer. The extent to which environmental factors influence the etiology of MMR-deficient cancers is unknown. 2-amino-1-methyl-6-phenylimidazo [4, 5-*b*] pyridine (PhIP) is a mutagen and carcinogen present in cooked meat that forms DNA adducts when metabolized. To determine whether PhIP represents a cancer risk to individuals with MMR-deficiency, *MLH1*<sup>-/-</sup> mice carrying the *cII* transgene were given 8 i.p. injections of 50 mg/kg PhIP. PhIP induced 3 times more mutations in the colons of *MLH1*<sup>-/-</sup> mice compared to their wildtype littermates, indicating that MMR normally suppresses PhIP-induced mutations. Analysis of mutational spectra in wildtype and *MLH1*<sup>-/-</sup> colon revealed that GC to TA transversions, the signature PhIP mutation, were similarly induced. In contrast, *MLH1*<sup>-/-</sup> mice were hypersensitive to -1 frameshifts, GC to AT transitions, and GC to CG transversions, indicating that both the level and types of mutation induced by PhIP are de-

termined by activity of the MMR system. In cancer studies, PhIP-treated *MLH1*<sup>-/-</sup> mice were hypersensitive to induction of colonic aberrant crypt foci. Adenomas of the small intestine were not induced, despite a similar induction of mutation in the small intestine as in the colon. Cell-turnover studies of colon and small intestine are in progress to determine the importance of MLH1-dependent apoptosis in PhIP-induced carcinogenicity. These data are consistent with the hypothesis that PhIP exposure increases mutagenesis and carcinogenesis in *MLH1*<sup>-/-</sup> mice, and support further evaluation of the risk that consumption of heterocyclic amines may impart to MMR-deficient individuals.

OXIDATIVE METABOLISM OF THE SERM, RALOXIFENE LEADS TO PROTEIN COVALENT MODIFICATION.

J. Liu, Q. Li, C. Luckie, X. Yang, M. Chang, R. B. van Breemen, G. R. Thatcher and J. L. Bolton. *Medicinal Chemistry and Pharmacognosy, College of Pharmacy, University of Illinois at Chicago, Chicago, IL.*

The selective estrogen receptor modulator (SERM), raloxifene is effective in the treatment of osteoporosis in postmenopausal women and is currently in clinical trials for chemoprevention of breast cancer. Similar to other SERMs, *in vitro* studies have shown that raloxifene can be metabolized to reactive intermediates by P4503A4 leading to enzyme inactivation. We have shown that raloxifene undergoes NADPH-dependent oxidation in liver microsomes to generate catechol and quinoid reactive intermediates, which form a variety of adducts with glutathione. In order to answer the question of whether raloxifene covalently modifies proteins, we have synthesized a raloxifene congener attached to a biotin tag via a linker moiety. This is a raloxifene covert oxidatively activated tag (COATag), that is unreactive towards isolated proteins and protein components of tissue homogenates. However, after incubation with rat liver microsomes in the presence of an NADPH generating system or incubation with glutathione-S-transferase in the presence of tyrosinase, the COATag covalently modified proteins. The COATagged proteins were quantified and identified by SDS-PAGE and Western blot analysis. Four major bands were observed in the blots from microsomal incubations, for which peptide mass maps were obtained using in-gel digestion with trypsin, followed by MALDI-TOF or ESI mass spectrometric analysis of the resulting peptide mixtures. Cytosolic glucose regulated protein (78 kDa, GRP78/BiP), protein disulfide isomerase isozyme A1 (57 kDa, PDIA1), and microsomal glutathione S-transferase, (17 kDa, mGST1) were identified. These data suggest that protein modification by raloxifene may contribute to its toxicity *in vivo*. This work was supported by NIH grant CA 79870.

IDENTIFICATION OF ELECTROPHILE BINDING MOTIFS ON QUINONE-THIOETHER ADDUCTED RENAL PROTEINS.

M. E. Bowen<sup>1</sup>, M. T. Labenski<sup>1</sup>, C. Kernag<sup>1</sup>, G. Tsaprailis<sup>1</sup>, M. A. Ali<sup>2</sup>, E. A. Mash<sup>2</sup>, T. J. Monks<sup>1</sup> and S. S. Lau<sup>1</sup>. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ and <sup>2</sup>Chemistry, University of Arizona, Tucson, AZ.*

Glutathione conjugates of hydroquinone (HQGSH) produce severe renal proximal tubular necrosis and carcinogenicity in rats via a combination of protein arylation and the generation of ROS. To identify HQGSH-covalent protein adducts which may contribute to nephrotoxicity and nephrocarcinogenicity, renal proteins were subjected to SDS-PAGE, and adducted proteins detected by immunostaining with antibodies recognizing HQGSH adducted proteins. The corresponding SDS gel bands were excised, digested in gel with trypsin, and a total of 30 proteins were identified by MALDI-TOF and LC-MS/MS (Finnigan-MAT LCQ-SEQUEST and SALSA search programs). Several adducted proteins, including actin, serum albumin, transferin, glutamate-cysteine ligase catalytic subunit, moesin, and microsomal aminopeptidase N, were also identified in rat urine after HQGSH treatment. Using cytochrome c as a model protein we have previously identified the sequences GGKHKTG (23-29) and GIKKK (84-88) as binding sites for BQ, with the lysine residues participating in the formation of a novel cyclized diquinone adduct. To ascertain features that predispose certain proteins, or motifs within proteins ["electrophile binding motifs (EBM)", to chemical adduction, we searched the amino acid sequence of each adducted protein to determine for runs of lysine residues. Interestingly all 30 adducted proteins possess lysine rich sequences in two main contexts (i) lysines surrounding a likely nucleophilic amino acid (KXK), or (ii) two lysine residues preceded or followed by a nucleophilic amino acid (XKK or KKX). Such motifs are largely absent in randomly selected non-adducted proteins. In attempts to definitively identify chemically adducted EBMs within the adducted proteins we have synthesized biotinylated HQ. The biotinylated EBMs should be readily identifiable by MS-based methodologies. The potential biological/toxicological consequences of adduction to rationally selected "electrophilins" is currently under investigation. (GM39338, ES06694)

## MOLECULAR MECHANISMS OF HYDROQUINONE INDUCED APOPTOSIS.

**S. H. inayat-hussain**<sup>1, 2</sup>, V. Gogvadze<sup>3</sup>, S. Orrenius<sup>3</sup> and **D. Ross**<sup>1</sup>. <sup>1</sup>*Pharmacology Sciences, University of Colorado, Denver, CO*, <sup>2</sup>*Biomedical Sciences, Faculty of Allied Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, WP, Malaysia* and <sup>3</sup>*Toxicology Division, Karolinska Institutet, Stockholm, Sweden*.

The mechanisms by which the benzene metabolite hydroquinone(HQ) induces apoptosis are currently unclear and have therefore been investigated using Jurkat cells. HQ treatment of Jurkat cells resulted in apoptosis as assessed by loss of mitochondrial membrane potential, caspase-2 activation and cytochrome-c release after 4hr treatment. HQ-induced dissipation of mitochondrial membrane potential was inhibited by the pancaspase inhibitor benzyloxycarbonyl-Val-Ala-Asp-fluoromethyl ketone (zVAD.fmk) but not the specific caspase-2 inhibitor benzyloxycarbonyl-Val-Asp-Val-Ala-Asp-fluoromethyl ketone (zVDVAD.fmk). Whereas the proteolytic cleavage of caspase-2 as assessed by both the fluorogenic VDVAD.AFC substrate and western blotting was inhibited by zVAD.fmk and zVDVAD.fmk, release of mitochondrial cytochrome c still occurred suggesting that HQ might also target the mitochondrial independently from caspase activation. Furthermore, Bongkrekic acid, a permeability transition pore inhibitor, also failed to inhibit cytochrome c release from HQ treated cells. Estimation of Ca<sup>2+</sup> buffering capacity in digitonin-permeabilized cells treated with hydroquinone confirmed mitochondrial damage. However, benzoquinone, a metabolite of hydroquinone autoxidation, but not hydroquinone, added to isolated liver mitochondria resulted in a rapid decrease in Ca<sup>2+</sup> buffering capacity. These observations indicate that hydroquinone is not directly toxic to mitochondria but during apoptosis, mitochondrial damage could be due to formation of its autoxidation product benzoquinone resulting in a caspase-independent loss of cytochrome c release. These data provide insight into the mechanisms of hydroquinone induced apoptosis which may have important implications in the pathophysiology of benzene-induced myelotoxicity. (This work has been supported by NIH RO1 ES09554)

## BIOCHEMICAL AND MICROARRAY ANALYSES OF BUPIVACAINE-INDUCED APOPTOSIS.

**A. Unami**<sup>1, 3</sup>, Y. Shinohara<sup>2</sup>, K. Omura<sup>1</sup>, M. Matsumoto<sup>1</sup>, Y. Oishi<sup>1</sup> and Y. Baba<sup>3</sup>. <sup>1</sup>*Toxicology Research Laboratories, Fujisawa Pharmaceutical Co., Ltd., Osaka, Japan*, <sup>2</sup>*Institute for Genome Research, The University of Tokushima, Tokushima, Japan* and <sup>3</sup>*Faculty of Pharmaceutical Sciences, The University of Tokushima, Tokushima, Japan*. Sponsor: M. Takahashi.

It was recently reported that some of local anesthetics induce apoptosis in the cultured cells and that this apoptotic effect might be involved in the pathogenesis of neuro- or myotoxicity induced by local anesthetics, however, the detailed mechanism has not been clear. In this study, the mechanism by which apoptosis is induced by bupivacaine, a potent uncoupler of mitochondrial oxidative phosphorylation, was investigated using human promyelocytic leukemia cells, HL-60. Bupivacaine induced apoptotic bodies formation and DNA fragmentation in a time- and concentration-dependent manner in HL-60 cells. In good correlation with the degree of DNA fragmentation, caspase-3, -8 and -9, which play a pivotal role in the initiation and execution of receptor- or mitochondria-mediated apoptosis, were all clearly activated. However, bupivacaine induced neither mitochondrial permeability transition nor release of cytochrome c in experiments with isolated mitochondria. In microarray analysis, HSPs, c-jun and c-fos genes were up-regulated and c-myc and poly (ADP ribose) polymerase gene were down-regulated preferentially in bupivacaine-treated cells. These results suggest that direct action of bupivacaine on mitochondria does not occur and that the removal of c-myc mediated repression of apoptotic signals, decreased cellular resistance and attenuation in DNA repair may accelerate bupivacaine-induced apoptosis. These biochemical and microarray analyses are of value in developing a better understanding of the molecular mechanism of local anesthetics-induced apoptosis leading to neuro- or myotoxicity.

## 1, 1-DICHLOROETHYLENE-INDUCED MITOCHONDRIAL DAMAGE PRECEDES APOPTOTIC CELL DEATH OF BRONCHIOLAR EPITHELIAL CELLS IN MURINE LUNG.

**E. J. Martin** and **P. Forkert**. *Department of Anatomy and Cell Biology, Queen's University, Kingston, ON, Canada*.

1, 1-Dichloroethylene (DCE) causes pulmonary injury that is characterized by necrosis of bronchiolar Clara cells. Mitochondria have been identified as an early target in the toxic response. As mitochondria have been implicated in both necrotic and apoptotic cell death, we have undertaken studies to test the hypothesis that DCE induces apoptosis, in addition to necrosis, in murine lung. A primary objective is to identify the biochemical events associated with pulmonary apoptosis.

Groups of female CD-1 mice were treated with DCE (75 mg/kg, i.p.) or corn oil. Using an antibody directed against DCE-cysteine conjugates, protein adducts were detected primarily in association with mitochondria in the apices of bronchiolar Clara cells. Furthermore, morphological studies demonstrated early mitochondrial alterations in Clara cells that included severe swelling and disruption of cristae. Western blotting of lung cytosolic proteins showed greater immunoreactivity for cytochrome c in fractions from mice treated with DCE for 4 h than in controls. Immunohistochemical studies with an antibody to activated caspase-3 and TUNEL staining were used to detect apoptotic cells. In both experiments, positive reactivities were observed in the bronchiolar epithelium at 12 and 24 h after DCE treatment, whereas reactivities were absent in tissues from control animals. Finally, bronchiolar epithelial cells showing morphological criteria of apoptosis (chromatin condensation and margination) were observed at 24 h after DCE. Apoptotic-like cells were more abundant in larger bronchioles. These data suggested that DCE produces pulmonary bronchiolar apoptosis by inducing mitochondrial perturbations, causing release of cytochrome c into the cytosol and caspase activation. (Supported by Grant MOP 11706 from the Canadian Institutes of Health Research).

## TMT TOXICITY IN HIPPOCAMPAL CELLS IS ASSOCIATED WITH INDUCTION OF BAX AND iNOS EXPRESSION.

**L. zhang**, **L. li**, **K. Prabhakaran**, **J. L. Borowitz** and **G. E. Isom**. *Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN*.

Trimethyltin (TMT) is an organotin that at low doses causes selective neuronal degeneration in the central nervous system, with the hippocampus being the most sensitive area. In turn TMT toxicity has been used as a model for neurodegeneration. In this study, primary cultured hippocampal neurons and an immortalized hippocampal cell line, HT-22, were exposed to TMT to assess the extent and type of cell death. The level of cell death was time and concentration dependent and HT-22 cells were more sensitive than primary neurons. TMT-treated cells exhibited apoptotic death as demonstrated by TUNEL staining, flow cytometry, DNA gel electrophoresis and increased caspase-3-like activity. The insult was abolished by the pan-caspase inhibitor z-VAD-FMK, indicating TMT-induced a caspase-dependent apoptosis. The cytotoxicity was characterized by an increase in reactive oxygen species (ROS) generation and reduction of mitochondria membrane potential ( $\Delta\Psi_m$ ). These actions were involved in the apoptosis since scavenging of ROS by free radical trapping agent, N-tert-butylnitron (PBN) or inhibition of the permeability transition pore opening with cyclosporin A, produced significant protection of HT-22 cells. TMT upregulated the expression of pro-apoptotic protein Bax and this was partly blocked by PBN. Also, immunoblot analysis showed an increased expression of iNOS after TMT treatment, which was associated with enhanced nitric oxide (NO) generation. Treatment with NG-monomethyl-L-arginine (L-NMMA), a specific inhibitor of iNOS, significantly decreased neuronal death and blocked the changes of Bax levels and caspase-3-like activity. It was concluded that ROS generation served as an initiator of the TMT-induced apoptotic cascade in which iNOS and Bax expression were upregulated and subsequent loss of  $\Delta\Psi_m$  led to caspase-executed cell death.

## GENDER -SPECIFIC DIFFERENCES IN APOPTOTIC INDICES IN RAT LIVER AFTER CHRONIC ETHANOL CONSUMPTION.

**T. V. Curry-McCoy**<sup>2</sup>, **R. L. White**<sup>1</sup>, **S. L. Toderi**<sup>1</sup> and **T. M. Donohue**<sup>1</sup>.

<sup>1</sup>*Research, VA Medical Center, Omaha, NE* and <sup>2</sup>*Pathology/Microbiology, University of Nebraska Medical Center, Omaha, NE*. Sponsor: **R. Pollenz**.

Chronic ethanol consumption causes liver injury and significant gender differences in susceptibility to liver damage have been demonstrated in males and females. Our aim was to determine whether the differential liver injury due to ethanol administration in males and females was due to enhanced apoptosis. We employed an oral ethanol feeding model in which fish oil was the major source of fat. Liver damage was evaluated in part by apoptotic indices, including the relative activities, in soluble fractions of the lysosomal cathepsins B and L, which indicate lysosomal leakage, which in turn, can initiate an apoptotic cascade. Male and female Wistar rats were pair-fed control and ethanol liquid diets for 8 weeks. At sacrifice, livers were homogenized. Subcellular fractions were prepared to determine the distribution of lysosomal cathepsins B and L in the particulate (mitochondrial/lysosomal) and soluble (cytosol) fractions. The content of cytochrome c, an indicator of mitochondrial damage and apoptosis was also assessed. Male and female ethanol-fed rats exhibited enlarged livers, and higher hepatic protein content than their controls. In both genders the total cathepsin B and L activities were the same in control and ethanol-fed rats. However the activities of these lysosomal enzymes in the cytosolic fraction (calculated as a percent of the total in lysosomes and cytosol) was 60% to two-fold higher in ethanol-fed females ( $p=0.03$ ) than their pair-fed controls, while no difference was detected in cathepsin B or L distribution in male rats. Similarly, cytochrome-c levels, calculated as a percent of that in the mitochondrial fraction, was

elevated three-fold in ethanol-fed female rats (compared with controls) while there was no significant increase in males. From these data we conclude that female rats consuming ethanol exhibited more severe liver damage than males and that part of this damage may have occurred due to enhanced apoptosis.

**2281** CALYCULIN A, A PP1/PP2A INHIBITOR, DELAYS APOPTOTIC SIGNALING IN TGHQ-TREATED HL-60 CELLS.

M. Yang, S. S. Lau and T. J. Monks, *Pharmacology and Toxicology, University of Arizona, Tucson, AZ*.

2, 3, 5-tris-(Glutathion-S-yl)hydroquinone (TGHQ) is present in the bone marrow of rats and mice co-treated with hydroquinone and phenol, hematotoxic metabolites of benzene. TGHQ is also hematotoxic in rats, and induces DNA damage, growth arrest, and apoptosis in human promyelocytic leukemia (HL-60) cells. During TGHQ-induced apoptosis of HL-60 cells, reactive oxygen species (ROS) generation occurs and thioredoxin but not glutathione, is oxidized. Cytochrome c is released into cytosol from the mitochondria, concomitant with the dephosphorylation of Bcl-2 pS70 and Bax translocation into the mitochondria, in the absence of a disruption of mitochondrial inner membrane potential. We now show that secondary mitochondria-derived activator (Smac) is also released from mitochondria into the cytosol along with cytochrome c, and that X-linked inhibitor of apoptosis protein (XIAP) and pro-apoptotic Bid are cleaved by active effector caspases. Calyculin A, a PP1/PP2A inhibitor, delays the translocation of Bax to the mitochondria and enhances phosphorylation of Bcl-2 and Bad, leading to a delay in the release of cytochrome c and Smac into the cytosol. Subsequently the cleavage of initiator caspase 9 and the processing of effector caspase 3 are both delayed, resulting in a concomitant delay in the activation of caspase 3. The mechanism by which calyculin A delays the processing of caspase 3 is under investigation. Finally, phosphatidyl serine externalization is delayed in HL-60 cells treated with a combination of TGHQ and calyculin A. These data indicate that calyculin A protects cells from TGHQ-induced apoptosis via pre-mitochondrial-mediated effect. (ES09224 and ES06694).

**2282** SINGLE-WALLED CARBON NANOTUBES ACTIVATE RAW 264.7 MACROPHAGES: ROLE IN OXIDATIVE STRESS AND INFLAMMATORY RESPONSE.

A. I. Potapovich<sup>1</sup>, A. N. Osipov<sup>1</sup>, E. R. Kisin<sup>2</sup>, D. Schwegler-Berry<sup>2</sup>, A. A. Shvedova<sup>2</sup> and V. E. Kagan<sup>1</sup>. <sup>1</sup>*Department of EOH, Center for Free Radical & Antioxidant Health, University of Pittsburgh, Pittsburgh, PA* and <sup>2</sup>*Pathology & Physiology Research Branch, NIOSH, Morgantown, WV*.

Single-walled carbon nanotubes (SWCNT) are an important member of nanomaterials with potentially broad range of revolutionary applications. Unprocessed SWCNT could become airborne and potentially reach lungs. Yet their pulmonary toxicity remains poorly characterized. The most commonly used technology in the manufacturing of SWCNT is catalytic disproportionation of gaseous CO on catalytic iron particles. Thus, SWCNT usually contain significant amounts (upto 40 wt%) of iron that may act as a catalyst of oxidative stress. Because inflammation induced by SWCNT provides a redox environment in which iron can fully realize their pro-oxidant potential, a combination of inflammatory response with catalytically-competent iron-containing SWCNT may synergistically enhance damage to cells and tissue. The primary responder that initiates inflammatory reaction to particle challenge is the pulmonary macrophages. Therefore, we used RAW 264.7 macrophages as a cell culture model to characterize the ability of these cells to respond to SWCNT with different levels of iron. Using EPR spectroscopy we found that non-purified in contrast to purified SWCNT displayed a broad signal attributable to high spin Fe<sup>3+</sup> in a distorted tetrahedral environment. Co-incubation of macrophages with SWCNT resulted in their engulfment detectable by TEM. Depletion of GSH and an increased number of apoptotic cells in response to SWCNT was observed. No intracellular production of superoxide (O<sub>2</sub><sup>·</sup>) or NO<sup>·</sup> was triggered by SWCNT as evidenced by flow cytometry. Iron-rich (but not iron-deplete) SWCNT effectively catalyzed conversion of extracellularly generated O<sub>2</sub><sup>·</sup> into hydroxyl radicals after zymosan activation of macrophages or in the presence of xanthine oxidase/xanthine as documented by EPR. Both iron-rich and iron-deplete SWCNT stimulated release of pro-inflammatory and fibrogenic cytokines IL-6 and TGF- $\beta$ , respectively. Supported by NIH HL70755.

**2283** PHYSICAL AND CHEMICAL INTERACTION BETWEEN CARDIOLIPIN AND CYTOCHROME C.

N. A. Belikova<sup>1,2</sup>, A. N. Osipov<sup>1,2</sup>, A. A. Kapralov<sup>1,2</sup>, M. V. Potapovich<sup>1,2</sup> and V. E. Kagan<sup>1,2</sup>. <sup>1</sup>*Center for Free Radical and Antioxidant Health, University of Pittsburgh, Pittsburgh, PA* and <sup>2</sup>*Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA*.

Cytochrome C (Cyt c), an electron carrier between respiratory complexes III and IV of mitochondria, regulates apoptosis by triggering caspase cascades. Because release of Cyt c during mitochondrial membrane permeabilization requires oxidation

of cardiolipin (CL), we studied binding and redox interactions of CL with Cyt c. Incubation of Cyt c in the presence of different molecular species of CL (tetraoleoyl-, tetralinoleoyl- and bovine heart CL) yields complexes with peroxidase activity as evidenced by EPR spectroscopy of etoposide radicals formation and fluorescence responses of from oxidation of 2', 7'-dichlorofluoresceine, H2DCF to DCF. Neither saturated CL species (tetramyristoyl-CL) nor phosphatidylcholine elicited peroxidase activity of Cyt c. We further quantified binding of Cyt c with CL by monitoring the effects of acridine orange 10-nonyl bromide (nonyl acridine orange, NAO), a known binder of CL ( $K_b=2\cdot10^6$  M<sup>-1</sup>), on Cyt c-CL complexes formation detectable by non-denaturing PAGE as well as agarose electrophoresis. We found that Cyt c binds unsaturated CL with high affinity ( $K_b$  in the range of  $K_b=1\cdot7\cdot10^9$  M<sup>-1</sup>). Staining of the gels for protein (Coomassie Blue), lipid (Sudan black B) and peroxidase activity (3, 3'-diaminobenzidine) revealed that only lipid-containing Cyt c-CL complexes possessed peroxidase activity. Neither Cyt c alone nor CL liposomes exerted peroxidase activity. We conclude that high-affinity binding of CL with Cyt c forms a complex with potent peroxidase activity capable of regulating H<sub>2</sub>O<sub>2</sub> at the expense of oxidation of different reductants in mitochondria. Normally, the complex functions as an antioxidant protector and removes oxidants generated by electron transport. In apoptosis, excessive production of superoxide and H<sub>2</sub>O<sub>2</sub> causes oxidative stress, CL oxidation, thus facilitating membrane permeabilization. Supported by NIH HL70755.

**2284** CARDIOLIPIN DESTABILIZES CYTOCHROME C IN MITOCHONDRIA AND MAKES ITS CATALYTIC SITE ACCESSIBLE TO SMALL LIGANDS: ROLE IN APOPTOSIS.

Ritov<sup>1</sup>, A. M. Choi<sup>3</sup>, S. W. Ryter<sup>3</sup> and V. E. Kagan<sup>1,2</sup>. <sup>1</sup>*Center for Free Radical & Antioxidant Health, University of Pittsburgh, Pittsburgh, PA*, <sup>2</sup>*Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA* and <sup>3</sup>*Department of Pulmonary Medicine and Surgery, University of Pittsburgh, Pittsburgh, PA*.

A small fraction of cyt c in mitochondria is tightly anchored to cardiolipin (CL) yielding conformationally destabilized cyt c. The latter acts as a CL-activated peroxidase that oxidizes polyunsaturated CL. Expression of peroxidase activity (PXA) of cyt c/CL complex (CCC) does not require the disruption of the hexa-coordinated form of cyt c and is evident before the characteristic absorbance band (700 nm) of Met80-heme disappears. Low temperature EPR spectroscopy revealed the formation of penta- and hexa-coordinated forms of CCC in the presence of Angel's salt. Heme-nitrosylated forms of CCC were also detectable after decay of its oxo-ferryl-associated tyrosyl radicals upon exposure to H<sub>2</sub>O<sub>2</sub> and then to Angel's salt. Conformational rearrangements and increased accessibility of the catalytic site to small ligands (H<sub>2</sub>O<sub>2</sub>, NO, NO<sup>·</sup>) is the major prerequisite for the CCC's PXA followed by the disruption of Met80-heme coordination bond. The latter was detectable by disappearance of its characteristic absorbance accompanied by heme degradation (accumulation of EPR signal with g=4.3, decrease of Soret band) dependent on the accessibility of heme to H<sub>2</sub>O<sub>2</sub>. One-electron reduction/oxidation of cyt c was not affected by CL. Unlike NO<sup>·</sup>, CO did not exert any significant binding with the reduced CCC and did not affect its PXA. Given that CL oxidation is critical for cyt c release, our results suggest that PXA of CCC is an important mechanism of mitochondrial apoptotic machinery and its modulation by small ligands such as NO<sup>·</sup> regulates apoptosis. Supported by NIH HL70755 and HL070807.

**2285** BLOCKADE OF N-METHYL-D-ASPARTATE RECEPTORS BY KETAMINE PRODUCES LOSS OF MONKEY FRONTAL CORTICAL NEURONS IN CULTURE.

C. Wang<sup>1</sup>, N. Sadovova<sup>3</sup>, X. Fu<sup>2</sup>, A. Scallet<sup>1</sup>, L. Schmued<sup>1</sup>, J. Hanig<sup>4</sup> and W. Slikker<sup>1</sup>. <sup>1</sup>*Division of Neurotoxicology, NCTR/FDA, Jefferson, AR*, <sup>2</sup>*Charles River Laboratories, Jefferson, AR*, <sup>3</sup>*Division of Biochemical Toxicology, NCTR/FDA, Jefferson, AR* and <sup>4</sup>*CDER/FDA, Rockville, MD*.

Ketamine, a noncompetitive N-methyl-D-aspartate (NMDA) receptor antagonist, has been used as a general pediatric anesthetic for surgical procedures in infants. Recent data suggest that anesthetic drugs may cause neurodegeneration, and there is also decreased expression of polysialic acid neural cell adhesion molecule (PSA-NCAM) in rodents treated with NMDA antagonists during development. The purpose of this study is to determine the robustness of ketamine-induced developmental neurotoxicity using newborn rhesus monkey frontal cortical culture and also to determine if dysregulation of NMDA receptor subunits promotes ketamine-induced apoptosis. Frontal cortical cultures were incubated for 24 hrs with 1, 10 or 20  $\mu$  M ketamine alone or co-incubated with ketamine and either NR1, NR2A, or NR2B antisense oligonucleotides (2  $\mu$ M). After washout of ketamine, cultures were kept in serum and glutamate-containing medium for 24 hrs. Ketamine (10 and 20

$\mu\text{M}$ ) caused a marked reduction in immunostaining for PSA-NCAM, a substantial increase in DNA fragmentation as measured by cell death ELISA, increased TUNEL-positive cells, a reduction in mitochondrial metabolism of MTT and a significantly increased release of lactate dehydrogenase. NR1 and NR2A, but not NR2B, antisenses protected the neurons from ketamine-induced degeneration. Western analysis showed that neurotoxic concentrations of ketamine resulted in a decrease in PSA-NCAM expression. NR1 and NR2B antisenses prevented this effect of ketamine, suggesting that ketamine-induced cell death is associated with a compensatory upregulation of the NMDA receptor. These data suggest that NR1 and NR2A antisenses offer neuroprotection from enhanced degeneration *in vitro*, and cortical cell death induced by ketamine negatively impacts cortical synaptogenesis, a process important in normal neural development. Supported by NCTR/FDA.

### ACTIVATION OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA ENHANCES HEPATOCYTE APOPTOSIS.

S. Xiao<sup>1</sup>, S. P. Anderson<sup>2</sup>, C. Swanson<sup>1</sup>, R. Bahnemann<sup>3</sup>, K. A. Voss<sup>4</sup>, A. J. Stauber<sup>1</sup> and J. C. Corton<sup>5,1</sup>. <sup>1</sup>CIIT, Research Triangle Park, NC, <sup>2</sup>GSK, Research Triangle Park, NC, <sup>3</sup>BASF Ludwigshafen, Germany, <sup>4</sup>USDA, Athens, GA and <sup>5</sup>ToxicoGenomics, Chapel Hill, NC.

Chronic exposure to peroxisome proliferators (PP) leads to increased incidence of liver tumors in rodents. Liver tumor induction is thought to require increased hepatocyte proliferation and suppression of apoptosis. Transcript profiling showed increased expression of pro-apoptotic genes and decreased expression of anti-apoptotic genes in the livers of mice exposed to the PP WY-14, 643 (WY). We tested the hypothesis that prior exposure to WY would increase susceptibility to apoptosis inducers such as Jo2, an antibody which activates the Fas (Apo-1/CD95) death pathway. When compared to their untreated counterparts, wild-type mice pretreated with WY exhibited increased caspase-3 activation and hepatocyte apoptosis following challenge with Jo2. Livers from WY-treated PP-activated receptor alpha (PPARalpha)-null mice were resistant to the effects of Jo2. In the absence of Jo2, wild-type mice treated with WY exhibited increases in the activated form of caspase-9. As caspase-9 is a component of the apoptosome, we examined the expression of upstream effectors of apoptosome activity including members of the Bcl-2 family. Only the levels of the anti-apoptotic Mcl-1 transcript and protein were significantly altered by PP. The effects of PPARalpha activation on apoptosis were not specific to Jo2 as PPARalpha-null mice were also resistant to another treatment that induces hepatocyte apoptosis. These results 1) demonstrate that PPARalpha activation increases sensitivity of hepatocytes to apoptosis, 2) imply that PP exposure does not consistently lead to suppression of apoptosis in hepatocarcinogenesis and 3) identify a mechanism by which PPARalpha could serve as a pharmacological target in diseases where apoptosis is a contributing feature.

## 2287

### METABOLISM OF NITRO-PAHS ELICITS APOPTOTIC AND NECROTIC RESPONSES IN HEPA 1C1C7 CELLS.

N. Asare<sup>1</sup>, K. Ask<sup>2</sup>, N. Landvik<sup>1</sup> and J. A. Holme<sup>1</sup>. <sup>1</sup>National Public Health Institute, Oslo, Norway and <sup>2</sup>Macmaster University, Hamilton, ON, Canada. Sponsor: E. Dybing.

Polycyclic aromatic hydrocarbons (PAHs) and nitro-PAHs are widespread environmental pollutants formed during incomplete combustion of organic material. Some of these PAHs have been found to be mutagenic/ carcinogenic and implicated in the increased frequency of lung cancers in humans. We focused on elucidating the possible mechanisms involved in the metabolic activation and toxic effects of 1-nitropyrene (1-NP) and its amine metabolite 1-aminopyrene (1-AP), in comparison to the pneumotoxic antiandrogen, nilutamide (NIL) and its amine metabolite (NAM) in Hepa 1c1c7 cells. In cell-free systems 1-NP and NIL were nitro-reduced in a time, concentration and protein dependent fashion. The reaction was exclusively anaerobic and required both FMN and NADPH as co-factors. HPLC analyses revealed among others that the nitro moieties of 1-NP and NIL were reduced to the corresponding amine derivatives. Based on mass spectra, UV absorption and retention times, we show that NIL is metabolised to the N-hydroxy derivative as well. Other uncharacterised metabolites were also observed under aerobic conditions in whole cell cultures. Use of relevant inhibitors suggests NOS, but not CYP enzymes are involved in the metabolic activation of these nitroarenes. 1-NP appears to be slightly more potent than 1-AP with an average cell death of 35% at 60 $\mu\text{M}$  and a 24h exposure. In contrast, NAM was slightly more potent than the parent compound NIL; causing an average cell death of 70% at 10 $\mu\text{M}$ . The arenes also caused a significant decrease in G1 and doubling of cells at S-phase. Western analyses revealed that all the arenes increased the phosphorylation of p53, p38 and JNK. Interestingly, the levels of both pro-apoptotic Bax as well as anti-apoptotic Bcl-2/Bcl-xL were increased. Survival signals such as increased phosphorylation of Akt and Bad were also observed. Taken together, the relative potencies of the compounds to activate the studied apoptotic and anti-apoptotic signals could only partly explain their apoptotic effects.

## 2288

### THE ROLES OF MITOCHONDRIA AND CASPASE-6 IN 7,12-DIMETHYL-BENZ[ $\alpha$ ]ANTHRACENE-INDUCED BONE MARROW B CELL APOPTOSIS.

J. K. Emberley<sup>1</sup>, L.J. Schlezinger<sup>2</sup>, H. Ryu<sup>2</sup> and D. H. Sher<sup>2</sup>. <sup>1</sup>Microbiology, Boston University School of Medicine, Boston, MA and <sup>2</sup>Environmental Health, Boston University School of Public Health, Boston, MA.

Polycyclic aromatic hydrocarbons, common environmental pollutants, are known to cause immunosuppression and carcinogenesis. 7, 12-dimethylbenz[ $\alpha$ ]anthracene (DMBA) treatment induces bone marrow B cell apoptosis *in vitro* and reduced bone marrow cellularity *in vivo*. We have recently shown that caspase-8 plays a role in the DMBA-induced apoptosis of bone marrow pro-B cells and a non-transformed pro/pre-B cell line (BU-11), but it does not appear to be the initiator of the caspase cascade. Here we investigate the role of mitochondria in DMBA-induced apoptosis and how its activation leads to caspase-8 activation. Cytochrome c release from mitochondria begins within 6 hr of DMBA treatment concurrent with caspase-9 activation. 3, 3'-dihexyloxacarbocyanine iodide (DiOC<sub>6</sub>(3)) staining shows a loss of mitochondrial membrane potential; however this change is small, occurs after cytochrome c release, and is unaffected by caspase inhibitors. Consistent with an important role for caspase-9 is the significant suppression of apoptosis by the caspase-9 peptide inhibitor LEHD-FMK. Activation of caspase-9 is followed by formation of active caspase-3, -6 and -8 fragments, as well as cleavage of their respective substrates -fodrin, lamin A and Bid. IETD-FMK suppresses DMBA-induced apoptosis and this could be interpreted to suggest that caspase-8 is the apical caspase; however, VAD-FMK, DEVD-FMK and IETD-FMK all block the formation of active caspase-8 fragments, suggesting that caspase-8 activation occurs downstream. The fact that IETD-FMK blocks lamin A cleavage supports a role for caspase-6 in DMBA-induced apoptosis and suggests that caspase-8 is activated by caspase-6. We conclude that DMBA-induced pro/pre-B cell apoptosis is initiated by mitochondrial permeabilization but not membrane potential loss, is dependent upon caspase-9 activation, and is amplified by caspase-6-dependent caspase-8 activation. This work is supported by grants RO1-ES06086 and P01-ES11624.

### AMELIORATION OF PARAQUAT AND CADMIUM CHLORIDE INDUCED APOPTOSIS BY $\kappa$ -CARRAGEENAN IN RAT PLEURAL MESOTHELIAL CELL CULTURES.

P. Kanade and J. M. Cerreta. Department of Pharmaceutical Sciences, Saint John's University, Jamaica, NY. Sponsor: L. Trombetta.

Pulmonary fibrosis can be the end result of exposure to cadmium chloride and paraquat. It is known that apoptosis induced by such toxicants plays a key role in the pathogenesis of this disease. The hypothesis underlying the current investigation is that apoptosis induced by such toxicants can be ameliorated by  $\kappa$ -carrageenan (derived from Eucheuma cottonii). The working concentrations for both toxicants were established by MTT cytotoxicity assay in cultures of rat pleural mesothelial cells (RPMC). The protective effect of  $\kappa$ -carrageenan was assessed at 1, 5, 10  $\mu\text{g}/\text{ml}$  with 1 hour incubation prior to the addition of the toxicant. Induction of apoptosis was confirmed by assessing the increased activity of apoptotic markers using the caspase-3 enzyme activity assay, single stranded DNA (ssDNA) Apoptosis ELISA assay and TUNEL assay. Similarly, the protective effect of  $\kappa$ -carrageenan was assessed by such methods. 20 $\mu\text{M}$  of cadmium chloride and 10 $\mu\text{M}$  of paraquat resulted in approximately 50% cell viability following 24 hours incubation with the toxicants and thus these two concentrations were selected for the study. 5 $\mu\text{g}/\text{ml}$  of  $\kappa$ -carrageenan resulted in approximately 50% modulation of toxicity with respect to the treatment and this concentration was selected for the study. There was a significant increase in the concentration of DEVD-pNA cleavage products in cultures treated with toxicants as compared to control cultures. ssDNA analysis revealed a significant increase in single stranded DNA in toxicant treated cultures as compared to controls. TUNEL assay of toxicant treated cultures indicated a statistically significant increase in TUNEL positive cells as compared to control cultures. Treatment with  $\kappa$ -carrageenan followed by toxicant exposure reduced by approximately 50% caspase-3 enzyme activity, formation of ssDNA and TUNEL positive cells in cultures as compared to toxicant treated cultures. Cadmium chloride and paraquat induced apoptosis in RPMC and such apoptosis can be ameliorated by prior treatment with  $\kappa$ -carrageenan.

### STUDY ON THE TOXICITY OF CADMIUM AND THE PROTECTIVE EFFECT OF FOOD COMPONENTS IN CELLS WITH HORMONE RECEPTORS.

T. Kim, T. Kang, H. Moon, I. Kang, Y. Lee and S. Han. Endocrine Toxicology Division, National Institute of Toxicological Research, Seoul, South Korea.

Cadmium, a human carcinogen, can induce toxicity in various cell lines and organs. Despite extensive research, the mechanisms of cadmium-induced apoptosis and cell arrest are poorly understood, and its toxicity and estrogenic potential in

human are not clear. This study was performed to investigate cadmium induced apoptosis and cell arrest on human breast cancer cells or human normal breast cells: MCF-7 cells, an estrogen receptor (ER) positive breast cancer cells, MDA-MB-231 cells, an ER negative breast cancer cells and MCF10A, human normal breast cells. MCF10A cells proved to be somewhat more sensitive (IC<sub>50</sub>= 100 uM at MCF-7 cells, 120 uM at MDA-MB-231 cells and 80 uM at MCF10A cells). All cells were treated with cadmium 100uM for 12hrs, and the apoptosis was determined by DNA fragmentation and DAPI staining. Our results showed that MCF-7 cells and MDA-MB-231 cells were arrested in S phase by flow cytometric analysis and G2/M phase and induced expression of p21 and p27 proteins by Western analysis after treated CdCl<sub>2</sub>. The expression of Cyclin A and Cdk2 proteins decreased in MCF-7 cells but no effect in MDA-MB-231 cells. The expression of Cyclin B1 and Cdc2 proteins decreased in MDA-MB-231 cells. ERK phosphorylation induced by cadmium (100uM). Co-treatment of zinc (100uM, 12hrs) recovered the cadmium-induced cell arrest in both cells. Also Our data showed that the cadmium induced apoptosis and cell arrest in human breast cancer cells by oxidative stress and antioxidants such as zinc inhibited cadmium-induced apoptosis and cell arrest.

DIFFERENTIATION OF CISPLATIN-INDUCED DNA DAMAGE AND APOPTOSIS BY PHOSPHORYLATION OF HISTONE H2AX.

X. Feng<sup>1</sup>, A. Modi<sup>2</sup>, K. Stams<sup>3</sup> and P. Lord<sup>1</sup>. <sup>1</sup>*Johnson & Johnson PRD, Raritan, NJ*, <sup>2</sup>*Columbia University, New York City, NY* and <sup>3</sup>*AstraZeneca Pharmaceuticals LP, Waltham, MA*. Sponsor: C. Wang.

The mechanisms of how cisplatin induced DNA damage leads toward cell death are beginning to be unravelled. Recent studies have shown that Histone H2AX, a universal component of chromatin structure in all eukaryotes, is phosphorylated on its Serine139 residue in response to different types of DNA damage such as DNA double strand breaks and hydroxyurea- or UV- induced replication blocks. In the present study, the phosphorylation of Histone H2AX induced by cisplatin and its clinically inactive isomer transplatin was compared by flow cytometric and immunoblotting methods. Both methods indicated that cisplatin is at least 100-fold more potent than transplatin in induction of phosphorylation of Histone H2AX. The time course study using Jurkat cells demonstrated that the significant elevation of phosphorylated Histone H2AX occurred about 4 hours after exposure to 30 mM cisplatin, earlier than cisplatin induced caspase activation, orientation change of phospholipids on cell membrane and DNA fragmentation during apoptosis. It is known that the tumor suppressor p53 protein plays an important role in response to DNA damage via a change of its intracellular level. Interestingly, after the treatment of cisplatin, the pattern of elevation of p53 is different from the formation of phosphorylated Histone H2AX. In response to cisplatin, the intracellular level of p53 was continuously elevated and peaked at 4 hours, whereas the increase of phosphorylated Histone H2AX was biphasic and reached its first peak about 1.5 hours followed by a decrease to basal level and initiation of a second increase. This study implies that, unlike the accumulation of p53, the change of phosphorylated Histone H2AX in the cells exposed to cisplatin reflects two different stages toward cell death. The first change might be an early indicator for the formation of the cisplatin-induced DNA lesion and the second increase might indicate activation of the apoptotic pathway in response to the cisplatin-induced damage.

**2292**

CISPLATIN-INDUCED APOPTOSIS OF GC1 TESTICULAR GERM CELLS MAY OCCUR BY AN AUTOCRINE MECHANISM INVOLVING FASL/FAS- OR TRAIL/DR5-MEDIATED SIGNALING.

Y. Ye and J. H. Richburg. *College of Pharmacy, The University of Texas at Austin, Austin, TX*.

Male infertility is a concern for patients who undergo cancer chemotherapy because testicular germ cells appear to be as sensitive to elimination by chemotherapeutic drugs as tumor cells. Recent evidence indicates that the Fas-associated apoptotic-signaling pathway plays a role in cisplatin-induced testicular germ cell loss. Previously it has been suggested that Sertoli cells, through a paracrine interaction via their expression of FasL, mediate the apoptotic elimination of Fas-expressing germ cells. To investigate the participation of the Fas- and DR5-death receptor signaling pathways in cisplatin-induced germ cell apoptosis, we utilized the spermatogonia-derived cell line, GC1, as an *in vitro* model system. Cisplatin (0.1-10  $\mu$ M) caused time- and dose-dependent increases in apoptosis in GC1 cells with the highest amount of apoptosis observed with a dose of 10  $\mu$ M after 24 hours. Surprisingly, by immunohistochemical analysis, we found that GC1 cells not only express Fas and DR5, but they also express their cognate ligands; FasL and TRAIL. Western blot analysis revealed that exposure to 10  $\mu$ M cisplatin for 24 results in a 53% increase in FasL protein levels over control values whereas TRAIL levels did not change. In contrast, both Fas and DR5 protein levels were increased 2-fold by 24 h after exposure. In addition, as early as 12 hours after cisplatin (10  $\mu$ M) exposure, a

significant increase of cleaved caspase-3 could be measured. The robust up-regulation of these two death-receptor signaling pathways indicates their potential participation in triggering germ cell apoptosis after cisplatin treatment. Furthermore, the intriguing finding that both the death receptors investigated and their ligands are expressed in the same germ cell type points to the possibility that cisplatin-stimulated germ cell death is triggered by an autocrine mechanism. (Supported, in part, by grants from the Lance Armstrong Foundation, NIH/NIEHS ES09145 and ES07784).

**2293**

A DECREASE IN AKT LEVELS CORRELATES WITH SENSITIVITY TO ARSENIC-INDUCED GROWTH INHIBITION.

M. Colombo, W. H. Miller and K. K. Mann. *Lady Davis Institute for Medical Research, McGill University, Montreal, QC, Canada*.

Arsenic trioxide ( $As_2O_3$ ) is a highly toxic agent that has proven to be effective against acute promyelocytic leukemia (APL). The mechanisms of action of  $As_2O_3$  involve the induction of apoptosis through the stress-activated c-Jun N-terminal kinase (JNK) in NB4 cells (an arsenic-sensitive APL cell line). However, resistance arises after treatment with  $As_2O_3$ , and the mechanisms underlying this resistance are poorly understood. Herein, we investigated the role for the anti-apoptotic protein kinase, Akt, in the development of this resistance. Akt, a serine/threonine protein kinase, plays an important role in mediating cell survival signals coming through phosphoinositide 3-kinase (PI3K). It may also inhibit the JNK pathway. If the JNK pathway is activated to a pro-apoptotic state by arsenic, decreased Akt protein levels might further activate JNK and promote cell death. Our results show that  $As_2O_3$  decreases total Akt mRNA and protein expression in NB4 cells, but not in the  $As_2O_3$ -resistant cell lines. Kinase assays for Akt activity show a corresponding decrease in Akt activity in NB4 cells. Furthermore, when treated with  $As_2O_3$  in combination with wortmannin (WM), an inhibitor of PI3K and thus Akt, NB4 cells and resistant cells exhibit increased sensitivity to the cytotoxic effects of  $As_2O_3$ .  $As_2O_3$  treatment also affects Akt in other cell types. Indeed, in MDA-MB-468, a breast cancer cell line overexpressing activated Akt, we show a decrease in the protein levels following  $As_2O_3$  treatment, which correlates with an  $As_2O_3$ -dependent growth inhibition. However, in MDA-MB-231 cell, a breast cancer cell line expressing normal levels of activated Akt, these effects are not observed. Taken together, our results suggest that Akt protein is a pro-survival factor that plays a role in  $As_2O_3$  resistance.

CARDIOLIPIN IS A PREFERRED SUBSTRATE FOR CYTOCHROME C INDUCED OXIDATION DURING INTRINSIC APOTOSIS.

V. A. Tyurin<sup>1</sup>, Y. Y. Tyurina<sup>1</sup>, A. A. Lysytsya<sup>1</sup>, A. A. Amoscato<sup>2</sup>, L. Jiang<sup>1</sup>, Q. Zhao<sup>1</sup>, M. Zou<sup>1</sup>, V. B. Ritov<sup>3</sup> and V. E. Kagan<sup>1</sup>. <sup>1</sup>*Department of Environmental and Occupational Health, Center for Free Radical and Antioxidant Health, University of Pittsburgh, Pittsburgh, PA*, <sup>2</sup>*Mass Spectrometry Facility, University of Pittsburgh, Pittsburgh, PA* and <sup>3</sup>*Department of Medicine, University of Pittsburgh, Pittsburgh, PA*.

We used an oxidative lipidomics approach to assess oxidation of different lipid classes in cells during intrinsic apoptosis. The protocol is based on 2D-HPTLC separation of phospholipids (PLs), their hydrolysis by phospholipase A2 and analysis of fatty acid hydroperoxides (FA-OOHs). FA-OOHs are reacted with a fluorogenic substrate, Amplex Red, in the presence of microperoxidase 11 to stoichiometrically yield hydroxy fatty acids and resorufin. The latter is assayed by fluorescence HPLC according to our newly developed assay. ESI-MS analysis of oxygenated molecular species of PLs was performed using a triple-quadrupole tandem mass spectrometer equipped with an electro spray interface. In model experiments, we used tetralinoleoyl-cardiolipin, the most abundant molecular species of cardiolipin (CL) in mitochondria as a reactive substrate. When tetralinoleoyl-CL/cyt c complex was incubated with H<sub>2</sub>O<sub>2</sub>, several oxygenated species, including those containing mono-, di, and tri-hydroperoxides of CL and its hydroxy-derivatives, were detected. We further found that CL underwent a remarkable and selective oxidation after stimulation of human myelogenous leukemia HL-60 cells or mouse embryonic fibroblasts with pro-apoptotic stimuli, staurosporine and actinomycin D. More abundant and more unsaturated PLs, phosphatidylethanolamine and phosphatidylcholine, remained non-oxidized under the same conditions. In cyt c deficient mouse embryonic cells, pro-apoptotic stimuli (actinomycin D) did not cause oxidation of any of PLs. Selective and massive oxidation of CL was also detected in H<sub>2</sub>O<sub>2</sub>-treated HL-60 cells as well as in isolated mouse liver mitochondria. We conclude that cyt c acts as a catalyst of selective CL oxidation, a critical event in regulation of apoptotic signaling. Supported by NIH HL70755.

CYTOCHROME C CATALYZED CARDIOLIPIN  
OXIDATION IS ESSENTIAL FOR THE RELEASE OF  
PROAPOPTOTIC FACTORS FROM MITOCHONDRIA.

J. Jiang<sup>1</sup>, V. A. Tyurin<sup>1</sup>, Y. Y. Tyurina<sup>1</sup>, V. Kini<sup>1</sup>, P. Cai<sup>1</sup>, V. B. Ritov<sup>2</sup> and V. E. Kagan<sup>1</sup>. <sup>1</sup>Center for Free Radical and Antioxidant Health, Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA and <sup>2</sup>Department of Medicine, University of Pittsburgh, Pittsburgh, PA.

Cardiolipin (CL) is ubiquitously present in the inner mitochondrial membrane and inter-membrane contact sites where it interacts with many proteins including cytochrome *c* (cyt *c*). CL has been suggested to play a critical role in the release of cyt *c* from mitochondria during apoptosis by either interacting with tBid or undergoing oxidative modifications. However, the mechanisms of CL involvement in mitochondrial membrane permeabilization remain elusive. In mitochondria, a small fraction of cyt *c* (5-10% Western Blot), likely CL-associated, remains membrane-bound after treatment with a channel-forming antibiotic, alamethicin, while the majority of electrostatically-bound cyt *c* is removed. Cyt *c* is activated to a peroxidase upon binding to CL as evaluated by oxidation of 2', 7'-dichlorodihydrofluorescein. Cyt *c*/CL complex catalyzes CL oxidation as determined by a newly developed fluorescence HPLC assay. We hypothesized that cyt *c* catalyzed CL oxidation is involved in the release of pro-apoptotic factors (e.g. cyt *c* and Smac/Diablo) during apoptosis. We utilized cyt *c* deficient mouse embryonic cells (Cyt *c*<sup>-/-</sup>) and wild type cells (Cyt *c*<sup>+/+</sup>) to investigate CL oxidation and release of cyt *c* and Smac/Diablo during apoptosis. Following actinomycin D (100ng/mL) treatment for 16 h, around 40% of Cyt *c*<sup>+/+</sup> cells were induced into apoptosis, while Cyt *c*<sup>-/-</sup> cells were resistant to this treatment. Both CL oxidation and release of cyt *c* and Smac/Diablo were observed in Cyt *c*<sup>+/+</sup> cells but not in Cyt *c*<sup>-/-</sup> cells. When isolated mouse liver mitochondria were incubated with oxidized tetralinoleoyl-CL containing liposomes, cyt *c* and Smac/Diablo were released to a greater extent as compared to incubation with tetralinoleoyl-CL containing liposome. Thus, catalysis by cyt *c* of CL oxidation is essential for the release of cyt *c* and other proapoptotic factors during apoptosis. Supported by NIH HL70755.

TWO FACETS OF ETOPOSIDE:PRO-APOPTOTIC  
AGENT AND ANTIOXIDANT.

V. A. Kini<sup>1</sup>, Y. Y. Tyurina<sup>1</sup>, V. A. Tyurin<sup>1</sup>, A. Lysytsya<sup>1</sup>, J. Yalowich<sup>2,1</sup> and V. E. Kagan<sup>1,2</sup>. <sup>1</sup>Department of EOH, Center for Free Radical and Antioxidant Health, University of Pittsburgh, Pittsburgh, PA and <sup>2</sup>Department of Pharmacology, University of Pittsburgh, Pittsburgh, PA.

Etoposide, a phenolic DNA topoisomerase II inhibitor and antitumor agent, is known to induce intrinsic apoptosis accompanied by production of reactive oxygen species. It acts as a powerful lipid antioxidant and prevents phosphatidylserine (PS) oxidation and its externalization in apoptotic HL-60 cells, leading to failure in recognition and clearance by macrophages. Cytochrome *c* (cyt *c*) binds with high affinity with anionic phospholipids such as PS and cardiolipin (CL) to form a complex with peroxidase activity capable of oxidizing polyunsaturated phospholipids, including CL. Release of cyt *c* from mitochondria plays a pivotal role in triggering of caspase cascades whereby CL oxidation is involved in mitochondrial membrane permeabilization. Thus control of CL oxidation is critical in regulation of early stages of apoptosis. Given the lipid antioxidant potency of etoposide, we hypothesized that cyt *c* catalyzed CL oxidation during apoptosis can be sensitive to etoposide, hence affect execution of the apoptotic program. We found that CL was selectively oxidized in isolated mouse liver mitochondria as well in HL-60 cells treated with H2O2. In a model biochemical system, we showed that 160pmol lipid hydroperoxides per nmol CL were generated when 100μM liposomes containing a mixture of either tetralinoleoyl-CL (TLCL) or bovine heart CL with dioleoyl phosphatidylcholine (DOPC) were incubated with 4μM cyt *c* and 400μM H2O2. Oxidation of CL and production of hydroperoxides was also confirmed using ESI-MS. In the model system, etoposide inhibited CL hydroperoxide production in a concentration dependent manner. Complete protection of CL against oxidation occurred at the etoposide concentration of 50μM, by far higher than those minimally required for triggering apoptosis. Thus etoposide-dependent inhibition of CL oxidation is not likely to interfere with the execution of apoptotic program via prevention of mitochondrial membrane permeabilization. Supported by NIH HL70755, CA90787

HL-60 CELLS WITH METABOLICALLY  
BIOENGINEERED POLYUNSATURATED CARDIOLIPIN  
MOLECULAR SPECIES EXERT INCREASED  
SENSITIVITY TO APOPTOSIS.

Y. Y. Tyurina, V. A. Tyurin, Y. Fujii and V. E. Kagan. Department of Environmental and Occupational Health, Center for Free Radical and Antioxidant Health, University of Pittsburgh, Pittsburgh, PA.

Recently we have shown that cardiolipin (CL)-bound cytochrome *c* (cyt *c*) functions as a peroxidase, catalyzing CL oxidation during apoptosis. Oxidized molecular species (MS) of CL were required for release of cyt *c* and other pro-apoptotic

factors from mitochondria. We hypothesized that MS of CL with highly unsaturated fatty acids such as C22:6 bound to cyt *c* are preferred oxidation substrates for peroxidase activity of the complex. Peroxidation of these MS of CL should enhance apoptotic responses of cells. Thus we attempted to manipulate intracellular levels of MS of CL enriched with C22:6 using its metabolic integration. Electro-spray ionization mass spectrometry revealed MS of CL with integrated C22:6 (m/z 1648 and 1656) in C22:6-treated cells. In addition, C22:4- and C22:5-CL species were present in the spectra. Control cells grown in standard medium contained C18:3-, C18:2-, and C18:1-fatty acids in CL (m/z 1472, 1474, and 1476, respectively) as a most abundant MS of CL. We found that CL underwent significant oxidation after STS stimulation in control cells. STS-induced oxidation of CL was more prominent in C22:6-treated cells compared to control cells. More abundant phospholipids such as phosphatidylcholine and phosphatidylethanolamine did not undergo any oxidation in both control and C22:6-treated cells under the same conditions of STS exposure. Notably, HL-60 cells grown in the presence of C22:6 showed an enhanced sensitivity to apoptosis induced by STS, as evidenced by caspase-3 activation and phosphatidylserine externalization. We conclude that MS of CL containing polyunsaturated longer chain fatty acids are prone to peroxidation during STS-triggered apoptosis due to their specific interactions with cyt *c* in the inner mitochondrial membrane. Our results demonstrate that dietary manipulations of CL fatty acid composition can be used as potent modulators of tumor cell sensitivity to apoptosis. Supported by NIH HL70755.

IDENTIFICATION OF NUR77 AGONISTS THAT  
INDUCE APOPTOSIS AND INHIBIT CANCER CELL  
SURVIVAL THROUGH NUCLEAR PATHWAYS.

S. Chintharlapalli<sup>1</sup>, S. Papineni<sup>1</sup>, R. Burghardt<sup>2</sup> and S. Safe<sup>1,3,4</sup>. <sup>1</sup>Biochemistry & Biophysics, Texas A&M University, College Station, TX, <sup>2</sup>Veterinary Anatomy & Public Health, Texas A&M University, College Station, TX, <sup>3</sup>Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and <sup>4</sup>Institute of Biosciences & Technology, Texas A&M University Health Science Center, Houston, TX.

Nur77 is an orphan receptor and a member of the nerve growth factor-1-B (NGF1-B) subfamily of the nuclear receptor family of transcription factors. Ligand-dependent activation of Nur77 was investigated in Panc-28 pancreatic and other cancer cell lines transfected with either GAL4-Nur77 chimeras or a Nur response element. A series of 1, 1-bis(3'-indolyl)-1-(*p*-substitutedphenyl)methanes were screened in transactivation assays in pancreatic and other cancer cell lines, and for the first time we identified Nur77 agonists typified by 1, 1-bis(3'-indolyl)-1-(*p*-anisyl)methane that activated GAL4-Nur77 chimeras expressing wild-type or the ligand binding domain (E/F) of Nur77. In Panc-28 pancreatic cancer cells, Nur77 agonists activate the nuclear receptor and downstream responses including decreased cell survival, induction of cell death pathways including tumor necrosis factor related apoptosis-inducing ligand (TRAIL), and PARP cleavage. Moreover, the transactivation and apoptotic responses are also induced in other pancreatic, prostate and breast cancer cells that express Nur77. In Panc-28 cells, small inhibitory RNA for Nur77 not only reverses ligand-dependent transactivation but also induction of TRAIL and PARP cleavage. These results identify ligands that activate Nur77 through the ligand binding domain and show that ligand-dependent activation of Nur77 through nuclear pathways in cancer cells induce cell death pathways and are a potential new class of anticancer agents. (Supported by NIEHS ES09106 and M.D. Anderson Pancreatic Cancer Spore P20-CA10193)

THE IBM OF SMAC IS DISPENSABLE FOR APOPTOTIC  
FUNCTION.

S. P. Burke and J. B. Smith. Pharmacology and Toxicology, University of Alabama Birmingham, Birmingham, AL. Sponsor: C. Lamartiniere.

Smac is a proapoptotic protein that is activated by removal of the first 55 residues, which are a mitochondrial localization sequence. During apoptosis Smac is released by the mitochondria into the cytosol where it binds to X-linked inhibitor of apoptosis protein (XIAP) disrupting its inhibition of caspases. The first four amino acids of active Smac, A-V-P-I, are considered an IAP binding motif (IBM). The IBM is thought to be crucial for binding XIAP. Cytosolic expression of Smac beginning with Ala 56 was accomplished by a ubiquitin (Ub) fusion protein. The Ub-Smac fusion was deubiquitinated intracellularly, generating active Smac that was recovered from the cytosol of transfected cells. Expression of cytosolic Smac56 or mutants was used to test the idea that Smac antagonizes XIAP, a known E3 Ub ligase, by promoting its autoubiquitination and proteasomal degradation. Ub ligase activity depends on a functional ring domain of XIAP which docks an E2 ubiquitin conjugating enzymes. Cotransfection experiments showed that Smac interacted strongly with XIAP and markedly increased autoubiquitination of XIAP. Smac60, a splice variant lacking residues 62-105, interacted weakly with XIAP and failed to stimulate XIAP autoubiquitination. Smac60, which lacks residues 56-59 interacted strongly with XIAP and stimulated its autoubiquitination. Hence, the first four

residues of active Smac are not essential for XIAP binding and autoubiquitination. Conversely, XIAP also appears to increase the levels of Ub conjugated active Smac. Mutation H467A in the ring domain of XIAP ablated both autoubiquitination of XIAP and transubiquitination of Smac. Treatment with TNF $\alpha$  decreased endogenous XIAP levels in a cell line expressing Smac56. Proteasome blockade potentiated caspase-3 activation in cell lines expressing Smac56, 60, and  $\delta$ . Observations of cell rounding and detachment suggest that Smac56 and Smac60 potentiate the induction of apoptosis following proteasome inhibition. These findings suggest that the IBM of Smac is not essential for autoubiquitination of XIAP, caspase-3 activation, and apoptosis.

### INVOLVEMENT OF THE AP-1 COMPLEX IN THE NEUROPROTECTIVE EFFECT OF PACAP AGAINST CERAMIDE-INDUCED TOXICITY.

N. Aubert<sup>1,2</sup>, A. Falluel-Morel<sup>2</sup>, C. Fisch<sup>1</sup>, D. Vaudry<sup>2</sup>, S. de Jouffrey<sup>1</sup>, A. Fournier<sup>3</sup>, R. Forster<sup>1</sup>, H. Vaudry<sup>2</sup> and B. Gonzalez<sup>2,4</sup>. <sup>1</sup>CIT, Evreux, France, <sup>2</sup>INSERM-IFRMP 23, Rouen, France and <sup>3</sup>INRS-Institut Armand Frappier, Quebec, QC, Canada.

Ceramides, that are produced by sphingomyelin catabolism, constitute a novel class of second messengers. There is now clear evidence that ceramides play an important role in programmed cell death induced by cytotoxic agents. In particular, we have recently shown that ceramides activate c-Jun phosphorylation and stimulate the expression of the pro-apoptotic factor Bax. The neuropeptide pituitary adenylate cyclase-activating polypeptide (PACAP) prevents ceramide-induced neurotoxicity and acts as a potent stimulator of the expression of both c-Fos and the anti-apoptotic factor Bcl2. As Bax and Bcl2 are known to be regulated by the transcription factor AP-1 (dimer of Fos/Jun members), the aim of the present study was to determine whether ceramides and PACAP differently affect the formation of AP-1 complexes. Gel shift experiments indicated that both PACAP and C2-ceramide stimulated AP-1 binding in a dose- and time-dependent manner. The effects of C2-ceramide (20  $\mu$ M) and PACAP (10-7 M) were maximum after 30 min of treatment. Co-incubation of granule neurons with PACAP and C2-ceramide resulted in an additive stimulation of AP-1 DNA binding activity. Characterization of the AP-1 complexes indicated that PACAP-induced AP-1 consisted in c-Fos/JunD heterodimers while C2-ceramide-induced AP-1 consisted in c-Jun homodimers. Western blot analysis showed that C2-ceramide increased p-c-Jun levels within 1 h of treatment and PACAP increased c-Fos expression within 30 min. The effect of C2-ceramide on c-Jun phosphorylation was blocked by PACAP, the JNK inhibitor and a PP2A blocker, while the action of PACAP on c-Fos was abrogated by C2-ceramide, an ERK blocker and a PKA inhibitor. These data suggest that the opposite effects of C2-ceramide and PACAP on Bax and Bcl2 expression may result from induction of different AP-1 dimers. This work was supported by INSERM, CIT, the LARC-Neuroscience network and the Conseil Regional de Haute Normandie.

### ACTIVATION OF ENDONUCLEASE, OR CASPASE-ACTIVATED DNASE (CAD), AS A MARKER OF APOPTOSIS RATHER THAN NECROSIS IN DRUG- OR CHEMICAL-INDUCED ONCOSIS IN VIVO.

S. D. Ray<sup>1</sup>, S. Stohs<sup>2</sup> and G. B. Corcoran<sup>3</sup>. <sup>1</sup>Mol. Toxicology. Prog./Pharmacology Scs., AMS College of Pharmacology/LIU, Brooklyn, NY, <sup>2</sup>Advocare International, Carrollton, TX and <sup>3</sup>Pharmaceutical Sciences, Wayne State University, Detroit, MI.

The relative contribution and importance of apoptosis and necrosis to cell death in living model systems during drug- and chemical-induced target organ toxicity is intensely debated. It is difficult to extrapolate results from *in vitro* models to the *in vivo* setting, and *in vivo* conditions promote both death modes. Results showing that specific drugs produce necrosis are often based on late morphologic assessment. Adequate emphasis may not always be placed on pre-oncotic events, particularly when cells appear committed to apoptosis. CAD-independent DNA laddering has not been convincingly linked to necrosis *in vivo*. We hypothesize that a ladder of genomic DNA fragments, although controversial, remains a viable indicator of pre-oncotic apoptosis. To test this hypothesis, necrogenic doses (mg/kg) of acetaminophen (AP) 500, diclofenac (DCLF) 300, chloroform (CHL) 500, doxorubicin (DOX) 120, and furosemide (FUR) 500 were administered to 3 mo old male ICR mice. Analysis of serum chemistry (24-36h) revealed large increases in ALT activity (U/L, control 25 $\pm$ 2) for AP 19, 200 $\pm$ 895, CHL 3, 270 $\pm$ 286, DOX 20, 500 $\pm$ 651, and FUR 19, 600 $\pm$ 767, and elevated BUN (mg/dl, control 19 $\pm$ 2) for CHL 138 $\pm$ 12, DCLF 166 $\pm$ 6, DOX 112 $\pm$ 7, and FUR 93 $\pm$ 7. These agents induced frank toxicity resulting in cell death with the late morphology of oncosis in respective target organs. This was preceded by extensive genomic DNA fragmentation (> 300%

control) with DNA-laddering, consistent with an apoptotic phase of cell death for all agents. Such findings suggest that a preponderance of oncotic over apoptotic features should not lead to the conclusion that necrosis was the predominant mode leading to oncotic cell death. When CAD activation and clear-cut DNA laddering occur, it is possible for late morphologic evaluation documenting oncosis to bias interpretation of the means leading to cell death in favor of necrosis.

### APOTOSE TRIGGERED MICRONUCLEI: THE ROLE OF APOPTOSIS ON THE OUTCOME OF MICRONUCLEUS ASSAY.

M. Kabiri. Sanofi-Aventis, Hattersheim, Germany. Sponsor: M. Bonnefond.

The formation of micronuclei, aberrant mitoses, a mitotic arrest and other cellular perturbations may be apoptotic in nature rather than due to the genotoxic activity. Apoptosis is a highly regulated, controlled type of cell destruction programme that can be induced by a variety of physiological and pharmacological influences. It has been shown that histone deacetylase (HDAC) inhibitors an emerging new class of potential anticancer agents trigger the G2 checkpoint in normal cells. Loss of this G2 checkpoint can result in an aberrant mitosis and as a consequence in the induction of apoptosis and polyploid or micro-nucleated cells. To assess the potential of protease inhibitors for induction of micronuclei and to figure out the mechanism of interaction, we investigated the structurally different HDAC inhibitors Apicidin, Sodium Phenylbutyrate, Trichostatin A, Sodium Butyrate, Valproic acid and MS-275. To detect micronucleated cells in micronucleus test (MNT) *in vitro* L5178y mouse lymphoma cells were exposed to test compounds for 3 h (with S9) and 20 h (without S9). Following treatment 1000 cells per culture were evaluated for the induction of micronuclei. Appearance of apoptosis was monitored by measuring caspase-3/7 enzymatic activity and DNA fragmentation in cultures treated for 24h. The occurrence of micronucleated cells along with an induction of apoptosis was observed for Apicidin. This effect could not be observed for other tested compounds. However the results of Apicidin demonstrate that apoptosis can interfere with the induction of micronuclei in *in vitro* MNT tests. Further studies are needed to prove that apoptosis is the pre-dominant factor inducing micronucleated cells under treatment with Apicidin. The identification of possibly non-DNA targeting genotoxic mechanisms like apoptosis results in a different risk assessment.

### ISOLATION OF THE APOPTOSIS INDUCING CONSTITUENTS OF *GUAIACUM SANCTUM* L. AND *GUAIACUM OFFICINALE* L. (ZYGOPHYLLACEAE) ON HUMAN BREAST CELLS *IN VITRO*.

K. J. Chavez<sup>1</sup>, S. Schwaiger<sup>2</sup>, K. Renner<sup>3</sup>, J. A. Flanders<sup>4</sup>, H. Stuppner<sup>2</sup> and E. Rodriguez<sup>5</sup>. <sup>1</sup>Department of Comparative Environmental Toxicology, Cornell University, Ithaca, NY, <sup>2</sup>Institute for Pharmazie, Abt Pharmakognosie, Universitae Innsbruck, Innsbruck, Austria, <sup>3</sup>Biozentrum, Division Molekulare Pathophysiologie, Medizinische Universitae Innsbruck, Innsbruck, Austria, <sup>4</sup>Department of Clinical Sciences and Molecular Medicine, Cornell University, Ithaca, NY and <sup>5</sup>Department of Plant Biology, Cornell University, Ithaca, NY.

*Guaiacum sanctum* L. and *Guaiacum officinale* L. are Zygophyllaceae plant species used in South American folk medicine. Extracts of the plants have been shown to possess anti-inflammatory activity, including immunomodulatory and analgesic properties. However, to date no studies exist that investigate the direct effect on antitumor activity of the crude extracts. Recent studies show that the bark and heartwood of *Guaiacum sanctum* L. exerts a dose-dependent antiproliferative effect on the growth of human breast cancer with apoptotic morphologic features seen as low as 12.5  $\mu$ g/ml and as early as 6 hrs. The present investigation was initiated to isolate the active constituents from the bark and heartwood of *Guaiacum officinale* L. and to screen it via bio-assay guided fractionation for the induction of apoptosis. Extracts were fractionated with reverse phase HPLC chromatography and/or sephadex column chromatography. Active constituents were analyzed with LC-MS and NMR. The apoptotic index was calculated with fluorescence microscopy "double stained" with propidium iodide and Hoechst 33342 and via fluorescence-activated cell sorter (FACS) using Annexin+ /PI- and Annexin+ /PI+ cells. The data indicates that the active constituents belong to the class of lignans with molecular weights ranging from 325-410. Apoptosis for specific fractions was induced in a dose-dependent manner with the presence of morphologic features and an apoptotic index IC50 at 25 ppm for human breast cancer cell line MB-MDA-231. These findings suggest that further evaluation of *Guaiacum officinale* L. as an antitumor agent against human breast cancer is warranted. The study was supported by MIRT/NIH T37TW00076.

ESTIMATION OF AQUATIC SPECIES  
SENSITIVITY AND POPULATION-LEVEL  
RESPONSES

M.G. Barron<sup>1</sup>, S. Raimondo<sup>2</sup>, F. Mayer<sup>2</sup>

<sup>1</sup>*Biological Effects & Population Responses, USEPA, Gulf Breeze, FL*, <sup>2</sup>*Gulf Ecology Division, USEPA, Gulf Breeze, FL*

Determining species sensitivity and population-level responses of aquatic organisms to contaminants are critical components of criteria development and ecological risk assessment. To address data gaps in species sensitivity, the U.S. EPA developed the Interspecies Correlation Estimation (ICE) program to predict acute toxicity to under-represented taxa, and the Acute to Chronic Estimation (ACE) program to predict chronic toxicity. ICE is based on existing acute toxicity data for 143 aquatic and terrestrial species, and estimates acute toxicity using least squares regression and over 4000 interspecies correlations. ACE uses linear regression and accelerated life testing to predict no-effect and low-effect concentrations for chronic mortality. Both ICE and ACE generally predict acute and chronic toxicity within two-fold of measured values and seldom exceeds four-fold. Population-level responses of aquatic species are estimated with matrix models using individual-level toxicity data, including altered survival and reproduction measured in life-cycle tests as input. Population modeling of pesticide toxicity to mysid shrimp has shown that population effects measured as changes in population growth rate can occur at both lethal and sublethal concentrations, and that population extinction correlates with median lethal concentrations. These modeling approaches provide useful tools for estimating the sensitivity of endangered species and other taxa with limited data, and for determining population-level responses from traditional organism-level toxicity test data.

## Z

# Key Word Index

(2-methoxyethoxy)acetic acid	191	Adaptation	73	Alternative Test Method	1997, 2005, 2007, 2009
(phyto and xeno)estrogens	1734	Additive effects	1440	Alternative Test Methods	661, 1196
1,1,1,2-tetrafluoroethane	906	additivity	1292	alternatives	2192
1,1,1-trichloroethane	2086	Adduct	1708	Aluminum	696, 1124
1,1,1-trifluoroethane	906	adduct formation	1572		
1,1-bis(3'-indolyl)-1-(p-substitutedphenyl)methane		Adduction	2275	Aluminum	1125
2298		adducts	469, 498, 702, 1136	aluminum	1126, 1660
1,2,3,4,6,7-hexachloronaphthalene	2069	adenovirus	798	Alveolar Macrophage	946
1,2,5,6-dibenzanthracene	890	ADHD	954	Alveoli	1016
1,3-Butadiene	198, 1572, 2262	adhesion	1364	Alzheimer	985, 1105
1,3-dinitrobenzene	1535, 1536, 1860	adhesion molecule	843	Alzheimer's disease	1534, 1661
1,3-DNB	1576	adipocytes	135	Ames II	698
1-bromopropane	190, 278, 732	adipogenesis	2047	amiodarone	934, 935
1-nitronaphthalene	916	adjuvant	1209	amitraz	1118
13C NMR Isotopomer Analysis	1835	adrenocortical enzyme	1748	amniotic fluid	1286
13C-NMR	732	Adverse Events	477	Amphibians	1757
2,3-dichloro-1,3-butadiene	951	Adverse Pregnancy Outcome	1076	amyloid precursor protein	1533
2,4,6-Trinitrotoluene	183	aerosol	1017, 1190, 2106	analogue	2048
2,4-DNT	1585	Aerosol tolerance	1012	analysis methods	2066
2-bromopropane	190, 2263	aflatoxin	738, 758, 1309, 1407, 1495, 1708, 1795	anatomy	1295
2-butoxyethanol	751, 843, 844	aflatoxin B1	1313, 2265	Anatoxin-a	1437, 1438
2-ethynylnaphthalene	725	Aflatoxin prevention	1402	androgen	548, 1730
3-Methylcholanthrene	714, 756	aflatoxin-albumin adduct	1283	Androgen receptor	1727, 1729
3,Äô-azido-3,Äô-deoxythymidine	2216	AFM	1862	androgenicity	1747
4-chloro-1,2-benzenediamine	2098	Africa	1411, 1439	anemia	1610
4-HNE	2217	Age1200, 1955, 2188		Aneuploidy	337
4-hydroxy-2-nonenal	1832	agent orange	431, 2072	angiogenesis	1427, 1820
4-hydroxynonenal	185, 1723, 1876	aging	215, 581	Angiosarcomas	1677
4-methoxyestradiol	1724	Aging and hepatoprotection	75	Aniline	221, 913
4-OH tamoxifen	1489	AH Receptor	86, 99, 100, 106, 107, 364, 503, 657, 991, 1113, 1357, 1358, 1361, 1362, 1658, 1807, 1808	Animal	1354
4-oxononenal	1723	Ah receptor nuclear translocator	98	animal alternative	1198
5-FU	1273	AhR	87, 89, 91, 92, 94, 103, 104, 353, 715, 990, 992, 993, 994, 995, 1111, 1112, 1154, 1359, 1360, 1364, 1806, 1837, 1867, 2022, 2038, 2045, 2046, 2267	animal model	1712
6-Hydroxydopamine	1525	AIDS	1813	animal models	454, 927, 1129, 1321, 1935, 1994
8-hydroxy-2'-deoxyguanosine	193	air pollution	18, 19, 304, 436, 439, 446, 455, 460, 929, 942, 1018, 1019, 1521, 2271	animal models for absorption	1691
8-hydroxydeoxyguanosine	1428, 2265	air-liquid interface	1017, 1461	animal studies	466
95%UCL	2074, 2075	airborne particulate matter	443, 450, 1881	Animal Welfare	948, 1351, 1353, 1356
A-esterase	1946	Airway	1016, 1295, 1450	ANIT	526
absorption	414, 2197	Airways	1892	ANNATTO	1212
Acetaminophen	60, 63, 64, 65, 66, 67, 68, 69, 127, 224, 225, 905, 1005, 1048, 1049, 1050, 1051, 1052, 1053, 1054, 1376, 1557, 1766, 1855, 1859	Akt186, 1722	anogenital distance	2143	
acetone	853	Akt kinase	1226	Antagonism	1783
acetylaminofluorene	741	Alachlor	736	antagonist	474, 1729
acetylated-LDL uptake	1841	alanine aminotransferase	533, 535	antalamin	1776, 1777, 1778
acetylation	1789	alcohol	74, 274, 422, 1031, 1046, 1048	anthocyanin	1393
acetylcholine	1068, 1069, 1951	alcohol dehydrogenase	1262, 1918, 1919	anthrax	766, 769
acetylcholinesterase	51, 785, 997, 998, 1948, 2154	alcohol/aldehyde dehydrogenase	1559	Anti-Tussive	1460
acinar cell	1821	Alcoholic Steatohepatitis	1047	anti-angiogenesis	802, 803
Aclarubicin	1527	aldehyde dehydrogenase	1723	anti-angiogenic	1393
acrolein	1844, 1865	Aldehydes	1294, 1917	Anti-cancer	2303
Acropora	1591	alkaline phosphatase	539	anti-epileptic drugs	1174
acrylamide	292, 293, 294, 295, 296, 361, 396, 397, 505, 699, 1403, 1546, 1552, 1553, 1978	alkylating agent	774	anti-inflammation	1415
action potential	826	Allanblackia	1392	anti-proliferation	2120
activation	1890	allergen	1197	antiandrogen	1374, 1731, 1732, 1743
acute	1474, 1476, 1478, 1479, 1480, 1482, 1484, 1485	Allergenicity	1307	Antibodies	174, 2020
acute exposure	2081	allergy	5, 253, 308, 450, 452, 453, 639, 1206, 1208, 1213, 1214, 1711, 1892	antibody	175, 1992
Acute Occupational Exposure	1477	Allethrin	2107	antibody microarray	1905
acute toxicity	352	Allo-enhancement	1877	anticancer	529
acyl-CoA oxidase	536	allo-MLC	1884	anticarcinogenesis	2231
		alpha tocopherol	206	antiestrogen	1573
		alpha2u-globulin	1800	Antimicrobials	111
		ALS	1522, 1852	antioxidant	468, 814, 1393, 1726
		alternative	2015	antioxidant response element	220, 1079, 1523, 1852
		alternative method	1123	antioxidants	704, 1009, 1827, 1833, 1834, 1853
		Alternative methods	660, 664, 665, 692, 1366	Antisense	13, 17
