## THE BASICS OF ENGINEERED NANOMATERIALS FOR TOXICOLOGISTS OR TUTORIAL: THE FUNDAMENTAL CHEMISTRY AND PHYSICS OF ENGINEERED NANOSTRUCTURES.

V. L. Colvin<sup>1</sup> and D. B. Warheit<sup>1</sup>. <sup>1</sup>*Chemistry, Rice University, Houston, TX and 2Pulmonary Toxicology, DuPont Haskell Lab., Newark, DE.*

Nanotechnology is an emerging multidisciplinary science that deals with the creation and use of molecules a few billions of a meter in size. Assessing the potential hazards of the nanomaterials in this technology, and the products constructed from nanoparticulates is an emerging area in toxicology and health risk assessment. The development of toxicity data sets and exposure assessments for various nanoparticles and nanomaterials is ongoing and evolving as new particles, materials and exposure methodologies are developed. A related issue in toxicology and risk assessment is the extent to which nanoparticle toxicity can be extrapolated from existing toxicology databases for macro and microscale particle-types. Additional information needs that are being addressed include the environmental and biological fate, transport, persistence, and transformation, as well as the recyclability and overall sustainability of manufactured nanoparticles. This sunrise lecture is designed to be a basic primer on the fundamental chemistry and physics of engineered nanomaterials. The understanding of the composition of and source generation of particles becomes fundamentally more important when one considers that the surfaces or surface coatings may comprise > 50% composition of small nanoparticles (< 30 nm), and herein will lie the interactions of nanoparticles with cells. Future studies likely will demonstrate that method of particle synthesis, surface coatings, aggregation potential, surface charge, and shape may be as or more important than particle size in modifying biological/toxicological effects. Methods to form materials such as single-walled carbon nanotubes, fullerenes, quantum dots, nanocrystalline ceramics (e.g., titania), and nanometals will be reviewed. For each material class, the essential properties and applications will be outlined. The tutorial will conclude with a discussion of the actual applications of these high performance materials and projections for the industry growth over the next decade.

## DOSE CONSIDERATIONS FOR *IN VITRO* STUDIES OF AIR POLLUTANT TOXICITY.

J. B. Morris<sup>1</sup>, E. Postlethwait<sup>3</sup>, R. B. Schlesinger<sup>4</sup> and J. Seagrave<sup>2</sup>. <sup>1</sup>*Toxicology Program, University of Connecticut, Storrs, CT; 2Lovelace Respiratory Research Institute, Albuquerque, NM, 3Department of Environmental Health Sciences, University of Alabama at Birmingham, Birmingham, AL and 4Department of Biological Sciences, Pace University, Pleasantville, NY.*

Technological advances have made possible the investigation of the cellular effects of air pollutants through variety of *in vitro* approaches. However, in order to be relevant to human health effects following ambient exposures, these methods must accurately model biologically relevant exposure pathways, doses and responses. This continuing education course will provide both theoretical and practical information on appropriate dose selection and dosage techniques for *in vitro* studies of air pollutant toxicity. The first presentation will cover the basic concepts of vapor dosimetry including the roles of partitioning, chemical reactivity and local metabolism. Specific information on regional respiratory deposition in laboratory animals and humans and its relevance to cellular microdosimetry will be provided. The second presentation will include specific examples of *in vitro* approaches with a focus on microdosimetric considerations for reactive gases; in particular the potential biological impacts of surface lining layers and their constituents will be emphasized. Basic concepts of size specific regional particle deposition and clearance will be covered in the third presentation. Specific information on regional respiratory deposition efficiencies in laboratory animals and humans and its relevance to cellular microdosimetry will be provided. The final presentation will describe specific examples of *in vitro* approaches on particle toxicity with a cellular dosimetric comparison of effects observed *in vitro* compared to those *in vivo*. Overall the course is aimed at providing information not only on the importance of employing *in vivo* dosimetric considerations in designing *in vitro* studies, but also with providing a firm conceptual foundation for the selection of relevant doses for such work.

**3**

## DEVELOPMENTAL TOXICOLOGY STUDIES: DESIGN, INTERPRETATION AND RISK ASSESSMENT.

R. D. Hood<sup>1</sup>, J. F. Holson<sup>2</sup>, D. G. Stump<sup>3</sup>, J. M. Rogers<sup>3</sup> and S. L. Makris<sup>4</sup>. <sup>1</sup>*RD Hood & Associates, Toxicology Consultants, Tuscaloosa, AL, 2WIL Research Laboratories, Ashland, OH, 3Developmental Biology Branch, USEPA, Research Triangle Park, NC and 4NCEA, USEPA, Washington, DC.*

Developmental toxicity studies are among the most complex and challenging in the field of toxicology. They entail multiple and interrelated endpoints and systems that are rapidly changing in characteristics and in their responses to toxic insults over time. These studies inherently generate large data sets. However, because of the de-

cline in relevant training programs, data from developmental toxicity studies are often managed or interpreted by individuals with limited backgrounds in these fields. Although published regulatory agency guidance is available, this course will extend such guidance by presenting in detail current study designs, procedures for study evaluation, and case studies. Lectures will cover fetal endpoints including mortality, growth, visceral exams and skeletal exams, as well as endpoints of maternal toxicity and their relationship to developmental toxicity. Developmental toxicity will be viewed in a broad context, including aspects of postnatal development and multigenerational effects. Proper analysis of developmental toxicity data requires specific statistical considerations, and these will be presented. Finally, putting together all the data from such studies for human risk assessment will be discussed. Considerations of design flexibility, endpoint sensitivities, and use of mode of action analysis and confirmatory studies will be included. Thus, the course will present key information required for understanding the biological and toxicological bases of findings from developmental toxicity studies and will provide guidance for analysis and interpretation.

**4**

## CLINICAL PATHOLOGY AS THE GRANDDADDY OF BIOMARKERS: CURRENT AND FUTURE DIRECTIONS.

T. M. Monticello<sup>1</sup> and G. Walter<sup>2</sup>. <sup>1</sup>*Drug Safety Evaluation, Aventis, Bridgewater, NJ and 2Gail Walter Consultant, Kalamazoo, MI.*

Research for novel biomarkers of toxicity continues to grow at a rapid pace. While biomarkers of tissue injury have a long history in the discipline of clinical pathology, the full value of these preclinical datasets are oftentimes under and/or over interpreted by scientists not extensively trained in this discipline. This basic course will emphasize current practices in clinical pathology utilized in drug discovery and preclinical safety studies and will also highlight advances in more novel biomarkers of toxicity. Basic interpretation of clinical pathology parameters will be presented in addition to factors to consider with respect to animal model, study design and the assays themselves. Examples of hepatic biomarkers and more recently identified biomarkers of toxicity will be highlighted. The applicability and pitfalls of utilizing reference ranges will be discussed, as will the approach in determining biological relevance of results versus statistical significance. Finally, regulatory perspectives on complete datasets and data interpretation will be addressed. This course is intended for the general toxicology community to improve their understanding of clinical pathology data and the role of clinical pathology in biomarker development.

**5**

## IMMUNOLOGY FOR TOXICOLOGISTS.

I. Kimber<sup>1</sup> and D. R. Germolec<sup>2</sup>. <sup>1</sup>*Syngenta Central Toxicology Laboratory, Macclesfield, Cheshire, United Kingdom and 2National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

The adaptive immune system that is found in mammals comprises a dedicated interacting system of tissues, cells and molecules that work in concert to provide specific immune responses and host resistance to pathogenic microorganisms and transformed cells. Specific immunity is supplemented by, and works in harmony with, the phylogenetically more ancient innate immune system. Immunotoxicology describes the study of adverse health effects that may result from the interaction of xenobiotics with one or more components of the immune system. Such health effects may take a variety of forms. These include frank immunotoxicity where there is functional impairment of the immune system. The concern here is that compromised immune function may translate into an increased susceptibility to infectious and/or malignant disease. A second potential consequence of the interaction of chemicals or proteins with the immune system is allergy; defined as the adverse health effects that may arise from the stimulation of a specific immune response. Allergic disease may take a variety of forms, those of greatest significance for toxicologists being skin sensitization and allergic contact dermatitis, allergic sensitization of the respiratory tract, food allergy and idiosyncratic allergic drug reactions. Finally, xenobiotics have been implicated in the induction or exacerbation of autoimmune reactions and autoimmune disease. This course will provide a grounding in fundamental and clinical aspects of immunology, and will describe the basic elements immunotoxicity, allergy and autoimmunity. The objective is deliver an accessible guide to the immune system and immunotoxicology for general toxicologists.

## EVALUATION OF CARDIAC DRUG TOXICITY IN PHARMACEUTICAL DISCOVERY AND DEVELOPMENT.

R. L. Phelps<sup>1</sup>, C. S. Louden<sup>2</sup>, Y. J. Kang<sup>3</sup>, and M. J. York<sup>4</sup>. <sup>1</sup>*Toxicology, Allergan, Irvine, CA, 2AstraZeneca Pharmaceuticals, Wilmington, DE, 3School of Medicine, University of Louisville, Louisville, KY and 4Preclinical Safety Sciences, GlaxoSmithKline, Hertfordshire, United Kingdom.*

The heart is an important potential target organ to evaluate in nonclinical and clinical studies during drug development as well as a therapeutic site of action for many cardiovascular diseases. There are examples in almost every therapeutic class of

drugs that produced unanticipated cardiotoxicity leading to market withdrawal or cessation of development. Toxicologists are an integral part of an interdisciplinary group, including physiologists, pharmacologists, pathologists, clinicians, and regulators, which assess cardiac safety. As such, toxicologists play a critical role in the screening of pharmaceutical agents for cardiotoxicity as well as in establishing an adequate margin of safety and working basis for monitoring therapeutic endpoints and clinical safety of trial participants. The goal of this continuing education course is to illustrate the integration of physiology, pharmacology, toxicology, and pathology of the heart addressing both recent scientific advances and practical knowledge in pharmaceutical company setting. This course will cover *in vitro* and *in vivo* models of drug-induced cardiac injury and recent advances in biomarkers of cardiac injury to improve the strategy for detection and nonclinical and clinical monitoring of drug-related cardiotoxicity. This CE course will provide current understanding of the physiology of the heart with a focus on normal and drug-induced disturbances in cardiac electrophysiology and cardiac function, as well as testing strategies for assessing potential cardioactive drug candidates prior to entry into clinical trials. It will also cover basic and advanced knowledge of pathology of the heart, including a review of cardiac pathological evaluation, and provide case examples of the integration of physiological and pathological parameters and risk assessment to humans. Biochemical, cellular and molecular mechanisms of cardiac toxicity, including recent work in experimental animal studies and novel approaches directed toward understanding mechanisms of drug-induced cardiac injury, cardiomyopathy and cardiac hypertrophy will be presented. Finally, biomarkers of drug-induced cardiac injury will be discussed. This will include a review of the findings of the Expert Working Group on Biomarkers of Drug-Induced Cardiac Toxicity, an in-depth look at serum troponins, and related work currently in progress under the ILSI-sponsored Subcommittee on the Development and Application of Biomarkers of Toxicity.

## 7A

### INTERNATIONAL HARMONIZATION OF TECHNICAL REQUIREMENTS FOR CONDUCTING NON-CLINICAL SAFETY STUDIES OF HUMAN PHARMACEUTICALS: GUIDELINES, CASE STUDIES, AND CHALLENGES.

R. Dixit<sup>1</sup>, S. Galloway<sup>2</sup>, M. Feuston<sup>3</sup> and D. Jacobson-Kram<sup>4</sup>. <sup>1</sup>Safety Assessment, Merck and Co., Inc., West Point, AL, <sup>2</sup>Safety Assessment, Merck and Co., Inc., West Point, PA, <sup>3</sup>Research Division, Sanofi-Synthelabo, Malvern, PA and <sup>4</sup>CDER, USFDA, Rockville, MD.

The International Conference on Harmonization of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH) was established in 1990 to standardize and harmonize technical requirements for the world-wide marketing approval of human pharmaceuticals. The six party ICH comprises the regulatory agencies and research-based pharmaceutical industrial organizations from three major geographical areas, the United States, the European Union and the Japan. The major goals of the ICH process are to minimize unique regional requirements, reduce the duplication of non-clinical toxicology and clinical testing requirements, and to accelerate the global development, registration and marketing of human pharmaceuticals in a cost-effective manner. Under Safety topics (non-clinical safety), 15 major guidelines have been harmonized and implemented through three major global regulatory agencies. These include guidelines on technical requirements for genotoxicity, toxicity, carcinogenicity, reproductive and development toxicity, biotechnology safety, toxicokinetics, safety pharmacology and joint safety and efficacy. This course is designed to provide a thorough understanding of the rationale behind ICH guidelines and the utility of the ICH guidelines in accelerating and global harmonization of safety evaluation of pharmaceuticals. The presentations will also highlight case studies with detailed examples, and experience in conducting non-clinical ICH safety studies. The presentations will also discuss the challenges, and problems encountered due to the differences in the interpretation, and the acceptance of the ICH Guidelines by the practicing regulatory organizations, reviewers and the traditional practices of specific geographical areas.

## 8

### MALE REPRODUCTIVE HAZARD IDENTIFICATION AND RISK ASSESSMENT IN PHARMACEUTICAL DEVELOPMENT (WHAT DO YOU DO NOW THAT YOU HAVE A SIGNAL?).

D. Creasy<sup>2</sup>, P. J. Wier<sup>1</sup> and K. Boekelheide<sup>3</sup>. <sup>1</sup>GlaxoSmithKline, King of Prussia, PA, <sup>2</sup>Huntingdon Life Sciences, East Millstone, NJ, and <sup>3</sup>Department of Pathology and Laboratory Medicine, Brown University, Providence, RI.

In the preclinical development of pharmaceuticals, there are numerous opportunities to observe effects on the male reproductive system. There are relevant endpoints in both routine repeated-dose toxicity studies and in the developmental and reproductive toxicity studies. In recent years methods for identification of male reproductive injury has expanded well beyond the traditional endpoints of fecundity in rodent fertility studies and routine microscopic examination of testes in repeated-dose and reproductive toxicity studies. There is an expectation, for instance, that

pathologists will examine testes with knowledge of and reference to the stages of the seminiferous epithelium. Assessment of number, motility and frequency of morphological abnormalities in epididymal sperm has become routine in rodent fertility studies. Recently, some emphasis has also been placed on identification of biomarkers for testicular injury. The next steps following identification of signal are ill defined. The purpose of this continuing education course is to address what types of signals are commonly observed and to present a rationale for interpreting these data with regard to risk assessment for volunteers and patients. The speakers in this course will place an emphasis on case studies and will provide their proposals for subsequent preclinical and/or clinical investigations.

## 9

### DEVELOPMENT AND INTERPRETATION OF TOXICOKINETIC DATA FOR RISK AND SAFETY ASSESSMENT.

J. C. Lipscomb<sup>1</sup>, J. G. Bessems<sup>2</sup>, R. M. Dixit<sup>3</sup> and H. A. Barton<sup>4</sup>. <sup>1</sup>NCEA, USEPA / ORD, Cincinnati, OH, <sup>2</sup>Food & Chemical Risk Analysis, TNO Chemistry, Zeist, Netherlands, <sup>3</sup>Department of Safety Assessment, Merck Research Laboratories, West Point, PA and <sup>4</sup>NHEERL, USEPA / ORD, Research Triangle Park, NC.

Drug development and environmental health risk assessment activities are based on knowledge of chemical disposition and tissue interactions, that may be separately considered as toxicokinetics (TK) and toxicodynamics (TD). Each activity is initiated with valuation of basic toxicity information, including characterizing effective doses and the dose-response relationship identifying critical organs, tissues and processes; examining metabolic characteristics and the toxic nature of metabolites. Each activity culminates with the assessment of TK and TD relative to the concentration/dose-response relationship. This basic continuing education course is intended for the general toxicologist desiring to increase the use of TK data to build compound dossiers, and to address the needs of scientists designing toxicity and pharmacokinetic studies, preclinical and clinical studies, and conducting safety and/or risk assessments. Four lectures will be presented; content will address the design, conduct and evaluation of studies to inform an understanding of chemical disposition and effectiveness in the biological system. Instruction will be given on the considerations of doses and concentrations used in whole-animal toxicity and ADME studies and in *in vitro* investigations; the biochemical basis of chemical metabolism and the considerations and assumptions necessary to interpret metabolism findings; best use of TK data to inform doses intended for use in TD studies; extrapolations of effective doses between and among species through the use of default and chemical-specific uncertainty/adjustment factors; available guidance on uncertainty factor derivation for human health risk assessment; overview of PBPK modeling and its application to extrapolations of dose, route and duration, between and among species; and the basis and results of choice of classical or PBPK modeling for drug development and risk assessment.

## 10

### PHOTOTOXICITY: CURRENT CONCEPTS, EXPERIMENTAL DESIGNS, AND REGULATORY EXPECTATIONS.

J. F. Nash<sup>1</sup>, J. Harbell<sup>4</sup>, P. D. Forbes<sup>3</sup>, J. Ferguson<sup>4</sup> and A. C. Jacobs<sup>5</sup>. <sup>1</sup>Procter & Gamble Co., Cincinnati, OH, <sup>2</sup>Institute for In Vitro Science, Inc., Gaithersburg, MD, <sup>3</sup>Argus Research-Charles River, Horsham, PA, <sup>4</sup>Nine Welles Hospital and Medical School, Dundee, United Kingdom and <sup>5</sup>USFDA/CDER, Rockville, MD.

Exposure to solar ultraviolet and visible radiation produces acute and chronic skin damage. Chemicals, including pharmaceutical agents, may exacerbate such effects following topical or systemic exposure. The aim of phototoxicological testing is to predict the likelihood of such events using various *in vivo* and *in vitro* models. The purpose of this course is to familiarize toxicologists with the basic concepts of phototoxicological testing. This is especially important in light of recent US and European regulatory guidances relating to photosafety testing. The program will describe the comparative anatomy, physiology, and basic photobiology of the skin, the basic principles and experimental designs used in phototoxicity testing in non-clinical species and people as well as *in vitro* models. The course will also address the most recent regulatory guideline from the US Food and Drug Administration regarding phototoxicity testing.

## 11

### ASSESSMENT OF RENAL INJURY *IN VIVO*: TRADITIONAL AND NOVEL BIOMARKERS.

S. G. Emeigh Hart<sup>1</sup>, A. Lavin<sup>2</sup>, D. I. Bounous<sup>3</sup>, J. T. MacGregor<sup>4</sup> and E. Harpur<sup>5</sup>. <sup>1</sup>SAUS, AstraZeneca Pharmaceuticals, Wilmington, DE, <sup>2</sup>ILSI Health and Environmental Sciences Institute (HESI), Washington, DC, <sup>3</sup>Bristol-Meyers Squibb Company, Laurenceville, NJ, <sup>4</sup>Toxicology Consulting Services, Arnold, MD and <sup>5</sup>Sanofi-Synthelabo, Media, PA.

Because the kidney is an important target organ of toxicity, there is a need for sensitive, specific and non-invasive assays that can be used to detect low-level, potentially reversible renal injury in both animal toxicology studies and the clinical set-

ting. Most of the available techniques do not allow identification of the segment(s) of the kidney affected by a toxicant. Better understanding of the pathophysiology of nephrotoxic processes, combined with information arising from genomic, proteomic and molecular biologic assessment of the effects of nephrotoxic chemicals has led to the identification of several promising new candidates that might serve as sensitive, segment-selective biomarkers of nephrotoxicity that can be applied readily in both the preclinical and clinical settings with adequate testing and validation. This basic CE course will provide an overview of renal structure and function, discuss the appropriate use and limitations of traditional clinical pathology assessment of renal injury, and describe the processes necessary for appropriate validation and subsequent regulatory acceptance of a novel biomarker. The final two speakers will describe the novel biomarker candidates under consideration by the Nephrotoxicity Working Group of the ILSI-HESI Technical Committee on the Development and Application of Biomarkers of Toxicity. The first of these will provide an overview of novel biomarkers for proximal tubular injury while the second will discuss the pathophysiology of renal papillary necrosis and how it relates to the identification of novel biomarkers of papillary injury.

## 12 EVALUATION OF CARDIAC DRUG TOXICITY IN PHARMACEUTICAL DISCOVERY AND DEVELOPMENT.

B. G. Short. *Toxicology, Allergan, Irvine, CA.*

The heart is an important potential target organ to evaluate in nonclinical and clinical studies during drug development as well as a therapeutic site of action for many cardiovascular diseases. Toxicologists are an integral part of an interdisciplinary group that evaluates cardiac safety, including screening of drugs for cardiotoxicity as well as in establishing an adequate margin of safety and working basis for monitoring therapeutic endpoints and clinical safety of trial participants. The goal of this continuing education course is to illustrate the integration of physiology, pharmacology, toxicology, and pathology of the heart addressing both recent scientific advances and practical knowledge in pharmaceutical company setting. This course will cover *in vitro* and *in vivo* models of drug-induced cardiac injury and recent advances in biomarkers of cardiac injury to improve the strategy for detection and nonclinical and clinical monitoring of drug-related cardiotoxicity. This CE course will provide current understanding of the physiology of the heart with a focus on normal and drug-induced disturbances in cardiac electrophysiology and cardiac function, as well as testing strategies for assessing potential cardioactive drug candidates prior to entry into clinical trials. It will also cover basic and advanced knowledge of pathology of the heart, including a review of cardiac pathological evaluation, and provide case examples of the integration of physiological and pathological parameters and risk assessment to humans. Biochemical, cellular and molecular mechanisms of cardiac toxicity, including recent experimental work and novel approaches directed toward understanding mechanisms of drug-induced cardiac injury, cardiomyopathy and cardiac hypertrophy will be presented. Finally, biomarkers of drug-induced cardiac injury will be discussed. This will include a review of the findings of the Expert Working Group on Biomarkers of Drug-Induced Cardiac Toxicity, an in-depth look at serum troponins, and related work currently in progress under the ILSI-sponsored Subcommittee on the Development and Application of Biomarkers of Toxicity.

## 7B INTERNATIONAL HARMONIZATION OF TECHNICAL REQUIREMENTS FOR CONDUCTING NON-CLINICAL SAFETY STUDIES OF HUMAN PHARMACEUTICALS: GUIDELINES, CASE STUDIES, AND CHALLENGES.

R. Dixit<sup>1</sup>, S. Galloway<sup>2</sup>, M. Feuston<sup>3</sup> and D. Jacobson-Kram<sup>4</sup>. <sup>1</sup>*Safety Assessment, Merck and Co., Inc., West Point, AL*, <sup>2</sup>*Safety Assessment, Merck and Co., Inc., West Point, PA*, <sup>3</sup>*Research Division, Sanofi-Synthelabo, Malvern, PA* and <sup>4</sup>*CDE, USFDA, Rockville, MD.*

The International Conference on Harmonization of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH) was established in 1990 to standardize and harmonize technical requirements for the world-wide marketing approval of human pharmaceuticals. The six party ICH comprises the regulatory agencies and research-based pharmaceutical industrial organizations from three major geographical areas, the United States, the European Union and the Japan. The major goals of the ICH process are to minimize unique regional requirements, reduce the duplication of non-clinical toxicology and clinical testing requirements, and to accelerate the global development, registration and marketing of human pharmaceuticals in a cost-effective manner. Under Safety topics (non-clinical safety), 15 major guidelines have been harmonized and implemented through three major global regulatory agencies. These include guidelines on technical requirements for genotoxicity, toxicity, carcinogenicity, reproductive and development toxicity, biotechnology safety, toxicokinetics, safety pharmacology and joint safety and efficacy. This course is designed to provide a thorough understanding of the ration-

ale behind ICH guidelines and the utility of the ICH guidelines in accelerating and global harmonization of safety evaluation of pharmaceuticals. The presentations will also highlight case studies with detailed examples, and experience in conducting non-clinical ICH safety studies. The presentations will also discuss the challenges, and problems encountered due to the differences in the interpretation, and the acceptance of the ICH Guidelines by the practicing regulatory organizations, reviewers and the traditional practices of specific geographical areas.

## 13 THE FUTURE OF MOLECULAR GENETIC THERAPEUTICS.

D. Monteith and V. Reddy. *Eli Lilly and Company, Greenfield, IN.*

During the last decade the decoding of the human genome has provided exciting possibilities for the treatment of human disease. The promise of gene therapy and antisense have stirred the imagination to the potential of redirecting abnormal cellular processes. These therapies provide potential advantages in specificity to gene targets and selectivity for protein intervention in some disease targets that are often considered 'undruggable' with traditional chemotherapies. To date, these technologies have provided interesting technologies as research tools to gain perspective with respect to effects of various targets; in particular antisense strategies using single-strand and siRNA provide tools to validate molecular targets in disease pathways. These antisense approaches utilize different mechanisms (i.e., RISK complex and RNase H) to reduce a target protein in a manner not achievable with a small molecule approach. Gene therapy has posed the potential to treat and possibly cure disease by replacing lost function with the insertion of a normal gene. Currently, there are numerous antisense and gene therapy clinical candidates in development by corporate sponsors as well as academic centers and investigators. The selection of disease candidates and targets is complex. The administration, delivery, cell permeability, and pharmacokinetic and pharmacodynamic attributes have played a critical role in the development of these therapies. This symposium will cover the biologic and safety hurdles these therapies have faced and the solutions that have been developed to evaluate these molecules in patients. The symposium will consist of an expert panel of presenters involved in the science and development issues surrounding molecular genetic therapies.

## 14 GENE THERAPY: A SIMPLE CONCEPT WITH COMPLEX CHALLENGES.

R. M. Lyons. *Self-Employed, Gaithersburg, MD.*

Gene therapy is a conceptually simple and straightforward approach to the treatment and possible cure of diseases with a defined genetic basis. The reality is more complex and presents significant challenges, including appropriate disease selection. Genetic diseases are logical candidates and many of the first gene therapy clinical trials focused on monogenetic disorders. The majority of current gene therapy clinical trials are for cancer, due in part to an increased appreciation of the genetic basis of cancer, a higher tolerance for risk when no alternative treatment exists, and a more attractive commercial opportunity. The gene transfer systems being investigated include viral vectors, plasmids, liposomes, and synthetic complexes. The most common gene transfer systems use human or animal viruses engineered to take advantage of specific biological properties or viral life-cycle features while minimizing pathogenicity. One of the more significant challenges continues to be efficient and specific gene transfer to target cells and tissues as most viral vectors have broad cell and tissue tropism. Viral vectors targeted to tissue-specific cellular receptors are frequently less robust or require multiple components, further complicating product development. The level and duration of gene expression is not controlled in current gene transfer systems and is likely to require innovative models and study designs to assess the potential for both acute and chronic effects. Integrating viral vectors may offer a curative therapy, but are also associated with the potential for insertional mutagenesis. Preclinical investigations have been unsuccessful in assessing the magnitude of this risk. In addition, recent clinical cases of vector-related insertional mutagenesis suggest that the risk may be disease specific, further complicating the development of relevant preclinical models for informative risk assessment. In light of these complex biological and technical issues as well as the large number of distinct clinical approaches being taken, the development of gene therapy candidates will continue to be science based and product specific.

## 15 DEVELOPMENT OF SHORT INTERFERING RNAs (SIRNAS) AS POTENTIAL THERAPEUTICS.

P. A. Pavco. *Development, Sirna Therapeutics, Inc., Boulder, CO. Sponsor: J. Lockridge.*

The recent discovery of the RNA Interference (RNAi) pathway has resulted in the use of short interfering RNAs (siRNAs) to direct potent and specific post-transcriptional gene silencing. Because siRNA can be designed to target virtually any disease-related mRNA, the potential use of siRNA as a therapeutic agent is quite broad.

However, the application of siRNA technology *in vivo* is not straightforward. Although extremely useful as a laboratory tool, particularly in cell culture, the development of siRNA as a therapeutic must also address the challenges of siRNA stability *in vivo*, delivery to the appropriate tissue and chemical synthesis of therapeutic amounts. The addition of stabilizing modifications to the siRNA greatly improves its pharmacokinetics and will be required for most therapeutic applications. Additional modifications and/or conjugates are possible that target the siRNA to various tissues. Methods for efficient and cost-effective production of siRNA to support clinical use have been developed. Recent progress with respect to these challenges will be reviewed.

## 16 ANTISENSE THERAPEUTICS: PROGRESS IN THE DEVELOPMENT OF A NOVEL THERAPEUTIC PLATFORM.

**S. P. Henry and A. A. Levin.** *Toxicology, Isis Pharmaceuticals, Carlsbad, CA.*

Dedicated research and development of antisense inhibitors for therapeutic use is now more than a decade old. The application of antisense inhibitors of gene expression while simple in concept and potentially broadly enabling, still faces the same challenges as any pharmacologic agent. In context of therapeutic discovery these challenges include selection of potent inhibitors, pharmacologic specificity in early *in vitro* *in vivo* pharmacology models, relevance of gene target, tissue distribution and cell uptake, target organ toxicity and therapeutic index for specific indications. Knowing the properties of compounds in a given platform such as antisense inhibitors should allow for these challenges to be addressed with relative high efficiency. This presentation will highlight the potential contributions of this technology, particularly in terms of regulating the expression of genes that are not easily inhibited with traditional approaches. Examples of disease studied include treatment of viral disease, cancer, inflammation and metabolic disease. Antisense oligonucleotides have also been studied using multiple routes of administration, including oral. The toxicity studies performed cover the full spectrum of regulatory safety studies including chronic administration, reproductive toxicity and genetic toxicity studies. The study design aspects unique to antisense oligonucleotides will be discussed in the context of general preclinical development strategy. The toxicities common to this class of compound will be described in the context of toxicokinetic and toxicodynamic relationships. The impact of these changes on safety assessment depends greatly on the intended indication, route of administration, and duration of treatment. A prospective look at potential for near-term and long-term applications, along with future directions, will be provided.

## 17 CLINICAL CONSIDERATIONS IN THE DEVELOPMENT OF MOLECULAR THERAPIES FOR CANCER.

**M. F. Burgess.** *Lilly Research Centre, Windlesham, Surrey, United Kingdom.* Sponsor: **D. Monteith.**

The exploration and exploitation of differences between the somatic and malignant cell genome has provided much promise for the delivery of new anticancer drugs to the clinic. A wide variety of therapeutic manipulations from small molecules to gene therapy have been encouraging preclinically, only to fail in the clinic. One of the most promising technologies which can be applied to almost any target in antisense therapy. This therapeutic platform highlights many of the difficulties in the translation of a preclinical tool into a clinically useful drug. Consideration needs to be given not only to concerns of the target, but also to concerns associated with drugability. Issues such as the distribution of antisense to the target tissue to achieve therapeutic concentrations have a fundamental effect on study design. The long half-life of these molecules combined with a hierarchy of organ penetration may compromise the ability to effect the target in the absence of toxicity. Additionally, toxicities may only become apparent after prolonged repeated administration leading to difficulties in assigning an MTD. Since the dose response curve is steep reduction in dose as a consequence of toxicity may result in subtherapeutic concentrations in the target and loss of clinical benefit. Implied within this is an adequate assessment of the pharmacodynamic effect as it pertains to malignant and normal cells. This may vary from target to target, but in general some estimate of the magnitude and duration of the effect of treatment is required. Ideally, this should be accompanied by local evaluation of ASO concentration. The penetration of ASO into tumor relative to surrounding normal tissue is largely unknown and makes prediction of therapeutic dose levels complicated. Scheduling of combination chemotherapy needs to be carefully evaluated in the face of the target knockdown data to optimally design combinations to achieve the greatest therapeutic benefit. All of the above needs to be considered within the context of acceptability to the patient which will be judged on the perception of risk vs benefit.

## 18 OVERVIEW INHALATION EXPOSURE AND SYSTEMIC IMMUNOTOXICITY: MECHANISMS LINKING THE LUNG AND IMMUNE SYSTEM.

**M. Selgrade**<sup>1</sup> and **J. Zelikoff**<sup>2</sup>. <sup>1</sup>*NHEERL, USEPA, Research Triangle Park, NC* and <sup>2</sup>*Department of Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

Although toxicity to the lung and cardiovascular system are the most frequently studied targets following inhalation exposure, suppression of systemic immune responses has been observed following exposure to a number of diverse compounds. Defects in a variety of immune effector mechanisms have been observed. Frequently, these effects are not a direct result of exposure of immune targets to the chemical or its metabolites, but involve instead the production of mediators in the lung that circulate widely and/or interactions with the nervous system. Often these exposures are to complex mixtures and the active components as well as pharmacokinetics are uncertain. Many of these issues have been considered in recent studies of JP-8 Jet fuel, Sarin, Tobacco smoke, and different gasoline formulations, all of which suppress systemic immune response and have the potential to impact susceptibility to infectious disease and tumor challenge in rodents. These studies have implications for public health, homeland security, industrial hygiene, and indoor environments. This symposium is a sequel to a 2004 symposium Modulation of Host Defenses by Ambient and Source Particulate Air pollutants which focused on pulmonary immune responses and infections

## 19 INTRODUCTION: INHALATION EXPOSURE AND SYSTEMIC IMMUNOTOXICITY: MECHANISMS LINKING THE LUNG AND IMMUNE SYSTEM.

**M. Selgrade.** *NHEERL, USEPA, Research Triangle Park, NC.*

Concerns regarding inhaled compounds, immune suppression and increased risk of disease have focused primarily on suppression of local immune responses in the lung and susceptibility to respiratory infections. However, studies also have shown that both gaseous ( $O_3$ ,  $NO_2$ ) and particulate (diesel, Cd-coated fly ash, cigarette smoke) air pollutants, as well as soluble metals ( $NiCl_2$ ,  $CdCl_2$ ) and a pesticide (carbaryl) administered by inhalation suppress systemic immune responses. These studies have most often assessed the antibody response to sheep red blood cells, lymphoproliferative responses to non-specific mitogens, and/or peripheral blood lymphocyte phenotypes. Although limited data are available, enhanced susceptibility to systemic infections has also been observed. Systemic immune suppression following inhalation exposure has been reported in both rodent and human studies. Results often varied depending on the exposure protocol. Because these same chemicals administered via other routes of exposure did not always suppress immune responses, mechanisms linking the lung and systemic immune system have been proposed. Inflammatory responses are thought to be involved. Potential mechanisms include production of long-lived free radicals, production of immunosuppressive mediators such as prostaglandin  $E_2$  and interleukin-10, and a shift in the balance of T helper (Th1) and Th2 lymphocytes in favor of Th2 responses. This latter possibility is attractive, because many of these same agents have adjuvant effects on the induction of allergic sensitization or are themselves allergenic. Also, as described in later talks, mechanisms have been suggested that involve effects on the nervous and/or endocrine system. Whereas reports of systemic immune suppression following inhalation exposure date back 30 years, the papers presented at this symposium represent some of the first studies to systematically assess the mechanisms (immunologic and metabolic) underlying these effects. (This abstract does not reflect EPA policy).

## 20 IMMUNOTOXICITY OF AEROSOLIZED JP-8 JET FUEL EXPOSURE AND ITS PREVENTION BY SUBSTANCE P.

**D. T. Harris**<sup>1</sup> and **M. Witten**<sup>2</sup>. <sup>1</sup>*Microbiology & Immunology, University of Arizona, Tucson, AZ* and <sup>2</sup>*Pediatrics, University of Arizona, Tucson, AZ.*

Exposure of C57Bl/6 mice to JP-8 jet fuel results in immunotoxicity. Short-term, low concentration inhalation of JP-8 suppresses natural killer (NK), cytotoxic T lymphocyte (CTL) and T-helper cell function, and increases susceptibility to tumor and viral challenges. Changes in immune function occurred within 1-hour post-JP-8 exposure and were cumulative, becoming maximal by 4 days post-exposure. Immune recovery to baseline levels did not occur for more than 30 days after exposure ended. JP-8 exposure at the time of tumor induction increased lung tumors 548%; JP-8 exposure prior to tumor induction increased lung tumors 863%. Morbidity and mortality were increased in mice exposed to JP8 for 7 days, infected with a sublethal dose of influenza virus, and sacrificed 1 wk later. There were fewer immune cells in the spleen and lymph nodes, indicating that the immune response to the virus had been suppressed. Immunophenotyping also indicated that T cell numbers and immune cell viability were decreased. *In utero* exposure to JP-8 in-

duced immune dysfunction in offspring that persisted for at least 8 wks after birth, was most pronounced in males, and directly correlated with the degree of immune dysfunction found in the exposed mothers. JP-8 exposure induced rapid increases in serum PGE2 and IL-10 levels. Treatment with a Cox-2 enzyme inhibitor significantly ablated PGE2 levels, but only partially restored immune function. Treatment of mice with substance P (SP) was observed to restore immune function whereas inhibitors of SP function exacerbated immune dysfunction. Immediately after human occupational exposures to JP-8, decreased total leukocyte numbers, increased neutrophils and eosinophils, and increased plasma PGE2 levels were observed. Also, there appeared to be a susceptible subpopulation within the group as a whole. In order to understand the mechanisms of JP-8's effects on the immune system, experiments are underway to identify the cells *in vivo* that secrete immuno-suppressive cytokines and are targets of jet fuel-induced apoptosis.

## 21 IMMUNOTOXICITY OF SARIN AND OTHER CHOLINERGIC AGENTS.

M. Sopori, R. Kalra, R. Langley, S. Razani-Boroujerdi, N. Mishra and R. Henderson. *Immunology, Lovelace Respiratory Research Institute, Albuquerque, NM*.

Chronic inhalation of subclinical doses of sarin (0.2 and 0.4 mg/m<sup>3</sup>, 1 h/day, for 5 days) suppresses the antibody-forming cell response to a T cell-dependent antigen (sheep red blood cells) and impairs T cell function (proliferative responses to Concanavalin A and anti-T cell receptor antibody). Using various cholinergic agents, we observed further that while the immunosuppressive effects of those agents that crossed the blood-brain-barrier (e.g., sarin, physostigmine) were apparent through inhalation or subcutaneous administration, cholinergic agents that did not cross the blood-brain-barrier (e.g., pyridostigmine bromide, edrophonium) required intracerebroventricular administration to induce the immunosuppression. Thus, the immunotoxicity of cholinergic compounds appears to be mediated through the central nervous system. Interestingly, all cholinergic agents significantly reduced serum corticosterone levels, suggesting that the immunosuppression induced by cholinergic compounds did not result from increased glucocorticoid production through activation of the hypothalamus-pituitary-adrenal axis. However, pretreatment of rats with the ganglionic agent chlorisondamine attenuated the sarin and pyridostigmine bromide-induced immunosuppression and partially blocked the drop in serum corticosterone levels. Chronic cholinergic stimulation increased the interleukin (IL)-1 $\beta$  level in the brain but not in the spleen, and chronic intracerebroventricular but not subcutaneous administration of IL-1 $\beta$  suppressed the antibody-forming cell response. Moreover, IL-1 $\beta$  activated the Src-like protein tyrosine kinase Fyn, and this activation was blocked by pretreatment with chlorisondamine. Thus, IL-1 $\beta$  may be critical in cholinergic immunotoxicity and neuroimmune communication. These results suggest that the immunotoxicity of inhaled cholinergic agents is mediated centrally through the autonomic nervous system. Moreover, serum corticosterone levels might be a biomarker for cholinergic toxicity.

## 22 PRENATAL EXPOSURE OF MICE TO CIGARETTE SMOKE ALTERS TUMOR SURVEILLANCE MECHANISM(S) IN THE JUVENILE AND ADULT OFFSPRING.

J. T. Zelikoff and S. P. Ng. *Nelson Institute of Environmental Medicine, School of Medicine, New York University, Tuxedo, NY*.

Over one million infants in America are born each year after exposure *in utero* from active or passive maternal smoke exposure. Since accumulating epidemiologic evidence suggests that prenatal exposure to intact cigarette smoke increases the incidence of cancer in the offspring, it was hypothesized that inhalation exposure of pregnant B6C3F1 mice to mainstream cigarette smoke (MCS) decreases offspring resistance to tumor challenge due to alterations in surveillance mechanisms critical for recognition/destruction of cancers. This study sought to: ascertain whether exposure of pregnant dams to a low-dose of MCS alters tumor development in the offspring; and, assess the degree to which exposure of dams to MCS during gestation modulates tumor surveillance mechanisms such as natural killer cell and cytotoxic T-lymphocyte (CTL) activity. Even at this relatively low level (equivalent to that measured in a home in which two packs of cigarettes were smoked), exposure to MCS from gestational d 4 to parturition reduced litter size and caused a significant shift in gender ratios (compared to those for controls). Prenatally exposed male and female pups challenged at 5 wk of age with neoplastic cells demonstrated a 2- and 4-fold increase in tumor incidence, respectively (relative to age- and gender-matched air exposed offspring); increased tumor incidence was also observed in prenatally exposed 10-wk-old offspring, but only for the males. Effects of smoke on CTL activity may in part be responsible for the increase in tumor incidence observed in the male offspring; CTL activity in the female pups were unaffected by *in utero* MCS exposure. Results demonstrate that inhalation exposure of pregnant

mice to a low dose of MCS increases susceptibility of the adult offspring to nascent tumors. Taken together, these studies provide biological plausibility for the notion that children of mothers who smoke have a greater risk of developing cancer later in life. This research was supported by Philip Morris USA Inc. and Philip Morris International.

## 23 COMPARATIVE INHALATION IMMUNOTOXICITY OF GASOLINE AND GASOLINE PLUS OXYGENATE ADDITIVES IN RATS.

L. Twerdok<sup>1</sup>, V. L. Peachee<sup>2</sup> and K. L. White<sup>2</sup>. <sup>1</sup>*American Petroleum Institute, Washington, DC* and <sup>2</sup>*Immuno Tox, Inc., Richmond, VA*.

Comparative immunotoxicity testing was conducted on evaporative emissions of gasoline alone, and gasoline plus ether or alcohol oxygenates in the Sprague-Dawley rat. The inhalation exposures simulate, at much higher exposures and durations, human exposures during self-serve refueling of automobiles. Seven vapor condensates of gasoline alone, or gasoline plus an ether or alcohol oxygenate were evaluated for effects on the humoral component of the immune system using antibody-forming cell (AFC) response to the T-dependent antigen, sheep erythrocyte. Female Sprague-Dawley rats were exposed to the test agents (2000, 10000 and 20000 mg/m<sup>3</sup>) by inhalation for 4 weeks (6 hrs/day, 5 days/week). Vapor condensates of gasoline alone, gasoline plus MTBE, tert-butyl alcohol (TBA), or tertiary amyl methyl ether (TAME) did not affect humoral response in the plaque assay. Vapor condensates of gasoline plus ethanol or diisopropyl ether (DIPE) did result in statistically significant decreases in the AFC response when evaluated as either AFC/106 spleen cells or AFC/spleen at the highest dose level. Gasoline plus ethyl tertiary butyl ether (ETBE) produced a statistically significant dose-dependent decrease in AFC response at the mid- and high-doses. Recently, there has been speculation in the literature that some immune effects are related, or secondary to concurrent neurotoxicity. Comparative neurotoxicity studies (functional observational battery and motor activity) at the same dose levels with these three test materials were negative, suggesting no relationship between immune and nervous system effects. The neat oxygenates (MTBE, TBA, TAME, ethanol, ETBE, DIPE) tested in these gasoline blends share a number of common metabolites (isopropyl alcohol; acetaldehyde, acetate). Although these studies were not definitive, the negative effects for gasoline alone, gasoline/MTBE, gasoline/TBA and gasoline/TAME suggest that neither gasoline components nor the common metabolites of the neat oxygenates are responsible for the positive effects observed for these mixtures.

## 24 THE DEVELOPMENT AND APPLICATION OF BIOMARKERS OF TOXICITY.

J. Dean<sup>2</sup> and A. L. Lavin<sup>1</sup>. <sup>1</sup>*ILSI Health and Environmental Sciences Institute, Washington, DC* and <sup>2</sup>*Sanofi-Synthelabo, Inc., Malvern, PA*.

A biomarker, or biological marker, is defined as a characteristic that is measured and evaluated as an indicator of normal biological processes, pathogenic processes, or pharmacological responses to a therapeutic intervention (FDA/NIH Definitions Working Group, 1999). Such biomarkers have long been used in preclinical safety studies during drug development. Nevertheless, many traditional biomarkers lack the sensitivity and specificity required to extrapolate results from preclinical studies to human clinical outcomes. As a result, interest in the discovery and validation of new bridging biomarkers of toxicity has expanded rapidly in recent years. This increase is due both to the advent of new “-omic” technologies, as well as to a shift in focus within the pharmaceutical companies and regulatory agencies towards finding safety biomarkers that can be of greater use in the drug discovery and safety assessment processes. These drivers have contributed to formation of the Health and Environmental Sciences Institute (HESI) Biomarkers Technical Committee, which is conducting a collaborative research program to evaluate possible new biomarkers for use in preclinical drug development. Biomarkers being explored by the committee for use in preclinical safety studies include serum cardiac troponins, a panel of nephrotoxicity biomarkers (the GSTs, PAP-1, KIM-1, and clusterin), and inhibin B as a biomarker of testicular toxicity. The use of such biomarkers will allow for integrated mechanistic and hypothesis-building studies conducted in the laboratory to be confirmed in man and vice versa.

## 25 NEW BRIDGING BIOMARKERS FOR SAFETY ASSESSMENT.

J. T. MacGregor. *Toxicology Consulting Services, Arnold, MD*.

Perhaps the greatest single limitation of current toxicological practice is the uncertainty associated with extrapolation from laboratory models to human outcomes. The dramatic advances in science and technology during the past two decades have

created an unprecedented opportunity to reduce or eliminate this uncertainty through the introduction of new "bridging biomarkers"—biomarkers of identical or analogous processes in laboratory models and in human subjects that can be measured directly in both cases. Such new markers include an extended set of biomarkers of cellular function and integrity (the traditional biomarkers used in safety evaluation) that are applicable to a broader range of cell and tissue targets, but are more specific to the individual targets. An increased understanding of the functional molecular systems of cells and their responses to cell and tissue damage offers the potential for new types of markers, such as those inducible by specific types of molecular damage and those involved in the signaling and cell activation pathways of cellular host-defense systems. Additionally, the ability to characterize molecular variations (polymorphisms) that convey susceptibility to toxicity or limit the efficacy of targeted therapeutics promises to allow greatly improved assessment of individual risks and benefits as well as improved laboratory models that contain molecular targets similar to those in humans. "-Omics" technologies promise to allow simultaneous measurement of very large numbers of such biomarkers in microformats requiring only microliter quantities of sample. This should lead to a shift toward quantitative risk-based regulatory judgments, integrated toxicity/efficacy toxicity assessments, and an improved mechanistic understanding of genetic, cell, and tissue damage. The use of biomarkers in current regulatory practice, the potential impact of such new approaches, and practical considerations for the introduction of new bridging biomarkers into regulatory practice will be discussed.

## 26 SERUM CARDIAC TROPONINS AS BIOMARKERS OF DRUG-INDUCED CARDIOTOXICITY.

M. J. York. *Pathology, GlaxoSmithKline, Ware, Hertfordshire, United Kingdom.* Sponsor: A. Lavin.

The cardiac troponins (cTnI and CtnT) are well established as the clinical gold standard for the detection of acute myocardial injury and their utility is well documented. In comparison, the usefulness of cardiac troponins in laboratory animal species as markers of cardiomyocyte damage is less comprehensive. A recent review of serum troponins (cTn) as biomarkers of drug-induced cardiac toxicity was conducted by the FDA Expert Working Group (EWG). The output from this group formed a proposal made to the ILSI HESI Biomarkers Technical Committee for a multi-laboratory approach to further progress the analytical and biological validation of cTn in laboratory animal species. The Troponins Working Group, comprising individuals from pharma, USFDA, academia and ILSI, was established and this group confirmed the critical data needs identified by the EWG to further assess the preclinical utility of the cardiac troponins: 1. Conduct further analytical and biological validation of selected cTnI assays, establishing degree of immunoreactivity and imprecision 2. Examine the impact of species-specific calibration on cTnI assays in rat and dog 3. Characterise the threshold and release of cTn response in rat, dog and monkey, thereby establishing the diagnostic window following drug-induced acute and chronic cardiomyocyte injury. 4. Examine the correlation of cardiac histopathology with timing and proportionality of troponin release 5. Examine cTn release in laboratory animal species An update of the progress of the Troponins Working Group in addressing these critical data needs will be presented, including the results of a recent analytical validation study and the future plans to further investigate the application of cTn assays in the detection of drug-induced cardiotoxicity.

## 27 INHIBIN B AS A POTENTIAL BIOMARKER OF TESTICULAR TOXICITY.

J. Stewart. *Safety Assessment, AstraZeneca Pharmaceuticals, Macclesfield, Cheshire, United Kingdom.* Sponsor: A. Lavin.

Inhibin B is a glycoprotein produced by the Sertoli cell which regulates FSH release in a negative feedback loop. In all species studied, circulating inhibin B is a marker of spermatogenesis where severe disturbances in spermatogenesis are associated with detectable decreases in circulating inhibin B. It is being increasingly used in the assessment of infertile males and in population studies evaluating reproductive function where it is proving a useful adjunct to more traditional biomarkers such as serum FSH and semen analysis. Inhibin B has a unique place among testicular biomarkers in that it is of Sertoli cell origin and therefore permits a more direct assessment of the intratubular environment. It could permit linkage between animal studies and monitoring of testicular function in clinical trials. An ILSI HESI Biomarkers sponsored project will evaluate the suitability and limitations of plasma inhibin B as a testicular toxicity biomarker. Although inhibin B can detect significant effects on spermatogenesis, the utility of inhibin B to detect more modest testicular dysfunction using experimental designs typical of a toxicity study is still unproven. Fortunately, the commercially available human inhibin B ELISA kits can detect rat inhibin B. Phase 1 of the HESI project will assess the ELISA kit performance against rat plasma inhibin B and will determine whether the interanimal variability in control animals is compatible with future detection of compound induced

effects. Each laboratory will then undertake experiments with one of seven selected testicular toxicants with aim of generating testicular lesions of variable severity and type. The histopathological lesions in the testes will be graded and compared to the circulating inhibin B concentrations. The panel of reference testicular toxicants will be chosen to have different primary target cells. The overall strategy to facilitate the adoption of inhibin B as a biomarker in regulatory toxicity studies will be described alongside the results of the first phase of the validation study and the choice of reference toxicants.

## 28 BIOMARKERS OF NEPHROTOXICITY.

S. Beushausen<sup>1</sup> and A. Lavin<sup>2</sup>. <sup>1</sup>WWSS, Pfizer, Inc., St. Louis, MO and <sup>2</sup>Health and Environmental Sciences Institute, Washington, DC.

Several classic biomarkers of nephrotoxicity have been developed for clinical use to report or monitor renal damage. Classic serum markers include BUN and creatinine. Urine biomarkers are classified into a number of categories including: urinary proteins (e.g. albumin, transferrin, and IgG), urinary enzymes (e.g. N-acetyl glucosaminidase,  $\gamma$ -glutamyl transpeptidase,  $\beta$ -galactosidase), cytotoxicity markers (tubular antigens, laminin fragments), and biochemical markers (fibronectin, kallikrein activity, scialic acid and glycosaminoglycans). Classical markers are limited by lack of sensitivity, indication of general rather than site-specific damage, and intra/inter variability between individuals. Consequently, these markers have limited utility as reporters of frank tissue damage. Pharmaceutical, medical, and academic professionals have agreed that there is an urgent need to develop safety biomarkers of nephrotoxicity that can predict toxicity before encountering irreversible tissue damage or that can help monitor low-grade compound-induced nephrotoxicity in the clinic. Development of pre-clinical safety biomarkers of nephrotoxicity would also be valuable towards helping curb the high cost of drug development and aid in the development of safer compounds. The ILSI-HESI Nephrotoxicity Working Group has examined a number of recently developed nephrotoxicity biomarkers for increased sensitivity and the ability to predict site-specific renal tissue damage. For example, acute and chronic compound-induced toxicity studies have been designed to examine levels of the GST isoforms  $\alpha$  and  $\mu$  to discriminate between proximal and distal tubule damage, respectively. A novel PAP-1 antibody was evaluated for sensitivity and predictive capability for renal papillary toxicity. The development and application of two novel protein biomarker assays include a clusterin assay to determine whether clusterin has utility as a sensitive biomarker of general nephrotoxicity and a KIM-1 assay as a sensitive and reliable biomarker of proximal tubule damage. A discussion around the utility of these biomarkers will be addressed in the presentation.

## 29 REGULATORY ASPECTS OF NEW BIOMARKERS OF TOXICITY.

F. Frueh. *FDA/CDER, Rockville, MD.* Sponsor: A. Lavin.

Pharmacogenomics introduced a new era in drug development with implications reaching from the discovery of novel chemical entities to the far end of individualized drug therapy. One characteristic that coalesces to the entire process is the availability of predictive biomarkers: from the discovery of genetic markers as novel targets for drug therapy to the use of e.g. genetic variations for the prediction of safety and/or efficacy, the adept use of proper biomarkers is of critical importance. In November of 2003, the FDA has released a draft "Guidance for Industry: Pharmacogenomic Data Submissions". The guidance includes three trees which delineate the decision process of whether a particular genomic data set is required to be submitted under current regulations or can be submitted on a voluntary basis - a new paradigm for FDA-Industry cooperation to break the knot that has hampered the use of pharmacogenomic data in the regulatory decision process. Each data set is evaluated according to the level of validation of its biomarkers and for what, if any, regulatory decision the biomarkers are used. For example, a valid known biomarker constitutes a biomarker that has been widely accepted in the scientific community to be a relevant indicator for establishing a particular safety or efficacy profile. Information based on the use of such a biomarker needs to be submitted to the FDA. Another example is the use of biomarkers in an exploratory nature, for example the use of a DNA array to identify genes associated with the cellular response upon disturbing the system by drug treatment. Without hard scientific evidence that such a data set has implications beyond its use as a discovery tool and, if not used for e.g. patient stratification for a clinical trial, no regulatory action will be taken. However, because the field is moving rapidly and new evidence for the validity of certain biomarkers is generated almost daily, the FDA encourages the submission of such data on a voluntary basis to ensure future scientifically sound reviews of investigational or new drug applications by the Agency. We have received several voluntary genomic data submissions. Examples will be presented.

## DOSE-ADDITION OF MIXTURES: WHERE ARE WE GOING WITH THE SCIENCE?

**R. Conolly.** CIIT Centers for Health Research, Research Triangle Park, NC.

A growing challenge in human risk assessment is development of methods to evaluate risks posed by low-level exposures to environmentally relevant mixtures. Development of Relative Potency factors (RPFs), which assume fundamental dose additivity, are currently used as the primary method for evaluating the risks of mixtures of compounds acting through similar modes of action. Examples of these are the RPF schemes for dioxins (Toxic Equivalency Factors) and organophosphate and carbamate pesticides. The aim of the workshop is provide a broad overview and discussion of the state of the science for the use and justification of relative potency factors in environmental and human health risk assessment. The workshop will include presentations describing specific examples of how RPFs are currently applied to cancer assessments of dioxin-like compounds and to non-cancer neurotoxicity endpoints such as exemplified by organophosphate and carbamate pesticides. The recently completed National Toxicology Program chronic rodent studies testing critical RPF hypotheses will be discussed as a specific example of the potential impact of experimental findings on RPF assumptions. In addition, the workshop will discuss the central importance of dosimetry and exposure assessments to evaluation of the RPF approach, particularly addressing implications for understanding potential health risks associated with low-level exposures to chemical mixtures. The Workshop presentations will be designed to engender both Panel and Audience discussion focused on defining the scientific justification and limitations of the use of RPF approaches, and identifying future research needs that will improve risk assessment tools used to assess health impacts associated with low-level exposures to a broad spectrum of environmental chemicals.

**31**

## CAN MODE OF ACTION PREDICT MIXTURE TOXICITY FOR RISK ASSESSMENT?

**C. J. Borger<sup>1,2</sup>.** <sup>1</sup>Applied Pharmacology and Toxicology, Inc., Gainesville, FL and <sup>2</sup>Physiological Sciences, University of FL College of Veterinary Medicine, Gainesville, FL.

Recent regulatory guidance for mixture risk assessments and for regulating pesticide chemicals recommend using information about the mode or mechanism of action of individual chemicals to predict dose response characteristics of mixtures. Dose addition is assumed for mixtures of chemicals that have similar mechanisms, and response addition for those with dissimilar mechanisms. Three different sets of criteria have been formulated to guide the selection of an appropriate data set for characterizing a chemical mode of action, but the sufficiency of those criteria to predict dose addition for a mixture has not been validated experimentally. Several examples from the pharmacological and toxicological literature challenge the premise that dose response characteristics of a mixture can be predicted from the modes of action of its components. Detoxification pathways may need to be understood before dose addition in the observable effect range can be extrapolated to mixture concentrations below the no observable effect levels of the mixture components. Because elucidating discreet mechanisms of action may be possible only for chemicals that exhibit a high degree of biological specificity and dose sensitivity, practical limitations on the approach must be defined. In order to reduce the large uncertainties inherent in the recommended approach, future research should be focused on defining the mechanistic features that predict dose additive toxicity in mixtures. A detailed characterization of pharmacodynamics, pharmacokinetics, and slope of dose response curves may be necessary to evaluate whether the toxicity of a mixture can be predicted by the mode of action of its component chemicals.

**32**

## THE USE OF TEFS IN ASSESSING MIXTURES OF DIOXINS, FURANS AND DIOXIN-LIKE PCBs.

**W. H. Farland, M. DeVito and L. Birnbaum.** Office of Research and Development, USEPA, Washington, DC.

Dioxin and related compounds always exist in nature as complex mixtures. These complex mixtures can be characterized through analytic methods to determine concentrations of individual congeners. Exposure to dioxin and related compounds can be quantified and the biological activity of the mixture can be estimated using relative potency values and an assumption of dose additivity. Such an approach has evolved over time to form the basis for the use of toxicity equivalence (TEQ) in risk assessment for this group of compounds. While such an approach is dependent on critical assumptions and scientific judgement, it has been characterized as a useful, interim method to deal with the complex mixture problem and has been accepted by numerous countries and several international organizations. Alternative approaches assessing complex mixtures of dioxin and related compounds, including the assumption that all congeners carry the toxicity equivalence of 2, 3, 7, 8-TCDD, or that all congeners other than 2, 3, 7, 8-TCDD have no activity, have been rejected as scientifically indefensible and inadequate for risk assessment pur-

poses. However, the degree to which the current point estimate TEFs introduce variability and uncertainty into the health risk assessment process cannot be characterized in a quantitative fashion. Such characterizations may be important in settings where numerous PCDD(F) and PCB congeners contribute to potential health risk. Recent work has focused on refining and updating the database underlying the TEFs and evaluating quantitative methods for assessing the variability and uncertainty in TEF estimates.

**33**

## TESTING THE TOXIC EQUIVALENCY FACTOR (TEF) HYPOTHESIS: THE NTP DIOXIN/PCB CANCER BIOASSAYS.

**N. J. Walker<sup>1</sup>, M. E. Wyde<sup>1</sup>, P. W. Crockett<sup>2</sup>, A. Nyska<sup>1</sup>, J. R. Bucher<sup>1</sup> and C. J. Portier<sup>1,2</sup>.** <sup>1</sup>NIEHS, Research Triangle Park, NC and <sup>2</sup>Constella Group, Research Triangle Park, NC.

The dioxin Toxic Equivalency Factor (TEF) approach is currently used worldwide for assessing and managing the risks posed by exposure to mixtures of certain dioxin-like compounds. Use of the TEF approach assumes that the combined effects of dioxin-like compounds in a mixture can be predicted based on a potency adjusted dose additive combination of constituents of the mixture. To test the TEF approach for carcinogenic risk the National Toxicology Program conducted multiple two-year rodent cancer bioassays in female Harlan Sprague-Dawley rats examining the carcinogenicity of several dioxin-like compounds, PCBs, a defined tertiary mixture, and two mixtures of PCBs. Statistically based, dose-response modeling was used to evaluate the dose-response for induction of both neoplastic and non-neoplastic effects seen in these studies, and to test for interactions between compounds within mixtures and interactions between dioxin-like and non-dioxin like PCBs. For the defined mixture of dioxin-like compounds the dose response for induction of carcinogenicity for the mixture was consistent with an additive combination of the potency adjusted doses of the individual compounds, when using administered dose as the dose metric. Overall these data support the use of the TEF approach for potency adjusted dose addition for use in cancer risk assessments for dioxin-like compounds.

**34**

## PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELING AS AN ALTERNATIVE TO RELATIVE POTENCY FACTORS (RPFs) IN CUMULATIVE RISK ASSESSMENT: AN EXAMPLE WITH ACETYLCHOLINESTERASE- (AChE) INHIBITING PESTICIDES.

**R. Conolly, J. Wang and Y. Tan.** Center for Computational Systems Biology & Human Health Assessment, CIIT Centers for Health Research, Research Triangle Park, NC.

RPFs are used to assess health risks associated with exposure to mixtures of chemicals. The RPF approach incorporates the key assumption that dose-response curves for mixture components are parallel. The prediction of cumulative risk based on RPFs is uncertain to the extent that this assumption does not hold. Cumulative risk for AChE inhibiting pesticides, including organophosphates and N methyl carbamates, is calculated from the degree of AChE inhibition due to the mixture, with AChE inhibition being used as a surrogate for frankly neurotoxic effects. PBPK modeling for AChE inhibiting pesticides can be used to predict cumulative risk while avoiding the assumption of parallel dose-response curves. PBPK models are first be developed for the individual components of the mixture and then linked together by describing interactions at sites of metabolism and at AChE. The resulting "mixture model" describes the overall degree of AChE inhibition for the mixture as a function of (1), the individual pharmacokinetic behavior of each chemical and, (2) the chemical-specific kinetics of AChE inhibition. We have developed a prototypical mixture PBPK model based on individual models for disopropylfluorophosphate, chlorpyrifos, and carbaryl. The model predicts dose responses for AChE inhibition for the individual compounds and for arbitrary dosing scenarios for the mixture. Departures from parallel dose-response, reflecting compound-specific differences in pharmacokinetics, are predicted. In addition, the trade off between the greater realism but resource intensiveness of the PBPK approach and the less ambitious RPF approach will be discussed.

**35**

## ROLE OF NUTRIGENOMICS IN SAFETY ASSESSMENT OF FUNCTIONAL FOODS.

**M. G. Soni<sup>1</sup> and T. R. Zacharewski<sup>2</sup>.** <sup>1</sup>Burdock Group, Vero Beach, FL and <sup>2</sup>Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI.

The recent completion of human genome (blueprint) has triggered an explosion in research into how drugs might be individualized to capitalize on each patient's unique genetic code. The line between food and drug is blurring in the era of the

genome. It appears that the food industry is on the verge of a new era where companies will design foods and market them to consumers according to the consumer's genetic makeup. Increased use of bioactive ingredients (so called functional foods) is challenging toxicologists when making safety determinations. This evaluation is different from that of drugs or toxins as efficacy or benefit analysis of the ingredients has not been factored in the safety determination. The evaluation of absorption, body distribution and metabolism will result in a realistic assessment of ranges in target tissue concentrations. Biological effects (both desirable and undesirable) can then be determined based upon genomic and proteomic changes, the result of which will be a bottom up approach rather than a top down methodology that imposes unrealistic safety factors. Thus, data from gene nutrient interaction will open the ways for new concepts of risk-benefit evaluation. The proposed workshop will cover recent discoveries in nutrition, genomics and proteomics and how these developments will change currently used methodology for risk assessment of bioactive/functional foods. This workshop will focus on applied genomic technologies and their impact on nutrition, health sciences and particularly on safety determination of functional foods. The objectives achieved will be: (1) Provide examples of the impact of genotype (cardiovascular diseases, cancer susceptibility, allergy, etc) on the response to foods and food components; (2) Identify relevant biomarkers that are applicable for assessing the benefits and risks of selected foods; (3) FDA's thinking on use of microarray data in regulatory approvals; and (4) Regulatory and other challenges in determining safety of "nutrionic" foods.

**36**

### RISK ASSESSMENT OF FOOD AND FOOD COMPONENTS AT (NEAR) PHYSIOLOGICAL CONCENTRATIONS.

B. van Ommen. *Physiological Sciences, TNO Nutrition and Food Research, Zeist, Netherlands.* Sponsor: M. Soni.

Development of new bioactives for functional foods multiple gene targets exist, which may be modified by food constituents. Functional foods are usually chronically administered and with a possible multitude of biological effects. Since the majority of these responses are believed to be mediated through effector genes, and genomic technologies allow for the determination of an abundance of relevant genes/proteins/metabolites and their effects on metabolism, functional genomics offer great opportunities in this research. Perturbations of homeostasis (as measured by transcriptomics, proteomic and metabolomic technologies) will open the way for a completely new concept of risk-benefit evaluation, based on multiple subtle changes. Analysis of these changes will present a profile or fingerprint of biomarkers and lead to new mechanistic insights. Thus, this type of analysis will allow for the assessment of risk at (or near) physiological concentrations, instead of the classical toxicological approaches with extrapolations from high doses. In combining many subtle changes into new biomarkers, the biomarker becomes much more sensitive and consequently allows for very early detection of changes. This has enormous potential for toxicological and nutritional research. Biomarkers will change from describing a diseased or pathological state (e.g. plaque formation in atherosclerosis) or negative effect (e.g. oxidative DNA damage) into describing subtle changes in health, both in a positive and negative way. In other words, exploiting holistic datasets, healthy homeostasis and related early changes can be carefully described. On top of this, the new science of systems biology is emerging, taking up the challenge of utilizing all available data generated by genomics technology in a complete description of a biological system. As a result, this new paradigm is ideally fit for the evaluation of many subtle changes in biological activity, as triggered by nutrition and toxicology. Here, a multitude of bioactive compounds act simultaneously and chronically in constantly changing combinations.

**37**

### GENE AND PROTEIN EXPRESSION CHANGES DURING IMMUNE RESPONSES TO FOOD ALLERGENS.

R. J. Dearman and I. Kimber. *Syngenta CTL, Macclesfield, United Kingdom.*

Food allergy is an important health issue. The estimated prevalence among adults in Western Europe is thought to be between 1 and 2%, with the frequency in infants being greater (approximately 5%). Most confirmed food allergies are associated with a relatively limited range of produce, including cow's milk, eggs, tree nuts, peanuts, wheat, fish and shellfish, although the prevalence of allergy to individual foods is known to vary geographically, due largely to differences in dietary practices. There is no doubt that genetic predisposition is also an important determinant. With the increasing interest in novel foods derived from transgenic crop plants, there is a growing need for the development of approaches for the characterization of the allergenic potential of proteins. Although most foreign proteins are immunogenic (able to induce IgG antibody responses), relatively few are important food allergens with the capacity to provoke IgE antibody production and immediate type hypersensitivity responses. Immune responses, including allergic responses, are orchestrated by activated T cell subsets and their cellular products (cytokines).

Characterization in allergen-activated lymph node cells of cytokine gene expression patterns by ribonuclease protection assay and of cytokine secretion profiles, using customized cytokine microarray (Luminex) flow cytometry, demonstrates that exposure of mice to allergenic proteins results in the selective induction of a Th2 cytokine phenotype. Current findings suggest that it may prove possible to use cytokine expression profiling (at either the protein or message level) to identify those proteins with the potential to cause food allergy.

**38**

### NUTRIGENOMICS AND INFLAMMATION.

K. Kornman. *Interleukin Genetics, Waltham, MA.* Sponsor: M. Soni.

The use of genetic and genomic information has various implications for the development of functional foods. Genetic information may be informative relative to both an individual's adverse reactions to dietary substances and the health benefits. Some dietary factors that are known to lead to disease may have a range of adverse health effects in different patients. Certain individuals, due to genetic variations in metabolism or disease causing mechanisms, may benefit from specific dietary substances, whereas others may have a less favorable response. This presentation will consider two examples of how genetic information may influence the response to diet and how this information may be applied to the development of functional foods. Coronary artery disease (CAD) is a complex clinical condition that may result from combinations of multiple biological components. One biological component is lipid metabolism, and specific lipid profiles are influenced by multiple factors, including diet and gene variations. For example, high dietary fat intake adversely influences the lipid profile in some individuals but not others, and the individuals with different biological responses can be distinguished by specific apolipoprotein gene variations. Another major component of CAD is inflammation. Specific cytokine gene variations increase inflammation and the risk for first CAD events, even in individuals with normal cholesterol. One approach to designing functional foods to benefit individuals with a life-long genetic tendency to over-express inflammation will be discussed, including the use of gene arrays in genotype-specific human clinical models to evaluate gene-nutrient interactions.

### USE OF MICROARRAY DATA IN REGULATORY APPROVAL.

D. G. Hattan and T. S. Thurmond. *Office of Food Additive Safety, USFDA Center for Food Safety & Applied Nutrition, College Park, MD.*

At present the FDA Center for Food Safety and Applied Nutrition (CFSAN) does not have a policy for the submission and/or acceptance of microarray-based data in support of the approval process for the food-related compounds over which it has jurisdiction. While CFSAN is following the developments in this field, for now this discussion is hypothetical and has no official standing in assessing the safety of functional foods. What are some of the present shortcomings of genomics? When a food additive material is tested for safety, a number of different toxicological tests are applied (intensity of testing differs based on the level of human exposure). Along with characterizing the compound's organ-related toxicologic profile, "effect" and "no-effect" doses are also determined. At present there is no one "omic" technique or series of techniques that can provide this complete characterization of toxicity. So for some indefinite period "omic" techniques will perform a supportive role in mechanism-determination and elucidation of differential responses. Thus, differences in toxicity between the rat and humans might be delineated by toxicogenomic techniques, but there would have to be some other biomarker or mechanistic data (e.g., relative to biosynthetic pathways, occurrence of enzymes, differences in anatomical structures, etc.) to integrate into the overall reasoning and explanation. Case Study: Test results for sucrose acetate isobutyrate left only the issue of species-dependent hepatotoxicity to be resolved. While the dog showed reduced clearance of bromsulfophthalein at low doses, the mouse and rat did not. Eventually the sponsor ran additional studies with primates and human subjects and convinced OFAS that the low-dose hepatotoxicity was only shown by the dog. If the actual mechanism of toxicity had been demonstrated to be strongly correlated with predictive genomic changes, then it might have been possible to substitute genomics testing for one-year feeding studies and special liver function tests to establish the dog as the sole species to manifest this toxicity.

### IMPACT OF MOLECULAR NUTRITION ON THE SAFETY ASSESSMENT OF FUNCTIONAL FOODS: A SWOT ANALYSIS.

P. Gillies<sup>1,2</sup>, P. Kris-Etherton<sup>2</sup> and J. Vanden Heuvel<sup>3</sup>. <sup>1</sup>*Nutrition & Health, DuPont, Newark, DE*, <sup>2</sup>*Department of Nutritional Sciences, The Pennsylvania State University, State College, PA* and <sup>3</sup>*Department of Veterinary Medicine, The Pennsylvania State University, State College, PA*.

The powerful tools of molecular nutrition generate massive amounts of information, but not necessarily knowledge and understanding. Using dietary fatty acids as a prototypic functional food, the impact of nutritional genomics and nutritional

proteomics on the safety assessment of functional foods will be presented in terms of Strengths, Weaknesses, Opportunities and Threats, i.e., a SWOT analysis. Fatty acids are particularly useful as a case study as their nutritional pharmacology is based, at least in part, on nuclear receptor activation with related changes in gene expression, modulation of the serum proteome, and perhaps most importantly, they have attendant biomarkers of exposure and clinical efficacy. With respect to the SWOT analysis, the utility of molecular nutrition in the safety assessment of nutritional bioactives encompasses the following: Strengths - the application of systems biology enables a holistic assessment consistent with the multifaceted nature of nutrition; Weaknesses - limited paradigms exist to accommodate the pleiotropic pharmacology of nutritional bioactives, let alone that of whole foods in the broader context of diet; Opportunities - identification of potential adverse effects and vulnerable populations elicited by nutritional products characterized by low potency, limited efficacy, but with significant consumer exposure; and Threats - premature application of promising technologies, some of which have bioethical ramifications.

41

#### A NEW GENERATION OF MULTIFUNCTIONAL NANOPARTICLES POSSESSING MAGNETIC MOTOR EFFECT FOR DRUG OR GENE DELIVERY.

K. Yu<sup>1</sup>, J. Kim<sup>1</sup>, M. Cho<sup>1</sup>, B. Kim<sup>2</sup>, J. Lee<sup>2</sup> and T. Yoon<sup>2</sup>. <sup>1</sup>*Laboratory of Toxicology, College of Veterinary Medicine, Seoul National University, Seoul, South Korea* and <sup>2</sup>*Materials Chemistry Laboratory, School of Chemistry, Seoul National University, Seoul, South Korea.*

Nanotechnology is expected not only to provide but to may cause risks. Cobalt-ferrite-silica magnetic nanoparticles(-50nm) labelled with organic dye were prepared by a modified PVP method and sol-gel process. The thickness of the silica shell was controlled by varying the ratio between magnetic nanoparticle(MNP) and tetraethoxysilane(TEOS) plus RITC or FITC dyes. The MNP surface was also modified with PEG. Incorporation of the dyes into the MNP enabled us to monitor the movement of nanoparticles under an external magnetic field by optical microscope. Biological distribution study revealed that the nanoparticles could penetrate the blood-brain-barrier(BBB) while not producing any detectable toxicity. Such penetration may provide useful methods for the study of delivery mechanism into BBB, thus, could be applicable to the biological labelling as well as detection, comprehensive drug or gene delivery systems. Supported by NSI-NCRC through KOSEF.

42

#### THE AGGREGATION OF SINGLE-WALLED CARBON NANOTUBES IN FRESH WATER AND SEA WATER.

H. Cheng and J. Cheng. *Biology and Chemistry, City University of Hong Kong, Hong Kong, N/A, Hong Kong.*

Single-walled carbon nanotubes (SWNTs) are comprised of nanometer-diameter cylinders. They are formed by deposition as a single graphene sheet and wrapped up to form a tube. They are considered as leading candidates for nanoscale electronic applications. Data on the life cycle assessment of SWNTs is not widely available. The fate, transport, transformation and toxicity of SWNTs are not well investigated. As a first step to study the life cycle assessment of SWNTs, we investigate the aggregation of free particles of SWNT in fresh water and sea water. The SWNTs are hydrophobic and they naturally clump together to form aggregates with diameters in the micro meter range. The size distributions of the aggregates do not change significantly with increasing salinity and temperature. In contrast, the size distribution differs with changing pH in the aquatic environment. Our data suggests that the aggregation of free particles of SWNTs in the aquatic environment will affect their impact on the biota in water.

43

#### PROTOCOLS FOR ASSESSING *IN VITRO* TOXICITY OF NANOPARTICULATES.

M. Palazuelos<sup>1</sup>, A. Moraga<sup>2</sup>, K. Powers<sup>1</sup> and B. Moudgil<sup>3</sup>. <sup>1</sup>*Particle Engineering Research Center, University of Florida, Gainesville, FL*, <sup>2</sup>*Interdisciplinary Center for Biotechnology Research, University of Florida, Gainesville, FL* and <sup>3</sup>*Center for Human and Environmental Toxicology, University of Florida, Gainesville, FL*. Sponsor: S. Roberts.

The growing development and use of nanoparticulate materials for commercial applications demands a better understanding of the possible effects and mechanisms of interaction of these materials with biological systems. In this study we have paid special attention to the full characterization of the nanomaterials tested. Well-characterized nanomaterials were then used in exposure studies to evaluate their *in vitro* effects at the cellular level. Several biological endpoint assays (LDH release, metabolic activity and apoptosis) were conducted as indicators of cell death, cell viability and cell proliferation. The cell line selected for these experiments is the human lung carcinoma A549 (type II alveolar epithelial cells). Four particulate materials

were evaluated: a nano aluminum powder (Nanotechnologies), two nanosized titanium oxides powders (Degussa P25 and NanoTek®), and crystalline quartz (Min-U-sil 5). The materials were well dispersed and characterized for size, surface properties, and morphology. Concentration and time courses were designed in order to evaluate the extent of cytotoxicity, and to define critical conditions for further research. Treatment consisted of exposing the cells to particles in culture for time periods ranging from 4 to 72 hours and in concentrations from 30 µg/ml to 500 µg/ml. Bioassays were run following standard procedures as outlined in the instructions provided with kits (Roche Diagnostics and BioSource). All measurements were obtained using appropriate controls in order to minimize artifacts such as light scattering by the particles themselves.

44

#### ASSESSING THE POTENTIAL HAZARD OF ENGINEERED NANOPARTICLES IN THE WORK ENVIRONMENT.

A. J. Nordone<sup>1</sup>, J. Jose<sup>2</sup> and C. A. Gray<sup>2</sup>. <sup>1</sup>*Cabot Corporation, Leuven, Belgium* and <sup>2</sup>*Cabot Corporation, Billerica, MA.*

Within the arena of nanoparticle development, innovation is running ahead of regulation. There are currently no regulatory guidelines for the protection of workers specifically from nanoparticle exposure. As a result, those organizations concerned must assess the potential hazard of the nanoparticles with which they are working and take the appropriate measures to ensure the safety of their employees. Here we present a simplified matrix that can be used to qualitatively assess the potential hazard associated with specific nanoparticles based on a number of physical and chemical characteristics. When considering the potential human health effects of nanoparticles, the popular press has focused almost exclusively on the influence of size. In reality, any potential human health effects associated with nanoparticle exposure would be the result of a number of factors including route of exposure, shape, surface properties, solubility as well as size. The combined influence of these factors can result in nanoparticles that range from extremely hazardous to relatively benign within the work environment. With such information, organizations can provide their employees with the appropriate protective equipment to ensure that risk of adverse health effects is minimal.

45

#### GENE EXPRESSION PROFILING OF NANOSCALE MATERIALS USING A SYSTEMS BIOLOGY APPROACH.

M. Cunningham<sup>1</sup>, S. R. Magnuson<sup>2</sup> and M. T. Falduto<sup>2</sup>. <sup>1</sup>*Life Sciences & Health, Houston Advanced Research Center, The Woodlands, TX* and <sup>2</sup>*GenUs BioSystems, Inc., St. Charles, IL.*

Nanomaterials are being developed and manufactured on a commercial scale. However, preliminary reports are mixed as to their toxicity. One of the major organ systems affected through environmental exposure is skin. In an effort to assess the risk to humans, human cell cultures and gene expression microarrays were used in a systems biology approach. This approach perturbs a biological system with a possible toxic insult and reiteratively samples it over time. Primary human neonatal epidermal keratinocytes (HEK) were treated *in vitro* with several nanoscale materials, including: silica (Min-U-Sil®5, SiO<sub>2</sub>), titanium dioxide (TiO<sub>2</sub>) and carbon black (Printex 90®). These particulate materials were used to treat randomly-proliferating HEK cultures at 8 time points ranging from 0 to 24 hr. Cell pellets were snap-frozen and stored at -80C. Biotinylated cRNA probes were synthesized from total RNA isolated from the cell pellets and hybridized onto CodeLink™ microarrays containing oligomers from 9, 970 unique human genes. After image analysis, the results were analyzed by statistical methods as well as both supervised and unsupervised methods. Analyzing the data from treating the HEK cultures with each compound at 1mg/mL for 24 hr. by hierarchical agglomerative clustering (Euclidean distance metric, complete linkage), the gene expression patterns for SiO<sub>2</sub> and TiO<sub>2</sub> were more similar to each other as compared to the gene expression pattern observed for Printex90. Approximately 75% of the 9, 970 probes passed a set of stringent quality control criteria. While all three materials regulated similar genes (e.g. several structural proteins, such as laminin), there were differences observed in the gene families of ribosomal proteins and cytokines. These families of genes have previously been reported to be effected by these particulates. Min-U-Sil and Printex90 are registered trademarks of US Silica Company and Degussa Corporation, respectively, and CodeLink is the trademark of GE Healthcare.

46

#### *IN VITRO* AND *IN VIVO* EXPOSURE TO ORTHO-SUBSTITUTED PCB 95 AND PCB 170 ALTER NEUROPLASTICITY IN THE RAT HIPPOCAMPAL SLICES.

K. Kim<sup>1</sup>, I. N. Pessah<sup>1</sup> and T. E. Alberston<sup>2</sup>. <sup>1</sup>*Molecular Biosciences: VM, U.C.Davis, Davis, CA* and <sup>2</sup>*Internal medicine :Medical school, U.C.Davis, Sacramento, CA.*

There is mounting evidence that exposure to non-coplanar PCB's is associated with significant changes in locomotor activity, spatial learning and memory in rodents. In this study, PCBs 95- and 170-induced changes in synaptic transmission of rat

hippocampal slices were monitored by electrophysiological measurements. Field excitatory postsynaptic potential (fEPSP) was evoked by single pulse stimulation of Schaffer Collateral/commissural fibers at stratum radiatum of the CA1 region in the hippocampus. Following exposure to 100 nM PCB 170, time-dependent changes in the slope and amplitude of fEPSP were seen, with phases of enhancement and depression. To investigate the contribution of inhibitory neurons in the actions of PCB 170, hippocampal slices were pre-treated with the GABAa receptor antagonist, picrotoxin (PTX, 100  $\mu$ M). Pre-treatment with PTX resulted in negligible change in fEPSP slope elicited by single pulse stimuli. Importantly PCB170 introduced in the presence of GABAa blockade produced a threshold response at 1nM and enhanced fEPSP slope of 250% at 100nM, revealing a significant facilitation of synaptic transmission. Non-coplanar PCBs therefore influence both excitatory and inhibitory pathways in CA1 that can mask their potent effects. These results demonstrate that blockade of inhibitory inputs with PTX can unmask the potent actions of ortho-substituted PCB 170 toward facilitating excitatory transmission. Studies of perinatal exposure to PCB 95 (6mg/kg/day) from GD5 to PND 21 were also performed to examine influences on hippocampal excitability in the offspring. PTX (100  $\mu$ M) application to hippocampal slices from PCB-treatment groups displayed a much higher sensitivity to synaptic facilitation in comparison slices isolated from corn oil control groups. These results show that ortho-substituted PCBs are especially potent excitatory neurotoxicants in the presence of GABAergic insufficiency. Highly synergistic xenobiotic mechanisms can dramatically enhance susceptibility of the hippocampus to non-coplanar PCBs.

47

#### OVEREXPRESSION OF NQO1 PROTECTS HUMAN DOPAMINERGIC SK-N-MC NEUROBLASTOMA CELLS AGAINST DOPAMINE INDUCED CELL DEATH.

S. H. Inayat-Hussain<sup>1,2</sup>, K. S. Zafar<sup>1</sup>, A. Bao<sup>1</sup> and D. Ross<sup>1</sup>. <sup>1</sup>*Pharmacology Sciences, University of Colorado, Denver, CO* and <sup>2</sup>*Biomedical Science, Faculty of Allied Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, WP, Malaysia.*

Dopaminergic neurons are selectively vulnerable to dopamine-quinones and reactive oxygen species generated by dopamine oxidation and destruction of dopaminergic neurons has been implicated in the pathogenesis of Parkinson's disease. NAD(P)H: quinone oxidoreductase (NQO1) can metabolize dopamine derived quinones (DAQ) and a lack of NQO1 due to NQO1\*2 polymorphism has been suggested to be a risk factor for PD. We have recently shown high NQO1 immunoreactivity in the substantia nigra of human Parkinson's brains. In order to confirm the role of NQO1 in the metabolism of dopamine, we have examined the potential role of NQO1 in human neuroblastoma cell line (SK-N-MC), which was transfected with NQO1. The NQO1 activity of stably transfected cells was 350nmole /mg/ min while vector control and parental cells had NQO1 activities of less than 40nmole/ mg/ min using standard activity assays. Incubation of 500 $\mu$ M dopamine for 24 hrs in both parental and vector control SK-N-MC cells resulted in 88% and 72% cell death as assessed by annexin-V/Propidium iodide analysis using flow cytometry. In agreement, 88% and 84% of parental and vector control cells respectively underwent loss of mitochondrial membrane potential (MMP) assessed by tetramethylrhodamine ethyl ester. In contrast, NQO1 transfected cells were resistant to dopamine toxicity and both cell death and loss of MMP were abrogated in NQO1-transfected SK-N-MC cells. Dopamine resistance in NQO1 over-expressed cells may be attributed to the role of NQO1 in the detoxification of DAQ and/or direct scavenging of reactive oxygen species (Siegel et al (2004), Mol Pharmacology 65; 1238-47) and may play an important role in the pathogenesis of Parkinson's disease. #### FORCED EXERCISE ATTENUATES KAINIC ACID-INDUCED NEUROTOXICITY IN THE HIPPOCAMPUS OF C57BL/6J MICE.

S. A. Benkovic, J. P. O'Callaghan and D. B. Miller. *TMBB, CDC-NIOSH, Morgantown, WV.*

Exercise is considered beneficial to overall health and may enhance the resiliency of the body to insult. Here, we investigated the ability of exercise to modulate neurotoxicity caused by kainic acid in male C57Bl/6J mice. Forced walking was achieved in a motorized exercise wheel (10 s/rev., 30 min., 4:00 P.M.). Mice were trained for three days, then exercised for 14 days prior to kainate treatment. On day 14 of exercise, mice received an injection of saline or kainic acid (20 mg/kg, intraperitoneal, at 12:00 P.M.). Additional non-exercised mice received similar injections for a total of four groups: saline, kainate, wheel saline, wheel kainate. Seizure severity was scored according to the Racine scale. At 24 hours post-injection, mice were decapitated, the brain was removed and bisected; the left hippocampus was dissected for analysis of GFAP by ELISA while the right hemisphere was immersion fixed for histological analysis of neurodegeneration by Fluoro-Jade B staining. Body, thymus, and spleen weights were recorded, and plasma was prepared for analysis of

corticosterone levels. The 24 hour time point for sacrifice was selected based on previous experimentation evaluating kainate-induced neurodegeneration, but preceded the peak of induction of GFAP. Kainic acid treatment caused minimal seizures (mouth and facial movements). Fluoro-Jade B staining revealed fluorescent pyramidal cells in kainate-treated animals indicating neuronal damage; no fluorescent neurons were observed in any exercised mice. GFAP levels were not significantly different between groups, but protein levels were slightly elevated in kainate treated mice, and attenuated in exercised animals. Additional time points will be examined which correlate with the peak of reactive gliosis. No differences in body or organ weights were observed; however, there was a trend of decreasing thymus weight in exercised animals. These data suggest exercise may be protective against kainate-induced excitotoxicity. The generality of these findings for other types of brain insults will be the topic of future investigations.

49

#### EVALUATING THE NMDA-GLUTAMATE RECEPTOR AS A SITE OF ACTION FOR TOLUENE, *IN VIVO*.

A. S. Bale<sup>1</sup>, Q. T. Krantz<sup>2</sup>, P. J. Bushnell<sup>1</sup>, T. J. Shafer<sup>1</sup> and W. K. Boyes<sup>1</sup>.

<sup>1</sup>*Neurotoxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC* and <sup>2</sup>*Experimental Toxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

*In vitro* studies have demonstrated that toluene disrupts the function of several ion channels localized in the brain, including the NMDA-glutamate receptor. This has led to the hypothesis that effects on ion channel function may contribute to toluene neurotoxicity, CNS depressive behavior, and altered visual evoked potentials observed in animals and humans. However, this hypothesis has not been tested *in vivo*. The present experiment examines potential toluene targets in whole animals by measuring visual evoked potentials (VEPs) during toluene exposure and challenging with a drug that antagonizes toluene's action at the NMDA-glutamate receptor. Therefore the goal of this study was to verify changes in VEPs during toluene exposure and demonstrate that toluene inhibits NMDA-glutamate receptor mediated functions in visual evoked potentials elicited from rats. One week prior to testing, recording electrodes were implanted in the rat skull above left visual cortex. Awake, restrained rats were presented with an onset/offset pattern containing a spatial frequency of 0.16 cpd, temporal frequency of 4.55 Hz, with a 60 percent contrast between bars. Baseline VEPs were recorded and rats were injected with either saline or NMDA (10 mg/kg, i.p.). Ten minutes after injection animals were exposed to air or toluene (2000 ppm). VEP amplitudes were calculated for 2X stimulus frequency (F2) for each rat. Thirty minutes after injection of NMDA or saline, NMDA/air (n=5) treatments decreased F2 by 15 percent, saline/toluene (n=6) decreased F2 by 42 percent and toluene/NMDA (n=6) decreased F2 amplitude by 63 percent, contrary to expectations. These results indicate an unanticipated, additive effect of toluene and NMDA on decreasing F2 amplitude. Thus, there appears to be an interaction between NMDA and toluene in the visual system. (This abstract does not reflect EPA policy)

50

#### INVOLVEMENT OF OXIDATIVE STRESS IN POTENTIATION OF NOISE INDUCED HEARING LOSS (NIHL) BY CHEMICAL CONTAMINANTS.

L. D. fechter, B. Pouyatos and C. A. Gearhart. *Research (151), Loma Linda VA Medical Center, Loma Linda, CA.*

Permissible workplace exposure limits for noise and for chemical contaminants generally rely upon laboratory and epidemiological investigations that entail exposure to the single agent of interest. However, a growing body of research shows that a variety of chemical contaminants, including those that have no effect upon auditory function, can potentiate noise induced hearing loss. Such potentiation is particularly noteworthy when it occurs for low intensity noise exposures that approach the permissible human noise exposure standards. We predict that chemicals able to impair intrinsic antioxidant mechanisms potentiate NIHL since reactive oxygen species may be generated even at low noise levels. Combined exposure of rats to hydrogen cyanide and mild noise yields significant auditory impairment while at neither agent given alone resulted in hearing loss. Using antioxidant drug treatments to protect auditory function and pro-oxidant drugs to promote oxidative stress we find support for our hypothesis that oxidative stress does play a role in potentiation of noise induced hearing loss by hydrogen cyanide. supported in part by NIOSH OH03481.

51

#### MODULATION OF CHOLINERGIC TOXICITY BY CANNABINOIDS.

A. Nallapaneni, N. Mirajkar, S. Karanth and C. Pope. *Physiological Sciences, Oklahoma State University, Stillwater, OK.*

Endogenous (e.g., anandamide) and exogenous (e.g., tetrahydrocannabinol) cannabinoids have been reported to decrease or increase acetylcholine release in different brain regions. Both the cholinergic agonist carbachol and the cholinesterase

inhibitor physostigmine increase cannabinoid release in hippocampal slices. Furthermore, some organophosphorus (OP) anticholinesterases block specific binding to cannabinoid CB1 receptors. We studied the effects of repeated exposure to the synthetic cannabinoid WIN 55, 212-2 (WIN) on acute toxicity of the potent OP anticholinesterase, paraoxon. First, motor activity and CB1 binding were studied in rats (n=8/group) treated (daily for 7 days) with 0.5, 1.5 or 5.0 mg/kg WIN. The low dosage (0.5 mg/kg/day) increased locomotor activity, but apparent habituation was noted in both vehicle and 0.5 mg/kg/day WIN groups over time. In contrast, 1.5 mg/kg/day WIN elevated motor activity with no apparent habituation, while rats treated with 5 mg/kg/day WIN initially showed reduced motor activity but hyperactivity at later time-points. CB1 binding was significantly reduced (24-31%) in hippocampus, 4 hours after the last WIN exposure (1.5 and 5.0 mg/kg/day), but was not significantly affected in either cortex or striatum or by the low dosage in any tissue. In parallel studies, similarly-treated rats were given paraoxon (0.4 mg/kg, sc, n=4/group) 4 hours after the final WIN exposure and signs of cholinergic toxicity (SLUD signs, involuntary movements, motor activity) were monitored at 1, 2, 4 and 16 hours after dosing. With involuntary movements, greater toxicity was noted in all WIN-pretreated rats from 1-4 hours. In contrast, SLUD signs were less prominent in WIN-pretreated rats at these time-points. No cholinergic signs were noted at the last time-point in either group. In general, there was reduced ambulation and rearing within the first hour after paraoxon exposure in WIN-pretreated rats, but relative hyperactivity at later time-points. These results suggest that co-exposure to cannabinoids may modulate the expression of cholinergic toxicity. (Supported by OSU Board of Regents).

52

#### TEMPORAL PARAMETERS OF ENVIRONMENTAL ENRICHMENT-INDUCED COGNITIVE ENHANCEMENT IN A RODENT MODEL OF LEAD NEUROTOXICITY.

C. D. Toscano, J. L. McGlothan, J. R. Moss and T. R. Guilarte. *Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.*

Environmental enrichment (EE), a non-pharmacological therapy that combines social interaction with a complex living environment, reverses molecular and cognitive deficits observed in a rodent model of lead intoxication (Guilarte et al, Ann. Neurol., 53:50, 2003). In order to translate this finding to the human condition, it is important to further understand the temporal parameters of this therapy. We tested whether the benefit of EE on cognitive function persists in adult rats after EE was removed and if a critical window exists for the application of this therapy. Rats were exposed to 0 or 1500 ppm lead acetate from conception until postnatal day (PN) 21 and then housed singly in standard rat cages (isolated) or in groups of 8 (enriched) in multi-level cages that contained toys until PN79. To test if the benefits of EE are long lasting, rats were raised in enrichment cages from PN21 until PN50 and then transferred to isolated cages until PN79 (permanence). To determine if a critical window existed for the benefit of the intervention, animals were placed in EE from PN50 to PN79. In all studies, spatial learning was assessed at PN79. Blood and hippocampal lead levels were elevated in lead exposed rats, however, no significant lead exposure effect was observed on the acquisition of the task. A significant housing effect was observed on the acquisition, probe and cue tests with rats currently receiving EE (enriched and critical window) performing significantly better on all three tasks. Nearly twice as many rats in the isolated and permanence groups exhibited a place strategy in the cue test which contributed to the significantly elevated latency in the cue test. In summary, these studies could not detect a significant cognitive deficit in lead exposed rats at PN79, which could be due to the degree of difficulty of the task. Further, EE is effective in enhancing cognitive performance but this benefit is lost after cessation of EE. [Supported by NIEHS grant # ES006189 to TRG]

53

#### PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR $\alpha$ IS REGULATED BY GSK3.

K. A. Burns and J. P. Vanden Heuvel. *Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA.*

Peroxisome proliferators-activated receptors (PPARs) are ligand-activated transcription factors belonging to the nuclear receptor family. PPARs can be activated by a large group of chemicals called peroxisome proliferators that include industrial pollutants and hypolipidemic drugs. PPAR $\alpha$ , similar to other nuclear receptors including the estrogen receptor and the glucocorticoid receptor, has been demonstrated to be a phosphoprotein through *in vivo* phosphorylation studies. However, the kinases and phosphorylation sites within PPAR $\alpha$  are not known. Many consensus phosphorylation sites for PPAR $\alpha$  are predicted. Within these sites, there are five conserved glycogen synthase kinase 3 (GSK3) sites in the A/B and C domains of PPAR $\alpha$ . GSK3 is involved in cell cycle regulation and may help explain the role PPAR $\alpha$  plays in cell cycle regulation. In this study, the effects of GSK3 on PPAR $\alpha$  phosphorylation and activity have been explored. Co-transfection of GSK3 with

PPAR $\alpha$  resulted in an increase in ligand-inducible reporter activity that was blocked by LiCl, a GSK3 specific inhibitor. *In vivo* phosphorylation studies were done to show the role of GSK3 in the phosphorylation of PPAR $\alpha$ . These studies suggest a role for GSK3 in the phosphorylation and regulation of PPAR $\alpha$ . (Supported by NIH ES07799)

54

#### PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA- AND P53-RESPONSIVE GENE REGULATION BY RIBOSOMAL PROTEIN L11.

L. Gopinathan<sup>1</sup>, J. P. Gray<sup>2</sup> and J. P. Vanden Heuvel<sup>1</sup>. <sup>1</sup>*Center for Molecular Toxicology and Carcinogenesis, Penn State University, State College, PA* and <sup>2</sup>*Department of Pharmacology and Toxicology, Rutgers University, Piscataway, NJ.*

Peroxisome Proliferator-Activated Receptor Alpha (PPAR  $\alpha$ ) is a member of the nuclear receptor superfamily. PPAR  $\alpha$  activation with peroxisome proliferators induces a mitogenic response in hepatocytes and a tumorigenic response in rodents. Upon activation, PPAR  $\alpha$  forms a heterodimer with Retinoid X Receptor alpha (RXR  $\alpha$ ) and the complex binds to response elements in the 5 regulatory regions of target genes. Our studies have demonstrated that PPAR  $\alpha$  associates with the ribosomal protein L11 (rpL11), a component of the large 60S subunit. Recent studies have shown that rpL11 suppresses the activity of MDM2, a negative regulator of p53, leading to the stabilization and activation of p53. We show that rpL11 inhibited the transcriptional activity of PPAR  $\alpha$ . This was associated with decreased heterodimerization of PPAR  $\alpha$  and RXR  $\alpha$  and decreased binding to the PPAR-response element (PPRE). In addition to inhibition of PPAR  $\alpha$  activity, we investigated if the formation of the PPAR  $\alpha$ -rpL11 complex also affected p53 signaling. Manipulation of rpL11 expression via ribosomal stress, serum deprivation and small inhibitor RNA (RNAi) was used to study the regulation of both p53 and PPAR  $\alpha$ -responsive genes by peroxisome proliferators. The convergence of PPAR  $\alpha$  and p53 signaling pathways may play an important role in the ability of peroxisome proliferators to regulate key growth regulatory genes. Supported by NIH DK49009.

#### THE PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR- $\beta$ (PPAR $\beta$ ) AGONIST GW0742 INHIBITS COLON CARCINOGENESIS.

H. E. Marin<sup>1</sup>, A. N. Billin<sup>2</sup>, T. M. Willson<sup>2</sup> and J. M. Peters<sup>3,1</sup>. <sup>1</sup>*Biochemistry, Microbiology, and Molecular Biology, The Pennsylvania State University, University Park, PA*, <sup>2</sup>*Nuclear Receptor Discovery Research, GlaxoSmithKline, Research Triangle Park, NC* and <sup>3</sup>*Veterinary Science and the Center of Molecular Toxicology and Carcinogenesis, Pennsylvania State University, University Park, PA.*

Recent data has shown that PPAR $\beta$  may be a moderating factor involved in the etiology of colon cancer. PPAR $\beta$  expression is reported to be elevated in human colon tumors containing an inactivated APC gene, as well as in human and azoxymethane-induced rodent tumors. Previously, the functional role of PPAR $\beta$  in colon carcinogenesis was investigated using azoxymethane (AOM)-treated PPAR $\beta$ -null mice. These studies showed that when treated with AOM, PPAR $\beta$ -null mice exhibit a dose-dependent increase in colon polyp formation as compared to AOM-treated wild-type mice. In the present studies, wild-type and PPAR $\beta$ -null mice were treated with AOM along with the PPAR $\beta$  ligand GW0742. Wild-type mice treated with AOM and ligand had a dose-dependent decrease of colon polyp formation as compared to wild-type controls treated with AOM alone. In contrast, PPAR $\beta$ -null mice treated with AOM and ligand showed no change in polyp formation as compared to PPAR $\beta$ -null control mice treated with AOM alone. Consistent with previous studies, colon polyp formation was exacerbated in PPAR $\beta$ -null mice when compared to their wild-type counterparts. These results support the hypothesis that PPAR $\beta$  attenuates colon carcinogenesis, and that the protective role is enhanced through activation of PPAR $\beta$  with the synthetic ligand GW0742. #### UNDERSTANDING GENE EXPRESSION CHANGES CONTROLLED BY THE PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR $\alpha$ IN RATS.

P. D. Cornwell<sup>1</sup>, W. J. Bailey<sup>2</sup>, A. T. De Souza<sup>1</sup> and R. G. Ulrich<sup>1</sup>. <sup>1</sup>*Preclinical Molecular Profiling, Rosetta Inpharmatics LLC (a wholly owned subsidiary of Merck & Co. Inc.), Seattle, WA* and <sup>2</sup>*LSIT, Merck Research Laboratories, West Point, PA.*

Peroxisome proliferator-activated receptors (PPAR's) are a group of nuclear receptors whose ligands include fatty acids, eicosanoids and the fibrate class of drugs. In humans, fibrates are used to treat dyslipidemias. In rodents, fibrates cause peroxisome proliferation, a change that might explain the observed hepatomegaly. In one

study, rats were treated with multiple dose levels of six fibrin acid analogues (including fenofibrate) for up to two weeks. Pathological analysis identified hepatocellular hypertrophy as the only sign of hepatotoxicity, and only one compound at the highest dose caused any significant increase in serum ALT or AST activity. RNA profiling revealed that the expression of 1288 genes was related to dose or length of treatment and correlated with hepatocellular hypertrophy. Based upon the biochemical pathways represented in this gene set, it is likely that these changes are linked to many of the clinical benefits of fibrate drugs. In light of the fact that all six compounds stimulated similar or identical changes in the expression of this set of 1288 genes, these results indicate that hepatomegaly, in addition to the clinical benefit, is due to PPAR $\alpha$  activation. However, the use of a PPAR $\alpha$  signature alone to identify receptor activation by drugs can be misleading. In another study, we examined the effects of MrkA (a CCR5 antagonist) and found that it generated a PPAR $\alpha$  signature comparable to that of fibrates. A small but significant additional signature was shared with known mitochondrial inhibitors, leading to our conclusion that for this compound the PPAR $\alpha$  signature was not a proximal effect but was likely due to the accumulation of endogenous ligands.

### OVERLAPPING TRANSCRIPTIONAL PROGRAMS REGULATED BY THE NUCLEAR RECEPTORS PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA, RETINOID X RECEPTOR AND LIVER X RECEPTOR IN MOUSE LIVER.

A. Laughter<sup>2</sup>, S. P. Anderson<sup>1</sup>, C. Dunn<sup>2</sup>, L. Yoon<sup>1</sup>, C. Swanson<sup>2</sup>, R. Chandraratna<sup>3</sup>, T. M. Stulnig<sup>4</sup>, K. R. Steffensen<sup>4</sup>, J. Gustafsson<sup>4</sup> and J. C. Corton<sup>5,2</sup>. <sup>1</sup>GSK, Research Triangle Park, NC, <sup>2</sup>CIIT, Research Triangle Park, NC, <sup>3</sup>Allergan, Irvine, CA, <sup>4</sup>Karolinska Institute, Huddinge, Sweden and <sup>5</sup>Toxicogenomics, Chapel Hill, NC.

Lipid homeostasis is controlled in part by the nuclear receptors peroxisome proliferator (PP)-activated receptor alpha (PPARalpha) and liver X receptor (LXR) through regulation of genes involved in fatty acid and cholesterol metabolism. Exposure to agonists of retinoid X receptor (RXR), the obligate heterodimer partner of PPARalpha and LXR results in responses that partially overlap with those of PP. To better understand the gene networks regulated by these NR, transcript profiles were generated from the livers of wild-type and PPARalpha-null mice exposed to the RXR pan-agonist AGN194, 204 or the PPAR pan-agonist, WY-14, 643 (WY) and compared to the profiles from the livers of wild-type and LXRApha/LXRbeta-null mice after exposure to the LXR agonist T0901317. All 218 WY-regulated genes altered in wild-type mice required PPARalpha. Remarkably, ~80% of genes regulated by AGN194, 204 required PPARalpha including cell-cycle genes, consistent with AGN-induced hepatocyte proliferation having both PPARalpha-dependent and -independent components. Overlaps of ~31-62% in the transcript profiles of WY, AGN194, 204 and T0901317 required PPARalpha and LXRApha/LXRbeta for statistical significance. Out of the 50 overlapping genes regulated by T0901317 and WY, all but one were regulated in a similar direction. These results 1) identify new transcriptional targets of PPARalpha and RXR important in regulating lipid metabolism and liver homeostasis, 2) illustrate the importance of PPARalpha in regulation of gene expression by a prototypical PP and by an RXR agonist and 3) provide support for an axis of PPARalpha-RXR-LXR in which agonists for each nuclear receptor regulate an overlapping set of genes in the mouse liver.

### THE TRANSCRIPTIONAL RESPONSE TO A PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA AGONIST INCLUDES INCREASED EXPRESSION OF PROTEOME MAINTENANCE GENES.

S. P. Anderson<sup>1</sup>, P. Howroyd<sup>2,3</sup>, J. Liu<sup>4</sup>, X. Qian<sup>4</sup>, R. Bahneemann<sup>5</sup>, C. Swanson<sup>3</sup>, M. Kwak<sup>6</sup>, T. W. Kensler<sup>6</sup> and J. C. Corton<sup>7,3</sup>. <sup>1</sup>GSK, Research Triangle Park, NC, <sup>2</sup>EPL, Research Triangle Park, NC, <sup>3</sup>CIIT, Research Triangle Park, NC, <sup>4</sup>NCI at NIEHS, Research Triangle Park, NC, <sup>5</sup>BASF, Ludwigshafen, Germany, <sup>6</sup>Johns Hopkins University, Baltimore, MD and <sup>7</sup>Toxicogenomics, Chapel Hill, NC.

The nuclear receptor peroxisome proliferator-activated receptor alpha (PPARalpha), in addition to regulating lipid homeostasis, controls the level of tissue damage after chemical or physical stress. To determine the role of PPARalpha in oxidative stress responses, we examined damage after exposure to chemicals that increase oxidative stress in wild-type or PPARalpha-null mice. Primary hepatocytes from wild-type but not PPARalpha-null mice pretreated with the PPAR pan-agonist WY-14, 643 (WY) were protected from damage to cadmium and paraquat. The livers from intact PPARalpha-null mice were more sensitive to damage after carbon tetrachloride treatment compared to wild-type mice. To determine the mo-

lecular basis of the protection by PPARalpha, we identified genes by transcript profiling whose expression was altered by a 7-day exposure to WY in wild-type and PPARalpha-null mice. Out of the 815 genes regulated by WY in wild-type mice ( $p < 0.001$ ;  $>1.5$ -fold or  $<-1.5$ -fold), only 2 genes were regulated similarly by WY in PPARalpha-null mice. WY increased expression of stress-modifier genes that maintain the health of the proteome including those that prevent protein aggregation (heat stress-inducible chaperones) and eliminate damaged proteins (proteasome components). Although the induction of proteasomal genes significantly overlapped with those regulated by 1, 2-dithiole-3-thione, an activator of oxidant-inducible Nrf2, WY increased expression of proteasomal genes independently of Nrf2. Thus, PPARalpha controls the vast majority of gene expression changes after exposure to WY in the mouse liver and protects the liver from oxidant-induced damage, possibly through regulation of a distinct set of proteome maintenance genes.

### ROLE OF PPARALPHA IN CALORIC RESTRICTION EFFECTS IN THE MOUSE LIVER.

J. C. Corton<sup>1,4</sup>, U. Apté<sup>2</sup>, S. P. Anderson<sup>3</sup>, P. Limaye<sup>2</sup>, L. Yoon<sup>3</sup>, J. Latendresse<sup>3</sup>, J. Everitt<sup>4</sup>, K. A. Voss<sup>6</sup>, C. Kimbrough<sup>3</sup>, J. S. Wong<sup>7</sup>, S. S. Gill<sup>7</sup>, R. A. Chandraratna<sup>8</sup>, M. Kwak<sup>9</sup>, T. W. Kensler<sup>9</sup>, T. M. Stulnig<sup>10</sup>, K. R. Steffensen<sup>10</sup>, J. Gustafsson<sup>10</sup> and H. M. Mehendale<sup>2</sup>. <sup>1</sup>Toxicogenomics, Chapel Hill, NC, <sup>2</sup>University of Louisiana, Monroe, LA, <sup>3</sup>GSK, Research Triangle Park, NC, <sup>4</sup>CIIT, Research Triangle Park, NC, <sup>5</sup>PAI, Jefferson, AR, <sup>6</sup>USDA, Athens, GA, <sup>7</sup>University of California, Riverside, CA, <sup>8</sup>Allergan, Irvine, CA, <sup>9</sup>Johns Hopkins University, Baltimore, MD and <sup>10</sup>Karolinska Institute, Huddinge, Sweden.

The obesity epidemic in industrialized countries is associated with increases in cardiovascular disease (CVD) and certain types of cancer. In animal models, caloric restriction (CR) suppresses these diseases as well as chemical-induced tissue damage. These beneficial effects of CR overlap with those altered by agonists of nuclear receptors (NR) under control of the fasting-responsive transcriptional co-activator, peroxisome proliferator-activated co-activator 1alpha (PGC-1alpha). In a screen for compounds that mimic CR effects in the liver, we found statistically significant overlaps between the CR transcript profile in wild-type mice and the profiles altered by agonists of lipid-activated NR including peroxisome proliferator-activated receptor alpha (PPAR), liver X receptor and their obligate heterodimer partner, retinoid X receptor. The overlapping genes included those involved in CVD (lipid metabolism, inflammation) and cancer (cell fate). Based on this overlap, we hypothesized that some effects of CR are mediated by PPAR. As determined by transcript profiling, 19% of all gene expression changes in wild-type mice were dependent on PPAR including Cyp4a10 and Cyp4a14, involved in fatty acid omega-oxidation, acute phase response genes and epidermal growth factor receptor but not increases in PGC-1alpha. CR protected the livers of wild-type mice from damage induced by thioacetamide, a liver toxicant and hepatocarcinogen. CR protection was lost in PPAR-null mice due to inadequate tissue repair. These results demonstrate that PPAR mediates some of the effects of CR and indicate that a pharmacological approach to mimicking many of the beneficial effects of CR may be possible.

The mouse is an invaluable model for the study of linkages between the genome and phenotype, facilitating an extensive knowledge base for genetic diversity, gene-environment interactions and toxicological endpoints. The integration of mouse genetics, toxicogenomics and conventional toxicology allows for a systems biology approach for discovery of the mechanisms of liver injury due to toxicant exposure. The multidimensional datasets that include detailed genotyping data, gene expression profiles and an array of phenotypic measures of liver injury could help to define a toxicity susceptibility state and aid in a discovery of biomarkers. Acetaminophen (APAP) was selected as a model hepatotoxicant because much information exists regarding the mechanisms of toxicity and conventional clinical markers largely fail to connect toxicity and the clinical outcome. A panel of 40 inbred strains that are used in the Mouse Phenome Project was selected for this study. Male mice were fasted for 18 hrs, administered an acute dose of APAP (300 mg/kg) or vehicle (0.5% methylcellulose), and sacrificed over a time course for up to 24

hrs. Liver tissue was harvested and sectioned for histology scoring and microarray analysis. In addition, blood was taken for serum analysis of classical markers of liver injury. A gradient of APAP-induced toxicity was detected across the 40 mouse strain panel. While some strains exhibited virtually no toxicity, remarkable levels of injury were detected in others. Our data indicate that strain-specific liver injury research may hold important clues to deciphering the mechanisms of a toxicity susceptibility state. Furthermore, the systems biology approach that includes recent advances in mouse genetics may aid in the prediction of individual susceptibility to a toxic agent. ### PARACETAMOL TOXICITY IN RATS PRETREATED WITH CYTOCHROME P450 OR GLUTATHIONE INHIBITORS USING AN INTEGRATED GENOMICS APPROACH.

M. F. DeCristofaro<sup>1</sup>, D. Bodian<sup>1</sup>, E. Perentes<sup>2</sup>, I. M. Nicholls<sup>2</sup>, P. End<sup>2</sup>, J. Harleman<sup>2</sup>, S. Chibout<sup>3</sup>, F. Staedler<sup>3</sup> and H. Firat<sup>3</sup>. <sup>1</sup>*Biomarker Development, Novartis Pharmaceuticals Corporation, East Hanover, NY*, <sup>2</sup>*Preclinical Safety, Novartis Pharmacology AG, Basel, Switzerland* and <sup>3</sup>*Biomarker Development, Novartis Pharmacology AG, Basel, Switzerland*.

Overdosed paracetamol (APAP) has been identified as a major cause of acute liver failure, classically linked to profound glutathione (GSH) depletion associated with oxidative cell stress and/or covalent binding of cellular proteins to the APAP intermediate metabolites. However, overdose of APAP induces kidney toxicity only in rare cases which can be reversible and isolated. Literature data indicate that diverse environmental, genetic and immunological factors may influence APAP toxicity both in the liver and kidney. In this study, the toxic signature of APAP in the liver and kidney was evaluated using a genomics approach in rats pre-treated with piperonyl butoxide (PBO), an inhibitor of cytochrome P450-dependent monooxygenase activity or with L-buthionine sulfoximine (L-BSO), a selective inhibitor of GSH synthesis. Liver and kidney transcript profiles of each animal were analyzed on rat DNA microarrays (RAE230 2.0+, Affymetrix). Clinical biochemistry, urinalysis, hematology, and histopathology were also investigated. Preliminary results suggest that the inhibition of cytochrome P450-dependent monooxygenase activity by PBO showed a moderate effect on the expression of genes involved in pathways of toxicity. However, inhibition of glutathione synthesis by L-BSO exhibited significant effects on the expression of genes involved in several pathways of toxicity. This data is consistent with the histopathologic evaluation as pre-treatment with L-BSO resulted in an increase in the severity of liver and renal toxicities. The concentration of the reactive metabolite was also increased together with decreased plasma GSH levels. These data provide additional insight into the mechanism of APAP induced liver and kidney toxicity and the use of a pre-sensitized animal model.

### DECREASED ACETAMINOPHEN AND BROMOBENZENE-INDUCED HEPATOTOXICITY AND LETHALITY IN TYPE 2 DIABETIC MICE.

M. S. Mitra<sup>1</sup>, S. P. Sawant<sup>1</sup>, A. V. Dnyanmote<sup>1</sup>, J. R. Latendresse<sup>2</sup>, A. Warbritton<sup>2</sup> and H. M. Mehendale<sup>1</sup>. <sup>1</sup>*University of Louisiana at Monroe, Monroe, LA* and <sup>2</sup>*NCTR, Jefferson, AR*.

Our previous studies showed that type 2 diabetic (DB) rats are highly sensitive to diverse hepatotoxicants (allyl alcohol, CCl<sub>4</sub> & bromobenzene). The present objective was to test whether marked species difference exists in the sensitivity of type 2 diabetes to model hepatotoxicants. Type 2 diabetes was induced in male Swiss Webster mice (25-30 g) by feeding high fat diet (20% fat, 24% protein, 54% carbohydrate) for 2 months followed by injection of streptozotocin (STZ, 120 mg/kg, ip, in citrate buffer). Ten days after STZ injection, the DB mice exhibited type 2 diabetes as evidenced by normoinsulinemia, hyperglycemia, impaired fasting glucose, and oral glucose intolerance. Exposure of DB mice to normally LD<sub>50</sub> doses of acetaminophen (APAP, 600 mg/kg, ip) and bromobenzene (0.5 mg/kg, ip) resulted in only 20% mortality indicating protection. To investigate the mechanism of this protection, a time course study (0 to 96 h) was conducted after injection of APAP. Liver injury progressed in the non-DB mice resulting in 80% mortality between 6 to 24 h after APAP administration. In contrast, even though the liver injury progressed in DB mice till 12 h, it was substantially lower (as indicated by plasma ALT, AST and histopathology) compared to the non-DB mice and furthermore regressed to normal by 96 h. CYP2E1 protein (Western blot) and enzyme activity (p-NP hydroxylation assay) as well as covalent binding of <sup>14</sup>C-APAP were unaltered in the DB mice indicating that the markedly lower hepatotoxicity cannot be explained by decreased bioactivation of APAP. Expression of CYP4A1 protein (Western blot), a well-established marker of PPAR- $\alpha$  activation was same in the DB mice as com-

pared to the non-DB mice, suggesting that PPAR- $\alpha$  activation may not have a role to play in the resiliency of the DB mice. The results indicate that type 2 DB mice are resilient to the hepatotoxicity of APAP and BB and point to a marked species difference in the sensitivity of type 2 diabetes to hepatotoxicity.

63

### ROLE OF POLY(ADP-RIBOSE) POLYMERASE (PARP) ACTIVATION IN ACETAMINOPHEN-INDUCED LIVER CELL NECROSIS IN MICE.

C. Cover<sup>1</sup>, P. Fickert<sup>2</sup>, T. Knight<sup>1</sup>, A. Fuchslechner<sup>2</sup>, M. Trauner<sup>2</sup> and H. Jaeschke<sup>1</sup>. <sup>1</sup>*Liver Research Institute, University of Arizona, Tucson, AZ* and <sup>2</sup>*Department of Medicine, Medical University of Graz, Graz, Austria*.

DNA strandbreaks can induce the excessive activation of poly(ADP-ribose) polymerases (PARP), which may lead to oncotic necrosis. Based on controversial findings with chemical PARP inhibitors, the role of PARP activation in AAP hepatotoxicity remains unclear. To assess the role of PARP in the pathophysiology in more detail, we assessed PARP activation by immunostaining for PAR and used both the PARP inhibitor 3-aminobenzamide (3-AB) and PARP gene knock-out mice (PARP-/-). Treatment of C3HeB/FeJ mice with 300 mg/kg AAP resulted in liver injury as indicated by the progressive increase in DNA fragmentation and plasma ALT activities between 3 and 12 h after AAP. PAR staining was detectable in most centrilobular hepatocytes at 6 h after AAP with a further increase in staining intensity at 12 h. Treatment with 500 mg/kg 3-AB 0.5 h before AAP completely eliminated liver injury, DNA fragmentation and PAR staining. However, 3-AB pretreatment attenuated the initial depletion of hepatic glutathione suggesting that 3-AB pretreatment inhibited metabolic activation of AAP. On the other hand, treatment with 3-AB at 1.5 or 2.5 h after AAP showed a partial protective effect as indicated by reduced ALT activities, DNA fragmentation and PAR staining. Treatment of SV129 wildtype and PARP-/- mice with AAP resulted in similar liver injury. However, there was no PAR staining in PARP-/- mice. To evaluate if 3-AB may protect independently of PARP, WT and PARP-/- mice were treated with 3-AB 1.5 h after AAP. 3-AB treatment significantly reduced the increase in plasma ALT activities by 95% in WT and 71% in PARP-/. Conclusion: AAP caused DNA fragmentation followed by PARP activation during the early injury phase after AAP overdose. However, PARP activation does not play a significant role in AAP-induced hepatocyte necrosis. The beneficial effect of the PARP inhibitor 3-AB against AAP hepatotoxicity was due to reduced metabolic activation or other, unknown mechanisms independent of PARP inhibition.

64

### PROTEOMIC ANALYSIS OF WHOLE LIVER AND SUBCELLULAR FRACTIONS FOLLOWING ACETAMINOPHEN-INDUCED HEPATOTOXICITY IN MALE RATS.

M. E. Bruno<sup>1</sup>, B. A. Wetmore<sup>1</sup>, J. H. Madenspacher<sup>1</sup>, R. Pieper<sup>1</sup>, A. M. McGrath<sup>2</sup>, C. L. Gatlin<sup>2</sup>, A. J. Makusky<sup>2</sup>, M. Zhao<sup>2</sup>, J. Zhou<sup>2</sup>, J. Taylor<sup>2</sup>, S. Steiner<sup>2</sup>, J. M. Fostel<sup>1</sup>, M. D. Waters<sup>1</sup>, R. W. Tennant<sup>1</sup>, K. B. Tomer<sup>1</sup> and B. A. Merrick<sup>1</sup>. <sup>1</sup>*National Ctr Toxicogenomics, NIEHS, Research Triangle Pk, NC* and <sup>2</sup>*Proteomics Division, Large Scale Biology Corporation, Germantown, MD*.

While acetaminophen (APAP) is a safe analgesic when taken therapeutically, overdose results in a severe and sometimes fatal centrilobular hepatic necrosis. CYP450-mediated generation of a quinone imine intermediate and binding to critical macromolecules after glutathione (GSH) depletion causes toxicity, although additional mechanisms have been implicated. Proteomic analysis of whole liver homogenates and subcellular fractions using 2D gel electrophoresis and mass spectrometry (2D-MS) was conducted to gain further insight into APAP hepatotoxicity. Male F344 rats treated with 0, a subtoxic (150 mg/kg) and toxic (1500 mg/kg) dose of APAP were sacrificed at pre-toxic (6 hr), toxic (24 hr), and recovery (48 hr) periods of acute APAP hepatotoxicity to identify treatment-related protein changes. Image analysis of the 2D gels revealed that APAP protein expression was most altered at 24 and 48 hr after the toxic dose (1500 mg/kg) of APAP with nearly 100 versus 70 proteins changed, respectively, in whole liver separations. Only minor protein changes were noted at the subtoxic dose. The nuclear fraction from the 48 hr subtoxic dose of APAP also yielded several changes, suggesting that an adaptive nuclear response was initiated. Up- and down-regulated proteins of note included glyceraldehyde 3-phosphate dehydrogenase (upregulated 20-fold), estrogen sulfotransferases 3 and 6, GST-omega, heme scavenger hemopexin, hepatic injury marker purine nucleoside phosphorylase, and Ca<sup>++</sup> binding protein regucalcin. This proteomic study has revealed APAP-related changes in whole liver and nuclear proteins that may prove helpful in understanding the pathophysiology of APAP hepatotoxicity and may eventually lead to prognostic indicators for survival following APAP overdose.

## ROLE OF THE XENOBIOTIC RECEPTOR PXR IN ACETAMINOPHEN HEPATOTOXICITY.

K. K. Wolf<sup>2</sup>, S. G. Wood<sup>1</sup>, B. W. Walton-Strong<sup>3</sup>, K. Yasuda<sup>7</sup>, L. Lan<sup>7</sup>, P. R. Sinclair<sup>1,3,2</sup>, S. A. Wrighton<sup>4</sup>, E. H. Jeffery<sup>5</sup>, R. M. Evans<sup>6</sup>, E. G. Schuetz<sup>7</sup> and J. F. Sinclair<sup>1,3,2</sup>. <sup>1</sup>*Veterans Administration Medical Center, White River Junction, VT*, <sup>2</sup>*Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH*, <sup>3</sup>*Biochemistry, Dartmouth Medical School, Hanover, NH*, <sup>4</sup>*Department of Drug Disposition, Lilly Research Laboratories, Indianapolis, IN*, <sup>5</sup>*Department of Food Science and Human Nutrition, University of Illinois, Urbana, IL*, <sup>6</sup>*Howard Hughes Medical Institute, Gene Expression Laboratory, The Salk Institute for Biological Studies, La Jolla, CA* and <sup>7</sup>*Department of Pharmaceutical Sciences, St. Jude Children's Research Hospital, Memphis, TN*.

The pregnane X receptor (PXR) is a key regulator of xenobiotic metabolizing enzymes and transporters at the transcriptional level. To investigate if PXR has a role in acetaminophen (APAP) toxicity, we examined APAP hepatotoxicity and metabolism in male wild-type and PXR(-/-) mice. PXR(-/-) mice were less sensitive to APAP hepatotoxicity than wild-type mice as indicated by plasma levels of ALT. Cytochrome P450 (CYP) 2E1 levels were identical in the two mouse lines. Hepatic levels of CYP3A protein were elevated 2.5-fold in PXR(-/-) mice. In contrast, hepatic levels of CYP1A2 were decreased 3-fold in PXR(-/-) mice. These findings suggest that CYP1A2 has an important role in the development of APAP hepatotoxicity. No significant differences in APAP metabolism were observed between wild-type and PXR(-/-) mice, as measured by the individual levels of glucuronide, sulfate, and glutathione-conjugated metabolites over time. APAP uptake, measured as the level of APAP in the serum over time, appeared to be greater in wild-type mice compared to PXR(-/-) mice, but APAP was not a substrate of the transport protein MDR1. Our overall findings suggest, that in untreated mice, PXR is a positive regulator of CYP1A2 expression. Our finding that APAP hepatotoxicity is decreased in PXR(-/-) mice, shows that PXR is an important modulator of APAP hepatotoxicity, possibly through up-regulation of CYP1A2 expression.

## THE EFFECT OF S-ADENOSYL-L-METHIONINE (SAME) ON MITOCHONDRIAL GLUTATHIONE AND PROTEIN CARBONYLS FOLLOWING ACETAMINOPHEN (APAP) TREATMENT IN MICE.

M. Terneus, K. Kiningham and M. Valentovic. *Pharmacology, Marshall University School of Medicine, Huntington, WV*.

Acetaminophen (APAP), in excessive doses, is associated with hepatic toxicity. To date in the United States, one-third of all acute liver failure cases are attributed to APAP. We have shown the protective effects of S-Adenosyl-L-methionine (SAMe), a nutraceutical, on APAP-induced hepatotoxicity in male C57BL/6 mice. In our studies, male C57BL/6 (16-25 g) n= 5 animals/group  $\pm$  SEM were used. The mice were randomly divided into 4 groups, vehicle treated, APAP treated, SAMe treated, and SAMe pretreatment plus APAP. The animals were injected intraperitoneal (ip) with 500mg/kg APAP or water. SAMe was administered as a 500mg/kg dose just prior to administration of APAP or water. We monitored hepatic glutathione levels, changes in ALT, lipid peroxidation levels, liver weight and histology as parameters of APAP toxicity. SAMe protected the liver from APAP-induced damage by decreasing ALT and lipid peroxidation levels as well as preventing depletion of glutathione. Further studies investigated the protective effects of SAMe pretreatment against APAP-induced hepatotoxicity on liver mitochondrial glutathione, 4-hydroxy-2-nonenal (4HNE) adducted proteins and protein carbonyls. The results of this study have found that SAMe protects the liver from production of protein carbonyls and 4HNE adducts. One particular protein carbonyl that we have found has an approximate mass of 40 kDa. Interestingly, cytochrome P450 2E1, the enzyme responsible for producing the toxic APAP metabolite N-acetyl-benzoquinone imine, has an active form (Delta 2E1) with a mass of 40 kDa. The mechanism of SAMe reduction of APAP toxicity may be identified by characterizing specific cellular targets and identifying particular proteins affected by SAMe and APAP.

## EVIDENCE SUGGESTING A ROLE FOR NAD(P)H:QUINONE OXIDOREDUCTASE 1 IN THE PROTECTION AGAINST ACETAMINOPHEN HEPATOTOXICITY BY CLOFIBRATE TREATMENT.

J. S. Moffit<sup>1</sup>, L. M. Aleksunes<sup>1</sup>, A. M. Slitt<sup>2</sup>, M. Kardas<sup>1</sup>, C. D. Klaassen<sup>2</sup> and J. E. Manautou<sup>1</sup>. <sup>1</sup>*Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT* and <sup>2</sup>*Department of Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS*.

Mice pretreated with the peroxisome proliferator clofibrate (CFB) are highly resistant to acetaminophen (APAP) hepatotoxicity. While the mechanism of protection is not entirely clear, CFB diminishes APAP arylation of hepatic proteins and glutathione depletion without affecting its bioactivation by CYP450. These results

suggest that treatment with CFB enhances the detoxification of the reactive metabolite of APAP, N-acetyl-p-benzoquinone imine (NAPQI). Considering that the putative toxic metabolite of APAP is a quinone, we investigated the effect of CFB treatment on mRNA levels, protein expression and catalytic activity of the detoxifying enzyme NAD(P)H quinone oxidoreductase 1 (NQO1) in the liver. Enhanced reduction of NAPQI back to APAP by NQO1 could explain this hepatoprotection. Administration of CFB (500 mg/kg, i.p.) to male CD-1 mice daily for 5 or 10 days resulted in a significant induction of NQO1 enzyme activity. Branched DNA signal amplification showed an increase in mRNA levels for NQO1 in the 5-day treatment regimen only. NQO1 protein expression was upregulated 1.3- and 1.8-fold in the 5 and 10-day treatments, respectively. Additionally, inclusion of human recombinant NQO1 (hNQO1) in an *in vitro* activating system for APAP significantly decreased the amount of NAPQI measured in microsomal incubations. Supplementing microsomal reactions with hNQO1 along with the NQO1 inhibitor dicumarol prevented this reduction in NAPQI measured. Similarly, inclusion of a catalytically inactive mutant form of the enzyme also restored microsomal NAPQI content to control levels. In summary, CFB-mediated induction of NQO1 coupled with the ability of NQO1 to decrease NAPQI levels suggests its possible role in diminishing APAP hepatotoxicity.

## ROLE OF VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) IN ACETAMINOPHEN HEPATOTOXICITY.

B. Donahower<sup>1</sup>, S. S. McCullough<sup>2</sup> and L. P. James<sup>3,2</sup>. <sup>1</sup>*Pharmacology, University of Arkansas For Medical Sciences, Little Rock, AR*, <sup>2</sup>*Toxicology, University of Arkansas For Medical Sciences, Little Rock, AR* and <sup>3</sup>*Arkansas Children's Hospital Research Institute, Little Rock, AR*. Sponsor: J. Hinson.

Vascular endothelial growth factor (VEGF) is a known mitogen for endothelial cells. Previous data have shown that VEGF is upregulated in models of partial hepatectomy and ischemia reperfusion injury. It was also recently shown that VEGF increases hepatic mitogens *in vitro* (i.e., hepatocyte growth factor and interleukin 6). We investigated the importance of VEGF in hepatocyte regeneration following acetaminophen (APAP) toxicity. Initial immunohistochemistry analyses for VEGF showed staining in the centrilobular regions of the liver of B6C3F1 mice treated with APAP (300 mg/kg i.p.) and sacrificed at 48 and 72 hours. Further studies were conducted in mice treated with APAP and sacrificed at 1, 2, 4, 8, and 12 hours. ALT was significantly increased at 4 hours and VEGF levels in liver homogenates were significantly increased at 12 hours ( $p \leq 0.01$ ). To investigate a possible role for VEGF in hepatocyte regeneration, SU5416, an inhibitor of VEGF receptor signaling, was administered to APAP treated mice. SU5416 alters VEGF mediated signaling through the inhibition of tyrosine kinase. In initial studies, mice were dosed with APAP, followed by SU5416 or saline at 3 hours, and sacrificed at 24 hours. No difference in ALT values was apparent at 24 hours in the two groups of mice. To examine the effect of SU5416 on hepatocyte regeneration, mice were dosed with APAP, followed by SU5416 or saline at 3 hours, then sacrificed at 48 and 72 hours. SU5416 (25 mg/kg s.c.) treated mice had ALT values that were approximately 70% higher at 48 hours, compared to mice receiving APAP only ( $p \leq 0.05$ ). Subsequent immunohistochemical analysis for proliferating cell nuclear antigen (PCNA), a marker of cellular proliferation, showed markedly reduced staining at 48 and 72 hours in the mice that received SU5416 after APAP, compared to the APAP only treated mice. These findings suggest that endogenous VEGF production has significant hepatoprotective effects in APAP toxicity by increasing hepatocyte regeneration.

## LIPOPOLYSACCHARIDE POTENTIATES ACETAMINOPHEN HEPATOTOXICITY.

S. W. Newport, C. M. Dugan, X. Deng, P. E. Ganey, R. A. Roth and J. F. Maddox. *Pharmacology and Toxicology, National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI*.

The doses of acetaminophen (APAP) required to cause hepatotoxicity vary considerably in people. Previous studies in animals demonstrated that nontoxic doses of some xenobiotic agents are rendered hepatotoxic by a mild inflammatory episode, suggesting that modest inflammation may be a determinant of sensitivity to hepatotoxicity. Accordingly, we tested the hypothesis that cotreatment of mice with normally nonhepatotoxic doses of lipopolysaccharide (LPS) and APAP leads to development of liver injury. Fasted, C57BL/6 mice were treated with either saline or LPS (44 x 106 EU/kg, ip), two hours before or two hours after treatment with APAP (100-250 mg/kg, ip) or saline. Mice were killed 24 hours after APAP-treatment, and hepatotoxicity was estimated from increased serum alanine aminotransferase (ALT) activity and evaluation of liver histopathology. No elevation in serum ALT activity was observed in mice that received vehicle or LPS alone. LPS cotreatment (either pre- or post-APAP) caused a leftward shift of the dose-response curve for APAP-induced hepatotoxicity. This effect was most pronounced in mice that re-

ceived LPS 2 hours before APAP. Consistent with the increase in serum ALT activity, histopathology revealed centrilobular, oncocytic necrosis only in livers of LPS/APAP-treated mice. Hepatic fibrin deposition was observed in livers of LPS/APAP-treated mice but not in livers from mice treated with either agent alone. The results suggest that normally noninjurious doses of APAP are rendered hepatotoxic by a modest inflammatory response. Furthermore, in APAP-treated mice, inflammation was associated with alterations in the hemostatic system. (Supported by NIH grant DK061315.)

#### POTENTIATION OF 3-(3, 5-DICHLOROPHENYL)-2, 4-THIAZOLIDINEDIONE (DCPT)-INDUCED HEPATOTOXICITY IN RATS BY DEXAMETHASONE (DEX) PRETREATMENT.

C. M. Crincoli, N. N. Patel, R. Tchao and P. J. Harvison. *Department of Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.*

3-(3, 5-Dichlorophenyl)-2, 4-thiazolidinedione (DCPT) is hepatotoxic in rats. This compound is structurally similar to insulin-sensitizing drugs, such as troglitazone, which have been shown to cause liver damage in some type-II diabetic patients. Data from the literature suggest that cytochromes P450 may have a role in generating hepatotoxic metabolites from troglitazone. The purpose of this investigation was to determine if the CYP3A inducer dexamethasone (DEX) could potentiate the hepatotoxic effects of a known non-toxic dose of DCPT. Male Fischer 344 rats ( $n = 4$ /group) were administered DCPT (0.2 mmol/kg) i.p. in corn oil after a three day dosing regimen of DEX (50 mg/kg/day) given i.p. in corn oil. Control rats were pre-treated with either corn oil (CO, 4 mL/kg/day) or DEX (50 mg/kg/day) for three days prior to a single dose of corn oil (4 mL/kg). All animals were euthanized 24 hours post-dosing. Our previous experiments with known hepatotoxic doses ( $> 0.2$  mmol/kg) of DCPT showed elevations in serum alanine aminotransferase (ALT) levels. ALT levels in rats in the DEX/DCPT group ( $160 \pm 16.0$  Sigma Frankel Units/mL) were significantly greater ( $p < 0.05$ ) than those in the CO/CO ( $34.3 \pm 6.9$ ), CO/DCPT ( $37.9 \pm 9.9$ ) or DEX/CO ( $74.5 \pm 8.2$ ) groups. Liver histology of CO/DCPT treated animals showed minimal change from the CO/CO treated group. In contrast, a significant hepatotoxic effect was seen in the liver histology of both the DEX/CO and DEX/DCPT treatment groups. In conclusion, these results suggest that CYP3A isozymes may be involved in DCPT-induced liver damage in rats. However, the nature of any hepatotoxic metabolites that are produced from DCPT requires further investigation. Supported by PHS grant ES012499.

71

#### PROTECTIVE EFFECT OF DIBROMOACETATE IN PRIMARY HEPATOCYTE CULTURES.

J. M. McMillan and K. McKelvey. *Pharmacology, Medical University of South Carolina, Charleston, SC.*

Chlorinated and brominated acetates are components of chlorinated drinking water. In addition di- and trichloroacetate (DCA and TCA) are the presumed hepatocarcinogenic metabolites of the groundwater contaminant trichloroethylene. These compounds have been shown to differentially induce peroxisome proliferation in mouse liver and in rodent hepatocyte cultures. One proposed mechanism for peroxisome proliferator-induced hepatocarcinogenesis is that suppression of normal hepatocyte apoptosis may promote survival of tumorigenic cells. DCA has been shown by others to inhibit spontaneous apoptosis in mouse liver. Previous studies in our lab have suggested that addition of DCA (1 mM) to sub-confluent hepatocyte cultures can ameliorate the normal cell loss that occurs in hepatocyte cultures. In the present studies we determined whether addition of various dihalogenated acetates to primary rat hepatocyte cultures could prevent the normal loss of cells from the cultures. Isolated rat hepatocytes were plated at confluence and treated, beginning 20 hrs after attachment, with 1 mM dibromo-, dichloro-, or difluoroacetate (DBA, DCA or DFA) for 48 hrs. Cell number was determined by measuring the reduction of 3-(4, 5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium (MTS). DBA treatment resulted in a significant decrease in cell loss over 48 hrs. In contrast, DCA and DFA treatment had no effect on loss of cells from the cultures. We also determined the effect of these acetates on TGF $\beta$ 1-induced hepatocyte cell death. TGF $\beta$ 1 is presumed to induce cell death in primary hepatocyte cultures via apoptosis. DBA (1 mM) treatment significantly decreased TGF $\beta$ 1 induced cell death, as determined by the MTS assay after 48 hrs. Treatment with 1 mM DCA or 1 mM DFA had no effect. Further studies are required to determine whether DBA is acting to prevent apoptosis or is acting to maintain the cell cultures and prevent toxicity through another mechanism. Supported by DOE Cooperative Agreement DE-FC09-02CH11109.

#### NICOTINAMIDE ALTERATION OF BROMOBENZENE-INDUCED HEPATOTOXICITY.

K. W. Hall<sup>1</sup>, P. C. Grivas<sup>1</sup>, C. Muro-Cacho<sup>2</sup> and R. D. Harbison<sup>1, 2</sup>. <sup>1</sup>*Toxicology, University of South Florida, Tampa, FL* and <sup>2</sup>*Pathology, College of Medicine, University of South Florida, Tampa, FL.*

Previous studies have shown extensive cellular damage can activate poly(ADP-ribose) polymerase-1 (PARP-1) and cause a rapid decrease in the levels of NAD<sup>+</sup> and ATP, thereby preventing apoptosis and promoting necrosis and inflammation. The purpose of this study was to extend previous observations that inhibitors of PARP-1 could alter acetaminopen and carbon tetrachloride-induced hepatotoxicity. Bromobenzene (BB) a glutathione dependent hepatotoxicant was tested. Groups of male mice were treated with a single dosage of 112mg/kg (0.075ml/kg) BB by the interperitoneal (ip) route. Each treatment group had at least ten mice per comparison. All animals were maintained in a controlled environment and provided food and water ad libitum. This dosage of BB resulted in hepatotoxicity as measured by an increase in serum alanine transferase (ALT). BB treatment resulted in a 5 fold increase in ALT. Moderate hepatotoxicity was detected with this treatment regimen. Subsequently, another group of mice was treated with BB and three treatments of nicotinamide at 1/2, 1, and 2 hours following BB treatment. The nicotinamide treatment significantly reduced both morbidity and mortality. Serum ALT elevations were reduced by 90% at 24 hours following BB and nicotinamide treatments. BB-induced liver pathology was also blocked by nicotinamide. Mortality among BB treated animals was also significantly reduced by nicotinamide treatment. Mortality among mice treated with BB and nicotinamide was near control. Inhibition of PARP-1 appears to alter chemical-induced hepatotoxicity that has either a glutathione dependent or independent mechanism. PARP-1 inhibitors may have pharmacological application for modifying chemical-induced liver injury.

73

#### COLCHICINE ANTIMITOSIS ABOLISHES SUBCHRONIC CHLOROFORM-INDUCED PROTECTION AGAINST LETHAL DOSE OF CHLOROFORM.

B. K. Philip<sup>1</sup>, S. S. Anand<sup>2</sup>, P. S. Palkar<sup>1</sup>, M. M. Mumtaz<sup>3</sup>, J. R. Latendresse<sup>4</sup> and H. M. Mehendale<sup>1</sup>. <sup>1</sup>*Department of Toxicology, University of Louisiana at Monroe, Monroe, LA*, <sup>2</sup>*University of Georgia, Athens, GA*, <sup>3</sup>*ATSDR, CDC, Chamblee, GA* and <sup>4</sup>*NCTR, Jefferson, AR.*

Previously we showed that subchronic exposure to CHCl<sub>3</sub> (150 and 300 mg/kg/day, po) offered complete protection against a LD<sub>90</sub> dose of CHCl<sub>3</sub> (750 mg/kg, po) in male Swiss Webster mice. The hepatic and renal tissue repair was robust in CHCl<sub>3</sub> pretreated mice, which disallowed progression of tissue injury, thereby leading to recovery and survival. The control group of mice received same volume of vehicle (Alkamuls EL-620, 10 ml/kg) for 30 days prior to challenge with a LD<sub>90</sub> dose of CHCl<sub>3</sub>. Ninety percent mortality was observed in control mice due to inhibited hepatic and renal tissue repair, which permitted progression of liver and kidney injury. Objective of the present investigation was to test the hypothesis that selective ablation of tissue repair by antimitotic colchicine (CLC, 1.5 mg/kg, ip) abolishes the adaptive protection against a lethal dose of CHCl<sub>3</sub>. Male mice (25-29 g) were pretreated with 150 mg CHCl<sub>3</sub>/kg/day via aqueous gavage for 30 days prior to challenge with a single LD<sub>90</sub> dose of CHCl<sub>3</sub>. Subchronically primed mice either received CLC or saline at 42 h after the lethal dose of CHCl<sub>3</sub>. Liver and kidney injuries were measured by plasma ALT and BUN, respectively, and by histopathological examination of H & E stained tissue sections. Tissue repair was assessed by <sup>3</sup>H-thymidine incorporation and proliferating cell nuclear antigen immunohistochemistry. In mice not receiving CLC, liver injury regressed after 48 h leading to 100 % survival. CLC intervention led to inhibited cell division and tissue repair in the primed mice receiving lethal challenge with CHCl<sub>3</sub>. Consequently, liver injury progressed leading to 40 % mortality by 72 h. Renal injury of CHCl<sub>3</sub> was unaffected by CLC intervention. These findings suggest that compensatory tissue repair plays central role in the subchronic CHCl<sub>3</sub>-induced protection against lethal dose of chloroform (Supported by ATSDR U61/ATD 681482).

#### UNDERNUTRITION FAILS TO EXACERBATE ALCOHOL-INDUCED LIVER DAMAGE DESPITE EVIDENCE OF INCREASED OXIDATIVE STRESS.

J. N. Baumgardner<sup>1, 2</sup>, B. N. Yarberry<sup>2</sup>, J. V. Badeaux<sup>2</sup>, M. Hidstrand<sup>1, 2</sup>, K. Shankar<sup>1, 2</sup>, T. M. Badger<sup>2, 3</sup> and M. J. Ronis<sup>1, 2</sup>. <sup>1</sup>*Pharmacology and Toxicology, University of Arkansas for Medical Sciences (UAMS), Little Rock, AR*, <sup>2</sup>*Arkansas Children's Nutrition Center, Little Rock, AR* and <sup>3</sup>*Physiology and Biophysics, UAMS, Little Rock, AR.*

Mechanisms and risk factors leading to alcohol-induced liver damage (ALD) remain obscure although it is widely accepted that nutrition plays important roles in modulating liver damage. Undernutrition is often present in alcoholics. To investigate the effects of undernutrition in ALD, female Sprague-Dawley rats (200g) were

infused by Total Enteral Nutrition (TEN) with or without EtOH (11g/kg/d). Diets were infused for 14 h using the overnight infusion model (1800 to 800h). Twenty-four hour urine EtOH concentrations were measured. Rats were sacrificed on day 50 and serum samples for assessment of alanine aminotransferase (ALT) and livers were collected. A combination of undernutrition and EtOH increased induction of both cytochrome P450 (CYP) 2E1 and CYP4A1 mRNA ( $p<0.05$ ). Western blotting showed that CYP2E1 apoprotein was elevated 3 and 6 fold in the 187 kcal EtOH and 154 kcal EtOH groups, respectively ( $p<0.05$ ). This was accompanied by a significantly enhanced activation of carbon tetrachloride dependent lipid peroxidation, a CYP2E1 activity marker, accompanied by an increase of thiobarbituric acid-reactive substances in liver homogenates only in the 154 kcal EtOH group ( $p<0.05$ ), indicating oxidative stress. In addition, EtOH clearance was impaired ( $p<0.05$ ), but was not accompanied by changes in ADH mRNA. Despite evidence of P450-dependent increases in reactive oxygen species production and significantly impaired EtOH clearance in the 154kcal EtOH group, alcoholic liver pathology showed comparable steatosis, macrophage infiltration and focal necrosis in both EtOH groups. ALT levels were elevated, but not significantly different between the two EtOH groups. This suggests that undernutrition does not exacerbate ALD, but appears to provide a protective response to enhanced oxidative stress. (This work was supported by RO1 AA12819 M.R.)

#### RESILIENCY OF AGED FISCHER 344 RATS TO CHLORDECONE-AMPLIFIED CARBON TETRACHLORIDE TOXICITY.

H. M. Mehendale, B. Murali and M. C. Korrapati. *Toxicology, University of Louisiana at Monroe, Monroe, LA.*

Objective was to investigate the effects of chlordecone (CD) +  $CCl_4$  in 3 (adult), 14 (middle aged), 24 month old (old aged) male F344 rats. After pretreatment with either 10 ppm dietary CD or normal diet, rats were challenged with a single non-toxic dose of  $CCl_4$  (100  $\mu$ l/kg, ip) or corn oil vehicle on day 16. Liver injury was assessed by plasma ALT, AST, and histopathology during a time course of 0 to 96 h. Liver tissue repair was measured by [ $^3H$ ]-thymidine incorporation into hepatic nuclear DNA, and PCNA immunohistochemistry. CYP2E1 protein, enzyme activity, *in vivo* metabolism of  $^{14}CCl_4$ ,  $^{14}CCl_4$ -derived covalent binding (2 & 6 h), and hepatic lipid peroxidation were estimated in all the age groups with or without CD diet. Exposure to  $CCl_4$  alone did not cause any mortality. The combination led to 100% mortality of young adult rats by 72 h, whereas no mortality occurred in the aged rats. Adult and middle aged rats exposed to CD +  $CCl_4$  had identical liver injury up to 36 h. Thereafter, liver injury escalated only in adults while it declined in middle aged rats. In the 24-month-old rats initial liver injury never developed to the level of the other two age groups but declined after 36 h as in the 14-month-old rats. Regardless of exposure to CD diet neither hepatomicrosomal CYP2E1 protein, the enzyme activity, nor covalent binding of  $^{14}CCl_4$ -derived radiolabel differed between the age groups. *In vivo*  $^{14}CCl_4$  metabolism was similar in all the age groups. Lipid peroxidation at 6 h was higher in the older rats, and CD pretreatment did not affect lipid peroxidation. Plasma glucose did not change in any age group. Hepatic glycogen was depleted only in adult rats exposed to CD +  $CCl_4$ . Liver tissue repair ( $^3H$ -T, PCNA) was inhibited in adults in contrast to prompt and robust response in the aged rats. Consequently, liver injury progressed only in the young adult rats. In conclusion, the remarkable resiliency of aged rats to CD +  $CCl_4$  toxicity appears to be due to prompt and robust stimulation of compensatory liver tissue repair response (NIH/AG19058).

76

#### PENTOXIFYLLINE AND ANTI-TUMOR NECROSIS FACTOR $\alpha$ ANTIBODIES ARE UNABLE TO PROTECT MICE FROM FUMONISIN HEPATOTOXICITY.

Q. He and R. P. Sharma. *The University of Georgia, Athens, GA.*

Fumonisin B<sub>1</sub> (FB<sub>1</sub>), the most abundant and toxic fumonisins produced by *Fusarium verticillioides* detected in corn and corn-based foods, causes species- and organ-specific toxicity such as equine leukoencephalomalacia, porcine pulmonary edema, and liver and kidney damage in most animal species. Fumonisin B<sub>1</sub> disrupts sphingolipid metabolism by inhibiting ceramide synthase and induces expression of many cytokines including tumor necrosis factor (TNF)  $\alpha$ . This study was designed to investigate the role of TNF $\alpha$  signaling in FB<sub>1</sub> hepatotoxicity. Male C57BL/6N mice were injected with pentoxifylline at 150 mg/kg twice a day for 5 days to inhibit TNF $\alpha$  production or anti-TNF $\alpha$  antibodies to block TNF $\alpha$  signal transduction. Mice were injected subcutaneously with 2.25 mg FB<sub>1</sub>/kg daily for 5 days, and euthanized one day after the last treatment. Blood and tissues were sampled. Results showed that both pentoxifylline and anti-TNF $\alpha$  antibodies augmented FB<sub>1</sub>-induced hepatotoxicity indicated by increases in plasma alanine aminotransferase and aspartate aminotransferase, and number of apoptotic hepatocytes. Pentoxifylline significantly reduced accumulation of free sphinganine and expression of TNF $\alpha$ . Anti-TNF $\alpha$  antibodies did not alter FB<sub>1</sub>-induced accumulation of free sphingoid bases and expression of TNF $\alpha$  in liver following FB<sub>1</sub> treatment. Neither pentoxi-

fyline nor anti-TNF $\alpha$  antibodies further increased FB<sub>1</sub>-induced expression of interleukin-12, interferon  $\gamma$ , and TNF $\beta$ , which are important inflammatory cytokines. Treatments did not alter expression of Fas and Fas ligand. Results suggest that the increased hepatotoxicity may be due to disruption of TNF $\alpha$  cellular repair mechanisms following inhibition of TNF $\alpha$  signaling. (Supported in part by USPHS ES 09403).

#### CALPASTATIN OVER-EXPRESSION PROTECTS AGAINST TOXICANT-INDUCED PROGRESSION OF INJURY ASSOCIATED WITH ACUTE LIVER FAILURE IN MICE.

P. B. Limaye<sup>1</sup>, V. S. Bhave<sup>1</sup>, P. S. Palkar<sup>1</sup>, J. R. Latendresse<sup>2</sup>, S. Yu<sup>3</sup>, J. K. Reddy<sup>3</sup> and H. M. Mehendale<sup>1</sup>. <sup>1</sup>*Toxicology, University of Louisiana at Monroe, Monroe, LA*, <sup>2</sup>*NCTR Jefferson, AR* and <sup>3</sup>*Northwestern University, Chicago, IL*.

We have recently reported that calpain released from the necrotic hepatocytes is the principal mediator of progression of acute liver injury (Limaye et al. *Toxicol. Appl. Pharmacol.* 191: 211-226, 2003). Timely onset of compensatory tissue repair is known to obtund the progression of injury and prevent acute liver failure (ALF) due to resistance of dividing/newly divided cells. Objective of the present work was to test the hypothesis that over-expression of calpastatin (CAST), an endogenous calpain inhibitor, in the dividing/newly divided hepatocytes is the underlying mechanism of their resistance against progression of injury. CAST expression was monitored over a time course in  $CCl_4$ -damaged (2 ml  $CCl_4$ /kg, ip, male SD rats) livers undergoing compensatory tissue repair and in two other models of liver cell division - early postnatal development (20 day old rats) and 70% partial hepatectomy in adult male SD rats. In each model of dividing/newly divided hepatocytes, CAST over-expression was confirmed by real-time RTPCR, Western blot, and immunohistochemical staining of liver sections. Over-expression of CAST declined to normal low levels with the cessation of cell proliferation. Cessation of cell division is known to restore the sensitivity to hepatotoxicants. These findings suggest that over-expression of CAST in the dividing/newly divided hepatocytes might underlie the resistance against progression of injury. To test this possibility, hepatic over-expression of CAST was induced in adult SW mice livers via *in vivo* adenovirus transfection, and challenged with a normally lethal dose of APAP (600 mg/kg, ip). Progression of APAP-induced liver injury was markedly attenuated in CAST over-expressing mice leading to 50% survival. These findings provide strong evidence for calpastatin's role in the resistance of dividing/newly divided cells against progression of injury initiated by APAP, culminating in ALF and animal death.

78

#### IMPAIRED HEPATIC REGENERATION IN METALLOTHIONEIN KNOCKOUT MICE AFTER PARTIAL HEPATECTOMY.

J. R. Oliver and G. Cherian. *Pathology, University of Western Ontario, London, ON, Canada.*

Although the translocation of metallothionein (MT) from cytoplasm to nucleus has been demonstrated in liver during times of high requirement for zinc (fetal development and the neonatal period), the role of MT in cellular growth is not well understood. In the present study, a potential role of MT in liver regeneration was investigated in wild type (WT) and MT I and II gene knockout (MT-null) mice after 35% partial hepatectomy (PH) or sham laparotomy. Hepatic MT levels and proliferation index were measured at 0, 5, 15, 24, 36, 48, and 60 hours after PH and 48 hours after sham laparotomy (control). MT levels were increased in WT mice (peak at 24 hours after PH) and declined to normal levels by 60 hours after PH. Immunohistochemical staining for MT in WT mice indicated the presence of MT in both nucleus and cytoplasm of hepatocytes at 24 hours after PH, whereas MT was present mainly in the cytoplasm at 36-60 hours after PH and 48 hours after sham laparotomy. Hepatic proliferation index in both WT and MT-null mice, as determined by argyrophilic nucleolar organizing region (AgNOR) staining and proliferating cell nuclear antigen (PCNA) immunohistochemical staining, reached a peak at 48 hours and declined by 60 hours after PH. Cell proliferation was significantly less in MT-null mice as compared to WT mice during liver regeneration after PH. These results suggest that MT may play a positive role in hepatic regeneration after PH. This research was supported by Canadian Institute of Health Research (CIHR) grants.

79

#### THE ROLE OF GLUTATHIONE DEPLETION AND OXIDATIVE STRESS ON CYTOTOXICITY OF CHROMIUM (VI) IN ISOLATED RAT HEPATOCYTES.

O. S. El-Tawil<sup>1</sup>, A. M. Mohamadini<sup>2</sup> and A. H. Abou-Hadeed<sup>3</sup>. <sup>1</sup>*Toxicology and Forensic Medicine, Faculty of Veterinary Medicine, Cairo University, Cairo, Egypt*, <sup>2</sup>*Department of Biochemistry, Faculty of Pharmacy, Al-Azhar University, Cairo, Egypt* and <sup>3</sup>*Department of Forensic Medicine and Toxicology, Faculty of Veterinary Medicine, Zagazig University, Zagazig, Egypt*.

Chromium (VI) is an environmental and occupational carcinogen. Although it has been investigated widely, the mechanism(s) of its action is/are not fully understood. The present study was designed to evaluate the role of Glutathione (GSH) modula-

tion and oxidative stress on cytotoxicity of Cr(VI) in isolated rat hepatocytes. Hepatocytes were isolated by collagenase perfusion technique and were exposed to different concentrations of Cr VI (dichromate) (1 and 5 microM) in a time-course experiment for up to 2 hr. Cr (VI) exposure induced a significant decrease in cell viability and a significant increase in the leakage of hepatic enzymes {alanine transaminase (ALT), asparagine transaminase (AST) and lactate dehydrogenase (LDH)} in a concentration and time-related manner. In the same experiment, GSH content and thiobarbituric acid reactive substances (TBARS) generation were determined as indices of oxidative stress and lipid peroxidation respectively. Cr (VI) exposure resulted in significant depletion of GSH and accumulation of TBARS in a dose and time-related manner. The obtained results suggested that 2 h-exposure of hepatocytes to 5 microM Cr (VI) was accompanied by submaximal responses. Therefore, a subsequent dose-response experiment was designed to evaluate the role of GSH depletion and oxidative stress in Cr (VI) toxicity in hepatocytes at 2 hr. LDH release and TBARS generation were used as indicators in this experiment.

ANTI-HYPERCHOLESTEROLEMIA DRUGS IN THE STATIN CLASS REDUCE GLUTATHIONE LEVELS AND INCREASE CASPASE 3 ACTIVATION IN AN *IN VITRO* CELL MODEL.

J. F. Pregenzer, J. M. McKim, Jr., P. C. Wilga and D. K. Petrella. *CeeTox, Kalamazoo, MI.*

The ability to identify and understand the potential adverse effects of new drugs early in the development process can help manage patient risk versus clinical benefit. Cerivastatin (CRV), simvastatin (SMV), lovastatin (LOV), atorvastatin (ATV), fluvastatin (FLV) and pravastatin (PRV) are in the statin class of cholesterol lowering drugs used in the treatment of hypercholesterolemia. All have been associated with hepatotoxicity and the skeletal muscle disorder rhabdomyolysis. CRV was recently withdrawn from United States markets because of reports of fatal rhabdomyolysis and high incidence of liver toxicity. It is believed that the mechanisms underlying these adverse effects are linked to energy depletion and apoptosis. The purpose of the present study was to screen the statin drugs in a battery of *in vitro* assays designed to evaluate cytotoxic, apoptotic, and oxidative stress potential. Rat hepatoma (H4IE) cells were seeded into 96-well plates (10, 000/well). Following a 48 hr equilibration period the cells were treated with compounds at concentrations of 0, 0.1, 1, 5, 10, 50, 100, and 300  $\mu$ M for 24 hr. Cytotoxicity was evaluated by measuring membrane leakage, mitochondrial function, and cell number. Oxidative stress was assessed by measuring total glutathione (GSH) and 8-isoprostanate. Apoptosis was determined via caspase 3 activity. The hydrophobic statins (FLV, CRV, SMV, LOV, and ATV) produced a modest decrease in ATP, cell number, and mitochondrial function, but had pronounced effects on the reduction of total GSH pools and induction of caspase 3 activity. In contrast, the hydrophilic statin (PRV) had no measurable effects in this system. These data are consistent with published studies in which the mechanism(s) associated with statin toxicity are energy depletion and induction of apoptosis. Moreover, these data indicate that early screening with a cell-based system that evaluates several biochemical processes can provide important information on the relative safety of new drugs prior to entering animal studies or beginning clinical trials.

**81**

EFFECT OF THIAZOLIDINEDIONE (TZD) RING MODIFICATION ON 3-(3, 5-DICHLOROPHENYL)-2, 4-THIAZOLIDINEDIONE (DCPT) INDUCED HEPATOTOXICITY IN RATS.

N. N. Patel, C. M. Crincoli, R. Tchao and P. J. Harvison. *Department of Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.*

Previously, we observed that DCPT caused hepatotoxicity in F344 rats. DCPT has a TZD ring which is also present in insulin-sensitizing drugs used for the treatment of diabetes. There have been reports of liver toxicity in some patients taking these drugs. Metabolism in the TZD ring might contribute to the hepatic damage. DCPT may be useful for investigating the potential toxicity of TZD ring-containing compounds. 3-(3, 5-Dichlorophenyl)-4-thiazolidinone (4-DCTD), a structural analogue of DCPT, was synthesized and tested to determine if DCPT-induced hepatotoxicity is sensitive to the modifications in the TZD ring. Male, F344 rats were administered DCPT or 4-DCTD (0.4, 0.6 and 1.0 mmol/kg) ip in corn oil. Control animals received corn oil (4 ml/kg) only. Liver and kidney function and morphology were assessed at 24 hr. Serum alanine aminotransferase (ALT) levels were unaltered in the 4-DCTD-treated animals, whereas in the DCPT-treated rats, ALT levels were significantly elevated compared to the controls. In contrast, blood urea nitrogen levels were not altered by any of the compounds. Blood glucose, urine protein and glucose levels were unaffected. There was no change in liver or kidney weights. Histological results showed pockets of liver necrosis in the DCPT-treated rats at 1.0 mmol/kg dose. At lower doses, hepatocellular damage was seen near the centrilobular vein; the cytoplasm in the cells was condensed and irregularly stained.

Sections from the 4-DCTD-treated rats showed no significant changes at any doses compared to the corn oil controls. Except for minor cellular swelling in some proximal tubules, there was no evidence of kidney damage in any of the treatment groups. Our results show that DCPT-induced hepatotoxicity is dependent on the presence of a carbonyl group in the 2 position of the TZD ring. This suggests that an intact TZD ring is critical for toxicity; however, this will require further investigation. Supported by PHS grant ES012499.

ENDOGENOUS FATTY ACID METHYL ESTERS AS A POTENTIAL MARKER OF HUMAN HEPATOCELLULAR CARCINOMA.

S. H. Khan, B. S. Kaphalia and G. Ansari. *Pathology, UTMB, Galveston, TX.*

Hypomethylation of DNA has been considered a major cause/effect of hepatocellular carcinoma. Due to the known higher rate of methylation of lipids compared to DNA and protein, fatty acid methyl esters (FAMEs) can serve as a surrogate marker of DNA methylation. In the present study, we determined the levels of FAMEs and determined corresponding synthetic and the hydrolytic activities in normal human liver and hepatoma tissues to comprehend altered homeostasis of FAMEs in hepatocellular carcinoma. Lipids were extracted from normal human liver and hepatoma tissues, separated by thin layer chromatography (TLC) and analyzed by gas chromatography. Hydrolytic and synthetic activities towards FAMEs were determined in the post nuclear fractions using [ $^3$ H-9, 10] methyl palmitate and [ $1-^{14}$ C] oleic acid as respective substrates. The resultant product(s) was separated by TLC and the radioactivity corresponding to the relative flow of fatty acid and ester was determined. The FAMEs levels were found to be drastically lower in hepatoma (4.5  $\mu$ g/g) than in the normal liver tissue (31.4  $\mu$ g/g). Both hydrolytic and synthetic activities were also decreased to 1724 vs. 554 nmol/hr/mg protein and 169 vs. 26 nmole/hr/mg protein in normal liver and hepatoma tissue, respectively. These results indicate that global hypomethylation in hepatocellular carcinoma can be monitored by the levels of FAMEs and related hydrolytic and synthetic activities.

AN INVESTIGATION INTO THE RELATIONSHIP OF VITAMIN A LEVELS AND HEPATITIS, HYPERPLASIA, BENIGN OR MALIGNANT LESIONS IN RODENT LIVERS.

C. Bray. *Covance Laboratories Ltd., Harrogate, United Kingdom. Sponsor: D. Everett.*

This poster presents the results of an investigation into the relationship between vitamin A levels in different liver lesions, and its correlation with the immunohistochemical staining pattern of retinol-binding protein. Vitamin A serves a number of functions in the body, it is known to be required for the maintenance of healthy epithelial tissue. Vitamin A-deficient animals have been shown to be more susceptible to both infections and cancer. The decreased resistance to infections is thought to be due to the keratinisation of the mucosal cell lining the respiratory, gastrointestinal, and genitourinary tract. It also has been suggested that vitamin A-deficiency may impair the immune system. The protective effect of vitamin A against many forms of cancer might be due to the antioxidant potential of beta-carotene (source of vitamin A) and the effects of retinol and retinoic acid in regulating cell growth. Retinol represents the most important transport and storage form of vitamin A. More than 90% of the body's vitamin A reserves are stored in the liver, where it is bound to a cellular retinol-binding protein (RBP). In this study retrospective samples of liver were obtained from in-house rat carcinogenicity studies. The liver samples were to include normal tissue, hepatitis, hyperplastic, benign, and malignant lesions. Which have been previously diagnosed/observed by H&E histopathology. Immunohistochemical staining patterns were observed using an antibody against RBP in each of these tissues. RBP demonstrated a cytoplasmic staining pattern and the results indicated a partial correlation between vitamin A and the different liver lesions.

CHARACTERIZATION OF A HIGH-POTENCY ENDOGENOUS LIGAND FOR THE ARYL HYDROCARBON RECEPTOR.

E. C. Henry<sup>1</sup>, J. C. Bemis<sup>1</sup>, A. S. Kende<sup>2</sup> and T. A. Gasiewicz<sup>1</sup>. <sup>1</sup>*Environmental Medicine, University of Rochester, Rochester, NY* and <sup>2</sup>*Chemistry, University of Rochester, Rochester, NY.*

A putative endogenous ligand for the aryl hydrocarbon receptor (AhR) was recently isolated from pig lung and identified as 2-(1'H-indole-3'-carbonyl)-thiazole-4-carboxylic acid methyl ester (ITE) [PNAS 99:14694]. We have synthesized this compound and further examined its activity in several *in vitro* and *in vivo* assays compared with the toxic ligand, TCDD. Electrophoretic mobility shift assays of AhR in

Hepa1c17 cell cytosol showed similar potency of activation by ITE and TCDD and similar levels of binding to the dioxin response element (DRE). In both Hepa (mouse) and human HepG2 cells stably transfected with a DRE-dependent reporter gene construct, ITE was less potent than TCDD, but elicited strong transactivation of luciferase activity which followed a similar time-course as in TCDD-treated cells. Immunocytochemistry showed rapid and strong nuclear localization of the AhR following ITE treatment of Hepa cells at 10nM and above. CYP1A1 protein induction by ITE was dose- and time-dependent; maximum levels reached were lower than maximum levels induced by TCDD. ITE (20 $\mu$ g/kg) was also administered i.p. to pregnant DRE-LacZ transgenic mice. The pattern of X-gal staining in the fetuses, indicative of AhR activation, was the same as that produced by TCDD [most prominent in genital tubercle, ear, paws]. Thus, despite the likelihood that it is readily metabolized, ITE (or an active metabolite) was able to cross the placenta and activate AhR in fetal tissues. Based on all these observations, we conclude that although ITE may differ from TCDD with respect to its cellular kinetics, it interacts with AhR very similarly to TCDD, and is a good candidate endogenous AhR ligand. #### NATURALLY OCCURRING ANTAGONISTS OF AHR PATHWAY: A NOVEL APPROACH OF CANCER CHEMOPREVENTION?

D. puppala and H. Swanson. *Pharmacology, University of Kentucky, Lexington, KY.*

The aryl hydrocarbon receptor (AHR), is a cytosolic receptor which upon activation by its agonists, translocates into the nucleus and forms a dimer with the ARNT (Aryl Hydrocarbon nuclear translocator). AHR/ARNT dimer alters the regulation of AHR battery genes by binding to the dioxin responsive elements (DRE). Many AHR agonists, like the polycyclic aromatic hydrocarbons and polyhalogenated hydrocarbons are human carcinogens. For example, dioxin or TCDD (2, 3, 7, 8 tetrachlorodibenzo-p-dioxin), is the best characterized and most potent AHR agonist and is an ubiquitous environmental contaminant class-I carcinogen. In addition, many dietary constituents that have chemopreventative properties are antagonists of the AHR pathway. Thus, by using naturally occurring antagonists of the AHR pathway one can propose a chemopreventative approach towards inhibiting many human cancers. In our quest to find a potent, naturally occurring antagonist of the AHR pathway, we have assayed the impact of 15 flavonoid compounds to inhibit ligand binding, DNA binding and transactivation of the AHR. Our results indicate that of these compounds, the most potent AHR antagonists are apigenin, emodin, kaempferol and resveratrol.

86

#### IMPACT OF NH-TERMINAL TAGS ON AH RECEPTOR LOCALIZATION AND DEGRADATION IN CELL CULTURE.

J. McQuown<sup>2,1</sup>, J. Wentworth<sup>1</sup>, E. Dougherty<sup>1</sup> and R. S. Pollenz<sup>1</sup>. <sup>1</sup>*Biology, University of South Florida, Tampa, FL* and <sup>2</sup>*Cancer Biology, Moffitt Cancer Center, Tampa, FL.*

The expression of a peptide/protein tag on the NH or COOH terminus of a target protein has become an important aspect of studying protein function in cell culture and transgenic animals. Since the expressed tag may impact the function of the target protein, studies were carried out to evaluate the impact of 3 distinct tags on AHR function in cell culture models. The AHR was tagged at the NH terminus with the FLAG epitope (8 amino acids), HIS/XPRESS tag (35 aa) or EGFP (238 aa). The tagged AHR was ligated into the pSI eukaryotic expression vector that drives expression with an SV40 promoter. In transient expression assays, all tagged AHRs were expressed at high levels and showed reduced levels of ligand-mediated degradation as well as both cytoplasmic and nuclear location as compared to control AHR that was not tagged. Since the high level of protein expression in transient assays are generally not physiological and may produce aberrant protein location and interactions, the tagged AHRs were ligated into retroviral expression vectors and used to generate stable cell lines. The advantage to this approach is that there are a low numbers of integration events, the cellular population is homogeneous and the level of protein expression is more physiologic. Several cell lines were selected for each tagged AHR as well as for control AHR with no tag. Western blot analysis revealed that the level of expression of the AHR in each cell was consistent with the level of AHR in wild type Hepa-1 cells and the subcellular location of the tagged AHRs was generally cytoplasmic. Importantly, exposure of the cells to TCDD resulted in nuclear accumulation of the AHR and degradation. However, the overall magnitude of AHR degradation was reduced when a tag was present on the NH-terminus. These studies suggest that the tagging of the AHR may impact ligand-mediated degradation and that the NH-terminus may be important in recognition of the degradation machinery. Supported by ES 10991.

#### COMPUTATIONAL APPROACH TOWARDS IDENTIFYING GENES WITH DIOXIN RESPONSE ELEMENTS IN HUMAN, MOUSE, AND RAT GENOMES.

C. Vezina, H. M. Theobald and R. E. Peterson. *School of Pharmacy, UW-Madison, Madison, WI.*

Computational Approach Towards Identifying Genes with Dioxin Response Elements in Human, Mouse, and Rat Genomes. H.M. Theobald, C.M. Vezina, and R.E. Peterson. University of Wisconsin-Madison, School of Pharmacy. The aryl hydrocarbon receptor mediates 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD, dioxin) toxicity by modifying transcription of genes containing promoter-based dioxin response elements (DREs). The current study employed a computational approach to identify putative DRE-driven genes in the mouse, rat, and human genomes. Genetic promoter regions (-5000 to +1 bp, relative to the transcription initiation site) were obtained from human, mouse, and rat Golden Path and Ensembl genome assemblies and subjected to DNA pattern matching to identify TNGCGTG consensus DRE heptamers. Sequence alignment of DRE-flanking regions in human, mouse, and rat gene homologs was employed to identify genes harboring DREs that were conserved among multiple species. This analysis yielded 34 gene promoters that contained DREs whose position relative to the transcription initiation site was similar (within 500bp) and exhibited significant sequence homology between mouse, rat, and human DRE-flanking sequences. An additional 255, 120, and 27 gene promoters exhibited one or more DREs with position and sequence conservation between rat and mouse, human and mouse, and human and rat, respectively. RT-PCR of liver, lung, kidney, and brain from vehicle and dioxin exposed (25  $\mu$ g/kg po, 24 hrs) adult male C57Bl/6J mice and urogenital sinus tissues from male mice exposed as fetuses (5  $\mu$ g/kg maternal dose, gestation day 13-16) was employed to confirm the dioxin responsiveness of selected genes containing these putative DRE sequences. (NIH grant ES01332).

#### IDENTIFICATION OF ZEBRAFISH ARNT1 HOMOLOGS: TCDD DEVELOPMENTAL TOXICITY IN ZEBRAFISH REQUIRES ARNT1.

A. L. Prasch<sup>1</sup>, R. L. Tangney<sup>2</sup>, W. Heideman<sup>1</sup> and R. E. Peterson<sup>1</sup>. <sup>1</sup>*University of Wisconsin, Madison, WI* and <sup>2</sup>*Environmental & Molecular Toxicology, Oregon State University, Corvallis, OR.*

In order to use the zebrafish as a model to study the effects of TCDD on early development, it is essential to know which proteins are involved in mediating toxicity. Previous work has identified zfAHR2 as the receptor which binds TCDD leading to downstream effects. One previously identified form of zfARNT2, zfARNT2b, can form a functional heterodimer with zfAHR2 *in vitro*. However, zfarn2 null mutants show no protection against endpoints of TCDD developmental toxicity demonstrating that zfARNT2b cannot be the physiological dimerization partner for zfAHR2 mediating several responses to TCDD in zebrafish embryos. The purpose of the current study was to identify an alternate dimerization partner(s) for zfAHR2 that may function to mediate TCDD developmental toxicity. The zebrafish genome was searched and a novel partial transcript was identified as a likely zebrafish isoform of ARNT1. The PCR-based RACE technique was used to obtain the 5' and 3' ends of the transcript. Two forms of cDNA that appear to be alternate mRNA splice variants were detected. Analysis of the zfARNT1 proteins *in vitro* demonstrated that one form of zfARNT1, zfARNT1a, can form a functional heterodimer with zfAHR2 that specifically binds xenobiotic response elements (XREs) in gel shift experiments and induces XRE-driven transcription in COS-7 cells exposed to TCDD. However, the other form, zfARNT1b, appeared nonfunctional with zfAHR2. A morpholino targeted against the 5' end of zfARNT1 (zfarn1-MO) was used to demonstrate that a zfARNT1 protein is a functional dimerization partner for zfAHR2 *in vivo*. Injection of the zfarn1-MO prior to TCDD treatment significantly decreased the induction of zfcYP1A mRNA and protein. In addition, the zfarn1 morphants were completely protected against TCDD-induced pericardial edema and showed partial protection against reduced peripheral blood flow and craniofacial malformations caused by TCDD. UW Sea Grant.

#### 5, 6-LEUKOTRIENE A4 A IS POTENT ACTIVATOR OF THE AH RECEPTOR.

C. R. Chiaro<sup>1</sup>, A. D. Jones<sup>2</sup>, Y. Cao<sup>1</sup>, J. Born<sup>3</sup>, C. Marcus<sup>3</sup> and G. H. Perdew<sup>1</sup>. <sup>1</sup>*Veterinary Science, Penn State University, University Park, PA*, <sup>2</sup>*Chemistry, Penn State University, University Park, PA* and <sup>3</sup>*Toxicology, University of New Mexico, Albuquerque, NM.*

The aryl hydrocarbon receptor (AhR) is a ligand activated transcription factor that can be activated by a broad range of structurally diverse chemicals ranging from environmental carcinogens to dietary metabolites. While the most potent agonists thus far identified are of synthetic origin, an increasing number of natural com-

pounds have been shown to activate the Ah receptor. Evidence supporting an endogenous role for the AhR in normal biology has been established; however no high affinity endogenous ligand has been identified. We now report the ability of 5, 6-Leukotriene A4 (LTA4), a lipoxygenase metabolite of arachidonic acid, as a potent activator of the Ah receptor pathway in HepG2 cells. Electrophoretic mobility shift assays (EMSA) have confirmed the ability of this eicosanoid to directly activate the AhR inducing heterodimerization and subsequent DNA binding. Due to the instability of 5, 6-LTA4 it was imperative to test the subsequent metabolites of this compound for Ah receptor activity. DRE-driven luciferase reporter assays along with gel shift assays have revealed that numerous 5, 12-DiHETEs including the enzymatically formed LTB4 along with 5, 6-DiHETE isomers of both enzymatic and non-enzymatic origin have failed to activate the Ah receptor. This result was anticipated based on data generated via molecular modeling programs. The shape of the DiHETE molecules differs significantly from that of LTA4 due to hydrolysis of the oxido ring. These results taken together indicate that 5, 6-Leukotriene A4, an unstable epoxide intermediate of leukotriene metabolism formed on the nuclear membrane, can directly serve as an AhR agonist.

90

ER- $\alpha$  REPRESSES TCDD-INDUCIBLE CYP1A1 GENE TRANSCRIPTION THROUGH A DIRECT PROTEIN-PROTEIN INTERACTION WITH AHR/ARNT.

T. Beischlag and G. H. Perdew. *Center for Molecular Toxicology and Carcinogenesis, Department of Veterinary Sciences, Penn State University, University Park, PA.*

The aryl hydrocarbon receptor (AHR) and the aryl hydrocarbon receptor nuclear translocator (ARNT) form a heterodimeric transcription factor that binds a wide variety of environmental pollutants, including 2, 3, 7, 8 tetrachlorodibenzo-p-dioxin (TCDD). The activation of this transcription factor mediates an organism's adaptive responses to environmental contaminants and plays an important role in development and physiological homeostasis. AHR target gene activation can be repressed by estrogen, and estrogen-like compounds. In this study, we demonstrate that a significant component of TCDD-inducible CYP1A1 transcription is the result of recruitment of ER $\alpha$  by AHR/ARNT as a transcriptional co-repressor. TCDD-activated CYP1A1 and CYP1B1 transcription was repressed approximately 50% by 17 $\beta$ -estradiol in MCF-7 cells in the presence of cycloheximide, as determined by reverse transcription/real-time PCR. In the absence of cycloheximide only CYP1A1 transcription was repressed, while that of CYP1B1 was enhanced. Furthermore, we have shown by ChIP that ER $\alpha$  is present at the CYP1A1 enhancer only after co-treatment with E2 and TCDD, in MCF-7 cells. Furthermore, sequential two-step ChIP assays were performed which demonstrate that AHR and ER $\alpha$  are present together at the same time on the CYP1A1 enhancer during transrepression. Taken together these data support a role for ER-mediated transrepression of AHR-dependent gene regulation.

91

ROLE OF ARNT2 IN NORMAL DEVELOPMENT BUT NOT TCDD DEVELOPMENTAL TOXICITY IN ZEBRAFISH.

A. J. HILL<sup>1</sup>, A. L. Prasch<sup>2,1</sup>, W. Heideman<sup>1,2</sup> and R. E. Peterson<sup>1,2</sup>. <sup>1</sup>*School of Pharmacy, University of Wisconsin, Madison, WI* and <sup>2</sup>*Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI.*

As a dimeric partner with the aryl hydrocarbon receptor (AHR), aryl hydrocarbon receptor nuclear translocators (ARNTs) play a pivotal role in mediating responses to environmental contaminants such as dioxins through the AhR signaling pathway. zfARNT2b, as a heterodimer with zfAHR2, induced xenobiotic response element- (XRE-) driven transcription in COS-7 cells when treated with 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD). In addition, zfahr2 and zfarn2a, b, c mRNAs were co-localized in the same tissues as the XRE-driven gene, zfcyp1a, after TCDD exposure. Although these results suggest that zfARNT2 may function with zfAHR2 in response to TCDD, two findings demonstrate that zfARNT2 is not the key AHR dimerization partner involved in mediating TCDD developmental toxicity. First, a morpholino oligonucleotide targeted against zfARNT2 and injected at the 1-cell stage into wild type embryos, subsequently exposed to TCDD, failed to protect against toxicity. Second, exposure of ARNT2 null mutant zebrafish embryos to TCDD also resulted in TCDD toxicity. Thus, neither knockdown of ARNT2 expression nor null mutation of ARNT2 rescued embryos from TCDD toxicity. To elucidate the role of ARNT2 in embryonic development (in the absence of TCDD), both ARNT2 morphants and ARNT2 null mutants were assessed. They were found to exhibit no gross malformations during development. However, reduced swimming motility in response to touch and startle stimuli was found in ARNT2 null mutants. Bradycardia and an arrhythmic event were found to characterize heart function and histological assessments revealed abnormal development

of the heart, brain and liver. This study suggests that ARNT1 (rather than ARNT2) may be the key dimerization partner for AHR2 in zebrafish, and although ARNT2 is not essential for TCDD developmental toxicity, it is required for normal brain, liver and heart development. (UW Sea Grant).

92

ALTERED CELL CYCLE REGULATION IN AH RECEPTOR-NULL MOUSE FIBROBLASTS.

X. Chang and A. Puga. *Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) is a ubiquitous environmental contaminant and causes diverse toxic effects. Most of the TCDD toxicity is mediated by the aryl hydrocarbon receptor (AHR). Conflicting evidence from various experimental systems indicates that the activated AHR promotes both cell cycle progression as well as cell cycle arrest. In the present study, we further investigate the role of AHR in cell cycle regulation by expressing the high-affinity mouse wild type AHR and a truncation variant that has a deletion of amino acids 323 to 494 in the PAS B domain with a tetracycline receptor-regulated system in AHR-null mouse fibroblasts. The mutant lacks the retinoblastoma protein (RB) interacting motif LXCE and is constitutively activated. In both AHR- and mutant-expressing cell lines, AHR expression were completely inhibited after 96 hours treatment of 5 $\mu$ g/ml doxycycline, while the expression of ARNT, the AHR nuclear translocator partner was not affected. TCDD treatment for 90 minutes induced the nuclear translocation of the wild type AHR protein. Consistently, Cyp1a1 induction by TCDD treatment in AHR expressing cells was comparable to expression in AHR+/+ fibroblasts, whereas Cyp1a1 mRNA levels were constitutively high in mutant-expressing cells and doxycycline treatment inhibited the induction of Cyp1a1 by TCDD. In both cell lines, doxycycline treatment significantly decreased the cell proliferation rate while TCDD had no significant effects on cell proliferation, suggesting that the presence of AHR, but not its activation by ligand is required for normal cell cycle progression. By flow cytometry, it was shown that the delay of cell cycle progression in the absence of AHR is due to a slow down of G1 and S phases. Gene expression microarray hybridization showed that the expression of a group of cell cycle negative regulators including E2F5, Cullin 5, CyclinG2 in AHR expressing cells were down regulated compared to AHR-null cell lines, providing a molecular basis for the cellular consequences of AHR function. —Supported by NIH grant ES06273

COMPARISONS OF RAT LIVER GENE EXPRESSION PROFILES FOR TCDD, D3T AND I3C: IMPLICATIONS FOR THE TOXICITY EQUIVALENCE FACTOR (TEF) APPROACH.

C. Sutter<sup>1</sup>, K. Illouz<sup>2</sup>, A. Possolo<sup>2</sup>, S. Goodwin<sup>1</sup>, Y. Huang<sup>1</sup>, T. Kensler<sup>3</sup>, J. Silkworth<sup>3</sup> and T. Sutter<sup>1</sup>. <sup>1</sup>*Feinstein Center for Genomic Research, University of Memphis, Memphis, TN*, <sup>2</sup>*Global Research, GE, Schenectady, NY* and <sup>3</sup>*Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Indole-3-carbinol (I3C) is a weak Ah receptor (AhR) ligand but it is not included in risk assessments of dioxin-like compounds because it is rapidly eliminated. I3C is also a cancer chemopreventive agent in animals, and is believed to act through multiple mechanisms to affect pre- and post-initiation steps in carcinogenesis. Some of this activity is attributed to its stimulation of metabolic enzymes, favoring detoxification. Although the estimated dioxin TEF for I3C is only 0.0001, its prevalence in the diet indicates that the daily dioxin-equivalent of this compound would exceed the daily intake of all other PCDD/PCDFs by more than 100 times. To better understand the effects of I3C, rats were administered 3 daily dosages by gavage of either control vehicle or 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), a prototypic AhR ligand at 3 mcg/kg bw; 1, 2-dithiole-3-thione, a prototypic activator of the Nrf2 transcription factor at 0.3 mmol/kg bw; or, I3C at 100 mg/kg bw. Using Affymetrix RG U34 arrays, liver RNA levels of three biomarkers of AhR response (CYP1A1, CYP1A2 and CYP1B1) and two biomarkers of Nrf2 mediated response (AFAR and GSTpi) showed the expected responses for TCDD and D3T. TCDD treatment increased the expression of CYP1A1 (45-fold), CYP1A2 (5-fold) and CYP1B1 (8-fold), but not AFAR and GSTpi, while D3T treatment had effects on only AFAR (10-fold) and GSTpi (15-fold). Of interest, I3C showed an AhR like response, increasing CYP1A1 (11-fold) and CYP1A2 (4-fold), and not AFAR and GSTpi. However, CYP1B1 was not elevated, indicating that not all AhR ligands affect the same sets of genes equally. Further analyses of the sets of genes responsive to these chemicals and their associated biological networks should provide additional insight into the action of I3C as an AhR agonist and improve the rationale for its TEF categorization.

NATURALLY OCCURRING MARINE COMPOUNDS  
SHOW A SPECIES-SPECIFIC DIFFERENCE IN AHR  
DRIVEN REPORTER GENE EXPRESSION.

D. DeGroot<sup>1</sup>, M. E. Hahn<sup>2</sup>, B. K. Carte<sup>3</sup>, T. Higa<sup>4</sup> and M. S. Denison<sup>1</sup>.

<sup>1</sup>Environmental Toxicology, University of California, Davis, CA, <sup>2</sup>Woods Hole Oceanographic Institution, Woods Hole, MA, <sup>3</sup>Ancile Pharmaceuticals, San Diego, CA and <sup>4</sup>University of Ryukyus, Okinawa, Japan.

The aryl hydrocarbon receptor (AhR) is a ligand-dependent transcription factor that mediates a variety of toxicological and biological effects, including gene expression in a diverse range of species and tissues. While the best characterized ligands for the AhR are halogenated aromatic hydrocarbons such as 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) and polycyclic aromatic hydrocarbons, recent evidence has demonstrated that the AhR can bind and be activated by structurally diverse synthetic and naturally occurring chemicals. As part of a larger effort to identify the spectrum of chemicals that can bind to and activate the AhR, we have examined a library of pure and closely related mixtures of compounds isolated from a variety of marine organisms. Using AhR-responsive recombinant cell bioassay systems generated in mouse, rat and guinea pig cell lines (Hepa1c1c7, H4IIE and GPC16, respectively), a library of 151 compounds were screened at a concentration of 2  $\mu$ M and those inducing AhR-dependent luciferase reporter gene expression identified. These studies have revealed a variety of novel structurally diverse chemicals that can activate AhR-dependent gene expression. The most striking result was the large species-specific difference in the number, type and relative potency of chemicals inducing AhR-reporter gene expression, with 13, 39, and 18 marine products identified as activators of the AhR mouse, guinea pig and rat cell lines, respectively. In addition, while some compounds were active in all three species others were species-specific. The diversity in response may result from differences in the AhR and/or components of the AhR signaling pathway as well as variation between the cell lines themselves. Our studies suggest that the guinea pig AhR is significantly more promiscuous than that of the rat or the mouse. (ES07685, ES04699, ES05707, WHOI Sea Grant)

PERSISTENT BINDING OF LIGANDS TO THE HEPATIC AH RECEPTOR FROM VARIOUS SPECIES.

J. E. Bohonowich and M. S. Denison. Environmental Toxicology, University of California Davis, Davis, CA.

The aryl hydrocarbon receptor (AhR) is a ligand activated transcription factor that mediates many biological and toxic effects of halogenated aromatic hydrocarbons (HAHs; such as 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD)), polycyclic aromatic hydrocarbons (PAHs; such as  $\beta$ -naphthoflavone (BNF)), and a wide variety of structurally diverse ligands. While the HAHs are several orders of magnitude more potent in producing biochemical effects than PAHs or other AhR agonists, only the HAHs have been observed to produce AhR-dependent toxicity *in vivo*. Here we have characterized the binding and dissociation of ligands from the AhR in order to determine whether these aspects play a role in the divergent potency/toxicity of these chemicals at the level of the AhR. Dissociation of [<sup>3</sup>H]TCDD from the hepatic cytosolic AhR of Hartley guinea pigs, Sprague-Dawley rats, C57BL/6 mice and Golden Syrian hamsters was measured over time at 25°C using hydroxyapatite. At 48 hours, the amount of [<sup>3</sup>H]TCDD specifically bound to the AhR was still 86%, 56%, 73% and 72% of time zero for the above species, respectively. This persistent occupancy was also observed for guinea pig hepatic cytosol incubated at 37°C, with 89% [<sup>3</sup>H]TCDD specific binding remaining at 44 hours. Dissociation experiments at 25°C with [<sup>3</sup>H]BNF revealed that at 48 hours, 86%, 32%, 66% of [<sup>3</sup>H]BNF was still specifically bound to guinea pig, rat, and hamster AhR, respectively. Our results demonstrate that both [<sup>3</sup>H]TCDD and [<sup>3</sup>H]BNF do not readily dissociate from the AhR of these species. The persistence of binding of both TCDD and BNF to the AhR suggests that their differences in potency/toxicity are more likely attributable to factors other than simply binding affinity/occupancy (i.e. metabolic stability). Our data also supports reassessment of previous AhR ligand binding affinity calculations and competitive binding analysis, since AhR ligand binding at these times are clearly not in equilibrium, a requirement for use of traditional receptor-ligand equilibrium binding kinetics equations. (NIEHS ES07685 and ES05707)

TCDD EXPOSURES ACTIVATE PKC, MAPK AND NFkB SIGNALING PATHWAYS IN HUMAN CANCER CELLS.

C. K. Yu, M. H. Wong and C. K. Wong. Biology, Hong Kong Baptist University, Hong Kong, China.

An anthropogenic compound - 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) is one of 75 possible chlorinated dibenzo-p-dioxin. It has no industrial or commercial use and was produced as inadvertent trace contaminants in the synthesis of pesticides, chlorine-bleaching processes or incineration. One of the toxic potency for

TCDD is recognized as its interaction with cytosolic high-affinity aryl hydrocarbon receptor (AhR), followed by heterodimerization with an Ah receptor nuclear translocator and a subsequent binding on the cis-acting dioxin responsive element. Other possible pathways included the modulation of signaling molecules, like PKC, Raf-1, MAP kinase and PKA have been reported. In this study, we determined the effects of TCDD on the phosphorylation of some selected protein substrates (i.e. MARCKS, p44/42 MAPK, I $\kappa$ B) in two human cancer cell-lines (i.e. HepG2 & CaCo2). TCDD induced EROD dose-dependent curves were determined whereas the EC50 for HepG2 and CaCo-2 were 100 pg/ml and 30 pg/ml respectively. Using the EC50 doses for the cells, we conducted Western blotting to determine the phosphorylation of the protein substrates. The levels of pMARCKS, phospho-p44/p42 MAPK and pI $\kappa$ B were significantly induced at 4 hrs after TCDD exposure and remained in high levels at 24 hrs of post-treatment. The results indicated that in addition to the AhR pathway, TCDD can activate various signaling pathways in the cells. The activation of these pathways might affect some basic cell functions, such as cell differentiation and proliferation. Taken together our study indicate that TCDD mediated biological effects are pleiotropic and can be the consequences of crosstalk among different signaling molecules.

THE ARYL HYDROCARBON RECEPTOR (AHR)  
ANTAGONIST EGCG, INHIBITS AHR ACTIVATION  
THROUGH AN INDIRECT MECHANISM INVOLVING  
BINDING TO HSP90: A NOVEL MECHANISM FOR A  
REPORTED ANTI-CANCER AGENT.

C. M. Palermo and T. A. Gasiewicz. Department of Environmental Medicine, University of Rochester, Rochester, NY.

The AhR is a ligand-dependent transcription factor known to mediate the toxic effects of numerous environmental contaminants including the polycyclic aromatic hydrocarbons. Although a tremendous amount of work has emphasized activation of the AhR signaling pathway, a key question remaining is how ligands might function to turn this signaling pathway off. Previous investigations in our laboratory have demonstrated that the green tea polyphenol, epigallocatechin gallate (EGCG), is capable of antagonizing AhR-mediated gene transcription. This line of investigation was directed at elucidating the molecular mechanism of this antagonism. Competitive binding assays under numerous conditions optimal for low affinity ligands demonstrated that EGCG does not bind to the AhR ligand binding site, indicating this compound functions through a mechanism unlike typical AhR antagonists. Affinity chromatography using immobilized EGCG implicates an indirect mechanism of action involving direct binding of EGCG to the AhR chaperone protein, hsp90. This binding to hsp90 influences the AhR complex in the absence and presence of TCDD. Alone, EGCG induces an AhR conformation capable of nuclear localization but incapable of binding DNA. These altered signaling events correlate with the formation of a multimeric complex with a much higher sedimentation rate than the latent or TCDD-activated receptor. In the presence of TCDD, EGCG prevents the formation of an AhR conformation capable of binding DNA, yet it is incapable of preventing TCDD-mediated nuclear localization or degradation of the receptor. These data suggest a model in which EGCG binding to hsp90 stabilizes the hsp90-AhR complex in an intermediary state associated with XAP2. This is the first time EGCG has been demonstrated to directly bind hsp90 and the first indication that EGCG may exert many of its biological effects through targeting of this common chaperone.

A NOVEL ARNT-INTERACTING PEPTIDE AINP2  
ENHANCES THE ARYL HYDROCARBON RECEPTOR  
SIGNALING.

Y. Li, T. C. Luu and W. K. Chan. Thomas J. Long School of Pharmacy & Health Sciences, University of the Pacific, Stockton, CA.

Aryl hydrocarbon receptor nuclear translocator (Arnt) belongs to the basic helix-loop-helix-PER-ARNT-SIM family. It plays a vital role in diverse biological functions mediated by the aryl hydrocarbon receptor (AhR) and hypoxia inducible factor-1 signaling pathways. In both pathways, Arnt acts as the dimerization partner for the formation of the heterodimeric complex, leading to the activation of transcription of the target genes. We are interested in identifying Arnt-interacting proteins that are essential for the Arnt-dependent signaling mechanisms. To do that, we employed phage display to isolate Arnt-interacting peptides from a human liver cDNA library. A thioredoxin fusion of an Arnt construct Cdelta418 (aa1-371, lacking the C-terminal 418 amino acids) was used as the bait. Co-precipitation assay using TALON resin was used for biopanning. After five rounds of biopanning, the phage titer was enriched to more than 100-fold (from 8 to 850 plaques) whereas the negative control (thioredoxin) gave only a 15-fold (from 2 to 30 plaques) enrichment. Plaque lift assay using 32P-labelled thioredoxin-Arnt Cdelta418 protein was performed to confirm the interaction between Arnt and the positive phages. Arnt-interacting peptide 2 (Ainp2), which contains 58 amino acids, was subse-

quently isolated and identified. Northern blot analysis revealed that Ainp2 is selectively expressed in human liver. BLAST search of the GenBank database did not reveal the identity of this peptide. Ainp2 interacts with Arnt *in vitro* and *in vivo* using GST pull-down assay and mammalian two-hybrid studies, respectively. RACE PCR was performed and an open reading frame of 231 nucleotides was obtained. Transient transfection studies showed that Ainp2 increases the 3-methylcholanthrene-induced luciferase activity by 1.73-fold +/- 0.06 (n=6), suggesting that Ainp2 play a role in the AhR signaling pathway.

### THE ROLE OF THE JUN N-TERMINAL KINASE PATHWAYS IN THE TISSUE-SPECIFIC TCDD TOXICITY.

Z. Tan, A. Puga and Y. Xia. *Environmental Health, University of Cincinnati, Cincinnati, OH.*

Exposure to 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) causes diverse and tissue-specific toxic effects both in animals and humans, most of which are mediated through its binding to and activation of the aryl hydrocarbon receptor (AhR). Upon activation, AhR translocates to the nucleus and complexes with its partner, the Ah receptor nuclear translocator (ARNT), and other proteins to regulate the transcription of target genes, such as CYP1A1, responsible for most of the toxic effects of TCDD. Our previous studies suggest that TCDD activates the Mitogen-Activated Protein (MAP) kinase pathways and that the MAPKs in turn contribute to AhR activation and CYP1A1 expression. In this study, we have used genetically deficient mice that lack components of the Jun N-terminal kinase (JNK) pathway, including JNK1 and JNK2, to investigate the role of the JNK MAPK pathway in TCDD-induced CYP1A1 expression in liver, thymus and spleen. We found that TCDD treatment of mice caused a robust CYP1A1 induction in the liver, at both RNA and protein levels, which was unaffected by JNK ablation. Comparing to that in the wild type mice, the CYP1A1 induction in thymus was suppressed up to 50% in *Jnk2*, but not in *Jnk1* knockout mice, while the induction in spleen was suppressed up to 45% and 25% in *Jnk1*- and *Jnk2* knockouts, respectively. Because MEK kinase 1 is an upstream regulator of the JNK pathway, we generated compound knockout mice, *Jnk1*-/-*Mekk1* +/- and *Jnk2*-/-*Mekk1* +/-, to test the gene dose effects of the JNK pathway on CYP1A1 induction. We found that deletion of one *Mekk1* allele caused further reduction in CYP1A1 expression in both *Jnk1*-/- and *Jnk2*-/- backgrounds and this reduction took place only in thymus and spleen, but not in liver. These results suggest that the JNK pathway is involved in the modulation of AhR signaling in thymus and spleen and that JNK1 and JNK2 may make unique contributions to the tissue-specific toxicity of TCDD. ### ISOLATION AND CHARACTERIZATION OF THE CYP1A1 PROMOTER REGION FROM ZEBRAFISH.

J. Wentworth and R. S. Pollenz. *Biology, University of South Florida, Tampa, FL.*

Danio rerio (zebrafish) has become an important model system in the study of development and signal transduction pathways. Recent studies indicate that zebrafish show sensitivity to 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) during development and the biological endpoints to TCDD exposure correlate well with those from mammalian systems. To gain an understanding of the molecular mechanism of TCDD action, it is necessary to gain insight into the binding of the AhR at the promoters of induced genes. Thus, studies were initiated to isolate and characterize the zfCYP1A1 promoter. Since the zfCYP1A1 sequence was not available through the zebrafish genome project, several oligonucleotide primer sets were designed to the most 5' portion of the zfCYP1A1 open reading frame. These primer sets were then used to PCR screen pools of PAC clones containing 100-120kB fragments of zebrafish genomic DNA. Two pools generated a positive signal and the PACs within the pool were then screened with zfCYP1A1 cDNA. 2 independent PACs were identified and these were analyzed by restriction digestion and Southern blotting. Both PACs produced identical signals. A 2.5kB fragment was isolated and sequenced. The fragment contained the putative ATG start site and first 140 nucleotides of the ORF and this sequence was 100% identical to the zfCYP1A1 mRNA from GeneBank. Similar to other CYP1A1 genes the 5' UTR contained an intron. Importantly, several xenobiotic response elements (5'-ANGCGTG-3') were identified in the upstream sequence. PCR was used to obtain various sized fragments from the promoter and these were ligated into the pGL2 vector to generate reporter constructs. The various constructs were transfected into either mouse Hepa-1 cells or zebrafish ZFL cells and treated with TCDD. Luciferase activity was detected in each cell line and compared to several constructs in which luciferase was driven by various mammalian promoters. The results show that the zfCYP1A1 promoter contains several functional XREs and can drive luciferase in both fish and mammalian cell lines. Supported by ES 08980

### MICROARRAY EXAMINATION OF TCDD MEDIATED CHANGES IN GENE EXPRESSION IN HEPA1C1C7 MURINE HEPATOMA CELLS.

E. Dere, D. R. Boverhof, L. D. Burgoon and T. R. Zacharewski. *Department of Biochemistry & Molecular Biology, Department of Pharmacology & Toxicology, Center for Integrative Toxicology, National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI.*

In an effort to characterize Ah receptor (AhR)-mediated gene expression, comprehensive temporal microarray assays were performed using murine Hepa1c1c7 wild-type (WT) and aryl hydrocarbon nuclear translocator (ARNT) defective C4 mutant hepatoma cells treated with 10 nM TCDD or vehicle (DMSO) for 1, 2, 4, 8, 12, 24 or 48 hrs. Gene expression profiles were monitored using custom cDNA microarrays containing 13, 361 cDNA clones representing 7, 810 unique genes. Statistical analysis using an empirical Bayes approach identified 407 significant changes in gene expression in treated WT cells at one or more time points that grouped into 5 distinct K-means clusters. In contrast, TCDD treatment had little effect in C4 cells beyond 1 hr. TCDD affected functional categories in WT cells included regulation of cell cycle, growth, apoptosis and oxidative stress. Computational examination within -1500 and +1500 of the transcriptional start site, the region with the highest occurrence of dioxin response elements (DREs), identified at least one putative DRE in 294 of the temporally responsive genes. Comparison of *in vitro* gene expression changes to responses observed in hepatic tissue of immature ovariectomized C57BL/6 mice treated with 30 µg/kg TCDD, identified 53 significant genes in common between the two data sets with the vast majority of these involved in xenobiotic metabolism. Expression profiles for most overlapping genes exhibited a comparable pattern in response to TCDD. However, there were contradictory profiles which may be a result of differing basal levels of expression in the two systems. The similarities and differences in gene expression patterns of these genes illustrate the advantages and caveats of using cultured cell lines as models of toxicity for whole tissue responses. Supported by grant ES11271.

### 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN ALTERS EXPRESSION OF RETINOIC ACID RECEPTORS IN NORMAL HUMAN KERATINOCYTES.

K. A. Murphy, C. M. Villano and L. A. White. *Biochemistry and Microbiology, Rutgers University, New Brunswick, NJ.*

Exposure to 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) results in a variety of pathological abnormalities in skin, including chloracne, enhanced invasiveness, hyperkeratinization, and keratinocyte immortalization. Most of TCDD's biological effects are mediated through activation of the aryl hydrocarbon receptor (AhR) pathway, however, data from knockout mice indicate that the AhR pathway is involved in retinoid signaling and homeostasis. Further, our data indicate that the AhR and retinoid signaling pathways interact in normal human keratinocytes (NHKs) where cotreatment alters matrix metabolism through activation of matrix metalloproteinases (MMPs). We propose that TCDD-induced skin lesions result from altered retinoid signaling. Retinoids, vitamin A derivatives, are important mediators of skin proliferation and differentiation. Ligand-bound retinoic acid receptors (RAR) and retinoid X receptors (RXR) regulate transcription directly, through binding to retinoic acid response elements (RAREs), or indirectly, through inhibiting binding of other transcription factors (AP-1). In addition, recent findings show that unliganded RAR/RXRs can lead to gene silencing through chromatin remodeling. Our data using quantitative RT-PCR demonstrate that expression of RAR $\gamma$  and RXR $\alpha$  is increased following TCDD exposure of NHKs. RXR $\alpha$  expression is induced by 2.5 fold 6h post treatment and is maintained up to 24 h; RAR $\gamma$  expression is induced by 6h post treatment as well, but returns to basal levels by 12 h. Experiments using the protein synthesis inhibitor cycloheximide demonstrate that de novo protein synthesis is necessary for TCDD-induced RAR $\gamma$  and RXR $\alpha$  expression. TCDD-induced alterations of retinoid receptor expression levels in normal human keratinocytes may lead to increased sensitivity to retinoid compounds, as evident from our data on the MMPs. Furthermore, TCDD-induced increases in RAR $\gamma$  and RXR $\alpha$  may also contribute to unliganded receptor-mediated gene silencing.

### HEPATIC GENE EXPRESSION IN AHR-/- AND C57BL/6J MICE TREATED WITH 7H-DIBENZO[C, G]CARBAZOLE.

D. Warshawsky, M. Genter, B. Warner, S. Goins, K. LaDow, A. Puga, M. Sartor and M. Medvedovic. *Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH.*

7H-dibenzo[c, g]carbazole (DBC) is a rodent carcinogen and an environmental pollutant found in combustion by-products. We examined changes in gene expression in the liver of two different genotypes of mice [C57BL/6J (B6) and *Abr*-/-, with the latter on a B6 background] following a single topical application of DBC (8 mg/kg

dissolved in acetone). Mice were sacrificed 1 day later and three target tissues for DBC carcinogenicity (liver, lung, and treated skin) were isolated. Total RNA was prepared from livers and used for microarray analysis (Operon 3.0). We determined genes that were significantly different in expression in untreated *Ahr*-/- mice compared to B6, and in treated vs. untreated mice of each genotype. Basal differences in gene expression were observed in untreated B6 vs. *Ahr*-/- mice, with underexpression by >2-fold of *Fmo3*, *Cyp17a1*, and *Cyp39a1* observed in *Ahr*-/- mice compared to B6 mice. In contrast, untreated *Ahr*-/- mice expressed a number of genes at a ≥2-fold higher level than B6 mice, including *Rbp1* and *Lpl*. DBC treatment did not cause an increase in expression of any of the AHR-regulated genes except for *Ephx1*. Cell cycle-related genes *p21* (indicative of DNA-damage-induced cell cycle arrest) and *Bax* (pro-apoptotic) were upregulated to a greater extent in B6 than in *Ahr*-/- mice following DBC treatment. *Thrsp* was dramatically downregulated in DBC-treated B6 mice, but not in treated *Ahr*-/- mice. The latter observation is suggestive of toxicity in the liver of B6 mice. Western blot analysis confirmed increased levels of p21 protein in both strains of DBC-treated mice. Approximately one-third of the 300 genes that were regulated by DBC in either *Ahr*-/- or B6 mice, or both, are of unknown function, but those of known function suggest that DNA damage, hepatotoxicity, and apoptosis are early events in DBC carcinogenicity. Supported by ES-04203-16A1 (Warshawsky PI).

#### ARYL HYDROCARBON RECEPTOR ACTIVATION INHIBITS E2F1-INDUCED APOPTOSIS.

**J. L. Marlowe, X. Chang and A. Puga.** *Environmental Health, University of Cincinnati, Cincinnati, OH.*

2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) is a ubiquitous environmental pollutant and confirmed carcinogen. The molecular basis for the biological effects of TCDD is largely unknown. TCDD mediates the transcription of the CYP1 family of P450 monooxygenases via activation of the AHR (aryl hydrocarbon receptor), but this does not adequately explain the diversity of TCDD effects. Transactivation by the AHR can explain gene induction, but not gene repression, which is a major effect of dioxin exposure that has not been characterized at the molecular level. We have shown that complexes containing AHR, the retinoblastoma protein RB, and the transcription factor E2F assemble at E2F-regulated promoters, resulting in repression of S-phase-specific genes and cell cycle arrest. Based on preliminary evidence, we hypothesized that AHR can also cause gene repression by forming complexes with E2F independently of RB. To test this hypothesis, we analyzed protein interactions between AHR and E2F in multiple assays. Pull-down assays using GST-E2F1 fusions as bait indicate that AHR binds directly to GST-E2F1. Additionally, immunoprecipitation experiments in RB-negative fibroblasts show that AHR and E2F1 interact *in vivo*. Using gel retardation assays, we show that AHR can specifically displace RB from its interaction with E2F at E2F binding sites occupied by RB(p105)/E2F/DP1 complexes, generating a novel complex containing E2F and AHR. We also used transient expression of a reporter gene driven by an E2F-dependent promoter in mouse hepatoma cells to show that direct AHR-E2F interactions lead to gene repression. In addition to controlling gene expression for cell cycle progression, several E2F family members, in particular E2F1, are able to activate apoptosis. Transient transfection and subsequent cell cycle analysis by flow cytometry indicate that AHR expression can inhibit E2F1-induced apoptosis. These data suggest that AHR establishes active repression interactions with E2F1 to down-regulate gene expression, thereby possibly inhibiting the apoptotic elimination of pre-neoplastic cells. #### ARNT1 AND ARNT2 ARE EXPRESSED IN HUMAN KERATINOCYTES *IN VITRO*.

**K. N. De Abrew<sup>1</sup> and B. Allen-Hoffmann<sup>1,2</sup>.** <sup>1</sup>*Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI* and <sup>2</sup>*Department of Pathology and Laboratory Medicine, University of Wisconsin, Madison, WI.*

The basic-helix-loop-helix PAS (bHLH-PAS) family member, Aryl Hydrocarbon Nuclear Translocator (ARNT) is a ubiquitous transcription factor that is involved in cellular sensing of the environment. Both ARNT1 and ARNT2 have been shown to dimerize with the Aryl hydrocarbon receptor (AhR), the hypoxia inducible factor -1(HIF-1α) and the Drosophila single-minded protein (Sim) in response to environmental contaminants, low oxygen levels and developmental cues respectively. ARNT1 knock out mice die at embryonic day 10.5 exhibiting defective angiogenesis and embryo wasting. Skin-specific targeted disruption of ARNT1 in mice results in early neonatal death due to compromised barrier function of the skin leading to severe dehydration. The role of ARNT2 in skin is not known. Rodent skin and human skin, although similar in protecting against dehydration and maintaining body temperature, exhibit numerous differences such as density of epidermal appendages, vascularity, overall thickness, and barrier function. We re-

port that ARNT2 as well as ARNT1 proteins are expressed in human keratinocytes. To access the importance of ARNTs in the growth of human skin, ARNT1 was specifically knocked down in monolayer cultures of the human keratinocytes using RNAi. Cells were tested for viability using the MTT assay and cell growth was assayed by cell counting and Ki67 staining. Results show that knock down of ARNT1 does not affect keratinocyte viability or growth in monolayer cultures. These studies suggest that ARNT1 and ARNT2 are functionally redundant in human keratinocytes. Studies are ongoing to further investigate the role of ARNTs in the growth and differentiation of keratinocytes using an organotypic model of human skin.

#### DETECTION OF AH RECEPTOR LIGANDS IN EXTRACTS FROM COMMON COMMERCIAL AND CONSUMER PRODUCTS USING AHR-BASED BIOASSAYS.

**M. S. Denison<sup>1</sup>, W. J. Rogers<sup>1</sup>, J. E. Bohonowich<sup>1</sup>, M. Ziccardi<sup>1</sup>, T. Pedersen<sup>2</sup>, K. Dettmer<sup>2</sup>, B. D. Hammock<sup>2</sup> and B. Zhao<sup>1</sup>.** <sup>1</sup>*Environmental Toxicology, University of California, Davis, CA* and <sup>2</sup>*Entomology, University of California, Davis, CA.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD) and related aromatic hydrocarbons produce a variety of toxic and biological effects, the majority of which are mediated by the Ah receptor (AhR) and AhR-dependent gene expression. While all AhR ligands were presumed to meet a defined set of criteria, recent studies have revealed that the AhR can be bound and activated by structurally diverse synthetic and natural chemicals. However, the spectrum of chemicals that can bind to and activate/inhibit the AhR remains to be established. We previously demonstrated the presence of AhR agonists in DMSO extracts of commercial and consumer products and here we have carried out a more detailed analysis of the ability of crude DMSO, ethanol and water extracts of plastic, rubber and paper products to interact with and activate the AhR signaling pathway in cells from several species. DMSO and ethanol extracts of plastic, rubber and paper products induced AhR-dependent luciferase expression in all cell lines, but induction was observed on with water extracts of newspapers. We found a good correlation between the ability of an extract (DMSO and ethanol) to competitively bind to the AhR using [<sup>3</sup>H]TCDD binding assays, to stimulate AhR DNA binding *in vitro* and to induce AhR-dependent reporter gene expression. Reductions in reporter gene induction by extracts at later time points suggests that they contain inducing chemicals are metabolically labile. Interestingly, ethanol extracts of newspapers exhibited high AhR agonist activity, suggesting the presence of relatively water-soluble agonists and bioassay-directed fractionation approaches are being used to identify the responsible chemical(s). While the toxicological and biological significance of these AhR agonists are unknown, our data reveal the widespread distribution of chemicals in everyday products that can specifically activate the AhR and AhR-dependent gene expression. #### INTERACTION BETWEEN THE AH RECEPTOR AND NF-KB PATHWAYS: ANTAGONISM AT THE LEVEL OF HISTONE MODIFICATIONS.

**T. Z. Yu, S. Ke and Y. Tian.** *Texas A&M University, College Station, TX.*

Recent studies have shown that residue-specific covalent modifications at the N-terminal tails of histone proteins are important regulatory mechanisms for transcriptional control of gene expression. These modifications, which include acetylation, methylation, ubiquitination, and phosphorylation are a result of ordered recruitment of histone modifying enzymes to the regulatory regions. The modifications give rise to a marking system (histone code) that determines the outcomes of the gene expression. In our early studies, we found a mutually antagonistic interaction between the Ah receptor and NF-κB pathways. Specifically we found that activation of NF-κB inhibits the acetylation of the histone H4 at the regulatory region of the *cyp1a1*. Here, we report that Ah receptor/NF-κB antagonism is also at the level of histone methylation. We found that: (1) In Hepa1c1c7 cells (mouse hepatoma cells) TNF-alpha treatment led to increases of methylation of arginine 3 on histone H4 (R3-H4) which is known to be the major histone substrate for PRMT1, while treatment with TCDD inhibited the methylation of the R3-H4; (2) TCDD treatment resulted in the strong acetylation of lysine 5 on H4, while activation of NF-κB by TNF-alpha abolished the acetylation of this residue; (3) In Hepa1c1c7 cells, transient cotransfection of PRMT1 suppressed AhR-driven luciferase reporter gene expression. Taken as a whole, our results suggest that histone modification is an important aspect of the interaction between the NF-κB and the AhR pathways. INTEGRATED ANALYSIS OF GENE EXPRESSION DATA, LITERATURE, AND BIOLOGICAL PATHWAYS OF MOUSE EMPHYSEMA STUDY.

V. L. Burnett<sup>1</sup>, P. J. Monroe<sup>1</sup>, K. Lee<sup>2</sup> and J. G. Pounds<sup>3</sup>. <sup>1</sup>OmniViz, Inc., Maynard, MA, <sup>2</sup>Battelle Toxicology Northwest, Richland, WA and <sup>3</sup>Pacific Northwest National Laboratory, Richland, WA.

Gene expression data from a mouse emphysema study was used to identify genes with altered expression levels that may be associated with the tissue damage observed in lungs of mice with elastase-induced emphysema. This was made possible through integrated analysis of the expression data along with thematic analysis of the scientific literature and direct linkage to biological pathway information. Male C57BL/6 mice were treated with 37.5 U/Kg of porcine pancreatic elastase by intratracheal instillation, confirmed by pathology and lung morphometry to induce emphysema. Control and treated mice were sacrificed 1 or 4 weeks after dosing, and total RNA was used for gene expression studies. Data was imported into the OmniViz software, normalized, clustered using hierarchical methods, and analyzed for genes with altered expression. Outliers could be easily determined, and correlations among groups evaluated. Using the SAM algorithm integrated into the software, a number of genes were determined to exhibit altered expression levels for treated vs control animals. Using the gene description information, the available MEDLINE literature was retrieved and linked to the gene expression analysis in order to further characterize the genes of interest. Genes pertaining to inflammatory processes and apoptosis were found to be particularly interesting. To understand the biological pathways involved in elastase-induced emphysema, genes were then mapped to existing pathways using the OmniViz Pathway Enterprise solution, and objects colored by the expression values. By this means, changes between control and treated levels could immediately be correlated to the different pathway processes, and co-regulation events identified. In summary, by integrating the analyses of all the available data (expression, literature, and pathways) in a common framework, the genes and processes of interest can be quickly and easily identified and evaluated. (Study Sponsored by Battelle BSTI IR&D)

TRANSCRIPTIONPATH, A NOVEL METHOD THAT IDENTIFIES AND QUANTIFIES GENE TRANSCRIPTION, DETECTS CHANGES ASSOCIATED WITH TOXICOLOGY.

M. E. Warren<sup>1</sup>, V. Alexiadis<sup>1</sup>, B. Egan<sup>1</sup>, J. Cashman<sup>2</sup> and P. Labhart<sup>1</sup>. <sup>1</sup>Genpathway, Inc., San Diego, CA and <sup>2</sup>Human BioMolecular Research Institute, San Diego, CA. Sponsor: D. Schlenk.

Recent reports have shown that changes in gene activity can provide valuable information about toxicological endpoints. To date, RNA profiling has typically been the method of choice to identify differential gene expression, but these methods have limitations. A new and novel platform technology called TranscriptionPath, which is based on chromatin immunoprecipitation of DNA-transcription machinery complexes, identifies genes undergoing active transcription inside cells and quantifies their levels of transcription. Sequences are analyzed by either QueryMode, which determines the transcription level of any genomic region of interest using real-time PCR, or DiscoveryMode, which identifies transcribed sequences across the genome without the need for an a priori list. TranscriptionPath has been used successfully in multiple cell and tissue systems, utilizes DNA (which is more stable than RNA), is highly quantitative and reproducible, and is especially effective at detecting early responses to drug treatments. A toxicology feasibility experiment involving i.p. administration of  $\beta$ -Naphthoflavone (BNF) or Ciprofibrate (CPF) to mice (both at 200 mg/kg) tested several cytochrome P450 genes in the liver at early time points. TranscriptionPath results showed that BNF induced transcription of Cyp1a2 within 1 hr of exposure and the transcription level remained high through the 8 hr time point. Cyp4a10 and Cyp4a14 were induced at relatively low levels only at the 1 hr time point. After treatment with CPF, Cyp1a2 did not change in transcription, but both Cyp4a10 and Cyp4a14 were highly induced (up to 25-fold induction at 4 hr). These results agreed with published RNA levels, although the latter changes were less dramatic. Thus, TranscriptionPath is informative in measuring early gene expression changes in tissues tested for toxicology, should help identify the primary targets of drugs at the beginnings of metabolic pathways, and will reduce the time and cost required for preclinical safety assessment.

CELL BASED ASSAYS REVEAL INDIVIDUAL AND COOPERATIVE ROLES FOR THE GLI TRANSCRIPTION FACTORS IN MEDIATING THE HEDGEHOG SIGNAL.

R. J. Lipinski<sup>2,1</sup> and W. Bushman<sup>1,2</sup>. <sup>1</sup>Surgery, University of Wisconsin-Madison, Madison, WI and <sup>2</sup>Molecular and Environmental Toxicology Center, University of Wisconsin-Madison, Madison, WI.

The Gli family of transcription factors (Gli1, 2 and 3) mediate the morphogenetic signal of secreted Hedgehog (Hh) proteins by regulating the expression of Hh target genes. Aberrations in Hedgehog signaling seriously affect vertebrate develop-

ment and mutations in Gli2 and Gli3 are associated with distinct classes of developmental defects. Postnatally, inappropriate activation of Hh signaling has been associated with several types of cancers. To characterize individual and cooperative roles of the three Gli transcription factors in regulating the expression of Hh target genes, we have generated embryonic fibroblast cells from Gli mutant mice. We first examined how loss of function of one Gli gene affected expression of the Hh target genes Patched1 (Ptcl) and Hedgehog interacting protein1 (Hip1) in the presence or absence of Sonic Hedgehog (Shh) peptide. Loss of Gli1 (Gli1<sup>-/-</sup>) had no effect on target gene induction. Gli2<sup>-/-</sup> cells showed markedly reduced induction of target genes, which was further reduced with the additional loss of Gli1 (Gli1<sup>-/-</sup>Gli2<sup>-/-</sup>). Loss of Gli3 (Gli3<sup>-/-</sup>) elevated basal and Shh-induced target gene expression, whereas cells lacking both Gli3 and Gli1 (Gli1<sup>-/-</sup>Gli3<sup>-/-</sup>) exhibited increased basal but not induced target gene expression. Gli2<sup>-/-</sup>Gli3<sup>-/-</sup> cells showed higher basal target gene expression but were not capable of Shh-stimulated target gene induction. These results demonstrate that Gli2 and Gli3 modulate Shh target gene expression directly and independently. They further show that Gli2 and Gli3 modulate Gli1 expression, which coordinately contributes to target gene regulation. These observations are consistent with genetic studies of Gli gene function and provide a comprehensive and tractable system by which to examine the mechanisms underlying the complex regulation of Hh target genes.

TOXICOGENOMIC ANALYSIS OF INTESTINAL RESPONSES TO NORMAL OR IMBALANCED HUMAN MICROFLORA IN GERM-FREE MICE OR HFA MICE EXPOSED TO ANTIMICROBIALS.

S. Jeong, S. Park, H. Kang and J. Cho. *Toxicology Division, National Veterinary Research & Quarantine Service, Anyang, South Korea.*

The human intestinal microflora is a balanced ecosystem that is very important in maintaining an individual's health as salvage of energy and absorption of nutrients by metabolic activities, control of intestinal epithelial cell proliferation and differentiation, development and homeostasis of the immune system and protection against pathogens. The gastrointestinal tract represents the first barrier met by exogenous compounds of food or orally delivered drugs. Although intestinal microflora system is generally stable, therapeutic doses of antimicrobials or low levels of antimicrobials that reside in livestock products may change the balance of microflora and impact human health. We colonized germ-free mice with normal human flora and global transcriptional responses in colon crypt cells were observed with mouse DNA microarray chip. The change of gene expression in colon crypt cell of human flora associated (HFA) mice exposed orally to tetracycline (200mg/kg) and ciprofloxacin (200mg/kg) for 4 days was also investigated to understand the response of colon crypt cells by the imbalanced microflora induced by antimicrobials. As a whole, the gene expression patterns were similar between germ-free mice and antimicrobials-treated mice compared to HFA mice. 92 genes including Tegt, Rpa1, Ccnd and etc were expressed in germ-free and antimicrobials-treated mice significantly different from HFA mice. These genes were related to apoptosis, cell cycling, immune response and signal transduction. Real-time RT-PCR analysis largely confirmed these findings by the comparison study between RT-PCR and DNA microarray chip on the expression of Tegt, Casp14, Sprr2a, Il6, Eif2ak3, Mpp1, Slc26a1, Saa3, Mt1 and Ang genes in germ-free, HFA and antimicrobials-treated HFA mice. Some of these 92 significant genes could play a role in understanding the interactions between host human and microflora and in assessment of the impact of exogenous compounds on microflora and human health using HFA mice.

INDUCTION OF CYCLOOXYGENASE-2 BY CORTICOSTERONE IN CARDIOMYOCYTES.

H. Sun and Q. M. Chen. *Pharmacology, University of Arizona, Tucson, AZ.*

Mental stress is an unavoidable event in life. It increases the level of glucocorticoids (GCs) in our circulating system. However, the biological effect of elevated GCs on the heart has not been well studied. Cyclooxygenase-2 (COX-2) is a rate-limiting enzyme of prostaglandin biosynthesis and a key mediator of inflammation. In lymphocytes, GCs suppress the expression of COX-2 and the immune response. In cardiomyocytes, we found increases of COX-2 mRNA and protein following corticosterone (CT) treatment. Elevation of COX-2 mRNA or protein was first detected in 2 hrs or 4 hours, respectively, and was sustained for at least 4 days. The GC receptor antagonist, mifepristone, blocked the induction of COX-2 mRNA and protein. COX-2 promoter analysis showed transcriptional activation of the gene by CT, and further analysis revealed that the cis-elements CRE and NF-IL6 contributed to COX-2 promoter activation. CT also induced the activation of Phosphoinositol-3 Kinase (PI3K) and phosphorylation of AKT. PI3K inhibitors, LY and Wortmannin, and an AKT inhibitor prevented CT from inducing COX-2 mRNA or protein, suggesting the involvement of the PI3K/AKT signaling pathway. This pathway is known to phosphorylate and deactivate GSK3beta, resulting in decreased phosphorylation of the transcription factor CREB at Ser129 and therefore activation of

CREB. Our data showed that inhibition of GSK3beta by LiCl or SB 216763 increased COX-2 promoter activity and gene expression. Finally, we tested the functional consequence of COX-2 induction using NS398 and found that this COX-2 specific inhibitor abrogated doxorubicin-induced apoptosis. Therefore CT induces COX-2 expression via a PI3K mediated CREB pathway. However, COX-2 induction may be detrimental to cardiomyocytes.

### DEVELOPING AN *IN VITRO* GENE EXPRESSION ASSAY FOR PREDICTING HEPATOTOXICITY.

S. Abel, Y. Yang and J. Waring. *Toxicogenomics, Abbott Laboratories, Abbott Park, IL.*  
A crucial step in the development of new pharmaceutical compounds is assessing the potential for toxicity. Hepatotoxicity is of primary concern because the liver is the principle organ involved with drug metabolism. Most toxicology studies are conducted in 1 or 2 week animal studies, requiring a significant quantity of time and drug. An assay that, requires a minimal amount of compound, can identify potential toxic liabilities, and be used in the earlier stage of drug discovery, would be of great benefit. Microarray technology is a potential tool that can be used for this type of analysis. The purpose of this study was to evaluate if gene expression profiles from rat hepatocytes could be predictive of the toxic mechanism and classification of known hepatotoxins based on animal studies. To begin this study, *in-vitro* conditions were evaluated using quantitative PCR for albumin and select cytochrome p450 gene expression. Treatment time points were then determined using full microarray gene expression. Finally, hepatocytes were treated with three classes of compounds: AhR Ligands, Peroxisome Proliferators, and non-hepatotoxins. Gene expression profiles were measured for each class of compound. Results show that 1) the conditions used to grow cells in culture are important in maintaining consistent gene expression in naïve hepatocytes, 2) duration of treatment affects gene expression, and 3) using *in vitro* conditions, compounds with distinct mechanisms of toxicity yield similar expression profiles.

A kinase inhibitor (compound X) in development for the treatment of asthma/rheumatoid arthritis, was terminated due to hepatic and renal toxicity in rats. The objective of the present study was to elucidate the mechanism(s) of toxicity using biochemical and molecular approaches and to develop a back-up selection strategy. Male rats were treated with compound X (0, 10, or 200 mg/kg/day; 1 or 14 days). Kidney and liver samples were collected for histopathology, toxicogenomics and -proteomics. Urine samples were collected for metabolomic analysis. Mechanism-based inactivation of CYP450 was assessed both *in vitro* and *in vivo*. Compound-related histopathology findings consisted of renal tubular dilatation/degeneration and hepatocellular hypertrophy. Toxicogenomics and -proteomics identified significant alterations of genes and proteins involved in xenobiotic metabolism, lipid and protein metabolism, and redox balance. Metabolomics identified methylguanidine, a product of creatinine formed via oxidation by reactive oxygen species, in the urine of rats treated with compound X. The results from these studies are consistent with free radical generation and oxidative stress as primary mechanisms of renal and hepatic toxicity for compound X. In addition, mechanism-based inhibition of CYP 3A was detected both *in vivo* and *in vitro*. The reactive moiety on compound X was identified via glutathione conjugates using LC/MS/MS in incubations with human liver microsomes. These findings correlated with cytotoxicity of a series of compounds in rat primary hepatocytes. In conclusion, the emerging technologies were successfully combined with biochemical approaches to elucidate the mechanism of toxicity induced by compound X. Results obtained from such an integrated approach helped to identify a compound from a new lead series that progressed as an early development candidate.

### CHARACTERIZATION OF FUNCTIONAL VARIATION IN HUMAN GSTM3 IN GLIOMA CELLS USING RNAI.

X. Liu, M. R. Campbell, G. S. Pittman and D. A. Bell. *Molecular genetics, NIEHS, Research Triangle Park, NC.*

Glutathione S-transferase M3 (GSTM3) is expressed in testis, lung, lymphocytes, brain, and in many tumor types. While GSTM3 can metabolize a number of xenobiotic chemicals, relatively little is known about the endogenous role of this, the an-

cestral, GSTmu gene. Some reports suggest that GSTM3 expression level may be associated with bronchogenic carcinoma and that GSTM3 protein may have prostaglandin E2 synthase (PGES) activity in human brain. We have observed that GSTM3 expression varies widely among individuals in both normal and tumor samples, and have characterized a common promoter polymorphism (A-63C, rs1332018) in humans that dramatically reduces GSTM3 expression (at least 9-fold). To explore the biological impact of phenotypic variation in GSTM3 on growth and metabolism, we created a congenic cell line system by stably transfecting constructs containing GSTM3 cDNA or a knock-down RNAi vector into glioma cell lines. These cell lines express highly different levels of GSTM3 and this was verified by Taqman and western blot analysis. To measure impact on growth we have compared growth curves and proliferation rates (measured by MTT assay) in these lines and observe that over-expression of GSTM3 was associated with higher rates of cell proliferation while lack of GSTM3 expression, and RNAi knockdown of expression, inhibited cell growth. Evaluation of impact on PGE synthesis and growth factor pathways are in progress. RNA from these cell lines was applied to Agilent human 1Av2 microarrays in order to identify candidate genes whose expression levels varied across the cell lines in parallel or contrary to GSTM3 overexpression and downregulation ( $p < 0.001$ ). We used real-time PCR to confirm differential expression of four candidate genes from the microarray analysis. These candidate genes are in cell cycle and growth factor pathways and play roles in growth stimulation, cell cycle arrest, tumor suppression, and inhibition of metastasis. Current effort focuses on determining if GSTM3 expression mediates growth through perturbation of candidate gene expression.

## 116

### DIFFERENTIAL GENE EXPRESSION IN F344 RATS FOLLOWING EXPOSURE TO EITHER POLYBROMINATED DIPHENYL ETHERS (PBDES) OR PCBs.

J. M. Sanders<sup>1,2</sup>, L. T. Burka<sup>1</sup> and M. L. Cunningham<sup>1</sup>. <sup>1</sup>*Laboratory of Pharmacology and Chemistry, NIEHS, Research Triangle Park, NC and <sup>2</sup>Department of Toxicology, NC State University, Raleigh, NC.*

PBDEs, widely used as flame retardants, are found as environmental contaminants and are present in mammalian tissues. 2, 2', 4, 4'-Tetrabromodiphenyl ether (BDE-47) and 2, 2', 4, 4', 5-pentabromodiphenyl ether (BDE-99), two major PBDEs in the environment, are components of the commercial mixture Great Lakes DE-71® (DE-71), used mostly in polyurethane foam. PBDEs are structurally similar to dioxins and PCBs, and may share mechanisms of toxicity with those chemicals. The goal of the present work was to determine if the DE-71 mixture and congener components influence expression of genes regulated through biological pathways affected by either coplanar or non-coplanar PCBs. Male F344 rats were dosed daily for three days by gavage, with up to 100  $\mu$ mol/kg of BDE-47 or -99, up to 150 mg/kg DE-71 (containing 100  $\mu$ mol/kg of BDE-47), 0.01  $\mu$ mol/kg of coplanar PCB126, or 10  $\mu$ mol/kg of non-coplanar PCB153. Rats were sacrificed 24 hr following the last dose, RNA was isolated from liver, converted to cDNA, and analyzed by real-time PCR for differential gene expression. Target genes were for isozymes of the CYP1A, 2B and 3A families. BDE-47, -99, and PCB153 had little or no effect on Cyp1a1 gene regulation. In contrast, PCB126 and 150 mg/kg of DE-71 increased Cyp1a1 mRNA ca. 2000-fold over controls. DE-71 at 15 mg/kg gave an approximate 80-fold increase. PCB153, but not PCB126, up-regulated both Cyp2b and 3a genes. These genes were also up-regulated by BDE-47, and -99 at doses of 100  $\mu$ mol/kg and by DE-71 at an equivalent dose. Results indicate that DE-71 may be a mixed-type inducer in rat. Up-regulation of Cyp1a1 gene expression by DE-71 appears to be due to components other than BDE-47 and -99. Differential gene regulation by PBDEs is demonstrated here in the rat at much higher doses than estimated for human exposure (ng range/person/day). Ongoing work will characterize differential gene expression in rodents exposed to more relevant lower doses of DE-71 and its congener components.

## 117

### EXTRACTION OF GENES WITH STABLE EXPRESSION IN RAT LIVER TREATED WITH VARIOUS COMPOUNDS - ANALYSIS OF THE DATA IN THE TOXICOGENOMICS PROJECT IN JAPAN -.

H. UEDA, T. KASAHARA, H. TOTSUKA, T. MIYAGISHIMA, T. URUSHIDANI and T. NAGAO. *Toxicogenomics Project, National Institute of Health Science, Setagayaku, Tokyo, Japan.* Sponsor: T. INOUE.

National Institute of Health Sciences and 17 pharmaceutical companies have started a five-year project, the Toxicogenomics Project in Japan (TGPJ) in 2002. The objective of TGPJ is to construct a large-scale database of over 150 drugs on rats and develop a system which will forecast the toxicity of new chemical in the early stage of drug development. In TGPJ, we are constructing a comprehensive gene expression database of rat liver and kidney (*in vivo*), rat primary cultured hepatocytes and human primary cultured hepatocytes (*in vitro*) treated with over 150

chemicals using Affymetrix GeneChip. In order to establish a useful forecasting system, quality of the data stored in the database should be as high as possible. As one of the ways to assure the quality of the data, we check the microarray data by Real Time PCR of internal controls of which expression is stable throughout the experiments. We evaluated all the gene expression data from male SD rats treated with 42 chemicals stored in the present database (3, 6, 9, 24 hours after single dose with three dose levels and 3, 7, 14, 28 days of repeated daily dose with three dose levels, using Affymetrix rat RAE 230A chip). We have extracted 12 stable genes including peroxisomal 2-enoyl-CoA reductase, integral membrane protein Timp21-1 (p23), etc., based on their expression level and variation. We also evaluated so-called "housekeeping genes", such as beta-actin, GAPDH, etc., which are commonly used as internal control genes for Real Time PCR, or other genes reported to be showing invariant expression. Among the 42 chemicals, 15 were selected as representatives of typical pharmacological action and gene expression profile. Expression of all these genes was confirmed by Real Time PCR in the samples from the control and the high dose group received repeated administration for 28 days. It was concluded that our new set of genes is superior to other genes in terms of the stability of their expression at least in our database.

118

CHARACTERIZATION OF AN ACUTE MOLECULAR MARKER OF NON-GENOTOXIC HEPATOCARCINOGENESIS IN RODENTS BY GENE EXPRESSION PROFILING IN A LONG-TERM CLOFIBRIC ACID STUDY.

C. Michel<sup>1</sup>, C. Desdouets<sup>2</sup>, R. A. Roberts<sup>1,3</sup>, K. R. Isaacs<sup>4</sup> and E. Boitier<sup>1</sup>.  
<sup>1</sup>Drug Safety Evaluation, Sanofi Aventis, Vitry-sur-Seine, France, <sup>2</sup>INSERM U370, Paris, France, <sup>3</sup>Safety Assessment, AstraZeneca, Cheshire, United Kingdom and <sup>4</sup>CITP, Harrogate, United Kingdom.

The evaluation of non-genotoxic potential, early during the development of drugs, is one of the current challenges in toxicology. In a short-term *in vivo* toxicity study, the NAD(P)H cytochrome P450 oxidoreductase (CYP-R) and the transforming growth factor- $\beta$  stimulated clone 22 (TSC-22) were identified as potential candidates as molecular markers of rodent hepatic chemical carcinogenesis (1). We investigated their modulation during a long-term non-genotoxic study in the rat, to evaluate their potential as acute markers of carcinogenesis. Clofibric acid (CLO), which belongs to the broad class of chemicals known as peroxisome proliferators was chosen as the non-genotoxic hepatocarcinogen. Male F344 rats were given a single non-necrogenic, but initiating dose of diethylnitrosamine (0 or 30 mg/kg) coupled with a diet containing none or 5000ppm CLO for up to 18 months. Necropsies of 5 rats per groups were performed at 18, 46, 102, 264, 377, 447 (for the Control, DEN and DEN+CLO rats), 524, and 608 days (for the CLO and Control rats). Gene expression modulation measured using Affymetrix microarrays did not confirm CYP-R gene expression alteration. TSC-22 gene expression, however, was found to be strongly down-regulated in peritumoral and tumoral liver tissue (validated by RT-PCR), already at the early stages of the carcinogenic process. In addition, we showed under-expression of TSC-22 was maintained throughout this long-term study, but disappeared after CLO withdrawal. TSC-22 has been previously linked to induction of apoptosis and its down-regulation upon CLO dosing could result in suppression of the apoptosis pathway. Taken together, our results showed that TSC-22, but not CYP-R, could be a potential acute early molecular marker for non-genotoxic hepatocarcinogens in rodents. PROFILES OF GLOBAL GENE EXPRESSION IN IONIZING RADIATION-DAMAGED HUMAN DIPLOID FIBROBLASTS REVEAL SYNCHRONIZATION BEHIND THE G1 CHECKPOINT.

T. Zhou<sup>1</sup>, J. W. Chou<sup>2</sup>, D. A. Simpson<sup>1</sup>, Y. Zhou<sup>1</sup>, T. E. Mullen<sup>1</sup>, M. Medeiros<sup>1</sup>, P. R. Bushel<sup>2</sup>, R. S. Paules<sup>2</sup>, X. Yang<sup>1</sup>, P. Hurban<sup>3</sup>, E. K. Lobenhofer<sup>1</sup> and W. K. Kaufmann<sup>1</sup>. <sup>1</sup>Pathology & Lab. Medicine, University of North Carolina, Chapel Hill, NC, <sup>2</sup>National Institute of Environmental Health Science, Research Triangle Park, NC and <sup>3</sup>Paradigm Genetics, Research Triangle Park, NC.

Cell cycle checkpoint function and transcriptional responses to ionizing radiation (IR)-induced DNA damage were quantified in human diploid fibroblasts. Assays of clonal expansion determined 1.5 Gy IR as the D0 dose in three telomerase fibroblast lines. Fibroblasts exhibited >90% arrest of progression from G2 to M at 2 h post-IR and from G1 to S 6-12 h after 1.5 Gy. Normal rates of DNA synthesis and mitosis 6-12 h after irradiation caused the S and M compartments to empty by over 70% at 24 h. Microarray technology monitored global gene expression in IR-treated cells and a new microarray analysis algorithm, EPIG, identified nine IR-responding gene expression patterns including a dominant p53-dependent G1 checkpoint response. Many p53 target genes, like CDKN1A, GADD45, BTG2 and PLK3, were significantly up-regulated at 2 h post-IR while numerous genes whose

expression is regulated by E2F family transcription factors were significantly down-regulated at 24 h post-IR, including CDK2, CCNE1, CDC6, CDC2, MCM2 and many other cell cycle regulators. Numerous genes that participate in DNA metabolism were also markedly repressed in checkpoint-arrested fibroblasts as a result of cell synchronization behind the G1 checkpoint. However, cluster and principal component analyses of gene expression revealed a profile of gene expression 24 h after IR with greatest similarity to that of G0 growth quiescence. These results demonstrate a highly stereotypic pattern of response to IR that reflects primarily synchronization behind the G1 checkpoint but with prominent induction of additional markers of G0 quiescence such as GAS1.

120

EXPRESSION OF THE HELIX-LOOP-HELIX INHIBITOR OF DNA BINDING-1 (ID-1) GENE IS REGULATED BY RETINOIC ACID IN NORMAL HUMAN KERATINOCYTES.

L. A. White and C. M. Villano. *Biochemistry and Microbiology*, Rutgers University, New Brunswick, NJ.

The Id proteins (Inhibitor of DNA Binding) are a class of helix-loop-helix (HLH) proteins that lack a DNA binding domain and function by forming inactive heterodimers with other HLH proteins. Ectopic overexpression of Id-1 results in immortalization or delayed senescence of normal human keratinocytes (NHKs), demonstrating that Id-1 is an important regulator of keratinocyte differentiation. Retinoids, vitamin A analogues, are powerful regulators of cell growth and differentiation and is necessary for the maintenance of epithelial differentiation. We have found that exposure of NHKs to all-trans retinoic (atRA) acid results in a significant increase in Id-1 mRNA and protein. Our hypothesis is that atRA-induced expression of Id-1 is a critical step in retinoic acid mediated effects in NHKs. Our data show that atRA stimulation of Id-1 is specific; no change was observed in Id-2 and -3 expression following atRA exposure. Retinoic acid stimulation of Id-1 does not involve mRNA stability, suggesting that it is regulated at the level of transcription. To investigate this possibility, we isolated 2.2 kb of the Id-1 promoter and linked it to a reporter gene (luciferase; pGL3) for transfection into NHKs, and our data demonstrate that atRA-induced Id-1 expression is mediated through sequences in the 2.2 kb 5' of the gene. Data from other laboratories suggest that the bone morphogenic proteins (BMPs) are involved in activation of Id-1 expression in other cell types. Furthermore, atRA exposure of chondrocytes results in increased expression of BMP-2 and -4. The goal of these experiments are to determine the mechanism of atRA-induced Id-1 expression, focusing on the role of the BMP proteins. Furthermore, these data will also elucidate the role of Id-1 in mediating atRA effects on skin differentiation. This will provide a better understanding of the mechanism of action of retinoic acid in skin, as well as to define the role of Id-1 in this pathway.

121

APPLICATION OF A CROSS-PLATFORM RNA STANDARD FOR ASSESSING MICROARRAY DATA COMPARABILITY.

Microarray data comparability remains a challenge for the integrated use of genomic data generated across sites and platform formats. Tools needed to address this issue include an RNA standard that performs similarly on multiple microarray formats and serves a function analogous to a standard reference material in single analyte assays. We have designed and tested a reagent that can provide a basis for performance assessments on Affymetrix RAE230A, CodeLink UniSet Rat I, and Agilent G4130A rat oligonucleotide arrays. The reagent is a set of two mixed tissue RNA samples formulated to contain different ratios of RNA for each of four rat tissues (brain, liver, kidney, and testis). The analytes in this assay bind to a subset of gene probes that were matched across platforms to the same UniGene cluster or GenBank accession number, were determined to be tissue-selective on each of the 3 platforms using average baseline expression levels in single tissue samples from control animals, and have signal intensities that span the dynamic range of each platform. This reagent forms the basis of a ratiometric assay in a complex biological background that can be used to objectively assess the effect of different array processing methods and conditions on microarray data comparability within and across platforms, and could be a paradigm for similar performance standards for mouse and human arrays.

## GENE EXPRESSION MODIFICATIONS IN A MOUSE EMPHYSEMA MODEL INDUCED BY ELASTASE.

**Q. Meng<sup>1</sup>, K. M. Waters<sup>2</sup>, J. M. Malard<sup>2</sup>, K. Lee<sup>1</sup> and J. G. Pounds<sup>2</sup>.** <sup>1</sup>Battelle Toxicology Northwest, Richland, WA and <sup>2</sup>Pacific Northwest National Laboratories, Richland, WA.

The purpose of this study was to characterize gene expression changes in the lung associated with elastase-induced emphysema in mice. Male C57BL/6 mice were administered porcine pancreatic elastase (0 or 37.5 U/Kg BW) by intra-tracheal instillation. Groups of control or treated mice (n = 6) were sacrificed at 1 or 4 weeks after dosing. Anatomical pathology and lung morphometry were used to confirm the induction of emphysema. Left lung lobes were snap frozen and total RNA was used for Cy3/Cy5 fluorescently labeled cRNA target amplification using Agilent's Low RNA Input Kit. The data were normalized with loess curve fit in Bioconductor and using an Aquantile method for between array variability. The normalized data were then examined to identify genes associated with tissue damage observed in elastase-instilled lung. Several genes associated with inflammatory diseases, such as Sjogren's syndrome antigen B and uteroglobin, were up-regulated at week 1 and remained up-regulated through week 4. Other genes, such as E-selectin and Dyrk1b, were up-regulated at week 1 but returned to normal by week 4. E-selectin initiates leukocyte recruitment and adhesion to lung endothelial cells, and Dyrk1B overexpression in lung epithelia destabilizes cyclin D1 to block cells in G0/G1. Zic2 expression was down-regulated at week 1 but returned to normal by week 4. Zic2 is a transcription factor repressor of D1A dopamine receptors, whose stimulation increases lung edema clearance by regulating Na<sup>+</sup> K-ATPase function in the alveolar epithelium. Calpastatin, an intracellular inhibitor of calpain, was down-regulated at week 1 and week 4. Activation of calpain triggers the cleavage of Bcl-2 proteins and induces the intrinsic apoptotic pathway in lung carcinoma cells. Further analysis of this data set, including future integration with proteomics and metabolomics data from the same study, will lead to a better understanding of pathogenesis of the elastase-induced emphysema model in mice. (Sponsored by Battelle BSTI IR&D)

## TUMOR SUBTYPE CHEMOTHERAPEUTIC RESPONSES IN THE BREAST.

**K. Hoadley<sup>1</sup>, M. A. Troester<sup>2</sup> and C. M. Perou<sup>1, 2, 3</sup>.** <sup>1</sup>Curriculum in Genetics and Molecular Biology, University of North Carolina, Chapel Hill, NC, <sup>2</sup>Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC and <sup>3</sup>Department of Genetics, University of North Carolina, Chapel Hill, NC. Sponsor: J. Swenberg.

Microarray studies have identified distinct and clinically relevant subtypes of breast tumors that arise from different cell types in the breast. To characterize the differences in response to therapy between two of these breast subtypes, we treated basal-like epithelium derived cell lines and luminal epithelium derived cell lines with doxorubicin (DOX) and 5-fluorouracil (5FU) and assayed for gene expression responses by DNA microarrays. Using Significance Analysis of Microarrays, we determined that the dominant gene expression response was a general stress response, common to both treatments yet specific to each cell type. A cluster of genes involved in DNA damage response was upregulated in both subtypes; however, they were more significantly induced in the luminal subtype. Similar analyses were conducted on breast tumors sampled before and after neoadjuvant chemotherapy with either DOX or 5FU/mitomycin C. We determined that the dominant *in vivo* response was again a general stress response and found a small set of induced genes. However, when we split the basal-like and luminal subtype tumors and did separate analyses, we saw independent lists with little overlap. We next compared the *in vitro* and *in vivo* data and identified a shared response within each subtype but with little similarity between subtypes. These studies illustrate that the cell type of origin plays a major role in response to treatment and further suggest that subtype specific therapies are needed.

## USE OF GENE EXPRESSION CHANGES IN CIRCULATING BLOOD CELLS TO MONITOR XENOESTROGEN EXPOSURE IN NEONATAL MICE.

**F. Lim, K. Antrobus, D. J. Moore, H. Tinwell, I. Kimber, J. Ashby, G. Orphanides and J. Moggs.** Syngenta CTL, Macclesfield, Cheshire, United Kingdom.

Many molecular alterations in blood cells and serum have been associated with toxicant-induced tissue damage, inflammation and repair. The analysis of molecular biomarkers in circulating blood is emerging as a powerful approach for monitoring toxicant exposure. We have used transcript profiling of circulating blood cells to investigate the utility of gene expression biomarkers for monitoring xenoestrogen exposure in a rodent model experimental system. Neonatal mice were given five daily subcutaneous doses (Post Natal Day (PND) 1-5) of an estrogenic chemical carcinogen

(diethylstilbestrol; DES) at a dose that induces increased uterine weight and that has previously been established to result in a high incidence of uterine tumours after 18 months, or vehicle control (arachis oil). Blood samples were obtained from treated mice by cardiac puncture at PND17, 30 and 50, and RNA was isolated using the PAXgene blood RNA System. Uterine weight, transcript profiling and histological data were collected in order to provide a reference bioassay for xenoestrogen exposure. Gene expression profiles of circulating blood cell RNA, measured using Affymetrix Genechip mouse genome 430 2.0 microarrays, reveal that DES treatment induced more than 100 gene expression changes at PND17. A large proportion of these changes showed a dose-dependent response to DES. RT-PCR analysis is currently being used to examine the temporal expression patterns and the inter-animal variability of these DES-responsive genes. We conclude that analysis of gene expression changes in circulating blood cells can be used to monitor exposure to xenoestrogens in our animal model. Moreover, our data suggest that the measurement of gene expression changes in circulating blood cells may lead to the identification of novel biomarkers for toxicant exposure.

## COMPARISON OF WHOLE BLOOD GENE EXPRESSION PROFILES FROM THREE NON-HUMAN PRIMATE SPECIES AND HUMANS.

**C. S. Phillips and J. F. Dillman.** Applied Pharmacology, USAMRICD, Aberdeen Proving Ground, MD. Sponsor: A. Sciuто.

Non-human primates (NHP) are often used to evaluate the potential safety and efficacy of medical countermeasures against chemical exposure. This is because rodents frequently do not respond to chemical insult as humans do, and because human clinical trials cannot be performed to determine efficacy of potential countermeasures. Three species of NHP have been used in the development of chemical warfare agent (CWA) medical countermeasures: *Macaca mulatta* (rhesus macaque), *Macaca fascicularis* (cynomolgus macaque) and *Cercopithecus aethiops* (African green monkey). We utilized a gene expression profiling approach to identify potential genomic biomarkers that may be used to develop methods for extrapolating safety and efficacy data obtained in NHP to humans. Whole blood was obtained from each species of primate. RNA isolated from whole blood was used to generate oligonucleotide microarray probes. A comparable number of genes were detected in each species after hybridization to human gene chips (Affymetrix Human U133 Plus 2.0 arrays). Principal component analysis of these gene expression profiles revealed that each NHP species partitioned away from the human samples in a similar manner. A Boolean analysis of the expression profiles revealed that 1, 079 genes were detected in all species and in all biological replicates within each species. These genes are distributed among 154 molecular functions and 156 biological processes. This set of genes provides the foundation for identifying potential biomarkers for use in determining safety and efficacy of CWA medical countermeasures and for developing methods to extrapolate results obtained in NHP to humans.

## THE BIOLOGY OF DRUG SIGNATURES.

**C. Pearson, R. Brennan, M. Fielden, B. Ganter, W. Hu, S. Tugendreich, A. Vladimirova and K. Kolaja.** Iconix Pharmaceuticals, Inc., Mountain View, CA.

We have developed a large library of Drug Signatures<sup>TM</sup>, biomarkers for toxicologic, pathologic, and pharmacologic mechanisms of action, to improve compound selection during drug discovery. These biomarkers are derived from a database integrating ~15, 000 gene expression microarray results from rats treated with >600 compounds with traditional measurements of toxicity, pathology, and pharmacology. Currently in our database we have over 350 unique signatures, 180 derived from liver data alone. As an example of the utility of signatures, two glucocorticoid compounds, fluocinolone acetonide and fludrocortisone acetate, which have known cardio-, immuno- and hepatotoxicities, were tested in rats at their respective maximum tolerated doses in 5-day studies. While hierarchical clustering of gene expression data from the liver revealed that both compounds were similar to other glucocorticoid agonists in the database, no information on toxicity was gleaned from this analysis. Both compounds, however, matched signatures that correlated with both their pharmacological mechanism of action and known toxicities. These signatures include, among others, the Glucocorticoid-Mineralocorticoid Receptor Agonist, ALT Increase, and Lymphocyte Decrease signatures. Fludrocortisone's lower scores on pathology signatures relative to fluocinolone's correlated directly with the lesser degree of toxicity induced by fludrocortisone relative to that induced by fluocinolone. Genes in the signatures that these compounds match provide useful information on the biology behind the pharmacology and toxicity of these compounds. In particular, genes in the Lymphocyte Decrease signature were primarily those that are highly expressed in lymphocytes. This observation indicates that toxicities in other organs can be readily detectable in the liver. The advantage of a large

database of signatures is that compounds can be characterized pharmacologically and toxicologically within minutes by scoring gene expression data against all of our signatures, hastening decision making during drug discovery.

127

#### GENE EXPRESSION ANALYSIS OFFERS UNIQUE ADVANTAGES TO HISTOPATHOLOGY IN PREDICTION OF OVERALL LIVER CONDITION.

A. N. Heinloth<sup>1</sup>, G. A. Boorman<sup>2</sup> and R. S. Paules<sup>1</sup>. <sup>1</sup>*NCT, NIEHS, Research Triangle Park, NC* and <sup>2</sup>*ETP, NIEHS, Research Triangle Park, NC*.

Histopathological analysis of liver biopsy samples has poor predictive value for Acetaminophen intoxication. One reason might lie in the great differences in the degree of liver damage observed in different regions of the liver. This study examines whether gene expression analysis provides a more representative picture of the overall condition of the liver or if it is closely linked to the liver phenotype at the origin of the mRNA sample. Rats were treated with a single dose of APAP (1500 mg/kg) and sacrificed 24 hours after exposure. Left, median and right anterior liver lobes were harvested for RNA extraction and histopathological analysis. Livers of sham-treated control animals were also collected and examined. Histopathological evaluation revealed major differences in the degree of necrosis observed in the three liver lobes. The most severe damage was observed in the right anterior liver lobe, followed by the median lobe, while the left liver lobe showed the least amount of necrosis. Gene expression analysis was performed comparing mRNA abundance in the three different liver lobes of individual treated animals with lobe specific pooled controls. Surprisingly, gene expression patterns of all three lobes were in strong agreement and elucidated alterations in the same biological processes, independent of the phenotypic appearance of the examined liver lobe. We concluded from our study, that in case of clear toxicity induced by acetaminophen, each liver sample provides similar gene expression information, independent of location and phenotype of the tissue. This has major implications for the clinical setting. Histopathology performed on human liver biopsy samples often has very poor predictive power, mainly due to marked regional differences in the degree of liver damage. In these cases, a small sample is not necessarily representative of the whole organ after intoxication with APAP. Our results suggest that genomic analysis of the same sample might have the potential to give a more precise indication of hepatotoxicity and overall prognosis for the patient.

128

#### CHANGES IN GENE EXPRESSION INDUCED BY TECHNICAL CHLORDANE, CIS-NONACHLOR, TRANS-NONACHLOR AND OXYCHLORDANE IN RAT LIVERS MONITORED BY OLIGONUCLEOTIDE MICRO-ARRAYS. CURRAN, I.H.A., HIERLIHY, A., AND BONDY, G., TOXICOLOGY RESEARCH DIVISION, FOOD DIRECTORATE, HPFB, HEALTH CANADA, OTTAWA, ONTARIO, CANADA.

I. Curran, A. Hierlihy and G. Bondy. *Toxicology Research Division, Food Directorate, Health Canada, Ottawa, ON, Canada*. Sponsor: G. Bondy.

Technical chlordane is a mixture of structurally related chlorinated compounds which have been utilized as a pesticide from the late 1940's until the late 1980's. The pesticide is stable in the environment and has been shown to induce hepatocellular carcinomas in male and female mice. This study examines the effects of chlordane, the major components cis-nonachlor and trans-nonachlor and the metabolite oxychlordane on gene expression in rat livers using micro-arrays and RT-PCR. In this study, female and male Sprague-Dawley rats were administered chlordane, cis-nonachlor, trans-nonachlor, oxychlordane or corn oil vehicle control by gavage for 28 days at a dose of 2.5mg/kg body weight. Livers were then extracted for total RNA and transcript profiles were compared between treatment and control groups using oligonucleotide micro-arrays (1152 genes). Semi-quantitative RT-PCR was performed on micro-array identified genes using individual male and female liver samples to verify results. Micro-array analysis in female rat livers found the following number of genes were up or down regulated two-fold in three trials for the following treatments: Chlordane, 3 genes; cis-nonachlor, 8 genes; trans-nonachlor, 15 genes; and oxychlordane, 31 genes. Classification of the genes identified gene products primarily involved in xenobiotic metabolism and ion/solute transport. Two of the metabolism genes affected were CYP2b19 and CYP3A, as expected from compounds classified as phenobarbital-type inducers. Verification of changes in gene expression via RT-PCR found the genes SDCT-1, gamma-ATPase, PEPT2 and TWIK were up-regulated in oxychlordane treated female rat livers and down-regulated in oxychlordane treated male rat livers. These compounds alter gene expression of solute/ion transporters, membrane channels and other membrane proteins and have sex related effects in rat models.

#### EFFECT OF REPRODUCTIVE TOXICANTS ON GENE EXPRESSION IN THE RAT TESTES.

T. Fukushima<sup>1,2</sup>, T. Yamamoto<sup>1</sup>, R. Kikkawa<sup>1</sup>, Y. Hamada<sup>1</sup>, I. Horii<sup>1</sup> and C. Mori<sup>2</sup>. <sup>1</sup>*Worldwide Safety Sciences, Pfizer Global and Research Nagoya Laboratories, Taketoyo, Aichi, Japan* and <sup>2</sup>*Bioenvironmental Medicine, Chiba University, Chiba, Chiba, Japan*. Sponsor: M. Kurata.

During research and development of drugs, several compounds were failure due to testicular toxicity. Therefore, biomarkers of testicular toxicity that can be used in early phase of drug development are needed. In the present study, 4 reproductive toxicants, 2, 5-hexanedione (2, 5-HD), ethylene glycol monomethyl ether (EGME), cyclophosphamide (CP) and sulfasalazine (SASP), were administered to male rats for one day and gene expression in the testes 6 hours post dosing was monitored by cDNA microarray and the testes were histopathologically examined. No histopathologically abnormal findings were detected in the 2, 5-HD, CP and SASP. EGME produced slight degeneration of spermatocytes as a primary change. cDNA microarray analysis revealed that the number of affected Sertoli cells-related genes was the highest in the 2, 5-HD group. Many germ cells-related genes and a few Sertoli or Leydig cells-related genes were altered in the EGME group. In the CP group, many spermatogenesis-related genes were affected and additionally, the number of changes in the expression of DNA repair-related genes was the highest among the treatment groups. SASP also affected spermatogenesis-related genes but the number of the affected genes was the lowest among the treatment groups. These showed that there were compound related features in the affected genes and it is considered that there are different toxicological pathways in each compound. Interestingly, however, it was found that the same 3 genes were affected by the all tested compounds. They were heat shock protein 70-2, insulin growth factor binding protein 3 and glutathione S transferase pi genes. The changes in genes expression were detected prior to histopathological changes or at the time primary pathological changes were found. Therefore, the 3 genes were considered as useful biomarkers for evaluating the testicular toxicity that has different mechanism and for applying to evaluate toxicity in early development of the drug.

#### GENE EXPRESSION CHANGES IN FETAL THYMUS EXPOSED TO ORGANIC COMPOUNDS EXTRACTED FROM DIESEL EXHAUST PARTICLES.

T. Ito<sup>1</sup>, H. Nagai<sup>1,2</sup>, T. Lin<sup>3</sup>, R. E. Peterson<sup>3</sup>, C. Tohyama<sup>1</sup>, T. Kobayashi<sup>1</sup> and K. Nohara<sup>1</sup>. <sup>1</sup>*National Institute for Environmental Studies, Tsukuba, Japan*, <sup>2</sup>*Science University of Tokyo, Noda, Japan* and <sup>3</sup>*University of Wisconsin, Madison, WI*.

Diesel exhaust particles (DEP) consist of a variety of toxic compounds, including polycyclic aromatic hydrocarbons (PAHs) and their derivatives (e.g., dioxins and quinones), on a carbon core. Although this feature seems to cause toxicity via multiple pathways, the mechanism of action of DEP has not been fully elucidated. In this study we investigated how DEP affect thymocyte cellularity via changes in gene expression in fetal thymus organ culture. Fetal thymuses excised from C57BL/6 mice were exposed to DEP extracts (DEPe) for 24 hr, and changes in gene expression were analyzed with an Affymetrix GeneChip. DEPe up-regulated 8 genes, and the most highly up-regulated gene was CYP1A1, which is well known as an arylhydrocarbon receptor (AhR) target gene. Other known AhR target genes (CYP1B1, Tiparp, and adseverin) were also up-regulated. Next, we compared changes in gene expression in response to AhR ligands and DEPe. Of the 8 genes up-regulated by DEPe, 6 genes were up-regulated by 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), and 7 were up-regulated by benzo[a]pyrene (B[a]P). These results suggests that AhR activation is the main pathway in the regulation of gene expression by DEPe. We also tested the possibility of involvement of reactive oxygen species from quinones in gene regulation. 1, 2-Naphthoquinone (NQ) up-regulated AhR target genes and other genes, whereas 9, 10-phenanthraquinone (PQ) exhibited some similarities to DEPe in gene expression profile. However, we did not identify any genes regulated by quinones among the genes changed by DEPe. Examination of effects on thymocyte cellularity revealed that DEPe decreased the numbers of thymocytes and skewed differentiation toward CD8 T cells. The same effects were observed when exposed to TCDD, B[a]P, or NQ, but not to PQ. Our results suggested that organic compounds adsorbed on to DEP regulate gene expression and then affect thymocyte development mainly through AhR activation.

131

#### MOLECULAR CLONING AND CHARACTERIZATION OF HUMAN CYT19, AN S-ADENOSYL-L-METHIONINE:AS-METHYLTRANSFERASE FROM HEPG2 CELLS.

A. McNally and D. Barber. *University of Florida, Gainesville, FL*.

Chronic arsenic exposure poses a threat to millions of people throughout the world due to arsenic in drinking water. Methylation has been considered the primary detoxification pathway of inorganic arsenic in many species but there is evidence that

methylation may increase arsenic toxicity. It has been shown that methylated arsenicals that contain AsIII are more cytotoxic and genotoxic than either arsenate or arsenite. Rat liver S-adenosyl-L-methionine: arsenicIII-methyltransferase has been identified and is homologous to human Cyt19, but there are species specific differences in arsenic biotransformation and toxicity. Additionally, there is considerable variation among humans in the rate of methylation of inorganic arsenic leading to measurable differences in toxicity. Therefore, it is important to better understand the enzymes that catalyze the methylation of arsenic in humans. In this study, we PCR amplified and cloned cyt19, a putative arsenic methyltransferase from human HepG2 hepatoma cells. The PCR product was ligated into an *E. coli* pET expression vector with a polyhistidine tag at the amino-terminal residue. The recombinant human cyt19 was successfully expressed in BL21 (DE3) and purified using a nickel-nitrilotriacetic acid metal-affinity chromatography. The recombinant protein catalyzes the methylation of arsenite as well as monomethylarsonic acid (MMA). The specific activity of arsenite methylation was 28 pmol/mg protein/min in a reaction mixture containing 5mM GSH, 1 mM DTT, 1 mM MgCl<sub>2</sub>, 100  $\mu$ M S-adenosyl-L-methionine, 50 $\mu$ M sodium m-arsenite, and 5  $\mu$ g of S-adenosyl-L-methionine: arsenic methyltransferase in 100mM tris/100mM sodium phosphate buffer pH 7.4 at 37 °C for 30 minutes. The results suggest that the human cyt19 gene, in fact is translated to an S-adenosyl-L-methionine: arsenic methyltransferase which methylates both arsenite and MMA.

**132** GLOBAL CHANGES IN POSTTRANSLATIONAL COVALENT HISTONE MODIFICATIONS MEDIATED BY LOW-DOSE ARSENIC.

J. F. Reichard and A. Puga. *Environmental Health, University of Cincinnati, Cincinnati, OH.*

*In vitro*, arsenic mediates induction of a large number of genes including the oxidative stress-response battery, a hallmark of arsenic exposure. In microarray experiments, arsenic also down-regulates at least as many genes as it induces, suggesting that arsenic triggers substantial alterations to chromatin structure through mechanisms that have yet to be elucidated. Gene promoter elements, when packaged as nucleosomes, exclude DNA-interacting proteins thereby preventing transcription, while active gene transcription necessitates relaxation of chromatin structure to permit protein access. Covalent modifications of promoter-region histones, spanning only a few nucleosomes, occur concomitantly with gene induction or repression. Here we investigate the global effects of low-dose arsenic treatment on covalent histone modifications. In general, acetylation relaxes histone structure permitting access of transcriptional proteins; conversely, deacetylation closes down chromatin structure, impairing transcription. Histones were isolated from human keratinocyte-derived HaCaT cells by acid extraction following exposure to 5  $\mu$ M arsenic. Reverse-phase high-pressure liquid chromatography (HPLC) was used to separate raw histone extracts into each major histone constituent, namely histones H2A, H2B, H3 and H4. Covalent modifications on each core histone were analyzed by matrix-assisted-laser-desorption ionization time-of-flight mass spectrometry (MALDI-TOF MS). In some instances, these modifications were confirmed using TAU-PAGE separation and immunoblot identification of specific modifications. The experiments presented here demonstrate that 1) at toxicologically relevant concentrations, arsenic modifies the pattern of covalent histone modification; 2) particular core histones are targets for arsenic-mediated covalent modification; 3) specific amino acid residues in each histone are targets for modification by arsenic. (Supported by NIEHS (2 T32 ES 07250 11 A 15 and P42 ES04908) and NIH (R01 ES10807))

**133** ARSENIC CAUSES DOSE-DEPENDENT ENHANCEMENT AND SUPPRESSION OF RETINOIC ACID RECEPTOR (RAR)-MEDIATED GENE ACTIVATION.

J. C. Davey, L. Ingram, C. Batki, J. Lariviere and J. W. Hamilton. *Pharmacology & Toxicology, Dartmouth Medical School, Hanover, NH.*

Chronic exposure to arsenic is a significant human health threat and is associated with increased risks of various cancers, diabetes, heart disease, reproductive and developmental problems and other diseases. We previously demonstrated that arsenic acts as a potent endocrine disruptor at very low levels, altering steroid signaling at the level of receptor-mediated gene regulation for all five steroid receptors (i.e., ER, PR, GR, MR, AR). The goal of these studies was to investigate the effects of arsenic on other members of the nuclear receptor superfamily: in particular, the Retinoic Acid Receptor which is a type II receptor that is normally a heterodimer of the ligand-activated Retinoic Acid Receptor (RAR) and the common binding partner, Retinoic Acid X Receptor (RXR). Human NT2 cells were treated with 0.01 to 5  $\mu$ M sodium arsenite (As) for 24 hr, with or without the RAR ligand, all-trans retinoic acid (ATRA). Gene expression was measured in a transiently transfected RARE-luciferase construct or in the endogenous retinoid-inducible CYP26A1

gene. ATRA at 10 nM (EC50) induced RARE-luc expression by 20-fold and CYP26A1 by 10-fold. Arsenic co-treatment increased ATRA induction of RARE-luc by approximately 1.5-fold at the lowest As concentrations of 0.01 to 0.25  $\mu$ M; whereas As above 1  $\mu$ M caused a 40% decrease in ATRA-inducible expression. Similar results were seen with the CYP26A1 gene. Arsenic alone at 2  $\mu$ M suppressed basal expression by approximately 50%. These results are essentially identical to those previously obtained for steroid receptor-mediated gene expression, indicating that arsenic has widespread effects on at least two classes of nuclear hormone receptors. These endocrine disrupting effects, particularly at the very low doses used, may be important for understanding the wide array of pathophysiological processes linked with chronic low level inorganic arsenic exposure. In addition, these results suggest there may be different patterns of biological responses at different exposure concentrations. (NIH-NIEHS P42 ES07373)

**134** ARSENITE INHIBITS CELL CYCLE PROGRESSION OF U937 MYELOID LEUKEMIA CELLS THROUGH INDUCTION OF CDC25A DEGRADATION.

G. McCollum Lehmann and M. J. McCabe. *University of Rochester, Rochester, NY.*

Arsenic acts as a toxicant, a carcinogen and an effective chemotherapeutic in the treatment of acute promyelocytic leukemia. Its effects on humans are well-documented, but arsenic's mechanism of action is not well-understood. Arsenic has been shown to inhibit cancer cell cycle progression, but the targeted cell cycle phase has been debated. We monitored the cell cycle progression of cell cycle phase-enriched populations of U937 cells in the presence and absence of 5 $\mu$ M NaAsO<sub>2</sub> and determined that arsenite inhibits cell cycle progression through each cell cycle phase. 5-Bromo-2'-deoxyuridine pulse chase experiments show that S-phase transit time is markedly increased by arsenite (15h with treatment vs. 11h without). G2/M appears to be the phase most sensitive to arsenite-induced apoptosis, but given the large percentage of S phase cells in an asynchronous population, arsenite's inhibition of S phase progression may contribute significantly to overall growth inhibition. Cell cycle progression is controlled by the activities of cyclin dependent kinases (cdks), which are in turn regulated by cyclin binding and by activating and inhibitory phosphorylations. Cdc25 dual specificity phosphatases dephosphorylate sites of inhibitory phosphorylation as the last step before cdk triggers progression into the next cell cycle phase. Treatment of U937 cells with 5 $\mu$ M NaAsO<sub>2</sub> for 2h results in a dramatic decrease in protein levels of cdc25A, which controls entry into and progression through S phase by dephosphorylating Tyr15 and Thr14 on cdk2. Cdc25A is regulated by ubiquitin-dependent proteasomal degradation, triggered by its phosphorylation. A time course of concurrent treatment of cells with cycloheximide and arsenite reveals that cdc25A is degraded more quickly in arsenite-treated cells. Arsenite-dependent degradation of cdc25A could contribute to inhibition of S phase entry and progression. Studies are ongoing to establish the dependence of arsenite-induced cdc25A degradation on ubiquitination and proteasome activity and the involvement of cdc25A in arsenite-induced growth inhibition.

**135** MOLECULAR MECHANISMS UNDERLYING INHIBITION OF INSULIN-STIMULATED GLUCOSE UPTAKE IN ADIPOCYTES EXPOSED TO TRIVALENT ARSENICALS.

D. S. Paul, A. W. Harmon and M. Styblo. *Department of Nutrition, University of North Carolina, Chapel Hill, NC.*

Chronic environmental or occupational exposures to inorganic arsenic (iAs) have been associated with increased prevalences of non-insulin-dependent (type-2) diabetes mellitus. The clinical symptoms of the disease indicate that iAs or its metabolites interfere with insulin signaling and/or suppress insulin-stimulated glucose metabolism in tissues. We have previously shown that exposures to subtoxic concentrations of arsenite (iAs<sup>III</sup>), methylarsine oxide (MAs<sup>III</sup>O) or iododimethylarsine (DMA<sup>III</sup>I) inhibit glucose uptake in murine 3T3-L1 adipocytes by interfering with insulin-stimulated GLUT4 translocation from the perinuclear compartment to the plasma membrane. The present work examined molecular mechanisms underlying these effects. We found that treatments of cultured 3T3-L1 adipocytes with iAs<sup>III</sup> or MAs<sup>III</sup>O resulted in suppression of insulin-dependent phosphorylation of protein kinase B (PKB/Akt) and inhibition of PKB/Akt activity. Neither iAs<sup>III</sup> nor MAs<sup>III</sup>O interfered with activation of the components of the insulin-activated signal transduction pathway upstream from PKB/Akt. Notably, in an *in vitro* assay system, both arsenicals inhibited activity of PKB/Akt isolated by immunoprecipitation from untreated insulin-stimulated adipocytes. Unlike iAs<sup>III</sup> and MAs<sup>III</sup>O, DMA<sup>III</sup>I did not suppress PKB/Akt phosphorylation or activity in intact adipocytes. However, DMA<sup>III</sup>I inhibited *in vitro* activity of the immunoprecipitated enzyme isolated from untreated cells. Expression of constitutively active PKB/Akt restored the normal pattern of insulin-dependent PKB/Akt phosphorylation and glucose uptake in cells treated with iAs<sup>III</sup> or MAs<sup>III</sup>O, but had no effect on inhibition of glucose uptake in cells exposed to DMA<sup>III</sup>I. These results suggest that

iAs<sup>III</sup> and MA<sup>III</sup>O interfere with insulin-stimulated glucose uptake in 3T3-L1 adipocytes by inhibiting PKB/Akt phosphorylation and the activity of the phosphorylated enzyme. The inhibition of glucose uptake by DMA<sup>III</sup>I may involve mechanisms independent of Akt.

### FURTHER STUDIES ON ABERRANT GENE EXPRESSION IN ARSENIC-INDUCED MALIGNANT TRANSFORMATION OF LIVER EPITHELIAL CELLS.

J. Liu<sup>1</sup>, L. Benbrahim-Tallaa<sup>1</sup>, Y. Xie<sup>1</sup>, X. Qian<sup>2</sup>, W. Qu<sup>1</sup>, J. Ostrom<sup>3</sup> and M. Waalkes<sup>1</sup>. <sup>1</sup>Laboratory of Comparative Carcinogenesis, NCI at NIEHS, Research Triangle Park, NC, <sup>2</sup>LST, NIEHS, Research Triangle Park, NC and <sup>3</sup>DNA Sequencing Core, NIEHS, Research Triangle Park, NC.

Inorganic arsenic induces liver tumors in humans and rodents. In prior research we found chronic exposure (>18 wk) of rat liver epithelial TRL1215 cells to low level arsenite (500 nM) induces malignant transformation. Initial microarray studies revealed changes in gene expression in these chronic arsenic exposed (CAsE) cells that warrant further study. Real-time RT-PCR showed large increases in CAsE cell stress-response genes like glutathione S-transferase-pi (GST- $\pi$ , 3-fold), heme oxygenase-1 (4-fold), superoxide dismutase-1 (5-fold) and metallothionein-1 (MT-1; 4-fold) compared to control. The positive cell-cycle regulatory genes cyclin D1 (10-fold) and PCNA (3-fold) were overexpressed in CAsE cells, while negative regulatory genes p21 (30% of control) and p16 (1%) were markedly depressed. In CAsE cells c-jun, c-met, c-myc, Wilms tumor protein-1 (WT-1) and  $\alpha$ -fetoprotein (AFP) expression increased from 3 to 13-fold, while expression of insulin-like growth factor II (IGF-II) and fibroblast growth factor (FGF) were abolished. Western-blot analysis confirmed increases in GST- $\pi$ , WT-1, AFP and decreases in p16 and p21 protein. MT overexpression was not due to DNA methylation as bisulfite sequencing showed the MT-1 promoter region was slightly more methylated in CAsE cells than controls. Treatment of CAsE cells with the DNA demethylating agent 5-aza-deoxycytidine (Aza; 2.5  $\mu$ M, 72 hrs) greatly increased MT-1 (19-fold) compared to control cells (5-fold), indicating CAsE cells are more sensitive to DNA demethylation stress. Conversely, Aza did not restore expression of p16, IGF-II, or FGF to control levels in CAsE cells, indicating suppression was due to factors other than DNA methylation changes. Thus, an intricate variety of gene expression changes occur in arsenic-induced malignant transformation, including oncogene activation and increased and decreased expression of genes critical to growth regulation.

## 137

### ARSENITE DECREASES CYP3A INDUCTION IN CULTURED RAT HEPATOCYTES BY DUAL MECHANISMS.

T. L. Noreault<sup>1</sup>, J. M. Jacobs<sup>3,4</sup>, R. C. Nichols<sup>2,3</sup>, H. W. Trask<sup>4</sup>, S. A. Wrighton<sup>5</sup>, P. R. Sinclair<sup>1,2,4</sup>, R. M. Evans<sup>6</sup> and J. F. Sinclair<sup>1,2,4</sup>. <sup>1</sup>Pharmacology & Toxicology, Dartmouth Medical School, Hanover, NH, <sup>2</sup>VA Medical Center, White River Junction, VT, <sup>3</sup>Microbiology/Immunology, Dartmouth Medical School, Hanover, NH, <sup>4</sup>Biochemistry, Dartmouth Medical School, Hanover, NH, <sup>5</sup>Lilly Research Laboratories, Indianapolis, IN and <sup>6</sup>Howard Hughes Medical Institute, Salk Institute for Biological Studies, San Diego, CA.

We previously reported that 24 h treatment with 5  $\mu$ M arsenite decreased induction of CYP3A protein in dexamethasone (DEX)-treated rat hepatocyte cultures, with minor decreases in CYP3A23 mRNA, as measured by solution hybridization. Here, we used a more sensitive assay to investigate earlier effects of arsenite on CYP3A23 mRNA. In rat hepatocyte cultures exposed to DEX and arsenite for 6 h, CYP3A protein was decreased greater than 90% compared to DEX treatment alone. At the same time, arsenite caused a 30-40% decrease in CYP3A23 mRNA in DEX-treated cultures, yet remained 5-fold higher than in untreated cultures. These results suggest arsenite acts through post-transcriptional as well as a transcriptional mechanism to decrease CYP3A. Since arsenite did not decrease intracellular glutathione or increase lipid peroxidation, we conclude these decreases do not involve oxidative stress. Exogenous heme did not prevent the arsenite-mediated decrease in CYP3A protein induction. Arsenite did not increase degradation of CYP3A holoprotein. We are currently investigating whether arsenite negatively regulates mRNA translation by interacting with the untranslated regions of CYP3A23 to result in decreased CYP3A protein levels. We examined whether arsenite effects CYP3A induction by the nuclear receptor PXR, the major mediator of CYP3A induction by steroids. Arsenite caused a 30% decrease in expression of a reporter construct containing the PXR-sensitive, CYP3A23 upstream regulatory region. Thus, one action of arsenite may be to inhibit transcription of CYP3A23 by interfering with PXR-mediated induction. We conclude that arsenite utilizes dual mechanisms to decrease CYP3A induction in primary cultures of rat hepatocytes.

## 138

### ANALYSIS OF GLOBAL AND GENE SPECIFIC DNA METHYLATION IN LIVERS OF NEWBORN MICE TRANSPLACENTALLY EXPOSED TO A CARCINOGENIC DOSE OF ARSENIC.

Y. Xie<sup>1</sup>, J. Liu<sup>1</sup>, L. Benbrahim-Tallaa<sup>1</sup>, B. Diwan<sup>2</sup> and M. Waalkes<sup>1</sup>. <sup>1</sup>Laboratory of Comparative Carcinogenesis, NCI at NIEHS, Research Triangle Park, NC and <sup>2</sup>BRP, SAIC-Frederick, NCI at Frederick, MD.

Arsenic is a human carcinogen that can target the liver. Our prior work has shown that exposure of pregnant mice to inorganic arsenic induces a high incidence of liver tumors in male offspring when they reach adulthood. Initial analysis of newborn mice exposed to a hepatocarcinogenic dose of arsenic *in utero* revealed remarkable gene expression changes. Some evidence indicates arsenic can alter gene expression by altering DNA methylation. Thus, this study examined early DNA methylation changes in arsenic-induced transplacental hepatocarcinogenesis. Pregnant mice received drinking water containing 85 ppm arsenic (as sodium arsenite) or unaltered water (control) from gestation day 8 to 18. Liver samples were taken from newborn males, and global genomic DNA methylation was determined by the methyl acceptance assay. Arsenic exposure *in utero* did not alter hepatic global DNA methylation in the newborn. Methylation in GC-rich regions was assessed using amplification of genomic DNA digested with methyl-sensitive restriction enzymes. Arsenic exposure resulted in 5 distinct regions of reduced methylation and 2 regions of increased methylation in GC-rich sites. PCR analysis of hepatic Ha-ras following methylation-sensitive enzyme digestion of DNA showed reduced methylation of a key CpG island after arsenic exposure. Although arsenic induced metallothionein-I (MT-I) overexpression, both methylation specific PCR and DNA sequencing following sodium bisulfite indicated the promoter region of MT-I gene was un-methylated in control and arsenic-treated mice, suggesting mechanisms other than methylation regulate arsenic-induced MT overexpression. Overall, hepatic global genomic DNA methylation status was not altered by arsenic, but GC rich methylation appeared reduced. Changes in gene specific methylation depended on the gene in question.

## 139

### ARSENITE INDUCES CYTOKERATIN EXPRESSION IN MICE LIVER.

P. Ramirez<sup>1</sup>, M. Carbon<sup>2</sup> and M. E. Gonsebatt<sup>3</sup>. <sup>1</sup>Laboratorio de Toxicología Celular, FES Cuautitlán, Cuautitlán, Mexico, <sup>2</sup>Biofísica, Facultad de Química, UNAM, Mexico, DF, Mexico and <sup>3</sup>Medical Genomics and Environmental Toxicology, Instituto de Investigaciones Biomedicas, UNAM, Mexico, DF, Mexico.

Increased levels of cytokeratins are observed in human liver disease such as primary biliary cirrhosis and in alcoholic liver disease related to Mallory bodies formation as a consequence of protein accumulation, essentially cytokeratins. Modified synthesis and abnormal organization of these intermediate filaments are considered indicators of liver damage. The liver is also the main organ where many carcinogens such as arsenic are metabolized. Studies in humans exposed to inorganic arsenic by the oral route have noted signs or symptoms of liver injury. Lipid vacuolation and fibrosis have been reported in rats exposed to arsenic in drinking water. Increased synthesis and disruption of cytokeratin 18 cellular organization, have been induced in WRL-68 human fetal hepatic cell line by sodium arsenite. In this work, male BALB/c mice were given orally 2.5, 5 and 7.5 mg/kg/day of sodium arsenite. Cytokeratin expression was monitored in liver after 2 and 9 days. Significant induction of CK18 mRNA and protein synthesis were observed in those animals exposed to the lower doses when liver samples were examined by RT-PCR and Western blotting respectively. We did not observe significant induction at the highest dose employed, suggesting that arsenite is inhibiting the synthesis of this important protein to hepatocyte architecture. The induction of cytokeratin 18 could be considered as an early indicator of liver damage by arsenic. This work was partially supported by PAPIIT and CONACYT.

## 140

### REDUCTION OF ARSENATE BY HUMAN ERYTHROCYTE (RBC) LYSATE AND RAT LIVER CYTOSOL (CS) IS LINKED TO GLYCOLYSIS.

B. Nemeti and Z. Gregus. Department Pharmacology, University Pecs, Med. School, Pecs, Hungary.

Reduction of arsenate (AsV) to the more toxic arsenite (AsIII) is carried out *in vivo* by hitherto unidentified enzymes. Purine nucleoside phosphorylase (PNP) is an efficient AsV reductase (AsVR) *in vitro*, though it seems to be irrelevant *in vivo* (Nemeti et al., Toxicol. Sciences, 74, 22, 2003). Intact human RBC possess an AsVR activity, which appears dependent on glutathione (GSH) and NAD supply but independent of PNP (Nemeti and Gregus, Toxicol. Sciences, in press). Studies on AsV reduction in intact RBC have led to the hypothesis that the AsVR activity lies between glyceraldehyde-3-phosphate dehydrogenase (GAPDH) and enolase in

the glycolytic pathway. To further characterize this PNP-independent AsVR, we examined the effects of GSH, glycolytic substrates, NAD, ATP, and related nucleotides on AsV reduction in lysed RBC and rat liver cytosol in the presence of BCX-1777, a PNP inhibitor. AsIII formed in the assays from AsV was quantified with HPLC-HG-AFS analysis. In both hemolysate and CS, GSH enhanced AsV reduction in a concentration dependent manner. Glycolytic substrates, especially fructose-1, 6-bisphosphate and phosphoglyceric acids (PGA), improved AsVR activity. NAD, especially together with these substrates, markedly increased AsIII formation, whereas NADH was a strong, ATP and ADP were moderate inhibitors. In CS but not in hemolysate, NADP enhanced AsV reduction moderately. In hemolysate but not in CS, 2-phosphoglycollate, which increases the breakdown of the RBC-specific compound 2, 3-bisphosphoglycerate to 3-PGA, doubled AsVR activity. Collectively, hemolysate and rat liver cytosol possess a PNP-independent AsV reductase activity that depends on the availability of GSH, NAD, and glycolytic substrates. Our data suggest that this activity might be ascribed to two functionally linked glycolytic enzymes, GAPDH and phosphoglycerate kinase (PGK), because GAPDH uses NAD while PGK uses 3-PGA as substrate. Testing of the AsVR activity of these two enzymes is presented in the accompanying poster (Gregus and Nemeti). (Supported by OTKA and the Hungarian Ministry of Health)

THE ROLE OF THE RAS SIGNALING PATHWAY IN ANDROGEN-INDEPENDENCE ACQUIRED DURING ARSENIC-INDUCED MALIGNANT TRANSFORMATION OF HUMAN PROSTATE EPITHELIAL CELLS.

L. Benbrahim-Tallaa<sup>1</sup>, M. Webber<sup>2</sup> and M. Waalkes<sup>1</sup>. <sup>1</sup>Laboratory of Comparative Carcinogenesis, NCI at NIEHS, Research Triangle Park, NC and <sup>2</sup>Michigan State University, East Lansing, MI.

In humans progression of prostate cancer to androgen-independence (AI) signals a marked worsening of prognosis, and is linked to autocrine or paracrine growth. Evidence indicates that the androgen receptor (AR) and Ras can be involved in acquired AI in prostate cancer. Inorganic arsenic is a potential human prostate carcinogen but its role in prostate tumor progression is undefined. Thus, we studied AI in CAsE-PE cells, a malignant transformant of the non-tumorigenic human prostate epithelial cell line RWPE-1 induced by chronic arsenic exposure. The transformant grew at a much faster rate in complete medium than control cells and also showed sustained growth in steroid-reduced medium. Although similar levels of AR occurred in control and CAsE-PE cells, androgens were less effective in stimulating cell proliferation and AR-related gene expression in CAsE-PE cells. For instance, dihydrotestosterone increased PSA transcript much more in control (4.5-fold) than CAsE-PE (1.5-fold) cells. CAsE-PE cells also showed relatively low levels of growth stimulation by non-androgen steroids, such as estradiol. These data indicate that arsenic did not induce AR over-expression or loss of AR ligand specificity, both of which can occur with acquired AI in prostate cancer. CAsE-PE cells did, however, display constitutively increased expression of unmutated K-Ras (13-fold). Ras is a common component of many signaling pathways activated in advanced prostate cancer. Indeed, events downstream of K-Ras, including A-Raf and B-Raf (both serine-threonine MAP kinases) showed increased constitutive expression in CAsE-PE cells (2.2-fold and 3.2-fold, respectively) compared to control. Thus, arsenic induced malignant transformation is associated with acquired AI in human prostate cells and Ras activation and up-regulation of down-stream pathways appear to correlate with this tumor progression.

**142**

ARSENITE BINDING TO SUBSETS OF THE HUMAN ESTROGEN RECEPTOR- $\alpha$ .

K. T. Kitchin and K. A. Wallace. Environmental Carcinogenesis Division, USEPA, Research Triangle Park, NC.

Enzyme inhibition by arsenicals has been described many times, but the underlying binding of trivalent arsenicals to peptides and proteins has received little attention. The purpose of this study was to determine Kd and Bmax values for arsenite binding to nine synthetic peptides (up to 25 amino acids long) which contained between 0 and 4 sulfhydryls. We selected the human estrogen receptor- $\alpha$  protein for study because arsenite is a potential nonsteroidal environmental estrogen and several interactions between arsenic exposure, estrogenicity and carcinogenicity are known. We utilized radioactive <sup>73</sup>As labeled arsenite and vacuum filtration methodology to determine the binding affinity of arsenite to synthetic peptides based on a zinc finger region containing up to 4 free sulfhydryls and the estrogen binding region containing up to 3 free sulfhydryls. In our studies, amino acids other than cysteine (including methionine and histidine) did not bind arsenite. Peptides modeled on the estrogen receptor with two or more nearby free sulfhydryls (2 or 5 intervening amino acids) had Kd values in the 1-4  $\mu$ Molar range. Peptides containing a single sulfhydryl or two sulfhydryls spaced 17 amino acids apart had higher Kd values in the 100-200  $\mu$ Molar range, demonstrating lower affinity. With the exception of peptide 24 which had an unusually high Bmax value of 234

nmol/mg, the binding capacity of the studied peptides was proportional to the number of free cysteines. Based on our experimental Kd values and published literature values for tissue sulfhydryls, 99% or more of arsenite *in vivo* should be bound to tissue sulfhydryls and not free. The binding of trivalent arsenicals to protein sulfhydryl groups and the ensuing enzyme inhibition and altered biological function can initiate at least five proposed modes of arsenic's carcinogenic action - induced chromosomal abnormalities, altered DNA repair, altered DNA methylation patterns, altered growth factors and enhanced cell proliferation. ALTERED PROTEIN EXPRESSION FOLLOWING *IN UTERO* EXPOSURE TO ARSENIC.

C. Lantz, J. S. Petrick and A. M. Hays. *Cell Biology and Anatomy, University of Arizona, Tucson, AZ.*

Inorganic arsenic is a known human carcinogen and common drinking water contaminant affecting millions of people worldwide. Though the effects of maternal arsenic exposure on the developing lung are unknown, this metalloid is known to cross the placenta. Using an *in utero* exposure model, we have previously identified genes that are altered by exposure to arsenic in the maternal drinking. A more complete understanding of the *in utero* effects of arsenic requires analysis of alterations in protein expression. We hypothesize that *in utero* exposure to inorganic arsenic through maternal drinking water causes altered protein expression in the developing lung, indicative of downstream molecular and functional changes. From conception to embryonic day eighteen, we exposed pregnant Sprague-Dawley rats to 500 parts per billion arsenic (as arsenite) via the drinking water. Protein was isolated from a single pup from 3 separate arsenic exposed litters. Protein was also isolated from three control pups (each pup from a different litter). Samples were pooled and arsenic-induced alterations in protein expression were determined using BD Power Blot analysis. This technique can analyze over 1000 separate proteins. Blots were run in triplicate and protein content was measured using densitometry. Each of the treated blots was compared against each of the control blots. Only those proteins in which expression was 1.25 up or down regulated by arsenic in each sample were considered as being altered. Thirty five proteins or posttranslationally modified proteins were identified as being altered (21 up- and 14 down-regulated). Analysis of potential protein function indicated that nucleus/nuclear transport proteins, cancer related proteins, tyrosine kinase substrates and cytoskeleton related proteins were altered by arsenic. The present study shows that arsenic induces alterations in protein levels in the developing lung. These data may be useful in the elucidation of molecular targets and biomarkers of inorganic arsenic exposure during lung development. Supported by NIH grants ES-04940 and ES-06694.

ABERRANT GENE EXPRESSION IN THE NEONATAL MOUSE LUNG FOLLOWING *IN UTERO* EXPOSURE TO INORGANIC ARSENIC.

J. Shen<sup>1</sup>, Y. Xie<sup>1</sup>, J. Liu<sup>1</sup>, B. Diwan<sup>2</sup> and M. Waalkes<sup>1</sup>. <sup>1</sup>Laboratory of Comparative Carcinogenesis, NCI at NIEHS, Research Triangle Park, NC and <sup>2</sup>BRP, SAIC-Frederick, NCI at Frederick, Frederick, MD.

Inorganic arsenic is a lung carcinogen in humans. Our prior work showed *in utero* exposure to arsenic in mice can induce lung cancers in female offspring after they become adults. To define early molecular changes in the lung after *in utero* arsenic exposure, pregnant C3H mice were given carcinogenic doses of arsenic in the drinking water (42.5 and 85 ppm arsenic as sodium arsenite) from day 8 to 18 of gestation and aberrant gene expression was examined in the lungs of female offspring as newborns. Real-time RT-PCR analysis was used to determine expression of thirty-six selected genes associated with carcinogenesis or arsenic exposure. After *in utero* arsenic exposure, estrogen receptor- $\alpha$  (ER- $\alpha$ ) showed marked, dose-related increases in expression in newborn female lung. Compared to control, pulmonary ER- $\alpha$  increased over 9-fold after 42.5 ppm arsenic and over 14-fold after 85 ppm arsenic. Recent clinical evidence indicates ER- $\alpha$  overexpression is common in lung tumor specimens from women, and may contribute to gender linked difference in lung cancer risk. Another gene highly overexpressed in female lung after *in utero* arsenic exposure was  $\alpha$ -fetoprotein (AFP) which showed a maximum increase in expression of over 11-fold compared to control. AFP is normally a fetal protein that is overexpressed in many tumors, including aggressive lung cancers. AFP is also considered a growth enhancing protein. Other gene expression changes in the lungs of arsenic-treated female newborn mice included increased expression of myc (2-fold), metallothionein-1 (3-fold), glutathione peroxidase (2-fold), betaine-homocysteine S-methyltransferase (10-fold), insulin-like growth factor-1 (IGF-1; 2-fold) and IGF-2 (2-fold). Overexpression of IGF-1 and IGF-2 is common in tumors. Thus, transplacental exposure to arsenic at doses that can be carcinogenic to the female lung produced rapid gene expression changes relevant to pulmonary carcinogenesis, such as increased AFP and ER- $\alpha$ .

ARSENIC INDUCES CHROMOSOMAL AND CENTROMERIC ABNORMALITIES IN HUMAN LUNG CELLS.

J. P. Lynch<sup>1,2</sup>, S. S. Wise<sup>1,2</sup> and J. P. Wise<sup>1,2</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME and <sup>2</sup>Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME.

Arsenic is a known human carcinogen, causing lung and bladder cancer. Studies have shown humans chronically exposed through drinking water, present increased micronuclei in oral mucosal cells, urothelial cells and lymphocytes. However, the genotoxicity of arsenic in human lung cells has not been investigated. Because lung is a major target for arsenic-induced carcinogenicity, we investigated its cytotoxicity, clastogenicity and centromeric effects in human lung fibroblasts. We found that arsenic is cytotoxic to human lung cells in a concentration-dependent manner, with 1, 5 and 10  $\mu$ M inducing 65, 45 and 25% relative survival, respectively. Arsenic is also clastogenic to human lung cells in a concentration-dependent manner, with 1, 5 and 10  $\mu$ M damaging 3, 7 and 15% of metaphases, respectively. Arsenic also caused concentration-dependent increases in centromere spreading, c-anaphase chromosomes and endoreduplication in human lung cells. Specifically evaluating cells treated with 5  $\mu$ M arsenic, we found 16% of metaphases with at least one spread centromere or c-anaphase chromosome. When cells treated with 5  $\mu$ M arsenic for 24 h were allowed to recover in arsenic free media, 20% fewer centromeric aberrations were noted and a 5% increase in endoreduplicated chromosomes when compared to those exposed to 5  $\mu$ M arsenic for 24 h. These data suggest centromeric abnormalities and endoreduplication may be causative mechanisms in arsenic-induced lung cancer. This work was supported by a grant from the Maine Cancer Foundation.

CHARACTERIZATION OF HUMAN BLADDER UROTHELIAL CELLS MALIGNANTLY TRANSFORMED BY ARSENITE.

K. E. Billings<sup>1</sup>, T. G. Bredfeldt<sup>1</sup>, X. H. Zheng<sup>1</sup>, M. J. Kopplin<sup>1</sup>, G. S. Watts<sup>2</sup>, D. A. Sens<sup>4</sup>, E. A. Mash<sup>3</sup> and A. J. Gandolfi<sup>1</sup>. <sup>1</sup>Depts of Pharmacology and Toxicology, University of AZ, Tucson, AZ, <sup>2</sup>AZ Cancer Center, University of AZ, Tucson, AZ, <sup>3</sup>Department of Chemistry, University of AZ, Tucson, AZ and <sup>4</sup>Depts of Pathology and Surgery, School of Medicine and Health Sciences, University of ND, Grand Forks, ND.

Arsenic is implicated in development of human bladder cancer. Chronic arsenite [As(III)] exposure can cause the malignant transformation of human urothelial cells (UROtsa). Since monomethylarsonous acid [MMA(III)] is reported to be more toxic than As(III) in normal UROtsa cells, studies were undertaken to compare the toxicity of MMA(III) and As(III) between the UROtsa and As(III)-transformed UROtsa cells. MMA(III) and As(III) were equally cytotoxic to normal and transformed cell lines with MMA(III) being 12-fold more toxic. The ability of transformed cells to biotransform As (III) was determined. While the UROtsa cells were found to oxidize and methylate As(III) to As(V), MMA(III), and MMA(V), biotransformation of As(III) by the transformed cells was limited to redox cycling to As(V). Gene expression studies comparing transformed UROtsa to control UROtsa were conducted with a two-fold change/repetition (N=3) for significance( $p>0.05$ ). Increased expression was seen with genes associated with cell signaling (Ca++ binding protein A8), metabolism/biotransformation (GSH-S-transferase M3), and cell receptors (glypican 3 mRNA). Down regulation was seen in genes related to signal transduction (TTK protein kinase), cell cycle (cyclin A1 and D2), tumor suppressor genes (p53 activated fragment-1), structural and cellular matrix associated proteins (annexin A3 and actin protein 2/3 complex B1), and cell adhesion molecules (metalloprotease 1 and 2 inhibitor). Studies are underway to transform UROtsa cells with MMA(III) to determine if similar effects will be seen. By characterizing the morphological and genetic differences between the normal and the transformed UROtsa, biomarkers of exposure or injury to the bladder may be identified that can be used in future epidemiological studies. (Supported by NIH grants ES04940, CA023074, ES06694, ES07091).

ARSENITE AND MONOMETHYL ARSONOUS ACID-INDUCED TOXICITY IN HUMAN UROTHELIAL CELLS.

T. G. Bredfeldt<sup>1</sup>, K. E. Billings<sup>1</sup>, X. H. Zheng<sup>1</sup>, E. A. Mash<sup>2</sup>, F. E. Domann<sup>3</sup>, S. S. Lau<sup>1</sup>, D. A. Sens<sup>4</sup> and A. J. Gandolfi<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, University of AZ, Tucson, AZ, <sup>2</sup>Chemistry, University of AZ, Tucson, AZ, <sup>3</sup>Radiation Oncology, University of IA, Iowa City, IA and <sup>4</sup>Pathology and Surgery, University of ND, Grand Forks, ND.

Arsenic is a known bladder carcinogen. However, the mechanism of arsenic-induced bladder injury or carcinogenesis is unknown. Studies investigating gene expression caused by arsenite [As(III)] and monomethylarsonous acid [MMA(III)]

exposure in human urothelial (UROtsa) cells revealed the presence of both oxidative stress and protein damage. These results prompted the study of reactive oxygen species generation in As(III) and MMA(III)-induced cytotoxicity in UROtsa cells. Reduction of intracellular glutathione levels via administration of bathionine S-R-sulfoximine (25  $\mu$ M) increased cytotoxicity of MMA(III) and As(III) by 4 and 7 fold, respectively, indicating the critical role of cellular antioxidant status. However, concurrent treatment of UROtsa cells with radical scavengers [DPPD (10  $\mu$ M and 100  $\mu$ M) and DMSO (0.1% and 0.5%)] only ameliorated the cytotoxicity of higher concentrations of As(III) and MMA(III). Thus efforts to block the production of As(III) and MMA(III)-induced reactive oxygen species via adenoviral-mediated infection of both superoxide dismutase and catalase are underway. In addition, to demonstrate that As(III) and MMA(III) produce reactive oxygen species and induce oxidative DNA damage, the fluorescent probe CM-H2DCFDA is being used to detect oxyradical production using confocal microscopy and increases in 8-hydroxy-2-deoxyguanosine (8-OHdG) are being detected via HPLC to illustrate oxidative DNA damage. These studies will improve the understanding of the role reactive oxygen species play in As(III) and MMA(III) toxicity in a target organ cell line (Supported by NIH grants ES04940, ES07091, ES06694).

METABOLISM AND TOXICITY OF ARSENIC IN HUMAN URINARY BLADDER EPITHELIAL CELLS EXPRESSING RAT ARSENIC (+3)-METHYLTRANSFERASE.

Z. Drobna<sup>1</sup>, S. B. Waters<sup>2</sup>, V. Devesa<sup>3</sup>, A. W. Harmon<sup>1</sup>, D. J. Thomas<sup>4</sup> and M. Styblo<sup>1,3</sup>. <sup>1</sup>Pediatrics, UNC Chapel Hill, NC, Chapel Hill, NC, <sup>2</sup>Curriculum in Toxicology, UNC, Chapel Hill, NC, <sup>3</sup>CEMALB, UNC, Chapel Hill, NC and <sup>4</sup>NHEERL, USEPA, Triangle Research Park, NC.

The enzymatic methylation of inorganic arsenic (iAs) is catalyzed by arsenic (+3)-methyltransferase (AS3MT). AS3MT is expressed in rat liver and in human hepatocytes but not in a human urothelial cell line (UROtsa), which does not methylate iAs. Thus, UROtsa cells are an ideal null background in which the role of iAs methylation in the modulation of toxic and cancer promoting effects of this metalloid can be examined. A retroviral gene delivery system was used in this study to create a clonal UROtsa cell line (UROtsa/F35) that expresses rat AS3MT. The metabolism and cytotoxicity of arsenite (iAs<sup>III</sup>) and methylated trivalent arsenicals were characterized in both UROtsa and UROtsa/F35 cells. In contrast to parental cells, UROtsa/F35 cells methylated iAs<sup>III</sup>, yielding methylarsenic (MAs) and dimethylarsenic (DMAs) that contained either As<sup>III</sup> or As<sup>V</sup>. When exposed to MAs<sup>III</sup> UROtsa/F35 cells produced DMAs<sup>III</sup> and DMAs<sup>V</sup>. MAs<sup>III</sup> and DMAs<sup>III</sup> were more cytotoxic than iAs<sup>III</sup> in both UROtsa and UROtsa/F35 cells. The greater cytotoxicities of MAs<sup>III</sup> and DMAs<sup>III</sup> as compared to iAs<sup>III</sup> were associated with greater cellular retention of both methylated trivalent arsenicals. Notably, UROtsa/F35 cells were more sensitive than UROtsa cells to the cytotoxic effects of iAs<sup>III</sup>, but were more resistant to the cytotoxicity of MAs<sup>III</sup>. Increased toxicity of iAs<sup>III</sup> in UROtsa/F35 cells was associated with inhibition of DMAs production and intracellular accumulation of MAs at high exposure levels. The resistance of UROtsa/F35 cells to moderate concentrations of MAs<sup>III</sup> was linked to a rapid conversion of MAs<sup>III</sup> to DMAs and efflux of DMAs. However, concentrations of MAs<sup>III</sup> that inhibited DMAs production by UROtsa/F35 cells were equally toxic for both cell lines. Thus, the extent of the production and accumulation of MAs<sup>III</sup> is a key factor that determines the toxicity of iAs in methylating cells. (This abstract does not necessarily reflect EPA policy.)

GLYCERALDEHYDE 3-PHOSPHATE DEHYDROGENASE (GAPDH) AS AN ARSENATE REDUCTASE IN HUMAN RED BLOOD CELLS (HRBC) AND RAT LIVER CYTOSOL (RLC).

Z. Gregus and B. Nemeti. Department Pharmacology, University Pecs, Med. School, Pecs, Hungary.

The mechanism for reduction of arsenate (AsV) to the more toxic arsenite (AsIII) is unknown. Purine nucleoside phosphorylase (PNP) works as an arsenate reductase (AsVR) *in vitro*, however, it appears irrelevant *in vivo* (Nemeti et al., Toxicol. Sciences. 74: 22, 2003). The accompanying poster (Nemeti and Gregus) demonstrated that hRBC lysate and rLC contain a PNP-independent AsVR activity that is supported by glutathione (GSH), NAD and glycolytic substrates, especially phosphoglyceric acids (PGA). Because NAD is substrate for GAPDH, whereas 3-PGA is substrate for phosphoglycerate kinase (PGK), the roles of these two functionally linked glycolytic enzymes in AsV reduction have been tested. AsIII formed in the assays from AsV was quantified by HPLC-hydride generation-atomic fluorescence spectrometry. A mix of purified GAPDH and PGK catalyzed GSH-dependent reduction of AsV, provided NAD was present and GAPDH was supplied with a glycolytic substrate, either with glyceraldehyde 3-phosphate (Ga3P) directly or indirectly by PGK (from 3-PGA and ATP). It was also shown that GAPDH (purified

from rabbit muscle or hRBC) alone exhibited AsVR activity that depended on the enzyme concentration, was enhanced in a concentration-dependent manner by its substrates (Ga3P, NAD) as well as GSH, and was strongly inhibited by NADH. Konigic acid, a selective GAPDH inhibitor, decreased both the classical enzymatic activity and the AsVR activity of rabbit muscle GAPDH in a concentration-dependent manner, abolishing both activities at 25 mM. Konigic acid also decreased both the GAPDH and the AsVR activities of intact hRBC, hRBC lysate and rLC, at high concentration abolishing AsIII formation in intact hRBC, almost completely inhibiting it in hRBC lysate and partially inhibiting it in rLC. Thus, GAPDH works as a GSH-dependent AsVR; it appears largely responsible for the PNP-independent AsVR activity in hRBC and partly responsible for such activity in rLC. The *in vivo* relevance of GAPDH as an AsV reductase remains to be tested. (Supported by OTKA and the Hungarian Ministry of Health)

## 150 ARSENITE INDUCES PROCOAGULANT ACTIVITY IN HUMAN PLATELETS BY PHOSPHATIDYL SERINE EXPOSURE AND MICROPARTICLE GENERATION.

O. Bae, K. Lim and J. Chung. *College of Pharmacy, Seoul National University, Seoul, South Korea.*

Many epidemiological studies reported that there are strong correlations between arsenic in drinking water and occurrences of cardiovascular disease as well as human cancer, but the exact mechanism is not clearly known. We investigated if arsenic can affect procoagulant activity of platelet, which is essential in blood clotting, thrombus formation and cardiovascular disease development. Effects of arsenic on platelet procoagulant activities are examined *in vitro* using human platelets and *in vivo* in a rat animal model. Arsenite significantly enhanced platelet procoagulant activity induced by thrombin in a concentration- and time-dependent manner as observed in prothrombinase assay. It is generally considered that the increase of procoagulant activity is mediated by exposure of anionic phospholipids (phosphatidylserine; PS) and microparticle (MP) generation. In flow cytometry analysis, we found that arsenite enhanced PS exposure and MP formation induced by thrombin. Generated MPs were also confirmed in confocal microscopy and found to have procoagulant activity like PS-exposed platelets. These effects of arsenic appeared to be mediated by enhanced calcium increase as investigated with Fluo-3. Pretreatment of calpeptin, a calpain inhibitor, abolished arsenic effects on platelets showing that calpain is involved in these processes. In addition, arsenite inhibited aminophospholipid translocase, suggesting exposed PS could be maintained in outer membranes. Consistent with arsenite-enhanced platelet procoagulant activity observed *in vitro*, arsenite infusion actually led to the increase of thrombus formation *in vivo* in rat venous thrombosis model. In conclusion, arsenite induces enhancement of procoagulant activity with the increase of PS exposure and MP formation in human platelets and resultant venous thrombosis as observed *in vivo*. These enhanced platelet procoagulant activity may be a major contributing factor in cardiovascular disease associated with chronic intake of arsenic in drinking water through enhanced blood clotting and thrombus formation.

## 151 ARSENIC METHYLTRANSFERASE CYT19 EXPRESSION AND ACTIVITY IN RAT TISSUES.

Y. Kobayashi<sup>1,2</sup>, T. Hayakawa<sup>1</sup> and S. Hirano<sup>1</sup>. <sup>1</sup>*Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Ibaraki, Japan* and <sup>2</sup>*Japan Foundation for Aging and Health, Chita, Aichi, Japan.*

Inorganic arsenicals such as arsenite (iAs<sup>III</sup>) and arsenate (iAs<sup>V</sup>) are well-known worldwide environmental contaminants and human carcinogen. Arsenic is known to be metabolized by repetitive reduction and methylation, and excreted mainly in urine as methylated arsenicals such as monomethylarsonic acid (MMA<sup>V</sup>) and dimethylarsinic acid (DMA<sup>V</sup>). Although it has been known that the arsenic methylation is catalyzed by arsenic methyltransferase, Cyt 19, very little is known about characteristics of the enzyme. In the present study we report gene expression and enzyme activity of Cyt19 in rat tissues. We investigated mRNA and protein levels of Cyt19 in rat tissues, such as heart, brain, spleen, lung, liver, skeletal muscle, kidney and testis, by Northern and Western analysis, respectively. The rat tissues cytosol was incubated at 37 °C for 3 h with 10 μM iAs<sup>III</sup>, 5 mM GSH and 1 mM S-adenosyl-L-methionine in 75 mM phosphate buffer (pH 7.0). The reaction was stopped by boiling the reaction mixture for 5 min, and then treated with H<sub>2</sub>O<sub>2</sub> to oxidize all arsenicals to pentavalency. The metabolites, MMA<sup>V</sup> and DMA<sup>V</sup>, were analyzed on a reversed phase column by high-performance liquid chromatography-inductively coupled argon plasma mass spectrometry (HPLC-ICP MS). Both mRNA and protein levels were highest in the liver. The intermediate expression of Cyt19 mRNA was observed in heart and testis. However, arsenic methylating activity was detected only in the liver cytosol using the current HPLC-ICP MS method.

## 152 THE ROLE OF VALENCE AND METHYLATION STATE ON THE ACTIVITY OF ARSENIC DURING MITOSIS.

A. D. Kligerman, C. L. Doerr and A. H. Tennant. *Environmental Carcinogenesis Division, USEPA, Research Triangle Park, NC. Sponsor: D. Wolf.*

Trivalent methylated arsenicals are much more potent DNA damaging agents, clastogens, and large deletion mutagens than are their inorganic and pentavalent counterparts. Previously, we had noticed that many of the arsenicals induced "c-type" anaphases characteristic of spindle poisons. In the present study, we exposed human lymphoblasts for 6 h to six arsenicals: sodium arsenite (NaAs5), sodium arsenite (NaAs3), monomethylarsonic acid (MMA5), monomethylarsonic acid (MMA3), dimethylarsinic acid (DMA5), and dimethylarsinic acid (DMA3). Slides were then prepared, and the mitotic indices (MI) were calculated. NaAs5 caused a small but significant increase in MI. MMA5 also caused only a slight increase in MI that just reached statistical significance. In contrast, DMA5 caused a highly significant increase in MI producing ~75% the MI of demecolcine, the positive control. NaAs3 had no significant effect on MI and was quite toxic. MMA3 induced more than a twofold increase in MI compared to the control. DMA3 gave inconsistent results. We also exposed each arsenical directly to tubulin and spectrophotometrically measured the effect on polymerization. None of the pentavalent arsenicals had a substantial effect on polymerization of tubulin. In contrast, NaAs3 inhibited polymerization at 1 mM and above, and MMA3 and DMA3 at 10 μM and above. Taken together, these results give a complex picture of how arsenicals may affect cells. Some are cytotoxic, which may prevent the cells from cycling, thereby reducing the MI. Simultaneously, at lower concentrations, these same arsenicals may react with the spindle and cause an apparent increase in MI by arresting the cells at metaphase or anaphase. Thus, the metabolites of arsenic are active not only as chromosome breaking and DNA damaging agents but can also interfere with cell division. They can effect this through interaction with the spindle potentially leading to aneuploidy, a common driving force in genomic instability and ultimately in tumor formation. [This abstract does not necessarily reflect EPA policy].

## 153 INORGANIC ARSENIC BIOTRANSFORMATION AND MMA(V) REDUCTASE/GSTO1-1 KNOCKOUT MICE.

U. K. Chowdhury, R. A. Zakharyan, M. D. Avram, M. Wollenberg, A. Hernandez, M. Kopplin and H. V. Aposhian. *Molecular and Cellular Biology, University of Arizona, Tucson, AZ.*

The hypothesis that GSTO1-1 knockout mice biotransformed inorganic arsenic differently than wild mice was tested. In the biotransformation of inorganic arsenic, MMA(V) reductase catalyzes the reduction of arsenate, MMA(V), and DMA(V) to the more toxic arsenic species. MMA(V) reductase and human GST-Omega (hGSTO1-1) are identical proteins. Methods: Male knockout mice, in which Exon 3, of the gene for GSTO1-1 has been eliminated, were injected i.m. with Na arsenate (4.16 mg As per Kg of body weight) and the arsenic species in tissues measured at 0.5, 1, 2, 4, 8, and 12 hours by HPLC-ICP-MS. The wild mice (W) used as controls were DBA/1LacJ. Results: The concentration of arsenate was greatest in the bladder and the kidneys and peaked in these tissues at 0.5 hour. The highest concentration of arsenite was in the kidneys and liver. MMA(V) concentrations were the lowest when compared with the other arsenic species. The highest concentration of MMA (III) was in the kidneys of both KO and W mice. DMA(V) accumulated more in the lungs and bladder, but the concentration of DMA(III) was highest in the bladder for both the KO and W mice. Conclusion: Our results suggest that there were only minor differences in the concentrations of arsenic metabolites in the tissues of KO and W mice. However, the MMA reductase/GSTO1-1 activity in the liver of KO mice was only 20% of that in wild mice. There appears to be another enzyme(s) able to reduce arsenic(V) species but to a small extent. (Supported by NIEHS Grant No. ES-04940).

## 154 DETERMINATION OF TRANSCRIPTION FACTORS IMPORTANT IN ARSENIC-INDUCED ALTERATIONS IN GENE EXPRESSION.

A. Hays<sup>1</sup>, R. Pandey<sup>2</sup>, R. Ahmed<sup>1</sup>, A. S. Andrew<sup>3</sup>, J. W. Hamilton<sup>3</sup> and C. Lantz<sup>1</sup>. <sup>1</sup>*Cell Biology and Anatomy, University of Arizona, Tucson, AZ*, <sup>2</sup>*Arizona Cancer Center, University of Arizona, Tucson, AZ* and <sup>3</sup>*Pharmacology & Toxicology, Dartmouth Medical School, Hanover, NH.*

Chronic arsenic ingestion has been linked with an increased incidence of cardiovascular and vascular disease and cancer in multiple organs, including the lung. What remains unclear are the disease risks and biological effects associated with chronic ingestion of arsenic at lower levels commonly found in the water supplies of the United States. To investigate these effects, C57BL/6 mice ingested drinking water with or without 50 ppb arsenic for five or eight weeks. RNA from three control and three arsenic exposed animals was labeled and hybridized on six independent Affymetrix mouse 430(A) arrays, each containing over 14 k full length genes.

Signals were normalized and statistical analysis for differential gene expression between the control and arsenic exposed groups was assessed. The genes with changing expression levels are involved in a variety of functional groups including: structural regulation, chaperones, receptors, signal transduction and immunological pathway members, cytokines, and enzymes. These data indicate that significant biological effects occur at drinking water arsenic concentrations routinely found throughout the US. To investigate regulation of these genes we used TRANSFAC® analysis tool, which provides comprehensive information on gene regulation at the level of transcription, which is generally considered the most important step in controlling gene expression. We examined transcription factors that were exclusively associated with either arsenic-induced up regulated genes or with arsenic-induced down regulated genes. Of interest were the zinc fingers, MAP kinase, and stress-induced transcription factors that were associated with arsenic-induced down regulated genes. These included: KR, GATA-1, GBF, Ttk69K, CBF1, SRF, TGA1A, and v-Maf. These data indicate that arsenic may down regulate gene expression by affecting transcriptional activation. Supported by NIEHS SBRP grants ES07373 and ES04940.

#### ARSENIC IN SEAFOOD: WHAT PERCENTAGE OF THE TOTAL IS INORGANIC ARSENIC?

L. L. Chappell<sup>1</sup>, J. Colman<sup>1</sup>, R. M. Lorenzana<sup>3</sup>, P. McGinnis<sup>2</sup>, R. Troast<sup>4</sup> and A. Yeow<sup>4</sup>. <sup>1</sup>Environ Sciences Ctr, Syracuse Research Corp, Syracuse, NY, <sup>2</sup>Syracuse Research Corp, Philadelphia, PA, <sup>3</sup>ORD Region 10, USEPA, Seattle, WA and <sup>4</sup>OSRTI, USEPA, Washington, DC.

One of the most significant sources of human exposure to arsenic is food, with the highest arsenic concentrations found in seafood. In most seafood, organic forms of arsenic, mainly arsenobetaine, predominate (80–99%); however, other arsenicals, both inorganic and organic, may also be present. Arsenobetaine is not considered toxic, but inorganic arsenic is toxic and carcinogenic. Consequently, the speciation of arsenic in seafood is a critical consideration for estimating human health risk from seafood consumption. Commonly, only the total arsenic concentrations are available. For estimating human cancer and non-cancer risks, an approximation is needed for the percent of the total arsenic that is inorganic. A survey and evaluation of the data on arsenic speciation in various types of seafood was performed in order to determine published concentrations of total arsenic and inorganic arsenic in finfish, aquatic invertebrates, and seaweed. Sources of data included the published literature and EPA documents, and covered seafood worldwide, as well as seafood from specific US sites. A goal of this survey was to determine if default values could be derived for the percent inorganic arsenic in various types of seafood. While average percent inorganic arsenic values typically are <10% for fish and shellfish, the percent inorganic arsenic values for individual samples of a particular type of fish or shellfish can vary widely from not detected to nearly 30%. Frequently, the quality of the data was not documented and the number of samples limited. In seaweed samples, the percent inorganic arsenic values vary even more widely, from <1% to 60%. Data were not adequate to determine whether the percent inorganic arsenic differs in seafood from contaminated versus uncontaminated areas. This literature review indicates that a nation-wide default that accurately characterizes the percent inorganic arsenic in fish, shellfish, or seaweed is not supported by the available published data.

156

#### ASSESSMENT OF EXPOSURE TO ARSENIC AND LIFE STYLE IN KOREAN.

J. Park<sup>1</sup>, W. Lee<sup>1</sup>, M. Choi<sup>4</sup>, E. Park<sup>2</sup>, K. Park<sup>3</sup> and S. Kim<sup>3</sup>. <sup>1</sup>Preventive Medicine, Chung-Ang University, Seoul, South Korea, <sup>2</sup>Pathology, Chung-Ang University, Seoul, South Korea, <sup>3</sup>Advanced Analysis Center, Korea Institute of Science and Technology, Seoul, South Korea and <sup>4</sup>Chung-Un University, Chung-Un, South Korea.

Arsenic(As) is widely distributed in environment and has been known as a human carcinogen. The main source of As in general population is a contaminated food or drinking water. We observed in previous study that seafood consumption increased urinary As metabolites, dimethylarsinic acid(DMA), in volunteers. In this study, we investigated the exposure level of As and life style/diet habit in Korean. We recruited 336 adults (137 males and 199 females) of over 30 years old from 3 districts (urban, rural and coastal areas). The subjects were interviewed for occupation, residence, smoking, drinking, drug, drinking water and past medical history, and were analyzed for diet habit by 24 hour recall method. Blood and urine sampled from subjects. Exposure level to As was evaluated with urinary total and inorganic As metabolites, and some biological indices, such as GSH, GPX, lipid peroxidation and uric acid, were analyzed. Urinary total As was analyzed by hydride generation method, and arsenic speciation was performed by using HPLC with ICP-mass spectrometry. The exposure level of As was age-dependent and affected by seafood consumption, while was negative correlated with animal protein, animal oil and meat consumption. The DMA was major arsenic species in urine. This result suggests that life style/diet habit could be role as one of factors to determine the exposure level to As in general population.

157

#### URANYL ACETATE INDUCED OXIDATIVE STRESS IN CHINESE HAMSTER OVARY AA8 CELLS: EFFECT ON DNA OXIDATION.

J. Orozco<sup>1</sup>, A. M. Hays<sup>1</sup>, M. Yazzie<sup>2</sup>, D. M. Stearns<sup>2</sup> and C. Lantz<sup>1</sup>. <sup>1</sup>Cell Biology and Anatomy, University of Arizona, Tucson, AZ and <sup>2</sup>Department of Chemistry and Biochemistry, Northern Arizona University, Flagstaff, AZ.

Environmental and occupational exposures to uranium as a result of uranium mining, residual mine tailings, uranium in drinking water and the use of depleted uranium in the military may lead to adverse health effects. Previous work has shown that uranyl acetate produced DNA strand breaks in the presence of vitamin C. The purpose of the current study was to determine whether uranyl acetate can cause DNA damage through production of reactive oxygen in mammalian cells. The ability of uranyl acetate to produce oxygen radicals was determined by loading CHO AA8 cells with the oxygen radical sensitive dye CM-H<sub>2</sub>DCFDA (Molecular Probes). Cells were exposed to uranyl acetate at concentrations up to 300  $\mu$ M and production of oxygen radical was determined using flow cytometry. Slight increases in radical production were seen immediately after addition of uranyl acetate to the cell suspension. Intracellular thiol status, as measured by the dye cell tracker green, was unchanged by the uranium exposure. In order to determine if the slight increase in radical production could lead to DNA oxidation, CHO AA8 cells were exposed to uranyl acetate at concentrations ranging from 50 to 300  $\mu$ M for 40 minutes or 24 hrs. Single cell gel electrophoresis (comet assay) was used to determine DNA strand breaks. No differences in total or oxidation dependent DNA strand breaks was seen between control and uranyl acetate exposed cells. These data indicate that uranium exposure alone may lead to minimal oxidative stress. However, the stress does not appear to be sufficient to cause significant DNA oxidation. Supported by NIH grants CA96320 and CA096281.

#### THE HPRT SPECTRA OF SPONTANEOUS, URANYL-ACETATE- AND HYDROGEN-PEROXIDE-INDUCED HPRT MUTANTS IN CHINESE HAMSTER OVARY EM9 CELLS.

V. H. Coryell and D. M. Stearns. Chemistry and Biochemistry, Northern Arizona University, Flagstaff, AZ.

Naturally-occurring uranium and depleted uranium (DU) are believed to be health hazards by virtue of both their chemical and radiological properties. The mechanism behind uranium's chemotoxic effects has yet to be elucidated. Previous work has shown that DU, as uranyl acetate (UA), was mutagenic at the hypoxanthine (guanine) phosphoribosyltransferase (hprt) locus in XRCC1-deficient CHO EM9 cells. The current study compared the mutations in these cells at the hprt locus brought about spontaneously and by exposures to UA and H<sub>2</sub>O<sub>2</sub> to suggest the molecular mechanism(s) that may be responsible for these mutations. Independent cultures of CHO EM9 cells were grown for 6 weeks to accumulate spontaneous mutations, or were exposed to 100  $\mu$ M H<sub>2</sub>O<sub>2</sub> or 200  $\mu$ M UA for 24 hours to induce mutations. Mutants at the hprt locus were selected with 6-thioguanine. The mutants' hprt mRNA was copied and amplified by RT-PCR and these cDNAs were sequenced. The genomic DNA of mutants with one or more exons absent in their cDNA sequences was isolated and the relevant hprt exons amplified by PCR. A total of 44 UA-induced, 33 spontaneous, and 17 H<sub>2</sub>O<sub>2</sub>-induced mutants were characterized; putative splicing mutants were not fully characterized. Base substitutions comprised 30%, 39%, and 12% of UA, spontaneous, and H<sub>2</sub>O<sub>2</sub> mutants, respectively. Insertions in cDNA sequences were 6 times more frequent in UA than spontaneous mutants, and no insertions were found in the H<sub>2</sub>O<sub>2</sub> mutants. Of the 52%, 58%, and 88% genomic deletions found in UA, spontaneous, and H<sub>2</sub>O<sub>2</sub> mutants, respectively, the frequency of spontaneous deletions that included more than one exon was 35% and 23% that of UA or H<sub>2</sub>O<sub>2</sub> mutants, respectively. This abundance of insertions and multixon deletions suggests that UA may generate mutations in ways that are distinct from both spontaneous and free-radical mechanisms, and points to strand breaks or crosslinks as being possible relevant DNA lesions. Supported by NIH grant CA096320.

#### CYTOTOXICITY, GENOTOXICITY AND MUTAGENICITY OF COMBINED EXPOSURES OF URANYL ACETATE AND SODIUM ARSENITE IN CHO CELLS.

Y. Monica<sup>1</sup>, W. H. Johnson<sup>1</sup>, J. T. Shelley<sup>1</sup>, H. M. Allison<sup>2</sup>, R. C. Lantz<sup>2</sup> and D. M. Stearns<sup>1</sup>. <sup>1</sup>Chemistry and Biochemistry, Northern Arizona University, Flagstaff, AZ and <sup>2</sup>Cell Biology and Anatomy, University of Arizona, Tucson, AZ.

High concentrations of uranium contaminate water sources in the Colorado plateau, the West Central Platform, and the Rocky Mountains. Arsenic levels have also been shown to be high in areas of uranium mining and processing, which are common in the Southwestern United States. This creates a potential for human co-exposures to arsenic and uranium. Previous work from our labs has shown that uranium as uranyl acetate (UA) caused DNA strand breaks *in vitro*, and was more cytotoxic and mutagenic in the XRCC1-deficient CHO EM9 cell line, than the

parental CHO AA8 line. Arsenic is known to inhibit DNA repair, to affect signal transduction, and to induce oxidative stress and apoptosis. The current hypothesis being tested is that if UA causes DNA damage and As(III) inhibits DNA repair or induces oxidative stress, then combinations of uranium and As(III) could be more toxic than either metal alone. This hypothesis was tested in CHO EM9 cells exposed to combinations of UA and sodium arsenite by measuring cytotoxicity through colony forming ability, mutations at the hypoxanthine (guanine) phosphoribosyltransferase (hprt) locus, and DNA damage using the comet assay. Cell survival data indicated a slight synergistic effect for combined exposures; however, 24 hr co-exposures to sodium arsenite at a range of 1-20 uM did not increase hprt mutations induced by 200 uM UA, and no increases in tail moment were observed for combined exposures by the comet assay. Thus under these conditions combined exposures of arsenic and uranium were not more genotoxic than individual exposures. Results from these studies could ultimately contribute to the interpretation of epidemiological studies in populations exposed to uranium by identifying confounding variables of human exposures. Supported by NIH grants CA096320 and CA096281.

#### GENOTOXICITY OF PARTICULATE URANIUM AND CHROMIUM.

**S. S. Wise**<sup>1,2</sup>, A. L. Holmes<sup>1,2</sup>, J. A. Moreland<sup>1,2</sup> and **J. P. Wise**<sup>1,2</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME and <sup>2</sup>Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME.

Depleted uranium (DU) and hexavalent chromate (Cr(VI)) are commonly used by the military and thus exposure of soldiers and non-combatants to these compounds is potentially frequent and widespread. Particulate forms of these metals are a concern because of their ability to impact and persist at bifurcation sites in the lung. Cr(VI) is a known human lung carcinogen and DU is considered a probable human carcinogen, affecting the bronchial cells of the lung. However, the mechanisms of Cr(VI)-induced carcinogenesis are unknown and only one investigation has studied particulate DU and only two have studied soluble DU in human bronchial cells. Thus the primary goal of this study was to characterize and compare the genotoxicity of Cr(VI) and DU in human bronchial cells. We found that lead chromate, was less toxic to human lung cells than similar concentrations of uranium oxide. Specifically, at concentrations of 0.5, 1, 5 and 10 ug/cm<sup>2</sup>, lead chromate induced 71, 43, 15, and 1 percent survival (relative to the control), respectively, while uranium oxide induced 57, 32, 1 and 0 percent survival respectively at these same concentrations. By contrast, we found that lead chromate was more clastogenic than uranium oxide in human lung cells. Uranium oxide induced 6, 9, 15 and 26 percent damage at concentrations of 0.5, 1, 5 and 10 ug/cm<sup>2</sup> while lead chromate induced 27 and 37 percent damage at the lower concentrations of 0.5 and 1 ug/cm<sup>2</sup>. At 5 and 10 ug/cm<sup>2</sup>, lead chromate induced cell cycle arrest and no metaphases were observed. Future work will consider potential effects of co-exposure to these cells and their ability to induce neoplastic transformation. This work is supported by a grant from the Army Research Office Department of Defense, and Grant # ES010838 from the National Institute of Environmental Health Sciences, National Institutes of Health.

#### NEPHROTOXIC EFFECTS OF DEPLETED URANIUM (DU) IN THE RAT. INTERACTIONS WITH STRESS.

**L. Tobias**<sup>1</sup>, **D. Barber**<sup>2</sup>, **K. Zimmerman**<sup>1</sup>, **S. Hancock**<sup>1</sup>, **J. Hinckley**<sup>1</sup>, **M. Ehrlich**<sup>1</sup> and **B. S. Jortner**<sup>1</sup>. <sup>1</sup>Virginia Tech, Blacksburg, VA and <sup>2</sup>University of Florida, Gainesville, FL.

Military use of DU has renewed interest in its toxicology. Data here are part of a larger study to assess neurotoxicology and toxicokinetics of DU and alteration by stress. Specifically we address the issue of the nephrotoxicity of soluble DU in the presence of stress. Adult male Sprague-Dawley rats were administered a single im dose of 0, 0.1, 0.3 or 1.0 mg/kg DU (as uranyl acetate). Just before day 0 dosing 1/2 were exposed to swim stress resulting in plasma corticosterone levels of 7644 +/- 131 (n=206) and 190 +/- 91 (n=200) ng/ml, mean +/- SD, for stressed and unstressed rats, respectively. Sacrifice was on days 1, 3, 7 and 30 (n=4/group/day). DU exposure in all rats resulted in dose-related elevation of blood serum urea nitrogen and creatinine (evident at day 1, further elevated by day 7, elevated with a downward trend by day 30). Serum albumin and hematocrit declined with time in high dose DU rats. Dose dependent increases in serum uranium values peaked at approximately 3 days. Renal lesions included prominent acute tubular necrosis at all treatment levels, primarily noted in the inner cortex and outer medullary stripe, with extension along the medullary rays in mid and high dose treatment groups. Tubular regeneration occurred rapidly in low dose (0.1 mg/kg) rats and was almost complete by day 30. High dose rats had more extensive tubular necrosis and a relatively

delayed regenerative response, with regions of multifocal chronic interstitial nephritis and cortical scarring on day 30. Rats receiving the mid dose (0.3 mg/kg) displayed lesions of intermediate severity. Stress had no effect on the nephrotoxicity. These data demonstrate that even very low doses of soluble DU are nephrotoxic, and that stress has no effect on this process. #### BIOLOGIC EFFECTS AFTER BRIEF INHALATION EXPOSURE TO URANIUM OXIDE OR DEPLETED URANIUM OXIDE AEROSOLS.

**E. F. Hahn**<sup>1</sup>, **E. B. Barr**<sup>1</sup>, **G. Bench**<sup>2</sup>, **J. Karlsson**<sup>3</sup> and **J. Lewis**<sup>3</sup>. <sup>1</sup>Lovelace Respiratory Research Institute, Albuquerque, NM, <sup>2</sup>LLNL, Livermore, CA and <sup>3</sup>University of New Mexico, Albuquerque, NM.

To study of the transport of inhaled uranium oxides to the brain, rats were exposed to aerosols of UO<sub>2</sub>, UO<sub>3</sub>, UO<sub>2</sub> + UO<sub>3</sub> or depleted UO<sub>x</sub> (DUO<sub>x</sub>). Control groups were exposed to TaO<sub>2</sub> or air only. The uranium compounds were purchased as 99.8% purity and the DUO<sub>x</sub> was prepared by heating DU 0.75% titanium metal to a 30 mesh powder and then ball-milling. Groups of 30 rats each were exposed for 15 min. to nominal aerosol concentrations of 500mg/m<sup>3</sup> and scheduled for sacrifice at 2 hr., 30, 180 and 365 days after end of exposure. The achieved aerosol concentrations were UO<sub>2</sub>, 572 mg/m<sup>3</sup>; UO<sub>3</sub>, 329 mg/m<sup>3</sup>; UO<sub>2</sub> + UO<sub>3</sub>, 302 mg/m<sup>3</sup> and DUO<sub>x</sub>, 609 mg/m<sup>3</sup>. The aerosol particle sizes were all respirable, ranging from 1.6 to 2.4 microm MMAD. Fifteen rats exposed to UO<sub>3</sub>, the most soluble of the compounds used, died 2 to 13 days post inhalation exposure (d.P.E.). All but one died of acute renal tubular necrosis and uremic pneumonia, characteristic of acute uranium-induced toxicity. Rats sacrificed 2 hr. P.E. had minimal nephropathy and minimal histologic changes in the lungs, regardless of exposure. In rats sacrificed 30 d.P.E., focal septal pulmonary fibrosis was present in 80-100% of those exposed to UO<sub>3</sub> or DUO<sub>x</sub>. None of those exposed to UO<sub>3</sub> and 17% of exposed to UO<sub>2</sub> + UO<sub>3</sub> had pulmonary fibrosis. The incidence of nephropathy was increased in all rats exposed to UO compounds relative to the 2 hr. sacrifice. In rats sacrificed 180 or 360 d.P.E. the pattern of increased incidence of nephropathy and pulmonary fibrosis continued in those exposed to the UO compounds. These results show that more soluble UO<sub>3</sub> can induce acute renal effects in rats after a brief inhalation exposure. In addition, pulmonary effects can be seen after brief inhalation of any of the UO compounds. These effects are most likely secondary to the acute renal toxicity. Research supported by US Army Medical Research Development Command under DAMD 17-01-1-0794

#### RENAL BIOMARKER RESULTS IN DEPLETED URANIUM (DU) EXPOSED GULF WAR VETERANS.

**M. A. McDiarmid**<sup>1,2</sup> and **K. Squibb**<sup>1,2</sup>. <sup>1</sup>Occupational Health, University of Maryland Medical Center, Baltimore, MD and <sup>2</sup>Depleted Uranium Followup Program, VA Maryland Health Care System, Baltimore, MD.

In the Exposure-Effect Pathway of toxicant insult (National Research Council, Committee on Biological Markers, 1987), intermediate perturbation steps are described in the continuum of insult that pre-date the ultimate health effect. Biomarkers of these intermediate steps (biologically effective dose, early biologic effect) allow qualitative and semi-quantitative estimates of these early, pre-clinical effects. Ideally, biomarker measures may serve as indicators of needed health interventions prior to progression to a clinically apparent and untoward outcome. In occupational cohorts exposed to renal toxicants, primarily heavy metals and solvents, a European Cooperative Study (*Diseases of the Kidney and Urinary Tract*, 2001 Schrier R.W. (Ed.), p. 1256), comprising a suite of renal biomarkers is underway. The aim of this collaboration is to determine if patterns of biomarker excursions are predictive of the specific toxicant of exposure. A cohort of Gulf War I soldiers who were victims of "friendly fire" involving depleted uranium (DU) munitions have been followed biennially over the last 12 years (McDiarmid, et al., 2000, *Env Res* 82:168-180; McDiarmid, et al., 2001, *J Occup Env Med*, 43:991-1000). Although no frank indicators of renal disease have been observed, during the last three surveillance visits (1999, 2001, 2003) spot urine samples have been submitted to the European Cooperative Study Group for biomarker analysis. Measures of B2 microglobulin, retinol binding protein (RBP), N-acetyl-B-D glucosaminidase (NAG), alpha<sub>1</sub>-microglobulin, microalbumin and total protein have been determined. Results from 2001 urine samples showed statistically significant increases in urine microalbumin and RBP concentrations standardized per gram creatinine in the group of soldiers excreting high urinary U and RBP mean concentrations were again elevated in 2003. These indicators of tubular effects are consistent with known renal targets of uranium and support the need for continued surveillance of this DU-exposed cohort.

## ASSESSING THE RENAL TOXICITY OF DEPLETED URANIUM AND OTHER URANIUM COMPOUNDS.

L. E. Roszell<sup>1</sup>, F. F. Hahn<sup>2</sup> and R. B. Lee<sup>1</sup>. <sup>1</sup>US Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD and <sup>2</sup>Lovelace Respiratory Research Institute, Albuquerque, NM.

The primary target for uranium toxicity is the kidney. The most frequently used guideline for uranium kidney burdens is the International Commission on Radiation Protection (ICRP) value of 3 µg U/g kidney, a value that is based largely upon chronic studies in animals. In the present effort, we have developed a risk model equation to assess potential outcomes of acute uranium exposure. Twenty-seven previously published case studies in which workers were acutely exposed to soluble compounds of uranium (as a result of workplace accidents) were analyzed. Kidney burdens of uranium for these individuals were determined based on uranium in the urine, and correlated with health effects seen over a period of up to 38 years. Based upon the severity of health effects, each individual was assigned a score (- to +++) and then placed into an Effect Group. A discriminant analysis was used to build a model equation to predict the Effect Group based on the amount of uranium in the kidneys. The model equation was able to predict Effect Group with 85% accuracy. The risk model was used to predict the Effect Group for soldiers exposed to DU as a result of friendly-fire incidents during the 1st Gulf War. This model equation can also be used to predict the Effect Group of new cases in which acute exposures to uranium have occurred.

## UTILITY OF PATIENT MAILED URINE SPECIMENS FOR RENAL BIOMARKER ANALYSIS IN DEPLETED URANIUM (DU) EXPOSED 1991 GULF WAR VETERANS.

K. S. Squibb<sup>1,2</sup>, M. Oliver<sup>1,2</sup>, P. Gucer<sup>1,2</sup>, S. Engelhardt<sup>2,1</sup> and M. McDiarmid<sup>1,2</sup>. <sup>1</sup>Program in Toxicology, University of Maryland School of Medicine, Baltimore, MD and <sup>2</sup>Depleted Uranium Program, VA Maryland Health Care System, Baltimore, MD.

Surveillance of health effects of chronic depleted uranium (DU) exposure in a cohort of 1991 Gulf War veterans is being conducted through the Baltimore VA DU Follow-up Program. Slow release of DU from metal fragments embedded in muscle tissue has resulted in ongoing exposure evidenced by elevated urine U concentrations. World-wide distribution of the affected cohort and logistic constraints of travel for participation in biennial surveillance assessments at the Baltimore VA have made it necessary to conduct urine U excretion surveillance by mail. More recently, concern about the development of renal insults as duration of exposure lengthens (now greater than 12 years) created the need to determine the feasibility of assessing renal proximal tubular function using mailed urine specimens. Tubes containing an aliquot of a stabilization buffer (1M imidazole, 2% Triton X-100, 20 mM benzamidine, 2000 U/ml Aprotinin, 1% sodium azide, pH 7.0) were mailed to each patient with instructions on how to collect, freeze and ship a specimen for overnight delivery. Specimens were analyzed for microalbumin, β2-microglobulin, retinol binding protein (RBP), α1-microglobulin, N-acetyl-β-D-glucosaminidase (NAG), intestinal alkaline phosphatase (IAP) and total protein by standard techniques. Results were consistent with samples collected at the Baltimore VA hospital during an in-patient admission within the last six months of obtaining the mailed-in specimen, indicating the utility of this method as a means of enhancing surveillance of renal proximal tubule function in this and other cohorts with chronic exposure to renal toxicants.

NK CELL CYTOTOXICITY EVALUATION: TECHNICAL AND ANALYTICAL ALTERNATIVES TO CONVENTIONAL <sup>51</sup>CHROMIUM RELEASE ASSAY.

E. R. Gore<sup>1</sup>, J. K. Gower<sup>1</sup>, E. Kurail<sup>2</sup> and D. J. Herzyk<sup>1</sup>. <sup>1</sup>Safety Assessment, GlaxoSmithKline, King of Prussia, PA and <sup>2</sup>Statistical Sciences, GlaxoSmithKline, King of Prussia, PA.

Natural killer (NK) cell cytotoxicity is commonly used to detect and/or characterize immunotoxic potential of new medicines and environmental agents. Moreover, European regulatory guidelines (CPMP/SWP/1042/99) specify use of NK cell cytotoxicity in the initial screening of new chemicals for immunotoxicity. The conventional and most widely used assay to measure NK cell cytotoxicity is based on <sup>51</sup>chromium release; however, hazardous and technically burdensome procedures associated with radioisotopes have prompted investigations into alternative methods. A fluorescent-based approach utilizing the lanthanide chelate, Eu<sup>+3</sup>-DTPA, was compared to <sup>51</sup>chromium release assay. Cynomolgus monkey peripheral blood mononuclear cells (PBMCs), pre-stimulated with rHuIL-2 (50 – 5000 U/mL), were cultured with NK target cells, K-562s, labeled with either <sup>51</sup>Cr or Eu<sup>+3</sup>-DTPA. A comparison of percent specific lysis indicated significant correlation between the two methods ( $r = 0.98$ ;  $p < 0.05$ ). Further evaluation of NK cell activity by Eu<sup>+3</sup>-DTPA release assay was conducted with human and non-human primate PBMCs pre-treated for 48 hours with culture medium or rHu-IL-2 (50 U/mL). Percent

lysis of K-562 target cells was converted to mean lytic units by statistical methods utilizing non-linear mixed effects model and Von Krogh's equation. Results from the analysis indicate that spontaneous killing of K-562 target cells by human NK cells is significantly greater than that of cynomolgus and rhesus monkey ( $p < 0.0001$ ). However, treatment with rHu-IL2 caused significant enhancement ( $p < 0.0001$ ) of NK cytotoxicity among all three species groups. These findings support utility of a fluorescent-based approach in the measurement of NK cell activity.

## ANTI-NKP46 IMPROVES DETECTION OF NATURAL KILLER CELLS IN MACAQUE BLOOD.

W. Frings and G. Weinbauer. Covance Laboratories GmbH, 48163 Muenster, Germany.

Immunophenotyping of lymphocyte subpopulations by flow cytometry has become an important and well established tool for detection of immunomodulatory actions of pharmaceuticals in toxicology. In humans, natural killer (NK) cells are identified by a combination of antibodies against CD16 and CD56 (defined as CD3 negative, CD16 and/or CD56 positive lymphocytes). It was observed that this CD combination is not well suited for macaques, since CD56 recognizes predominantly monocytes and is not strongly expressed on NK cells. Therefore NK cells are normally defined as CD3 negative and CD16 positive lymphocytes in macaque samples. In order to optimize the identification of NK cell in macaques, we tested another NK-marker, NKP46, which is highly specific for NK cells. Blood samples from six adult rhesus monkeys (Macaca mulatta), 9 adult and 25 juvenile cynomolgus monkeys (Macaca fascicularis, aged 5 to 13 years and 12 to 18 month, respectively) were tested using CD16 and NKP46 antibodies alone or in combination. In rhesus monkey, 97% of CD16 and/or NKP46 positive cells were detected by CD16 alone, but only 62% by NKP46 alone. The recognition pattern in cynomolgus monkey was different with CD16 recognizing 88 or 91% and NKP46 identifying 84 or 87% of the CD16 and/or NKP46 positive cells. These data indicate that a combination of these markers provides a better estimation of NK cell numbers as compared to CD16 alone. For rhesus monkeys, this difference is rather small with only 3 % of NK cells being not recognized whereas in cynomolgus monkeys approximately 10 % of NK-cells are not detected. It was also observed, that the CD4/CD8 ratio and the relative amount of NK-cells was significantly lower in juvenile versus adult/elderly cynomolgus monkeys. In conclusion, NKP46 can be used for optimized detection of NK-cells in macaque blood.

## IMMUNE SYSTEM DEVELOPMENT IN THE CYNOMOLGUS MONKEY: LYMPH NODES AND SPLEEN.

G. Habermann, S. Friderichs-Gromoll, J. Kaspereit and E. Buse. Covance Laboratories GmbH, 48163 Muenster, Germany. Sponsor: G. Weinbauer.

Immunosuppression and immunomodulation are highly relevant parameters during toxicological evaluation of biologics. Given the broad medical spectrum of biologics, information on the prenatal and ontogenetic development of the immune organs is becoming pivotal. Lymph nodes and spleen are peripheral sources of numerous immune cell types. Hence these organs are important targets for drugs and drug-related side effects. Organ development in the cynomolgus monkey was studied from day 35 of gestation (gd 35) until adulthood. Special emphasis was placed on immune cell generation during development. Histological standard stains and immunocytochemical methods (e.g. CD-antibodies) were used to distinguish between different immune cell subpopulations. At gd 35, spaces in mesenchyme were visible indicators of lymph node development in the cervical position cranial to the apertura thoracica. They were filled with a mesenchymal reticulum at gd 50 which was settled with first lymphocyte-like cells on gd 70. At gd 60 there was an initial immunoreactivity with anti-HLA-DR antibody (Human Leucocyte Antigen D Region) followed by CD3 immunoreactivity indicative for T-lymphocytes at gd 70. Until perinatally, lymph node development and maturation was followed by a cascade of immunoreactivities indicating lodging of natural killer cells (M1014), T-cells (CD2), B-lymphocytes (CD20) and B- and T-cell precursors (CD117), whereas T-helper (CD4) and T-suppressor cells (CD8) were first apparent in postnatal animals. This development pattern is similar to that reported for lymph nodes in humans. In conclusion, the cynomolgus monkey represents a suitable model for evaluation of the immune system in developmental toxicity studies.

## ANALYTICAL VALIDATION OF PERIPHERAL BLOOD IMMUNOPHENOTYPING FOR CYNOMOLGUS MONKEY.

R. Caldwell, J. Fishel, G. Leatherberry and P. Marshall. Covance Laboratories, Madison, WI. Sponsor: P. Thomas.

A study was conducted to evaluate the precision, linearity, antibody titer optimization, and stability of blood samples for a peripheral blood immunophenotyping assay in cynomolgus monkeys. Validation included quantification of total T lymphocytes, helper and cytotoxic T lymphocytes, B lymphocytes, and natural killer

(NK) cells using flow cytometry. Immunophenotyping was conducted using a dual-platform methodology and heterogeneous lymphocyte gating strategy. Potassium EDTA was used as the standard anticoagulant in order to facilitate the dual platform methodology. The intrasample precision was assessed by taking ten measurements of one immunophenotyping set from one peripheral blood sample per animal. Intersample precision was evaluated using ten immunophenotyping sets from one peripheral blood sample per animal. The linearity was determined by preparing replicate immunophenotyping samples with decreasing blood volumes. To assess antibody titer optimization, replicate immunophenotyping samples were prepared with decreasing antibody volumes. To assess stability, lymphocyte values for whole blood samples and fixed immunophenotyping samples were compared at multiple timepoints over a 72-hour period. Stability testing also included a comparison of lymphocyte values for blood samples shipped via overnight courier. The assay was determined to be accurate, precise and linear over a wide range of blood volumes. In addition, the antibody cocktail can be used at many dilutions. Both fresh whole blood and fixed immunophenotyping samples were stable over extended periods, and when shipped via overnight courier. During validation, it was discovered that to correctly delineate natural killer cells, serum must be removed from the peripheral blood sample prior to staining with the antibody cocktails. The validation has shown that the assay generates precise and reproducible data for detection of lymphocyte populations in peripheral blood samples from cynomolgus monkeys.

IMMUNOGENICITY AND IMMUNOTOXICITY ASSESSMENTS OF TWO DRUG AFFINITY COMPLEX COMPOUNDS IN CYNOLOGUS MONKEYS.

S. Wen<sup>1</sup>, V. Iordanova<sup>1</sup>, C. N. Papagiannis<sup>2</sup>, M. Rebelatto<sup>2</sup>, T. Najarian<sup>1</sup> and J. Castaigne<sup>1</sup>. <sup>1</sup>ConjuChem, Inc., Montreal, QC, Canada and <sup>2</sup>MPI Research, Inc., Mattawan, MI. Sponsor: J. Daniels.

The Drug Affinity Complex (DAC) is a technology that enables covalent binding (conjugation) of a drug to albumin, thus extending the half-life ( $t_{1/2}$ ) of the pharmacophore to a duration comparable to that of albumin. The immunogenic and immunotoxic potential of two DAC compounds, CJC-1131, a glucagon-like peptide (GLP-1) analogue, and CJC-1295, a growth hormone releasing factor (GRF<sub>1-29</sub>) analogue, were evaluated in Cynomolgus monkeys. Four monkeys/sex/group were administered multiple subcutaneous (SC) injections of a vehicle control and pharmacologically active doses of CJC-1295 (50 µg/kg), CJC-1131 (2 µg/kg), as well as native GRF<sub>1-29</sub> (50 µg/kg) and GLP-1 (2 µg/kg) as controls over a 6-month treatment period. Dosing occurred daily during Months 1 and 4, and weekly during Months 3 and 6. The animals were not dosed during Months 2 and 5, and for 28-day recovery period following the last dose. All animals were observed for clinical signs daily during the treatment periods and assessed for immunogenicity and immunotoxicity prior to dosing, and at the end of each month. Evaluation of the pharmacological activity of the test articles was after the first dose, and at the end of Months 3 and 6. There were no treatment-related effects on survival, clinical signs, peripheral blood immunophenotyping, leukocyte function (natural killer cell activity) or peripheral lymphocyte activation in this study. There was no clear indication of presence of neutralizing antibodies, as measured by pharmacological endpoints, i.e., oral glucose tolerance test (OGTT) for CJC-1131 and GLP-1. In conclusion, the two DAC compounds produced no evidence of immunogenic or immunotoxic effects in Cynomolgus monkeys.

**171**

DEVELOPMENT AND VALIDATION OF SEMI-QUANTITATIVE ASSAYS FOR TOTAL AND NEUTRALIZING PRIMATE ANTIBODIES AGAINST A HUMAN THERAPEUTIC MONOCLONAL ANTIBODY.

X. Guo<sup>1</sup>, D. Finco-Kent<sup>1</sup>, C. Soderstrom<sup>1</sup>, B. Cohen<sup>1</sup>, H. Wang<sup>1</sup> and T. Kawabata<sup>1</sup>. <sup>1</sup>Pfizer Inc., Groton, CT and <sup>2</sup>Pfizer Inc., Groton, CT.

A therapeutic human monoclonal antibody (Compound X) to a receptor that has been associated with the growth of certain tumors is being developed. Compound X binding to receptors results in receptor internalization and degradation, thus decreasing receptor expression. Preclinical toxicity studies in cynomolgus monkeys included the assessment of the anti-Compound X (primate anti-human antibody, PAHA) response. Semi-quantitative assays for total and neutralizing PAHA antibodies were developed and validated. The total PAHA assay is an ELISA-based assay and has demonstrated good intra- and inter-assay precision (4.1% and 1.6% respectively) and sensitivity. Antibody levels of approximately 0.624 µg/ml and greater are detectable in the assay. A bioassay was developed to determine the neutralizing activity of the PAHA. This involved using an ELISA to measure receptor levels in the MCF-7 tumor cell line after exposure to Compound X either with or without test serum. The bioassay is able to detect changes in receptor levels at 0.1-5ng/ml of Compound X. The Compound X-induced decreases in receptor levels

were attenuated with positive control anti-Compound X antibodies. The intra- and inter-precision are 9.2% and 15.95% respectively. The sensitivity of the bioassay is 1.25 µg/ml. Both validated assays were used to support regulatory toxicity studies for the compound. Preclinical toxicity studies demonstrated rapid development of PAHA that altered the pharmacokinetics of Compound X.

**172**

TEMPORAL STABILITY OF WHOLE BLOOD AND MONONUCLEAR CELL CULTURES TO SUPPORT LYMPHOCYTE PROLIFERATION FOLLOWING MITOGEN AND RECALL ANTIGEN STIMULATION.

M. Wing, S. Wilkins, J. Hubbard and K. Gilbert. , Huntingdon Life Sciences Ltd., Huntingdon, United Kingdom. Sponsor: S. Dean.

Immunology endpoints are increasingly being applied to preclinical and clinical studies to evaluate drug immunotoxicity and immunopharmacology. Because of the logistical delay which may occur between sample withdrawal and immune function analysis, it is necessary to evaluate the impact of this delay on the suitability of the test system. We have compared the stability of lymphocyte proliferation assays using unseparated whole blood with mononuclear cell cultures. Heparin blood was obtained from healthy volunteers and stored at room temperature. After 3-48 hrs, mononuclear cells were purified, then cultured in RPMI+10% human serum with PHA (phytohemagglutinin) or PPD (tuberculin purified protein derivative) for up to 6 days. Whole blood was diluted to 10% v/v with RPMI and cultured as above. The proliferating cells in both cultures were labelled with tritiated thymidine for the last 18 hrs of the assay, then incorporated radioactivity measured by liquid scintillation counting. Both cultures supported PPD and PHA responses after storage of blood at ambient temperature for at least 24 hrs. Peak stimulation for PHA and PPD was observed after 4 and 6 days respectively in both cultures, consistent with the known kinetics of a mitogen versus a recall antigen response. Importantly the hierarchy of responsiveness observed between the individuals was seen in both cultures using blood which had been stored for up to 24 hours. The results from whole blood cultures using 48 hr old blood indicated that the rank order for some individuals had started to change as the proliferative capacity of these cultures started to significantly decline. These results indicate that it is possible store blood for up to 24 hrs prior to performing a lymphocyte proliferation assay. Since there was no obvious difference between either culture, the inclusion of all cell types in the whole blood assay and the ease of set up offers an advantage over the traditional mononuclear cell culture.

PERIPHERAL LYMPH NODES: ISSUES WITH THE COLLECTION AND ANALYSIS FOR IMMUNOTOXICITY STUDIES.

P.J. Haley<sup>1</sup>, L. Chouinard<sup>2</sup>, P. Ciaccio<sup>1</sup>, D. Ennulat<sup>3</sup>, L. Gore<sup>3</sup>, S. Emeigh Hart<sup>1</sup> and J. Lapointe<sup>4</sup>. <sup>1</sup>Global Safety Assessment, AstraZeneca, Wilmington, DE, <sup>2</sup>CTBR, Montreal, QC, Canada, <sup>3</sup>GlaxoSmithKline, King of Prussia, PA and <sup>4</sup>Pfizer, Groton, CT.

There is great interest in identifying reliable, sensitive indicators of immunotoxicity in safety assessment studies following the finalization of regulatory guidances in the USA and Europe. Because evaluation of peripheral lymph node weights and histopathology from routine safety assessment studies has been proposed as standard procedure for identifying immunotoxic potential of new chemical entities, we elected to evaluate: 1) variability of weights for specific peripheral nodes, and 2) histomorphologic variability of specific peripheral lymph nodes, in normal rats. Popliteal lymph nodes (n= 87), spleen (n=196) and thymus (n=132) from control rats in ten studies conducted at three different laboratories were collected, weighed and microscopically examined. Control rat popliteal lymph node weights ranged\* as follows: AZ (4 studies) CTBR (1 study) GSK (2 studies) Across All ABS 1.5-5.5X 3.3-3.9X 4.4-5.7X 1.5-5.7X %BW 1.5-5.0X 3.3-4.7X 4.0-5.0X 1.5-5.0X Control rat spleen weights ranged as follows: AZ (2 studies) CTBR(4 studies) GSK (2 studies) Across All ABS 1.6-2.0X 1.5-2.0X 1.3X 1.3-2.0X %BW 1.3-1.6X 1.5-1.7X 1.3X 1.3-1.7X Control rat thymus weights ranged as follows: AZ (0 studies) CTBR(4 studies) GSK (2 studies) Across All ABS 1.7-2.6X 2.0-2.3X 1.7-2.6X %BW 1.3-2.9X 1.8-2.2X 1.3-2.9X \* Weight ranges expressed as ratio of highest to lowest weight (g). Popliteal nodes demonstrated considerable histologic variability for all lymph node compartments due to sectioning differences, marked variation of normal tissue architecture and variability in background immunostimulation. Histologic variation was less in control spleen and thymus. These data suggest that organ weights are more variable for popliteal node than spleen and/or thymus, and that peripheral lymph nodes histology from normal rats can be highly variable. Consequently, evaluation of popliteal lymph nodes is subject to variable interpretation.

VALIDATION OF A METHOD FOR THE DETECTION OF ANTI-PROTEIN-X IgG ANTIBODIES IN RAT AND DOG SERUM BY ENZYME LINKED IMMUNOSORBENT ASSAY (ELISA).

M. Ionescu, N. Rouleau, G. Desilets, A. Michaux, M. Duchesneau and L. LeSauter. *Immunology, CTBR Bio-Research Inc., Senneville, QC, Canada.*

The undesired host immune response against biopharmaceutical therapeutics have become a serious concern for manufacturers, regulatory agencies and clinicians, as the biopharmaceutical's immunogenicity could lead to serious side effects or loss of product efficacy. A qualitative ELISA for the detection of anti-Protein-X IgG antibodies was developed and validated at CTBR. The anti-Protein-X antibodies present in rat or dog serum are captured on a Protein-X coated plate and detected using secondary antibodies conjugated to peroxidase. Parameters validated included cut-off determination, specificity and recovery, precision and stability. The inhibition of the positive control antibody binding to the plate in the presence of Protein-X in excess (immunodepletion) or in dosing amounts (drug interference) was also assessed. High, medium, low and species (rat or dog immunoglobulin) positive controls were used in the validation. The cut-off was established as the mean value of individual lots of normal serum (rat or dog) plus 1.645 SD. The inter- and intra-assay precision, expressed as the coefficient of variation (CV), met the acceptance criteria of  $\pm 20\%$  for high and medium positive controls, and  $\pm 25\%$  for the low positive control. The minimum required serum samples dilution was established at 1/10. No prozone effect was evident for positive control antibody concentrations up to 100  $\mu\text{g}/\text{mL}$ . Stability of spiked serum samples at room temperature for approximately 6 hours, at approximately 40°C for approximately 24 hours, and after three freeze-thaw cycles at approximately -80°C met the acceptance criteria, with the difference of the stability samples being within  $\pm 25\%$  when compared to the control samples. The longterm stability at approximately -80°C is ongoing.

THE REAL TIME MONITOR OF ANTIBODY-CELL BINDING BY BIOSENSOR ASSAY.

K. Harada, N. Otake, S. Hayashi, E. Furukawa, Y. Kikuchi and J. Kawahara. *Pharmaceutical Development Laboratories, Pharmaceutical Division, Kirin Brewery Co., Ltd., Maebashi-shi, Gunma, Japan.* Sponsor: E. Weaver.

The binding of antibody(Ab) to cell with target antigen is generally detected by flow cytometry. Flow cytometry is useful for detecting whether Ab bind to cell or not. But, the association and dissociation can't be directly detected by flow cytometry. We tried direct monitor of Ab-cell binding and could monitor on real time by biosensor assay using Biacore 3000. Rituxan, human Ab drug, was immobilized on Biacore sensorchip with the level of about 10000 RU. Raji cells, Burkitt's Lymphoma cell line, at  $1 \times 10^4$ ,  $1 \times 10^5$  and  $1 \times 10^6$  cells/mL were applied on Rituxan-immobilized sensor chip, and the binding response contented association phase and dissociation phase could be directly monitored in the cell concentration dependent manner. Additionally, the binding response of Raji cells was inhibited when anti-Rituxan Ab was pre-treated. These results suggest that biosensor assay is useful for direct monitor of Ab-cell binding.

ADVANTAGE OF USING WHOLE SHEEP RED BLOOD CELLS VERSUS CELL MEMBRANE IN ELISA ASSAYS TO ASSESS IMMUNOSUPPRESSION *IN VIVO*.

T. Tsuchiya, A. Minakawa, H. Watanabe, E. Ohta, M. Sasaki, T. Ikeda, K. Samura and M. Nishikibe. *Tsukuba Safety Assessment Laboratories, Banyu Pharmaceutical Co., Ltd., Tsukuba, Ibaraki, Japan.* Sponsor: N. Imura.

To detect a T-cell dependent antigen-induced primary antibody response, an ELISA using sheep red blood cells (SRBC) membranes is generally used. A problem of this method is that SRBC-specific antibody titers are different among lots of SRBC membrane preparations and are not consistently detected in sera from all SRBC-immunized rats. In order to resolve the problem, whole SRBC instead of SRBC membranes were used in the present experiment. However, the ELISA using whole SRBC has not been widely used because of the weak attachment of SRBC to ELISA plates. The objectives of this study are to improve attachment of whole SRBC to ELISA plates and to validate the SRBC-specific antibody response assay using whole SRBC-ELISA. Male Sprague-Dawley rats were injected with  $3 \times 10^8$  SRBC/animal iv (Day 0) and bled on Day 6. To fix and attach SRBC to the plate, a small amount of high-concentrated glutaraldehyde solution was added after SRBC suspension was inoculated into a well of the plate. As a result of cell fixation procedure with glutaraldehyde, the attachment of SRBC to ELISA plates was maintained throughout ELISA procedures. With respect to lot differences of SRBC, antibody titers measured using the same lot used for immunization was nearly identi-

cal to those measured using different lots of SRBC. As additional advantages, IgM was detected in all of sera from rats immunized with whole SRBC-ELISA, but not SRBC membrane method. The ELISA method using whole SRBC in detecting immunosuppression in rats was validated with well-known immunosuppressive agents, cyclosporin and cyclophosphamide. The immunosuppressive effects of these compounds were observed at doses used in routine toxicological evaluation. These results indicate that the improved whole SRBC-ELISA method provides reproducible and reliable results in the T-cell dependent antibody response assay.

AN ALTERNATIVE KLH-BASED PROTOCOL FOR THE SRBC PLAQUE-FORMING CELL ASSAY: DOSE RANGE FINDER STUDY.

M. van Zijverden, E. Klein Koerkamp, P. van den Berg and A. Penninks. *Toxicology and Applied Pharmacology, TNO Nutrition and Food Research, Zeist, Netherlands.* Sponsor: V. Feron.

To assess potential effects of pharmaceuticals on the immune system, a primary antibody response to a T cell-dependent antigen is suitable to complete the initial screening phase (EMEA guidance CPMP/SWP/1042/99, and FDA Guidance for Industry, Immunotoxicology Evaluation of Investigational New Drugs Oct 2002). A standard protocol is based on immunization with the antigen sheep red blood cells (SRBC). Since there are different disadvantages related to this protocol, a new design is wanted, with a standard antigen (for example keyhole limpet haemocyanin, KLH), different time points for determination of the response (IgM as well as IgG), and less variability. This would greatly improve the assessment of T cell-dependent immunity. Therefore we assessed the response to KLH in rat during a 28 day treatment study with two known immunosuppressiva (cyclosporine A, cyclophosphamide), comparing different routes of KLH dosing (day 21). Both a single i.v. and i.p. injection appeared to be suitable in inducing a KLH-specific IgM and IgG response (measured at day 7 after injection), whereas especially cyclophosphamide induced a clear immunosuppression. In June 2004, a European group of labs has shared results and designed what they considered to be the optimal design for a validation study: the Immunotoxicity Inter Laboratory Project, to be performed in January 2005. Before this ring-study can take place, a dose range finder is currently being performed, in which the optimal dose of KLH is determined. In this study, three doses of KLH (100, 300, 900  $\mu\text{g}/\text{animal}$ ) are tested, in two strains of commonly used rats (Wistar, Sprague-Dawley), and these results will be presented as well. The final ring-study will involve different immunomodulating substances, measurement of both primary as well as secondary (IgM, IgG) responses, and a direct comparison with the traditional read-out (SRBC PFC-assay).

SENSITIVITY OF THE KEYHOLE LIMPET HEMOCYANIN (KLH) ELISA MODEL IS DIRECTLY RELATED TO DOSE USED FOR SENSITIZATION.

V. L. Peachee<sup>1,2</sup>, C. M. Sheth<sup>1</sup>, A. M. Halpen<sup>2</sup> and K. L. White<sup>1,2</sup>.

<sup>1</sup>*Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA* and <sup>2</sup>*ImmunoTox, Inc., Richmond, VA*.

The plaque assay, T-dependent antibody response to sRBC, has been reported to be a sensitive and predictive functional immune assay for detecting immunomodulatory compounds. It is one of the functional assays accepted by various regulatory agencies for evaluation of humoral immune responses. Numerous laboratories have chosen to use ELISA to the T-dependent antigen KLH as an alternative to the plaque assay. The objective of these studies was to compare the sensitivity of the KLH ELISA to plaque assay using known immunosuppressive agents. Dose response studies were conducted in female B6C3F1 mice with cyclophosphamide, CPS, (5, 10, 20, 40, 60 mg/kg); azathioprine, AZA, (25, 50, 100, 200 mg/kg); and dexamethasone, DEX, (0.1, 0.3, 1.0, 3, 5 mg/kg). Dosing began on day of sensitization and continued until sacrifice. Assays were evaluated on peak response day. In CPS treated mice, the mg/kg dose producing statistically significant suppression was 10 in the plaque assay, 60 using 100  $\mu\text{g}$  KLH (sensitizing dose), and 10 using 2 mg KLH. In AZA treated mice, 25 in the plaque assay, 200 using 100  $\mu\text{g}$  KLH and 100 using 2 mg KLH. For DEX treated mice, 3 in the plaque assay, none using 100  $\mu\text{g}$  KLH and none using 2 mg KLH. Additional studies demonstrated that a CPS dose of 20 mg/kg produced a response 9% of control in the plaque assay, 82% of control using 100  $\mu\text{g}$  KLH, 45% of control using 500  $\mu\text{g}$  KLH, 40% of control using 1 mg KLH and 9% of control using 2 mg KLH to sensitize. Ongoing studies in rats also indicate a sensitization dependent response in the KLH ELISA model. These studies demonstrate that the KLH sensitization dose dramatically affects the magnitude of suppression observed and must be considered when using the KLH ELISA for hazard identification and risk assessment. (Supported in part by the NIEHS Contract ES 05454).

## EVALUATION OF T CELL RESPONSES TO KEYHOLE LIMPET HEMOCYANIN IN THE RAT MODEL.

A. E. Hillegas, C. A. Genell, C. C. Maier and D. J. Herzyk. *Safety Assessment, GlaxoSmithKline, King of Prussia, PA.*

The rat primary antibody response model is routinely used to identify immunomodulatory or immunotoxic potential of novel drugs. In this model, the key parameters measured are anti-KLH IgM and IgG antibody responses in rats given a single intravenous dose of keyhole limpet hemocyanin (KLH). The robust anti-KLH antibody titers indicate that antigen-specific T cell help was provided, suggesting that this model could potentially be adapted to measure direct effects on T cells as well. To characterize antigen-specific T cell responses in this model, *ex vivo* stimulation with KLH of lymphocytes in spleen obtained 14 days after KLH administration was used to evaluate cytokine production and cell proliferation. IFN- $\gamma$  and IL-2 production were measured at the single cell level by ELISPOT and a panel of cytokines (IL-1 $\alpha$ , IL-1 $\beta$ , IL-2, IL-4, IL-6, IL-10, GM-CSF, INF- $\gamma$  and TNF- $\alpha$ ) secreted into supernatants were measured by multiplex bead-based assays (Bio-Plex). In the ELISPOT assays on splenocytes from KLH-immunized rats, there were KLH concentration dependent increases in the number of spot forming cells (SFCs) secreting IL-2 or IFN- $\gamma$  of up to 4 and 5-fold, respectively, relative to unstimulated splenocytes. In the Bio-Plex assay there were KLH-induced increases in IFN- $\gamma$ , GM-CSF and IL-4 in KLH-immunized rats, and KLH-dependent proliferation was greater in splenocytes from KLH-immunized rats than non-immunized control rats. These data demonstrate that KLH-dependent T cell responses can be measured in the anti-KLH primary antibody response rat model. The parallel evaluation of antigen-specific T cell and antibody responses in this model could contribute significantly to the understanding of mechanisms of drug-induced immunotoxicity.

## COMPARISON OF ANTIBODY TITER AND CONCENTRATION IN A RAT IMMUNOTOXICITY MODEL.

J. R. Piccotti, J. D. Alvey, C. Y. Malinczak and R. M. Slim. *Worldwide Safety Sciences, Pfizer Global Research & Development, Ann Arbor, MI. Sponsor: M. Bleavins.*

Numerous laboratories are developing assays to measure a primary T-cell dependent antibody response to evaluate the immunotoxicity potential of drug candidates. Methods evaluating antibodies specific to keyhole limpet hemocyanin (KLH) commonly measure antibody titers or quantitated concentrations ( $\mu$ g/mL); however, a direct comparison of the sensitivity of these approaches for evaluating immunosuppression has not been reported. The current study evaluated anti-KLH IgM responses in rats following treatment with cyclophosphamide (CP) by measuring endpoint titers and quantitating antibody concentrations. Male and female Sprague-Dawley rats were treated orally with CP at 3 and 6 mg/kg for 14 days. Animals were given a single intravenous injection of KLH at 0.35 mg/kg 5 days prior to sacrifice. Sera were diluted 1:100, and then serially diluted to 1:25, 600 or greater to determine anti-KLH IgM endpoint titers. To quantitate the concentration of anti-KLH IgM, a standard curve was generated using a rat anti-KLH IgM monoclonal antibody. The results of this study demonstrated a strong correlation ( $r^2 > 0.9$ ) between the endpoint titer values and the quantitated concentrations of IgM in control and drug-treated animals. Cyclophosphamide at 3 and 6 mg/kg caused statistically significant decreases in anti-KLH IgM endpoint titers and concentrations in male rats when compared to controls. The concentrations of IgM specific to KLH were decreased by 34% and 98% in males given CP at 3 and 6 mg/kg, respectively. In females, significant decreases (96%) in IgM concentrations were seen in rats dosed 6 mg/kg; however, statistical significance was not reached at 3 mg/kg. The quantitative data in females were consistent with the endpoint titer values. The findings of this study show good correlation between the quantitated antibody concentrations and endpoint titer data, and demonstrated comparable sensitivity. In addition, the magnitude of suppression seen following oral CP administration was comparable to previous studies using intraperitoneal injections.

## THE UTILITY OF HOST RESISTANCE ASSAYS IN LEAD CANDIDATE SELECTION AND PHARMACEUTICAL SAFETY ASSESSMENT.

S. Groom, C. Thompson and K. Rioux. *Toxicology, CTBR, Senneville, QC, Canada.*

The successful conduct of host resistance assays is partly an art and partly science, primarily because of the complexity of the host/pathogen interactions although the traditional reliance upon morbidity or survival as the parameter of interest has also been a factor. This poster presents data generated for a host resistance to listeria infection assay in which tissue infectivity and body temperatures were measured, in addition to, survival. Balb/C mice were pretreated with 20, 40 or 80 mg/kg doses of

cyclophosphamide, or saline, for 3 days prior to experimental infection with approximately  $2 \times 10^4$  CFU of *Listeria monocytogenes* by intravenous injection. Following infection, animals were monitored for mortality, signs of ill health and/or hypothermia and were euthanized on Day 6 or Day 10. Liver infectivity was '0.67, '1.35 and '78.25 of the saline control values for animals pretreated with cyclophosphamide at doses of 20, 40 and 80 mg/kg/day, respectively. These results validated the use of the 80 mg/kg/day dose as an immunomodulatory control in this experimental model. To illustrate the versatility of host resistance models for lead candidate selection as well as safety testing, data are also presented for a host resistance to *Candida albicans* infection assay adapted to screen compounds for anti-fungal activity and for a tumoral host resistance assay adapted to screen compounds for immunostimulatory activity. Finally, this poster presents methodological considerations for host resistance assays including techniques for experimental infection in a host resistance to influenza virus assay.

## ALTERED SIGNAL TRANSDUCTION IN HUMAN KERATINOCYTES FOLLOWING EXPOSURE TO BI-FUNCTIONAL ALKYLATING AGENTS.

G. D. Minsavage and J. F. Dillman. *Applied Pharmacology Branch Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Human basal keratinocytes are adversely affected by cutaneous exposure to vesicating agents. Both bis-(2-chloroethyl) sulfide [sulfur mustard; SM] and bis-(2-chloroethyl) methyamine [nitrogen mustard; NM] are vesicants and potent bi-functional alkylating agents capable of covalently modifying DNA and protein. Previous reports indicated that the NF- $\kappa$ B and p53 signaling pathways could be modulated following exposure to these agents. Here we investigate potential *in vitro* model systems to elucidate the initial effects of bi-functional alkylating agents on cellular signaling events. We hypothesized that SM and NM would rapidly induce p53 phosphorylation and I $\kappa$ B $\alpha$  degradation in keratinocytes cultured *in vitro*. Immortalized human HaCaT keratinocytes (a p53-mutated cell line) and cultured normal human epidermal keratinocytes (NHEKs) were exposed to 12.5, 50, 100 or 200  $\mu$ M SM for up to 4 hrs. SM-induced p53 phosphorylation increased in a concentration- and time-dependent manner. As determined by immunoblotting, SM exposure resulted in phosphorylation on serine 15 of p53 within 15 min in both cell lines. The total level of p53 remained unchanged in HaCaT cells and increased in NHEKs following 4 hrs of SM exposure. SM-induced phosphorylation of p53 was only partially blocked by pretreatment of the cells with caffeine, an inhibitor of cell cycle checkpoint kinases. Exposure of each cell line to NM resulted in phosphorylation of p53 similar to that seen after SM exposure. Loss of I $\kappa$ B $\alpha$  was observed only in NHEKs following exposure to 200  $\mu$ M SM or NM by 4 hrs. Treatment of keratinocytes with the mono-functional molecule 2-chloroethyl ethylsulfide or with bis-(2-hydroxyethyl) sulfide did not result in phosphorylation of p53 or I $\kappa$ B $\alpha$  loss within the 4-hr timeframe examined. These data provide a basis for understanding the initial biochemical and molecular events that are modulated in response to bi-functional alkylating agents in immortalized and normal keratinocytes *in vitro*.

## 2, 4, 6-TRINITROTOLUENE CAUSES REDUCTION OF ENOS ACTIVITY BUT PHOSPHORYLATES ENOS THROUGH ACTIVATION OF PI3K/AKT SIGNALING IN ENDOTHELIAL CELLS.

Y. sun and Y. Kumagai. *Social and Environmental Medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan. Sponsor: A. Naganuma.*

Exposure of humans to environmental pollutants causes a cardiovascular dysfunction, but the mechanism is not well understood. 2, 4, 6-Trinitrotoluene (TNT), which is widely used in explosives, is an important occupational and environmental pollutant. We have reported that TNT has a potent inhibitory action on the enzyme activity of neuronal NOS (nNOS) by shutting electrons away from the normal catalytic pathway, resulting in decreased nitric oxide (NO) formation and concomitant generation of H<sub>2</sub>O<sub>2</sub> derived from O<sub>2</sub><sup>-</sup>. However, our epidemiological study in TNT factory, China and experiments with rats revealed that TNT exposure caused an increased systemic NO production *in vivo*. Since H<sub>2</sub>O<sub>2</sub> can activate PI3K/Akt signaling, leading to endothelial NOS (eNOS) phosphorylation, we hypothesized that such a phenomenon caused by TNT exposure may be associated with an adaptive response to the chemicals. We found that although TNT inhibited eNOS activity in a cell-free system with IC<sub>50</sub> value of 49.4  $\mu$ M, exposure of bovine aortic endothelial cells (BAEC) to TNT (100  $\mu$ M) upregulated phosphorylation of eNOS that is regulated by activation of Akt, but not ERK1/2. These phosphorylations of eNOS and Akt caused by TNT were markedly blocked by wortmannin and LY294002, inhibitors of PI3K and NAC, a free radical scavenger. These results indicate that TNT-dependent phosphorylation of eNOS is mediated by presumably H<sub>2</sub>O<sub>2</sub> through PI3 kinase/Akt signaling.

PROTEIN KINASE C $\zeta$  MEDIATES LPS ACTIVATION OF NUCLEAR FACTOR KAPPA B (NF- $\kappa$ B) IN KIDNEY EPITHELIAL CELLS.

W. W. Polk, J. V. Kushleika, M. E. Ellis, P. L. Simmonds and J. S. Woods. *Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.*

PKCs are known to mediate multiple signaling transduction processes in mammalian cells. Here, we report the participation of the atypical PKC isoform, PKC $\zeta$ , in the activation of the mammalian transcriptional activator, NF- $\kappa$ B, by lipopolysaccharide (LPS) in kidney epithelial (NRK52E) cells. Treatment of NRK cells with LPS (1 $\mu$ g/l) rapidly induced NF- $\kappa$ B-DNA binding, as measured by EMSA, with maximal binding intensity by 30 minutes after LPS administration. This effect was preceded by rapid phosphorylation and degradation of the NF- $\kappa$ B inhibitor protein, I $\kappa$ B $\alpha$ . Pretreatment of NRK cells with various PKC inhibitors demonstrated that a cell-permeant pseudosubstrate specific to PKC $\zeta$  completely prevented LPS-induced NF- $\kappa$ B-DNA binding and reduced cytoplasmic I $\kappa$ B $\alpha$  phosphorylation, whereas other PKC inhibitors (Go 6976, Ro-31-8220, H8, bisindolylmaleimide) were without effect. Further studies showed that LPS promoted PKC $\zeta$  translocation from cytosol to membranal fractions and induced PKC $\zeta$  activity in a manner consistent with the kinetics of NF- $\kappa$ B-DNA binding. Transfection of cells with a PKC $\zeta$ -expressing plasmid (PKC $\zeta$ -WT) synergistically increased the duration and intensity of LPS-inducible NF- $\kappa$ B-DNA binding. Conversely, transfection with a dominant negative PKC $\zeta$  mutant (PKC $\zeta$ -DN) prevented LPS-induced degradation of I $\kappa$ B $\alpha$ . These findings support the view that PKC $\zeta$  mediates signaling events involved in the activation of NF- $\kappa$ B by LPS in kidney epithelial cells. Supported by ES04696, ES07032 and ES07033.

4-HYDROXYNONENAL-MEDIATED INHIBITION OF ERK-ELK-AP-1 SIGNALING.

B. P. Sampey, J. A. Doorn and D. R. Petersen. *Pharmaceutical Sciences, University of Colorado HSC, Denver, CO.*

Lipid peroxidation products (e.g. 4-hydroxynonenal, 4-HNE), and the extracellular-signal-regulated kinases 1 and 2 (Erk1/2) are implicated in many pathologic states (e.g. alcoholic liver disease). The mechanism by which chronic alcohol consumption inhibits Erk1/2 signaling is unknown. To establish the potential for 4-HNE to affect this kinase pathway, sequence analysis of the Erk1/2 proteins shows these enzymes to be rich in amino acids reactive toward 4-HNE (ie: His, Cys, Lys). To determine the mechanism(s) involved in hepatic Erk1/2 inhibition that correlates with lipid peroxidation, an *in vitro* system was utilized to demonstrate Erk-2 is a target for 4-HNE modifications. Additionally, tryptic digest and mass spectral analysis of the purified, adducted Erk-2 identified two specific modification sites at His178 and Cys63. Primary rat hepatocyte cultures were employed to verify Erk1/2 adduction *in situ* by 4-HNE at pathologically relevant concentrations. Using western blot analysis, it was confirmed that the Erk modification(s) resulted in a concentration-dependant inhibition of induced Erk phosphorylation, which corresponded to a decrease in kinase activity of the immunoprecipitated phospho-Erk. 4-HNE also inhibited the Erk1/2-mediated phosphorylation of Elk-1 and its substrate AP-1, in both total cell lysates and nuclear fractions. In fact, 4-HNE treatment of hepatocytes resulted in a decrease in activated AP-1, as determined by its ability to bind the TPA-responsive element (TRE) sequence. To our knowledge, these are the first data to show 4-HNE covalently modifies Erk1/2 both *in vitro* and in primary cell culture systems. The modification of His178, which lies in the phosphorylation-site of Erk-2, reveals a mechanism by which 4-HNE inhibits the Erk-Elk-AP1 survival pathway in hepatocytes. The comprehensive data presented here corroborate this hypothesis. Because Erk1/2 is central to proliferation and survival, 4HNE-mediated inhibition of the kinase may impact a multitude of disease states related by oxidative stress and lipid-peroxidation. (supported by NIH/AA09300 to D R P)

INORGANIC PHOSPHATE CONTROLS CELL GROWTH THROUGH AKT/MEK-MEDIATED ERK-DEPENDENT MNK1 TRANSLOCATION IN NORMAL HUMAN BRONCHIAL EPITHELIAL CELLS.

S. Chang<sup>1</sup>, G. R. Beck<sup>2</sup>, K. Lee<sup>3</sup>, D. Cho<sup>4</sup> and M. Cho<sup>1</sup>. <sup>1</sup>*Laboratory of Toxicology, College of Veterinary Medicine, Seoul National University, Seoul, South Korea*, <sup>2</sup>*Laboratory of Cancer Prevention, National Cancer Institute, Frederick, MD*, <sup>3</sup>*Laboratory of Molecular Oncology, Korea Institute of Radiological & Medical Sciences, Seoul, South Korea* and <sup>4</sup>*Reproductive Toxicology, National Institute of Toxicological Research, KFDA, Seoul, South Korea.*

Inorganic phosphate (Pi) is abundant in the diet, and the kidney where sodium-dependent Pi(Na/Pi) transport systems in the brush-border membrane mediate the rate-limiting step in the overall Pi absorptive process, is a major regulator of Pi

homeostasis. Among 3 Na/Pi co-transporters, two types (type II, III) have been identified in mammalian lung. The Pi transport into the lung cells is regulated mainly by dietary and serum Pi values. The potential importance of Pi as a novel signaling molecule and pulmonary expression of Na/Pi co-transporters with poor prognosis of lung cancer prompted us to begin to define the pathways by which phosphate regulates lung cell growth using nontumorigenic human bronchial epithelial cells (NHBE). Pi activated Akt phosphorylation on Thr308, and activated signal transmits on the MEK/ERK signalling cascades. Our data clearly indicate that Pi controls cell growth by activating the ERK cascades as well as the translocation of MnK1 into nucleus through manipulating the Akt and MEK pathways. Such Akt- and MEK-mediated signaling of Pi may provide critical clues for treatment as well as prevention of diverse lung diseases including cancer. Supported by BK21

ACTIVATION OF THE TRANSCRIPTION FACTOR AP-1 BY 2, 2', 4', 4'-TETRACHLOROBIPHENYL (TCB) INVOLVES EXTRACELLULAR SIGNAL-REGULATED KINASES (ERKs) ENHANCED EXPRESSION OF C-FOS PROTOONCOGENE AND IN RAT LIVER CELLS.

G. Chen, B. V. Madhukar and B. Wood. *Pediatrics/Human Development, Michigan State University, East Lansing, MI.*

Signal transduction pathways play a central role in cell proliferation, differentiation and many physiological processes through altered gene expression. In ongoing studies with polychlorinated biphenyls (PCBs) we observed that orthochlorine substituted congeners activated the extracellular signal-regulated kinases (ERKs) a sub-group of mitogen activated protein kinase (MAPK) family of signal transduction kinases in liver epithelial cells. The activation of ERKs may, in turn, activate nuclear transcription factors that regulate gene expression. In this study, we examined the enhanced DNA binding activity of the transcription factor AP-1 of WB-F344 rat liver epithelial cells in response to 2, 2', 4', 4'-tetrachlorobiphenyl (TCB) and the involvement of ERKs in the activation of AP-1. Using gel-shift assays and RT-PCR we examined AP-1 DNA binding activity and the induction of AP-1 components. Nuclear extracts from WB cells treated with the TCB (20.0  $\mu$ M) caused a time dependent increase in DNA binding activity. Gel supershift analysis showed that the DNA binding was due to c-jun protein and was independent of c-fos protein. In contrast, RT-PCR analysis showed that TCB increased the expression of c-fos mRNA but not that of c-jun in these cells. Pre-treatment of WB cells with an inhibitor of ERK kinase U-0126 (10.0  $\mu$ M), completely abolished AP-1 DNA binding and decreased the expression of c-fos gene. These results suggest that diorthochlorinated PCBs induce AP-1 transcription factor activity and alter cellular gene expression through ERK activation (supported by NIEHS/Superfund grant no. ES-04911 and a Philip Morris Research grant).

EFFECT OF EXTRACTION TECHNIQUE, LONG-TERM STORAGE AND GENDER ON GENE EXPRESSION PROFILES OF HUMAN WHOLE BLOOD.

S. Kim<sup>1</sup>, R. N. Murrell<sup>2</sup>, J. E. Schmid<sup>3</sup>, K. E. Thompson<sup>3</sup>, D. J. Dix<sup>3</sup> and J. C. Rockett<sup>3</sup>. <sup>1</sup>*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC*, <sup>2</sup>*Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC* and <sup>3</sup>*RTD/NHEERL/ORD, USEPA, Research Triangle Park, NC.*

Blood gene expression profiles (GEPs) may be a good surrogate for determining whether toxicologically-induced changes have occurred in inaccessible target tissues. For blood to be used in this way, it is first necessary to elucidate how biological and technical factors can contribute to the final GEPs. Blood was obtained from 42 adult volunteers. Two whole blood RNA extraction kits (PAX and ZR) were used to extract RNA. To determine the effects of storage, GEPs from blood which had been stored for 96 days in PAX tubes at -20C were compared to GEPs from blood of the same subjects (n=5 females) which had been isolated within 24h of collection. To determine the effect of isolation technique, RNA was isolated within 24h of blood collection (n=5 males) using both PAX and ZR. All samples were hybridized to Affymetrix genechips. RNA isolated after storage showed a slight decrease in quality. Hierarchical clustering and principal component analysis showed GEPs from the paired fresh and frozen samples partitioned by individual rather than time of preparation. GEPs from samples isolated using different RNA extraction methods partitioned by method rather than individual. GEPs also partitioned between the sexes. We conclude that biological differences account for the largest degree of variation in GEPs, with intergender variation being greater than intra-gender variation. Technical variation, whilst less significant, is nevertheless a contributing factor. Most important is the method of RNA collection/extraction. Long-term frozen storage also appears to affect GEPs to some degree. This may be related to a slight overall reduction in the quality of RNA obtained from blood which has been frozen for an extended time. ## NANBIOTECHNOLOGY: DEVICES TO QUANTIFY CELLS AND THEIR FUNCTIONS.

R. T. Emeny, T. J. Zieziulewicz, N. Mishra, J. N. Turner and D. A. Lawrence.  
Wadsworth Center, Albany, NY.

*In vivo*, the efficacy of an immune response is dependent on the existence of the appropriate types and numbers of immune cells and their ability to communicate. The ability of immune cells to properly communicate is dependent on their ability traffic to centers of interaction (secondary lymphoid organs) and effector sites (sites of infection or cancer) in tissues. Cell trafficking requires expression of chemokine receptors and adhesion molecules as well as cytoskeletal changes affecting cell deformability. A microelectronic device consisting of a 100  $\mu\text{m}^2$  electrode coated with antibody to capture specific cell types has been developed to quantify the absolute number of a lymphoid subset in one  $\mu\text{L}$  of blood. Three additional microdevice designs have been developed to assess cell deformability and chemotaxis. Differential deformability and chemotaxis occurs after various forms of stressors (e.g., oxidative stress and cold restraint), which cause a loss of reactive cellular thiols. Differences in deformability and chemotaxis have been observed with blood leukocytes from young (<6 mon) vs older (>18 mon) mice as well as with blood leukocytes after *in vitro* exposure to impermeant (copper:phenanthroline) or permeant (hydrogen peroxide) oxidants. In cold restraint stressed mice, the subset that appears most sensitive to loss of surface thiols is the NK population. Loss of surface thiols is shown to prevent lymphocytes from being able to flow through into 5  $\mu\text{m}$  channels or chemotaxis through 5  $\mu\text{m}$  gaps in response to SDF-1 $\alpha$  or C3a. Supported by the Nanobiotechnology Center, a STC program of NSF (ECS-9876771).

## A HEADSPACE PROCEDURE FOR THE QUANTIFICATION OF 1- AND 2-BROMOPROPANE IN HUMAN URINE.

C. B'Hymer and K. L. Cheever. BHAB, NIOSH, Cincinnati, OH.

A test procedure was developed to detect and quantify the levels of 1- and 2-bromopropane in urine. 1-Bromopropane (1-BP) is a commonly used industrial solvent, and 2-bromopropane (2-BP) is often found as an impurity component in industrial grade 1-BP. Both are of a health concern for exposed workers because of their chronic toxicity. Central neurological and peripheral neuropathy disorders have been reported in workers exposed to 1-BP; reproductive and hematopoietic disorders has been reported for workers exposed to 2-BP. In the test procedure described, urine samples were diluted with deionized water and placed into a sealed headspace vial. A static-headspace sampler (Teledyne-Tekmar Model 7000) was used to heat each sample at 75°C for a 35 minute equilibrium time. Quantification of the two analytes was by means of a gas chromatograph equipped with a dimethylpolysiloxane capillary column and an electron capture detector. 1-Bromobutane was used as an internal standard for this test procedure. A multi-level recovery study using fortified urine samples (0.5 to 8  $\mu\text{g}/\text{ml}$ ) demonstrated full recovery; 104 to 121% recovery was obtained. Precision ranged from 5 to 17 % for the 15 to 20 spiked samples at each level analyzed over multiple experimental trial days. The limit of detection for this test procedure was approximately 2  $\text{ng}/\text{ml}$  1-BP and 7  $\text{ng}/\text{ml}$  2-BP in urine. A six week storage study was conducted to determine the most appropriate method to collect and store fortified urine samples. Glass serum vials with crimped caps and Teflon lined septa stored at 4°C demonstrated full recovery of both 1-BP and 2-BP.

## EVALUATION OF TEST PROCEDURES FOR THE QUANTIFICATION OF URINARY (2-METHOXYETHOXY)ACETIC ACID.

K. L. Cheever and C. B'Hymer. Molecular and Genetic Monitoring, NIOSH, Cincinnati, OH.

(2-Methoxyethoxy)acetic acid (MEAA) is a metabolite and biomarker for exposure to 2-(2-methoxyethoxy)ethanol [diethylene glycol monomethyl ether, DEGME, or DiEGME], a glycol ether which is of concern because of general toxicity. Glycol ethers have been frequently reported to damage the hematopoietic system, the male reproductive system and have demonstrated fetal/embryonic developmental toxicity. Specifically of interest to this laboratory is the use of 2-(2-methoxyethoxy)ethanol as an anti-icing additive to the military jet fuel JP-8. 2-(2-Methoxyethoxy)ethanol is readily absorbed through the skin and of concern for human dermal exposure. Test procedures to quantify the level of MEAA in human urine were developed and compared. Gas chromatography using a mass selective detector and a 50-m X 20.20-mm (id) dimethylpolysiloxane capillary column were used in each procedure studied. Two derivatization procedures were used in this evaluation. First, MEAA was extracted from fortified urine with ethyl acetate. Esterification of MEAA to the corresponding ethyl ester was one approach, and de-

rivatization of MEAA to the corresponding t-butyldimethyl silane derivative was the second approach for gas chromatographic analysis. Recovery studies using 2, 5, 10 and 20  $\mu\text{g}/\text{ml}$  MEAA fortified human urine samples demonstrated good accuracy and precision for both procedures. Recoveries using the ethyl ester procedure varied between 95-105% with precision [measured as percent relative standard deviation (%RSD)] as high as 14.3%, and recoveries using the silylation reagent were between 94-99% with precision (%RSD) as high as 7.3%. The t-butyldimethyl silane derivative procedure was less labor intensive and demonstrated better precision. The diethyl ester derivative procedure had better chromatographic performance from the more extensive sample cleanup.

## AUTOMATIC BIOSENSOR ANALYZER FOR RAPID ASSAY OF NEUROPATHY TARGET ESTERASE (NTE) IN BLOOD.

V. V. Malygin<sup>1</sup>, G. F. Makhaeva<sup>1</sup>, N. N. Strakhova<sup>1</sup>, L. V. Sigolaeva<sup>2</sup>, L. G. Sokolovskaya<sup>2</sup>, A. V. Eremenko<sup>2</sup>, I. N. Kurochkin<sup>2</sup> and R. J. Richardson<sup>3</sup>.

<sup>1</sup>Institute of Physiologically Active Compounds RAS, Chernogolovka, Russian Federation, <sup>2</sup>Faculty of Chemistry, M. V. Lomonosov Moscow State University, Moscow, Russian Federation and <sup>3</sup>EHS Department, Toxicology Program, University of Michigan, Ann Arbor, MI.

Previous studies showed that whole blood NTE measured with a biosensor is a reliable biomarker of exposure to neuropathic (NP) organophosphorus compounds (OPs). For rapid assessment of human exposure to NP OPs, a prototype electrochemical flow-injection device for analysis of NTE in blood was created. The device operates automatically with 96-well plates and allows 8 samples to be analyzed simultaneously. NTE is assayed by the differential inhibition method using phenyl valerate as substrate. All sampling and analysis steps are carried out and monitored automatically. A "user friendly" interface enables all functions easily to be controlled and monitored by a computer and specially developed software, so that a minimum of operator effort is required. Data processing and calculation of NTE activity are done automatically using a phenol calibration curve. A new approach to construction of the amperometric biosensors was studied using layer-by-layer technology, resulting in 4-fold enhancement of biosensor sensitivity. Validation of electrode measurements was done using hen brain NTE. NTE activities and  $I_{50}$  values for NTE inhibitors determined with the standard spectrophotometric method were statistically identical to respective values obtained by the new LBL biosensor. Using the new device, blood and brain NTE inhibition by mipafox, DFP, ethyl- and propyl-dichlorvinylphosphates, and three fluorinated 1-aminophosphonates,  $(\text{RO})_2\text{P}(\text{O})(\text{CF}_3)_2\text{NHS(O)}_2\text{C}_6\text{H}_5$ , were well correlated ( $r = 0.995$ ,  $n = 7$ ), supporting the use of blood NTE as a biochemical marker of exposure to NP OPs. The results indicate that the new device could be used for rapid assessment of human exposures to NP OPs, e.g., to support consequence management and minimize risks of chemical terrorist attacks. (Supported by CRDF RB2 2488 and ARO DAAD19-02-1-0388).

## AN IMPROVED METHOD FOR THE QUANTITATION OF 8-HYDROXY-2'-DEOXYGUANOSINE IN BIOLOGICAL SAMPLES.

A. M. Luke<sup>1</sup>, S. Liao<sup>2</sup>, G. Boysen<sup>2</sup> and J. A. Swenberg<sup>1, 2</sup>. <sup>1</sup>Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC and <sup>2</sup>Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.

8-Hydroxy-2'-deoxyguanosine (8-oxodG) is an important biomarker of oxidative stress. Numerous methods have been established for quantitation of 8-oxodG, including HPLC-ECD, LC-MS/MS, GC/MS, ELISA and the comet assay using FPG. However, concentrations several orders of magnitude different have been reported for endogenous 8-oxodG, demonstrating the need for an improved quantitation method. Moreover, 8-oxodG is prone to artifactual formation, which must be prevented to achieve accurate quantitation. We hypothesized that coupling immunoaffinity (IA) chromatography to capillary LC-ESI<sup>+</sup>-MS/MS would provide the requisite accuracy, sensitivity, and specificity required to measure 8-oxodG in a variety of samples while using reasonable amounts of DNA. Capillary LC typically offers 10-fold greater sensitivity over micro LC; thus, we developed such a method for the analysis of 8-oxodG. The presence of the free radical scavenger 2, 2, 6, 6-tetramethylpiperidine-N-oxyl (TEMPO) during DNA isolation and enzymatic hydrolysis prevented artifactual formation of 8-oxodG from digested DNA samples and reduced the appearance of interference peaks compared to HPLC clean-up. 8-OxodG was quantified using stable isotope internal standard, [<sup>15</sup>N]<sub>5</sub>-8-oxodG. The limit of detection was determined with standards to be 0.5 fmol on column with a signal-to-noise ratio of 3, enabling the detection of 8-oxodG in as little as 5  $\mu\text{g}$  DNA. Preliminary data

demonstrated that endogenous 8-oxodG levels in freshly isolated calf thymus DNA was  $0.5 \pm 0.06$  8-oxodG/10<sup>6</sup> dG after IA clean-up, as compared to  $1.8 \pm 0.5$  after HPLC clean-up. This difference is thought to be due to lower amounts of interference, providing more accurate integration. Commercially available calf thymus DNA gave endogenous 8-oxodG levels of  $15.8 \pm 0.4$  8-oxodG/10<sup>6</sup> dG, reflecting artifact due to improper DNA isolation. Based on these preliminary data, this method appears to be suitable for the assessment of oxidative damage *in vivo*.

#### BIOLOGICAL SAMPLE ANALYSIS METHODS DEVELOPMENT AND VALIDATION FOR A TOXICOKINETIC STUDY OF BIS(2-CHLOROETHOXY)METHANE.

B. L. Burbank<sup>1</sup>, S. Hong<sup>1</sup>, J. D. Johnson<sup>1</sup>, S. W. Graves<sup>1</sup>, J. Merrill<sup>1</sup> and C. Smith<sup>2</sup>. <sup>1</sup>Chemistry Technical Center, Battelle, Columbus, OH and <sup>2</sup>NIEHS, Research Triangle Park, NC.

The purpose of this work was to develop and validate analytical methods supporting toxicokinetic studies of bis(2-chloroethoxy)methane (CEM) in rodents. Two methods were required for this purpose; one for CEM and a second for thiadiglycolic acid (TDGA), the metabolite of interest. For CEM the method consisted of extraction of the CEM from the plasma or tissue followed by gas chromatography coupled with mass spectrometry (MS) using selective ion monitoring (SIM). For thiadiglycolic acid the method consisted of methylation of the acid, followed by extraction of the metabolite with toluene and analysis by gas chromatography coupled with MS/SIM. CEM-d8 and ethyl-3-mercaptopropionate were used as internal standards (IS) for CEM and TDGA methods, respectively. TDGA was derivatized with boron trifluoride-methanol complex. Standards for the CEM analysis were prepared in rat plasma and acceptable for quantifying mouse plasma and rat and mouse heart and thymus. Standards for the TDGA were prepared in water because of the possibility of endogenous amounts in plasma and tissue. Quality control samples for each were prepared in both plasma and tissues from both species. Quadratic regression equations weighted 1/x were necessary to relate the response ratio of analyte to internals standard (y) to the concentration (x) of CEM and TDGA. The chromatograms from specificity samples of rat plasma and tissue (heart and thymus) had no significant interfering peaks. The analytical method met the acceptance criteria for accuracy and precision with a maximum relative error and relative standard error less than 20 %. The plasma and tissue samples of CEM and TGA were stable when stored at -20 oC. The analytical methods were determined to be acceptable for quantitation of CEM and TDGA that will be generated from a definitive toxicokinetic study of CEM in F344 rat and B6C3F1 mice. [Supported by NIEHS Contract No. N01-ES-05456.]

#### VALIDATION OF A METHOD FOR THE DETECTION OF ANTI-KEYHOLE LIMPET HEMOCYANIN (KLH) IgM ANTIBODIES IN THE NEONATAL/JUVENILE CD-1 MOUSE SERUM BY ENZYME-LINKED IMMUNOSORBENT ASSAY (ELISA).

N. Rouleau, C. Gelinas and L. LeSauter. Immunology, CTBR, Senneville, QC, Canada.

Recent Guidance (FDA, EMEA, MHLW/JPMA) have recommended the T-cell dependent antibody response (TDAR) assay to assess the immune response. There is also growing interest in the assessment of potential immunotoxicity to the developing immune system. In this study, neonatal/juvenile CD-1 mouse were immunized intra-peritoneally with 0.5 mL of keyhole limpet hemocyanin (KLH; 0.2 mg/mL) on 2 occasions (28 and 35 days pp) and blood was collected pre-KLH, and 7 and 14 days post-KLH. In addition, one group of mice received 25 mg/kg/day of cyclophosphamide for 4 consecutive days. The results obtained 7 and 14 days post-KLH were from 0.59 to 2.20  $\mu$ g/mL and 1.75 to 5.74  $\mu$ g/mL respectively for anti-KLH IgM, and from 0.28 to 18.96  $\mu$ g/mL and above the upper limit of quantitation ( $> 10 \mu$ g/mL) respectively for anti-KLH IgG. Cyclophosphamide did not significantly inhibit the anti-KLH antibody response at the dose tested. Validation of ELISA methods for the detection of anti-KLH IgM and anti-KLH IgG antibodies, included specificity/selectivity, linearity of dilution / parallelism, intra- and inter-assay precision and accuracy, stability, and prozone effect. The validated detection ranges were from 7.81 to 1000 ng/mL and 3.13 to 400 ng/mL for anti-KLH IgM and anti-KLH IgG respectively. The intra- and inter-precision and accuracy met the acceptance criteria and no prozone effect was observed up to 10000 ng/mL. The specificity of the ELISAs was good; the results were below LLOQ. The selectivity, linearity of dilution, parallelism, and stability of study samples at room temperature for approximately 6 hours, at 40C for approximately 24 hours, after 4 freeze-thaw cycles at -80oC, and long-term storage at approximately

-80oC are ongoing. The detection of anti-KLH IgM and anti-KLH IgG using these ELISA methods will prove useful in toxicology studies. Optimization of KLH immunization and cyclophosphamide dose is presently ongoing.

196

#### NANBIOTECHNOLOGY: GRATING-COUPLED SURFACE PLASMON RESONANCE (GCSPR), A CELL AND PROTEIN MICROARRAY PLATFORM FOR THE ANALYSIS OF TOXICANT EFFECTS.

D. Unfricht<sup>1</sup>, A. Sweatt<sup>1</sup>, S. Fernandez<sup>2</sup>, G. Jin<sup>1</sup>, T. Zieziulewicz<sup>3</sup>, D. Lawrence<sup>3</sup> and M. A. Lynes<sup>1</sup>. <sup>1</sup>Molecular and Cell Biology, University of Connecticut, Storrs, CT, CT, <sup>2</sup>Cientia, Inc., E. Hartford, CT and <sup>3</sup>Wadsworth Center, Albany, NY.

Grating-coupled surface plasmon resonance (GCSPR) technology is a novel method for molecular and cellular measurements in a microarray format. This technology uses an optical reflectance method to measure the optical properties of an aqueous medium close to a gold surface. Polarized light illuminates a gold surface coated with receptors and the angle of minimal reflectance is measured. An increase in mass, resulting from ligand or cell capture by surface-immobilized receptors, increases the GCSPR angle that is detected at multiple regions of interest (ROI) on each gold chip using a CCD camera to measure light intensity. We have previously shown that GCSPR can detect antibody, IL-2, and metallothionein. At present, the GCSPR assay approximates an ELISA in sensitivity and is amenable to improvements in sensitivity. GCSPR can also detect intact mammalian cells, bacteria, viruses and toxin analogs. GCSPR could detect Jurkat T cells captured by chip-bound anti-CD3 antibody. GCSPR was also used to detect apoptotic cells on immobilized Annexin V. *Bacillus globigii* (B.g.), a surrogate bacterial pathogen, was detectable using immobilized anti-B.g. antibody. These results indicate that complex samples can be characterized via GCSPRI according to the patterns of expressed cell surface antigens that uniquely identify each target population. Furthermore, specific and multiplexed detection was demonstrated on a single biosensor chip for B.g. and ovalbumin. We are currently developing a GCSPRI assay of polycyclic aromatic hydrocarbons, and are also developing PDMS stamps for micro-contact printing of receptors on the chip surface. Our results indicate that GCSPRI is a label-free, real-time, multiplexed technology that can be used to detect bacterial pathogens, toxins and toxicants in both environmental and clinical samples. Supported by NIEHS ES25490, NASA NAS 9-02016, and NSF DMI 0215192.

#### RAT KIDNEY INJURY MOLECULE-1 (RKIM-1) ELISA: A SENSITIVE ASSAY FOR EARLY DETECTION OF KIDNEY TUBULAR INJURY IN PRECLINICAL TOXICITY STUDIES.

V. S. Vaidya, T. Ichimura and J. V. Bonventre. Renal, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Kidney injury molecule-1 (Kim-1), a type 1 transmembrane glycoprotein, is upregulated ~10-100 fold following renal proximal tubular damage in humans, rats, and mice. Following renal injury the ectodomain of Kim-1 is shed into the rat and human urine and it can serve as a useful biomarker for early diagnosis of renal injury. The objective of the present work was to develop an ELISA for detecting Kim-1 in rat urine that can be used in preclinical drug development studies to screen for nephrotoxicity. A fusion protein of rat Kim-1 ectodomain and human Fc was generated by standard techniques and stably transfected into Chinese Hamster Ovary (CHO) cells. Transfected CHO cells were grown in serum free media and rat Kim-1-Fc was purified using a protein A-sepharose column to yield ~200  $\mu$ g/ml. Two mouse monoclonal antibodies were made against Kim-1Fc protein by standard antibody production techniques and these were used to construct a sandwich Kim-1 ELISA. To validate this ELISA we collected daily urine samples (0 to 10 days) from male Sprague-Dawley rats (n=5; 250-275 g) kept in metabolic cages and treated with three doses of cisplatin (2.5, 5, or 7.5 mg/kg respectively). Other rats were treated with 5 or 7.5 mg cisplatin/kg respectively and sacrificed at day 1, 2, 3, 4, or 5 (n = 4 for each group). Blood and kidneys were collected to estimate the extent of renal damage. The Kim-1 ELISA was sensitive over a concentration range of 200 pg/ml to 6 ng/ml. Kim-1 levels were undetectable in vehicle-treated controls. After 5 mg/kg cisplatin, Kim-1 was detectable in the urine on day 1, increased to 400 pg/ml on day 2, 2.5 ng/ml on day 3, and peaked at 7 ng/ml on day 5 whereas other conventional biomarkers (plasma creatinine, BUN, urinary N-acetyl- $\beta$ -glucosaminidase, glycoursuria, proteinuria) had normal values until day 3. Thus, we have established a non-invasive, rapid, sensitive, reproducible, and high throughput method to detect nephrotoxicity that can serve as a valuable tool for preclinical studies and risk assessment.

ANALYSIS OF HYDROXYMETHYLVINYL KETONE DERIVED 1, *N*<sup>2</sup>-PROPANODEOXYGUANOSINE BY LC-MS/MS.

M. W. Powley<sup>1</sup>, V. E. Walker<sup>2</sup> and J. A. Swenberg<sup>1</sup>. <sup>1</sup>*Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC* and <sup>2</sup>*Lovelace Respiratory Research Institute, Albuquerque, NM*.

The carcinogenic effect of 1, 3-butadiene (BD) is dependent on metabolism to several mutagenic metabolites. 1, 2,3, 4-Diepoxybutane (DEB) is hypothesized to be the main metabolite involved in mutagenicity following exposure to low levels of BD in mice, while metabolites of 3-butene-1, 2-diol (BD-diol) are thought to become involved in the mutagenic responses observed in both mice and rats at higher exposures. We have previously demonstrated that the dose-response curves for DNA and hemoglobin adducts of 3, 4-epoxy-1, 2-butanediol (EB-diol) mimic the dose-response curves for *Hprt* mutations in rodents exposed to BD-diol, suggesting that EB-diol is involved in this mutagenic response. However, because BD-diol can also be metabolized to hydroxymethylvinyl ketone (HMVK), it is necessary to evaluate the formation of this reactive metabolite. The goal of the current project was to develop a MS based method to quantify the  $\alpha$ , regioisomer of HMVK derived 1, *N*<sup>2</sup>-propanodeoxyguanosine ( $\alpha$ -HMVK-dGuo) and evaluate the formation of this adduct in exposed rodents. The method involved enzymatic hydrolysis of DNA, HPLC purification of the hydrolysate, and adduct measurement by LC-ESI<sup>+</sup>-MS/MS. Validation experiments indicated that the intra- and inter-experimental variabilities were 11% and 5-20%, respectively. The limit of detection approached 5 fmol of analyte standard injected onto the column or 5 fmol/200  $\mu$ g DNA. Using this method, DNA samples from liver of female F344 rats exposed to 0 or 36 ppm BD-diol for 4 weeks, and liver from female Sprague-Dawley rats exposed to 1000 ppm BD for 13 weeks were analyzed. Preliminary data showed that the adduct was not present in detectable amounts. While experiments must be conducted to understand the mechanism(s) behind these results, the data indicate that HMVK may be efficiently detoxified and unable to significantly contribute to BD-diol associated mutagenicity.

DEVELOPMENT AND VALIDATION OF A BIOANALYTICAL METHOD FOR TUNGSTEN.

D. Kracko<sup>1</sup>, R. Marr<sup>1</sup>, R. Arimoto<sup>2</sup> and J. McDonald<sup>1</sup>. <sup>1</sup>*Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM* and <sup>2</sup>*Carlsbad Environmental Monitoring and Research Center, Carlsbad, NM*. Sponsor: J. Mauderly.

Tungsten (W) has been nominated for study to the National Toxicology Program (NTP) because of reported associations between concentrations of W in drinking water and childhood leukemia. As part of the NTP study on W, the chemical disposition of W in plasma, liver, kidney, uterus, femur, and intestine or rodents are being defined after exposures by oral gavage, intravenous, or drinking water. Transplacental disposition is also being characterized by conducting drinking water exposures during gestation. Prior to disposition studies, a bioanalytical method has been developed and validated for each of the aforementioned tissues. The method includes both W and molybdenum (Mo), which is being measured in liver and small intestine because W replaces Mo in Mo dependant enzyme systems. The method requires acid digestion followed by analysis by inductively coupled plasma mass spectrometry. The method has been evaluated by spiking several concentrations of W and Mo into all of the tissues. The method showed acceptable linearity (correlation coeff. > 0.99), precision (coefficient of variation < 20 % across range), accuracy (within 20 % across range), recovery (within 20 %) and stability. The range of the assay spans -50 ng to 30  $\mu$ g per sample. The assay is suitable for chemical disposition studies of W in rodents.

N-(2, 3, 4, 5, 6-PENTAFLUOROPHENYL)DITHIOCARBAMATE AS A SENSITIVE DERIVATIZING REAGENT FOR THE ESTIMATION OF EPOXIDES OF 1, 3-BUTADIENE AND OTHER PETROCHEMICAL ALKENES.

R. M. Uppu. *Environmental Toxicology, Southern University and A&M College, Baton Rouge, LA*.

1, 3-Butadiene (BD) is one of the 20 highest volume chemicals produced in the US. In addition to its release from automobile exhaust in urban areas with traffic congestion, it is present in areas of petrochemical production. Apart from being an environmental pollutant, BD has been shown to be a probable human carcinogen falling under group 2A as per a recent evaluation by IARC. The enzymes of the cytochrome P450 system metabolize BD forming electrophilic intermediates 1, 2-epoxy-3-butene (EB) and 1, 2,3, 4-diepoxybutane (DEB), which, in turn, mediate the toxicity of BD. Several methods have been reported for the measurement of EB

and DEB, including GC-MS, MALDI-MS/MS, and <sup>32</sup>P-postlabeling followed by HPLC. These methods are cumbersome apart being expensive. In the present work attempts were made to develop a sensitive method for the determination of low levels of epoxides of BD, with an emphasis on simplicity of adaptation. We exploited the technique of derivatization of epoxides using N-(2, 3, 4, 5, 6-pentafluorophenyl)dithiocarbamate (PFDTC). The reaction of 2, 3, 4, 5, 6-pentafluoroaniline with carbon disulfide in the presence of strong base such as potassium ethoxide facilitated the preparation of PFDTC in a highly pure form. Standards and samples were analyzed by HPLC using a ODS column (4 mm x 150 mm; Supelco) with 40% acetonitrile in water as mobile phase (flow = 1 mL/min; detection: 234 nm). Using the present method low levels of epoxides of BD and other alkenes could be determined in cell culture, plasma, and tissue homogenates. The present method is highly reproducible with recoveries of  $\geq$ 95%, and as low as 1 pmol of the analyte can be successfully detected. This cost effective method can be standardized for routine analysis of epoxides and related compounds. Further, the present approach opens up avenues for improving the sensitivity by use of gas chromatography with electron capture detection. (Funding from NIEHS ES10018 and Louisiana Biomedical Research Network is acknowledged.

A LUMINESCENT METHOD FOR MEASURING DRUG-DEPENDENT CHANGES IN P-GLYCOPROTEIN ATPASE ACTIVITY.

J. Cali, R. Bulliet and D. Ma. *Promega Corp, Madison, WI*.

P-glycoprotein, also known as P-gp or MDR1, is an ATP-dependent efflux pump for a wide range of drugs that plays an important role in multi-drug resistance and certain adverse drug-drug interactions. Drugs that are transported by P-gp can be identified as stimulators of its ATPase activity and we have developed a luminescent method to detect this effect. The method relies on the ATP-dependence of the light-generating reaction of firefly luciferase. After a pool of ATP is first exposed to the P-gp ATPase ATP consumption is detected as a decrease in luminescence from a second reaction with firefly luciferase. The quantity of ATP consumed can be interpolated from a luciferase/ATP standard curve and from this the rate of ATPase activity can be calculated. We used a stabilized mutant of the luciferase enzyme in a formulation that provided stable, glow-style signals from multi-well plates. The method detected the stimulation of recombinant human P-gp ATPase activity by various drugs with fold increases and EC50s in good agreement with published values. Stable reagents are used to produce stable luminescent signals in a method that is easily configured in high throughput mode.

COMPARISON OF CALUX BIOASSAY AND HRGC/MS CHEMICAL ANALYSIS FOR THE DIOXIN LEVEL IN ENVIRONMENTAL MATRICES.

Y. Y. Sheen<sup>1</sup>, K. E. Joung<sup>1</sup>, K. N. Min<sup>1</sup>, J. S. Kim<sup>1</sup>, M. J. Seo<sup>1</sup>, S. Y. Yang<sup>1</sup> and Y. H. Chung<sup>2</sup>. <sup>1</sup>*Pharmacy, Ewha Womans University, Seoul, South Korea* and <sup>2</sup>*Water Research, National Institute of Environmental Research, Incheon, South Korea*. Sponsor: J. Chung.

Two different methods, HRGC/MS chemical analysis and CALUX bioassay were used for testing environmental water and soil samples if CALUX bioassay is applicable for the measurement of dioxin-like compounds. Furthermore, REPs for 17 kinds of dioxin-like compounds were determined and compared with WHO-TEFs of corresponding compounds. In the water samples, HRGC/MS-TEQs ranged from 0 to 2.281 pg-TEQ/L, and the highest TEQ value was 2.281 pg-TEQ/L. All samples except one sample showed total-TEQ values below the 1 pg-TEQ/L. HRGC/MS-TEQ values of soil samples was in a range of 0 to 65.6 pg-TEQ/g (dry) and the highest TEQ value was found in Maseo, where the refinery used to be near. CALUX-TEQs of water samples ranged from 0.7 to 18 pg-TEQ/L and CALUX-TEQs of soil samples ranged from 0.6 to 650 pg-TEQ/g (dry). The correlation between CALUX-TEQs and HRGC/MS-TEQs was very high ( $r^2 = 0.982$ ). However, the absolute values obtained by CALUX bioassay were always higher than that by HRGC/MS. To interpret this data, the REP values for 17 kinds of dioxin-like compounds were determined by CALUX bioassay. And REP values were compared with WHO-TEF values. The correlation between estimated REP-TEQs and HRGC/MS-TEQs turned out to be very high ( $r^2 = 0.998$ ) and the absolute values obtained by the analysis of HRGC/MS and estimated based on REP EC50 were appeared to be very similar. And also, there were good correlation ( $r^2 = 0.970$ ) between estimated REP-TEQs and CALUX-TEQs. However, the absolute TEQ values obtained by CALUX bioassay were always about ten times higher than the estimated REP-TEQ values. Thus, the CALUX bioassay can be highly recommended as an early warning system for routine measurement of dioxin-like compounds in environmental matrices. A METHOD FOR REPEATED JUGULAR-VEIN TOXICOGENETIC BLOOD SAMPLING IN CONSCIOUS, NON-CANNULATED RATS.

R. E. Kubaszky, G. Washer, N. Galliard, J. Laliberte and H. M. Moldovan.  
*General Toxicology, ITR Laboratories Canada, Baie d'Urfe (Montreal), QC, Canada.*

Repeated blood sampling for toxicokinetics is a common requirement in rat toxicology studies of pharmaceuticals. Most collection techniques have limitations in terms of the degree of invasiveness (e.g. retroorbital sampling or surgical cannulation), low sample volume (e.g. caudal venipuncture) or the need for terminal sampling and/or anesthesia (e.g. cardiac puncture or abdominal aorta). Jugular vein sampling under anesthesia raises concerns over drug-anesthetic interaction and the effect of anesthesia on the animals (e.g. potential to cause peripheral vasodilatation with associated risk of hemorrhage). Our laboratory routinely employs a jugular blood sampling technique in conscious, minimally-restrained rats. Critical to the success of the technique is extensive training in the method of minimal-restraint and in identifying the location of the jugular vein. The rat is held vertically in one hand with thumb and middle finger directing its forelimbs dorsally. The index finger pulls downward the back of the head/neck, in order to cause the rat's head to tilt upwards. This maneuver results in hyper-extension of the rat's upper body, and causes the jugular veins to be more evident on both sides of the sternoclavicular area. The other hand inserts the needle/syringe into the vein and the sample is withdrawn normally. Samples of at least 1 ml can be easily collected once the technique is mastered. On completion of the sampling, pressure is applied until the bleeding ceases. This technique enables repeat samples from the same puncture site within a single day and over multiple treatment days (dependant upon the volume of blood collected at each timepoint). Evaluation of clinical signs, behavior, body weight and food intake indicate no evidence of undue stress on the animals. Once the technique has been mastered, the success rate in terms of on-time sample collection is close to 100%, even in instances of very tightly scheduled collection times on multiple animals.

ELECTROSTATIC SURFACE CHARGE OF NANOPARTICLES ACTIVATES CNS MACROPHAGES (MICROGLIA).

M. Pooler<sup>1</sup>, O. Makwana<sup>1</sup>, J. Carter<sup>2</sup>, I. Beck-Speier<sup>3</sup>, W. Kreyling<sup>3</sup> and B. Veronesi<sup>2</sup>. <sup>1</sup>Toxicology Program, NCSU, Raleigh, NC, <sup>2</sup>NHEERL, USEPA, Research Triangle Park, NC and <sup>3</sup>National Research Center for Environment and Health, GSF Research Center, Munich, Germany.

Nanometer size particles carry free radical activity on their surface and can produce oxidative stress (OS)-mediated damage upon impact to target cells. The initiating event of phage cell activation (i.e., the oxidative burst) is unknown, although many proximal events have been identified (e.g., phagocytosis, increases in NADPH oxidase and NF- $\kappa$ B activity). Data generated in an immortalized microglia cell line (BV2) suggest a role for electrostatic surface charge in this activation. Nanometer size, spherical polystyrene micelle (SPM) beads, coated with either carboxyl (COOH-) or dimethyl amino ((CH<sub>3</sub>)<sub>2</sub>-N-) functional groups, measured 860 nm and 850 nm in diameter, respectively. Confluent BV2 cells were labeled with a H<sub>2</sub>HFF-based fluoroprobe that fluoresces in the presence of the reactive oxygen species, H<sub>2</sub>O<sub>2</sub>. Kinetic readings, collected on cells exposed to either COOH- or (CH<sub>3</sub>)<sub>2</sub>-N- coated SPM showed significantly higher fluorescence relative to baseline, in a concentration-response fashion. Subsequent experiments demonstrated that both COOH- and (CH<sub>3</sub>)<sub>2</sub>-N- labeled SPM stimulated significant levels of IL-1 $\beta$  and TNF $\alpha$  after 6 and 24 hr, respectively. Confocal microscopy was used to document the translocation of FITC-labeled COOH- SPM as they entered the microglia and formed large aggregate populations within the cytoplasm over a 24 hr period. Efforts are underway to determine if charge can stimulate other inflammatory changes proximal to the cytokine release in microglia and macrophages. Previous studies (Veronesi et al., 2003) reported that COOH- and (CH<sub>3</sub>)<sub>2</sub>-N- SPM could stimulate cytokines and their message in human epithelial cells, a phenomenon thought to be mediated through ASICS and VR1 receptors. It is currently unknown whether these or other charge sensitive (e.g., scavenger) receptors are involved in the electrostatic activation of phage cells. (This abstract has been reviewed by the USEPA, NHEERL and does not necessarily reflect its policy).

INCREASED REACTIVE OXYGEN SPECIES PRODUCTION AND METABOLIC ALTERATIONS IN MITOCHONDRIA OF EXPERIMENTAL DIABETIC RAT TISSUES.

H. Raza<sup>1,2</sup>, S. K. Prabu<sup>2</sup> and N. G. Avadhani<sup>2</sup>. <sup>1</sup>Biochemistry, UAE University, Al Ain, United Arab Emirates and <sup>2</sup>Animal Biology, University of Pennsylvania, Philadelphia, PA.

We have previously shown a tissue-specific increase in oxidative stress in streptozotocin (STZ)-induced diabetic rats. In this study, we have further investigated the production of reactive oxygen species (ROS) in different subcellular fractions of the

pancreas and other tissues in STZ-diabetes. We have demonstrated that mitochondria from diabetic rats have strong adaptive response against oxidative stress. Protein carbonylation, a marker for aldehyde-dependent protein oxidation, was increased in the cytosol and microsomes of the tissues while mitochondria exhibited only a marginal change. The maximum effect was seen in the pancreas. Nitric Oxide synthase (NOS) activity was increased in the pancreatic microsomes while mitochondrial and cytosolic NOS were inhibited. Pancreatic mitochondria showed an increased utilization of oxygen and increase in the activities of respiratory complexes II, III and IV. Expression of oxidative stress marker proteins, Hsp70, heme oxygenase 1 and GSTA4-4 was also increased in the pancreas from experimental animals. The expression of complex IV- 70 kDa and 30 kDa subunits were also increased in diabetic rats. These results may suggest an important role for mitochondria in diabetes. The increased mitochondrial metabolic adaptation may have implications in the progress of disease. (Supported by NIH Grant GM34883-18 (NGA) and FMHS/Terry Fox Research Funds (HR).

FAILURE OF DIETARY VITAMIN E TO PREVENT DOXORUBICIN-INDUCED CARDIAC MITOCHONDRIOPATHY *IN VIVO*.

J. M. Berthiaume<sup>1</sup>, P. Oliveira<sup>2</sup>, M. W. Fariss<sup>3</sup> and K. B. Wallace<sup>1</sup>. <sup>1</sup>*Biochem. & Mol. Biology, Toxicology Graduate Program, University of Minnesota, Duluth, MN,* <sup>2</sup>*Center for Neurosciences and Cell Biology, University of Coimbra, Coimbra, Portugal* and <sup>3</sup>*Pharmaceutical Sciences and Cancer Center, University of Colorado Health Sciences Center, Denver, CO.*

Doxorubicin (DOX) is a potent, broad-spectrum antineoplastic agent whose clinical use is limited by a cumulative and irreversible cardiomyopathy. The mechanism of toxicity is assumed to involve redox cycling of DOX by mitochondria to generate oxygen free radicals, making mitochondria both a primary source and target of oxidative injury. This investigation was designed to assess the cardioprotective potential of dietary d-alpha-tocopherol succinate (TOCO) in the prevention of mitochondrial cardiomyopathy resulting from DOX treatment. Adult male Sprague-Dawley rats received 7 weekly s.c. injections of either 2 mg/kg DOX or saline and had free access to either normal rat chow or rat chow supplemented with 2 g TOCO/kg (n=12, with 4 treatment groups). Dietary TOCO significantly enriched the d-alpha tocopherol content in serum, liver, and heart mitochondria, though not in whole heart. Heart mitochondria specifically showed a 2-fold increase in TOCO concentration. Oxidative injury in cardiac tissue due to DOX treatment was evidenced by a 3-fold increase in protein carbonyl content. TOCO was protective against this DOX-induced oxidative damage to cardiac proteins. However, dietary TOCO did not protect against mitochondrial dysfunction (defined by decreases in calcium loading capacity and respiration rates) or damage to cardiomyocytes noted by histological examination. From this we conclude that although dietary TOCO enriches cardiac mitochondrial membranes, either 1) this dietary-mediated enrichment of d-alpha tocopherol is not sufficient to protect mitochondrial membranes from oxidative injury or 2) oxidative stress alone is not responsible for the persistent mitochondrial cardiomyopathy caused by long-term DOX therapy. (Supported by HL-58016 and the 3Gasper and Irene Lazzara Foundation.

PRIMAQUINE-INDUCED HEMOLYTIC ANEMIA: ROLE OF SPLENIC MACROPHAGES, LIPID PEROXIDATION AND CYTOSKELETAL PROTEIN ALTERATIONS IN THE HEMOTOXICITY OF 5-HYDROXYPRIMAQUINE.

Z. Bowman<sup>1</sup>, J. D. Morrow<sup>2</sup>, D. J. Jollow<sup>1</sup> and D. C. McMillan<sup>1</sup>. <sup>1</sup>*Cell and Molecular Pharmacology, Medical University of South Carolina, Charleston, SC and* <sup>2</sup>*Department of Medicine, Vanderbilt University School of Medicine, Nashville, TN.*

We have recently demonstrated that the phenolic primaquine metabolite, 5-hydroxyprimaquine (5-HPQ), is a direct-acting hemolytic agent in rats. To investigate the fate of red cells *in vivo* after *in vitro* exposure to 5-HPQ, rat 51Cr-labeled red cells were incubated with 5-HPQ then re-administered intravenously to rats pretreated with clodronate-loaded liposomes, which have been shown to deplete splenic macrophages. Blood, spleen and liver samples were taken at various intervals and the radioactivity counted. In saline-liposome treated rats given 5-HPQ-treated red cells, an enhanced rate of removal of radioactivity from the circulation was observed as compared with vehicle-treated red cells. The loss was matched by a corresponding increase in radioactivity appearing in the spleen. In contrast, the rate of removal of radioactivity from the circulation of clodronate-liposome rats was significantly lower, and the appearance of radioactivity in the spleen was markedly delayed. Splenic removal of red cells damaged by treatment with 5-HPQ was not found to be associated with oxidative damage to membrane lipids. However, splenic removal was found to correlate with profound alterations in erythrocyte membrane skeletal proteins, principally in the form of disulfide-linked hemoglobin-skeletal protein adducts. The data indicate that splenic macrophages are responsible for removal of intact 5-HPQ-treated red cells and that cytoskeletal protein damage rather than membrane lipid oxidation may underlie the process of macrophage recognition.

OXIDATIVE STRESS CAUSED BY GLUTATHIONE  
SYNTHESIS INHIBITOR BUTHIONINE SULFOXIMINE  
RESULTS IN GENOME REARRANGEMENTS IN MICE.

R. H. Schiestl and R. Reliene. *Pathology, Environmental Health and Radiation Oncology, UCLA, Los Angeles, CA.*

Oxidative stress has been associated with cancer and other diseases, such as neurodegenerative, bronchopulmonary and cardiovascular diseases, to name a few. A number of xenobiotics, including cigarette smoke, diesel exhaust, and certain pharmaceuticals, cause oxidative stress. L-Buthionine-S, R-sulfoximine (BSO) is used to pharmacologically induce oxidative stress in research studies on the effects of oxidative injury. BSO induces endogenous oxidative stress by irreversibly inhibiting  $\gamma$ -glutamylcysteine synthetase, an essential enzyme for the synthesis of glutathione (GSH), a major cellular thiol antioxidant. We tested whether lowering cellular antioxidant capacity by BSO can lead to genomic rearrangements that may play a role in carcinogenesis or other genetic disease. We determined the frequency of DNA deletions, the levels of oxidative DNA damage measured by 8-OH deoxyguanosine (8-OHdG), and GSH levels, in mouse embryos exposed to BSO via drinking water given to pregnant dams. A low (2 mM) BSO dose treatment resulted in elevated frequencies of DNA deletions, higher 8-OHdG levels, but no changes in GSH concentration. A 10-fold higher (20 mM) BSO dose caused a 1.6-fold increase in DNA deletion frequency, 5-fold higher levels of 8-OHdG and depleted GSH to 30% of control level. The thiol antioxidant N-acetyl-L-cysteine had a protective effect against BSO treatment-induced DNA deletions. This study showed that endogenous oxidative stress results in genomic rearrangements that may play a role in development of cancer.

INHIBITION OF HSP90 $\alpha$  CHAPERONE ACTIVITY BY  
4-HYDROXY-2-NONENAL.

D. R. Petersen<sup>1</sup>, D. L. Carbone<sup>1</sup>, J. A. Doorn<sup>2</sup> and Z. Kiebler<sup>1</sup>. <sup>1</sup>*University of Colorado Health Sciences Center, Denver, CO* and <sup>2</sup>*University of Iowa, Iowa City, IA.*

Intracellular concentrations of 4-hydroxy-2-nonenal (4-HNE), malondialdehyde (MDA) and other lipid-derived aldehydes are elevated under conditions of oxidative stress. These aldehydes have a documented ability to modify proteins, thereby disrupting function. Proteomic analysis of rat liver subcellular fractions has demonstrated consistent modification of heat shock protein 90 (Hsp90) by 4-HNE and MDA in a model of chronic alcoholic liver disease. A series of *in vitro* studies were conducted to test the hypothesis that these lipid aldehydes interfere with Hsp90 chaperone activity. Purified recombinant Hsp90 $\alpha$  was treated with increasing concentrations of 4-HNE and MDA, resulting in a corresponding increase in the severity of protein modification by these aldehydes, demonstrated by immunoblot. 4-HNE protein adducts were confirmed and located by tryptic digest and HPLC-MS/MS peptide analysis. Pretreatment of Hsp90 $\alpha$  with 10  $\mu$ M 4-HNE resulted in a 68% inhibition in chaperone activity using a firefly luciferase refolding system, while the chaperone was completely resistant to inactivation following pretreatment with 10  $\mu$ M MDA. Pretreatment with 10  $\mu$ M 4-oxononenal (4-ONE), which is highly reactive towards Cys residues, also resulted in significant inhibition of Hsp90-assisted protein refolding. Because MDA is comparatively less reactive toward Cys than 4-HNE or 4-ONE, these results suggest a Cys specific mechanism. Finally, disappearance of luciferase was measured throughout the duration of the timecourse; however, rapid substrate degradation does not account for the observed 4-HNE-mediated inhibition of protein refolding, as demonstrated experimentally. The data presented here demonstrate modification of Hsp90 by 4-HNE and MDA in the livers of rats fed a chronic high fat/ethanol diet, and inhibition of Hsp90 chaperone-like activity by Cys-reactive lipid aldehydes. HIGH FAT DIET DIFFERENTIALLY AND SITE-SPECIFICALLY ALTERS LUNG GLUTATHIONE AND ACUTE CYTOTOXICITY IN MALE AND FEMALE MICE.

L. S. Van Winkle<sup>1</sup>, R. Stelck<sup>1</sup>, J. Graham<sup>2</sup>, K. Sutherland<sup>1</sup>, C. Brown<sup>1</sup>, J. Shimizu<sup>1</sup>, A. Buckpitt<sup>3</sup>, P. Havel<sup>2</sup> and G. Baker<sup>1</sup>. <sup>1</sup>*VM:APC, UC Davis, Davis, CA*, <sup>2</sup>*Nutrition, UC Davis, Davis, CA* and <sup>3</sup>*VM: Mol Biosci, UC Davis, Davis, CA.*

The average American consumes 37% of their calories from fat. Very little is known about the effect of high fat diet on lung cells. To evaluate the effect of diet on the lung, male and female C57Bl/6J mice were fed a high fat diet (58% kcal fat) or a matching low fat diet (10.5% kcal fat) beginning at 4 wks of age. Body weight and intra-abdominal fat pad weight (8-12 wks of age) were significantly increased by the high fat diet ( $P < 0.01$ ). Intrapulmonary and extrapulmonary airways were microdissected for analysis of glutathione (GSH; measured using HPLC) and total glutathione S-transferase activity (GST; turnover of CDNB substrate). GST activity did not vary significantly between high and low fat groups, by airway level or by

sex. However, GSH levels were significantly elevated by high fat diet in intrapulmonary airways of female mice ( $P < 0.01$ ). GSH levels in extrapulmonary airways of females and both airways in the male were unaffected by diet. Lungs from mice fed a high fat diet were more fibrous on dissection. Collagen deposition defined by picrosirius red staining was increased in mice fed a high fat diet. Additional animals were challenged with naphthalene (NA) i.p. to assess pulmonary responses to injury at 1 and 24 hrs. Female animals were more susceptible than males to NA injury. High fat diet reduced the amount of NA injury in the large intrapulmonary airways of female mice but had no effect in males. Male mice increased intrapulmonary GSH levels in response to NA injury and this was unaffected by diet. However, female mice were incapable of increasing their 1 hr GSH levels in response to NA injury in either the high or low fat diet groups. We conclude that a high fat diet changes the steady-state biology of the lung and that changes in response to diet and/or injury challenge are airway level and sex-specific. MOLECULAR PATHOLOGICAL ANALYSIS OF  
HEPATOCARCINOGENESIS IN MICE TREATED WITH  
DICYCLANIL.

M. moto<sup>1</sup>, T. Umemura<sup>2</sup>, M. Okamura<sup>1</sup>, Y. Kashida<sup>1</sup>, N. Machida<sup>1</sup> and K. Mitsumori<sup>1,2</sup>. <sup>1</sup>*Tokyo University of Agriculture and Technology, Tokyo, Japan* and <sup>2</sup>*NIHS, Tokyo, Japan.* Sponsor: M. takahashi.

In order to clarify the mechanism of hepatocarcinogenesis induced by dicyclanil (DC), molecular pathological analyses in the liver of mice were performed. At Experiment I, a large-scale cDNA microarray and the validation of RT-PCR were performed using the liver of mice given the diet containing 0 and 1500 ppm of DC for 2 weeks. The gene expressions of metabolism- or oxidative stress- related genes, such as Cyp1a, Aldh1a1, and Txnrd1, were predominantly up-regulated in the liver of mice treated with DC. At Experiment II, in addition to histopathological analyses, stress pathway-specific small-scale microarray and the validation of real-time RT-PCR were performed in the liver of mice using a two-stage hepatocarcinogenesis model, in which they were given 1500 ppm of DC for 7 weeks after injection of dimethylnitrosamine (DMN) with a partial hepatectomy (PH). The number of gamma-glutamyltransferase (GGT)-positive cell and PCNA Labeling Index were significantly increased in the liver of the DMN+DC+PH group that showed fluctuations of gene expressions of Cyp1a, Txnrd1, Ogg1, and Gadd45a related to oxidative stress or DNA damage/repair. To evaluate oxidative stress and DNA damage induced by the treatment of DC, 8-hydroxy-2-deoxyguanosine (8-OHdG) was measured in the liver DNA of two-stage hepatocarcinogenesis model mice given DC for 13 weeks (Experiment III). In addition to the formation of GGT positive foci, significant increases of 8-OHdG were observed in the DMN+DC+PH groups. These results suggest that DNA damage due to oxidative stress is partially associated with the mechanism of DC-induced hepatocarcinogenesis on mice.

ROLE OF NITRIC OXIDE IN DIESEL EXHAUST  
PARTICLE-INDUCED GENOTOXIC AND MUTAGENIC  
ACTIVITIES IN THE RAT LUNG.

J. Y. Ma<sup>1</sup>, H. W. Zhao<sup>1</sup>, X. J. Yin<sup>2</sup>, M. W. Barger<sup>1</sup>, J. K. Ma<sup>2</sup> and V. Catranova<sup>1</sup>. <sup>1</sup>*HELD, NIOSH, Morgantown, WV* and <sup>2</sup>*School of Pharmacy, West Virginia University, Morgantown, WV.*

Exposure of rats to diesel exhaust particle (DEP) has been shown to induce the formation of inducible nitric oxide synthase (iNOS) and elevate nitric oxide (NO) production by alveolar macrophages (AM). DEP are known to induce pulmonary inflammation and increase pulmonary susceptibility to infection through altered metabolic function and secretion of pro- and anti-inflammatory cytokines. The present study examines the role of NO in DEP-altered P450 activities which mediate genotoxic and mutagenic effects in the lung. Male Sprague-Dawley rats were intratracheally (IT) instilled with saline, DEP (35 mg/kg) or the DEP organic extract (DEPE). To illustrate the role of iNOS, another group of rats was treated with an iNOS inhibitor, aminoguanidine (AG, 100 mg/kg), by i.p. injection 30 min prior to and 3, 6 and 9 h after IT exposure. At 1 day post exposure, DEP-induced genotoxicity and lung-S9 dependent mutagenicity were monitored via comet assay and the Ames test with *S. typhimurium* YG1024, respectively. The results show that AG treatment markedly inhibited DEP-induced NO production by AM without affecting iNOS levels. DEP-exposed AM exhibited significant DNA damage compared to controls. Both DEP and DEPE induced CYP1A1 activity, which was significantly reduced by AG. However, DEP and DEPE attenuated CYP2B1 activity that was not altered by AG. CYP1A1 and CYP2B1 supersomes activated 2-aminoanthracene (2-AA) mutagenicity in the Ames test, suggesting that both CYP isoforms were involved in 2-AA activation. DEP- and DEPE-S9, although containing less CYP2B1, activated 2-AA to a similar extent as the control. AG treatment significantly lowered DEP- and DEPE-S9, but not control-S9, dependent activa-

tion of 2-AA mutagenicity. These results demonstrate that DEP exposure induces genotoxicity and mutagenicity in the lung. The organic component of the particle is responsible for DEP-induced CYP1A1, while NO plays a major role in DEP-induced mutagenic effects in the lung by regulating CYP1A1 activity.

#### CONTRIBUTION OF REACTIVE OXYGEN SPECIES TO PARA-AMINOPHENOL-INDUCED CYTOTOXICITY.

B. D. Foreman and J. B. Tarloff. *Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.*

Para-aminophenol (PAP), a metabolite of N-acetyl-para-aminophenol (APAP), causes toxicity in the renal proximal tubule. LLC-PK1 cells show a concentration-dependent loss of viability following a 4-hour PAP treatment with an EC50 of 0.1mM. Oxidation of PAP is a key step in its cytotoxicity, however the mechanism is yet to be determined. Previously we have shown that pre-incubation and/or co-incubation with ascorbic acid or glutathione (GSH) protects cells from PAP toxicity. This suggests that PAP may be causing the formation of reactive oxygen species (ROS). The present studies were designed to determine the presence of ROS and to identify the species that may be produced. LLC-PK1 cells were pre-treated with varying concentrations of catalase (0-100 units/ml), hydroxyl radical scavengers [DMTU (0-50mM) and mannitol (0-75mM)], or metal chelators [1, 10-phenanthroline (0-0.25mM), and bathocuproine (0-10 mM)] for 30 minutes. We then added 0, 0.1mM PAP or 0.15mM PAP, incubated for an additional 4 hours and measured cell viability 20 hours later. Menadione was used as a positive control as it undergoes redox cycling leading to formation of superoxide anions. Toxicity due to PAP was attenuated by all pre-treatments. These data suggest that PAP cytotoxicity is at least partially due to generation of reactive oxygen intermediates. Supported by NIH R15GM065196.

#### ENVIRONMENTAL BASIS OF NEURODEGENERATION (ND) AND AGING: DIBROMOACETONITRILE (DBAN) INDUCES PROTEIN OXIDATION, INHIBITS PROTEASOMAL ACTIVITY AND ALTERS CYTOSOLIC PROTEOME IN NEUROGLIAL CELLS.

A. E. Ahmed<sup>1</sup>, A. Kurosky<sup>2</sup>, J. R. Perez-Polo<sup>2</sup>, B. Kurian<sup>1</sup> and S. Jacob<sup>1</sup>. <sup>1</sup>*Pathology, University TX Medical Branch, Galveston, TX* and <sup>2</sup>*HBC&G, University TX Medical Branch, Galveston, TX.*

Our goal is to investigate the role of environment in fetal basis of ND/aging. Epidemiological studies indicated that *in utero* exposure to drinking water disinfectant byproducts (DBP) such as DBAN causes susceptibility to adverse pregnancy outcomes including CNS anomalies. Our previous studies indicated that DBP cross the placenta, retain in fetal brain cortex and hippocampus, where it induces oxidative stress (OS) and apoptosis. OS-mediated oxidation of amino acid side chains (protein carbonyls) are increased in ND/aging. Inefficient degradation of carbonylated proteins by proteasomes result in the accumulation of proteolysis resistant protein aggregates in ND/aging. We hypothesize that DBP-induced OS causes protein carbonylation, accumulation of oxidized proteins and proteasomal inhibition leading to neuronal loss. Neuroglial cells (Rat C-6 glioma) were exposed to DBAN (0-400 ppb) for 24 or 48 h. The results indicated that DBAN induced a concentration and time-dependent increase (128-136% of control, p < 0.05) in carbonylated proteins and a decrease (65-58% of control) in proteasomal activities. DBAN-induced changes in cytosolic proteome was evaluated by 2D gel electrophoresis (2DGE) at variable pH ranges. Replicate 2DGE from control and treated cells were scanned and analyzed using Progenesis software. Several of the expressed proteins with a  $\pm$  2 fold variation were identified using peptide mass finger printing- MALDI-TOF MS. Notable among the up-regulated proteins at 50-400 ppb DBAN was the proteasomal C-5 component [AA56702]. Identification of this protein was further validated by LC/MS/MS. Up-regulation of proteasomal C-5 protein indicates cellular stress to overcome carbonylated protein accumulation. In conclusion, increased accumulation of carbonylated protein following DBAN treatment may have a role in ND/aging. Ongoing studies using mice at various age levels will further clarify the role of DBP in fetal basis of ND/aging.

#### AGE-RELATED ALTERATIONS IN KAINIC ACID-INDUCED NEURONAL OXIDATIVE DAMAGE.

D. Milatovic<sup>1</sup>, S. Zaja-Milatovic<sup>1</sup>, R. C. Gupta<sup>2</sup> and T. J. Montine<sup>1</sup>. <sup>1</sup>*Pathology, University of Washington, Seattle, WA* and <sup>2</sup>*Toxicology, Murray State University, Hopkinsville, KY.*

Aging is associated with processes that lead over time to an increase in vulnerability to cellular and tissue damage and the probability of death. Recent research findings in brain have highlighted increased excitatory stimulation as contributors to aging

as well as neurodegeneration that accompanies Alzheimer's disease, HIV-associated dementia, ischemic stroke, and some forms of epilepsy and cerebral palsy. Associative data from patients' tissue and animal models have widely supported the hypothesis that neuronal oxidative damage is a major effector contributing to neurodegeneration. Mice exposed to kainic acid (KA, 1 nmol/5  $\mu$ l, icv) showed increase in cerebral F<sub>2</sub>-isoprostanes (F<sub>2</sub>-IsoPs, 158%), F<sub>4</sub>-neuroprostanes (F<sub>4</sub>-NeuroPs, 237%) and citrulline (249%) formation 30 min after the exposure. At the same time, pyramidal neurons in the hippocampus of young and old mice had significant reduction in dendritic length (60%) and spine density (40%) compared to control (100%). Pretreatment with ibuprofen (14  $\mu$ g/ml of drinking water for 2 weeks) or  $\alpha$ -tocopherol (100 mg/kg, i.p. for 3 days) completely blocked the icv KA-induced increase in cerebral F<sub>2</sub>-IsoPs, F<sub>4</sub>-NeuroPs, citrulline and decrease in spine density of hippocampal pyramidal neurons in young mice. Importantly, the neuro-protectant effects of these agents were lost in old mice following excitotoxicity. These data strongly suggest that different mechanisms are involved in cerebral neuroprotection of aged mice compared to young mice. The existence and nature of changes with aging have important clinical implications for therapeutic strategies for neuroprophylaxis in both normal aging and neurodegenerative disease. #### PROTECTIVE EFFECTS OF TAURINE AGAINST REACTIVE OXYGEN SPECIES IN ARPE-19 CELLS.

M. Tsang and R. Tchao. *Department of Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.* Sponsor: J. Tarloff.

Reactive oxygen species (ROS) are generated in the retina as a result of its constant exposure to light radiation. Damaged retinal cells may result in cell death without replacement. Loss of retinal cells is a factor in many ocular diseases. Retinal pigmented epithelial cells (RPE) are responsible for supporting the rods and cones during oxidative stress and the loss of RPE cell functions have been shown to be an early indicator of retinal disease such as age-related macular degeneration. Human RPE cells contain high concentrations of a number of antioxidants including taurine (B-amino-ethane-sulfonic acid), a non-essential amino acid. Deficiency in taurine can lead to loss of RPE cells and blindness. A human RPE cell line (ARPE-19) is used in this present study to model the effects of taurine on oxidative damage. The oxidative stress was provided by ROS such as hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) and menadione. ARPE-19 cells were routinely grown in DMEM/F12 medium plus 10% FBS and gentamicin prior to being switched to a serum free medium since FBS naturally contains taurine. Cells were seeded in 24 well plates and incubated with or without 2mM taurine for 72 hours. The cell cultures were then exposed to various concentrations of H<sub>2</sub>O<sub>2</sub> for 30 minutes. After rinsing, 10% alamarBlue in culture medium was added to each well and the fluorescence developed in 4 hours was measured in a fluorescent plate reader. The results showed that at high cell densities, the LD50 of H<sub>2</sub>O<sub>2</sub> cytotoxicity in ARPE-19 cells was raised from 7.8mM to 27.9mM in taurine treated cells. At low cell density, the LD50 was raised from 7.3mM to 65.8mM. Similar studies are being conducted with menadione cytotoxicity. We demonstrated that taurine, *in-vitro*, exhibits a partial protective effect against oxidative damage in ARPE-19 cells.

#### INDUCTION OF INFLAMMATORY MEDIATORS AND ANTIOXIDANTS FOLLOWING EXPOSURE OF MACROPHAGES TO PARAQUAT.

R. Mukhopadhyay<sup>1</sup>, J. P. Gray<sup>1</sup>, D. E. Heck<sup>2</sup>, A. T. Black<sup>1</sup>, V. M. Mishin<sup>2</sup>, M. Thiruchelvam<sup>1</sup>, D. A. Cory-Slechta<sup>1</sup> and J. D. Laskin<sup>1</sup>. <sup>1</sup>*Environmental and Occupational Medicine, UMDNJ-Robert W Johnson Med. School, Piscataway, NJ* and <sup>2</sup>*Pharmacology and Toxicology, Rutgers University, Piscataway, NJ.*

Paraquat (1, 1'-dimethyl-4, 4'-bipyridinium), a commercially important herbicide, is known to be a potent inducer of lung fibrosis in rodents and humans. It is also cytotoxic for nigral dopaminergic neurons and may be an environmental risk factor for Parkinson's disease. Macrophages are phagocytic cells known to release a variety of inflammatory mediators and are thought to participate in the cytotoxicity of paraquat. In many cell types including macrophages, paraquat undergoes redox cycling which can generate active radical species which cause modifications in cellular macromolecules and promotes lipid peroxidation. In the present studies we determined if paraquat activated macrophages to produce inflammatory mediators. Using RAW264.7 murine macrophages, we found that paraquat readily undergoes redox cycling as determined by the formation of hydroxyl radicals as measured by the hydroxylation of terephthalate. This was associated with a time- and concentration-dependent induction of heme oxygenase-1 (HO-1), a potent antioxidant. Following paraquat treatment macrophages were found to express cyclooxygenase-2 (COX-2), inducible nitric oxide synthase and tumor necrosis factor- $\alpha$  mRNA as determined by real time PCR. Maximal induction of HO-1 as well as production of inflammatory mediator gene products was observed after 24 hr and 300  $\mu$ M paraquat suggesting that they are coordinately regulated. Our data demonstrate

that paraquat is an effective inducer of a variety of pro-inflammatory and cytotoxic mediators in macrophages. Moreover, prostaglandins and nitric oxide, as well as TNF- $\alpha$  may mediate cytotoxicity in target cells. Paraquat is also an effective inducer of an antioxidant known to be important in promoting macrophage survival. Taken together, these data suggest a potential mechanism mediating the actions of paraquat. Supported by NIH grants ES05022, ES10791, CA093798 and CA100994.

ASCORBATE INHIBITS UROPORPHYRIA IN ASCORBATE-REQUIRING MICE.

P. R. Sinclair<sup>1,2</sup>, N. Gorman<sup>1,2</sup>, H. W. Trask<sup>1,2</sup>, A. Zaharia<sup>1,2</sup> and J. F. Sinclair<sup>1</sup>.  
<sup>2</sup> *Research, VA Med. Ctr, White River Junction, VT and <sup>2</sup>Biochem/Pharmacol-Toxicol, Dartmouth Med. School, Hanover, NH.*

Hepatic accumulation of uroporphyrin (URO) (uroporphyrin) is modulated by ascorbic acid (AA) in AA-requiring ODS rats. Microsomal CYP1A2-catalyzed oxidation of uroporphyrinogen is inhibited by AA. In patients with the human uroporphyrin disease, porphyria cutanea tarda (PCT), plasma AA is in the deficiency range. High hepatic iron levels enhance development of experimental uroporphyrin. Phlebotomy to remove iron is the important therapy in PCT. In this study, AA-requiring mice (*Gulo(-/-)*) in a C57BL/6 background) were used to examine the effect of AA in uroporphyrin induced by treatment with PCB126, and 5-aminolevulinate (ALA), with and without iron dextran treatment. Mice were continuously fed either low (75 ppm) or high (1000 ppm) AA in the drinking water. At low AA consumption, yielding hepatic AA in the range of 0.15-0.25 mM, hepatic URO levels after 2 weeks of ALA feeding were 4-6 fold higher than when animals were given AA sufficient to raise hepatic AA to 0.7-0.9 mM, similar to wild-type levels. When animals were administered Fe dextran (500mg Fe/kg), as well as PCB and ALA, high levels of hepatic URO accumulated, regardless of the amount of AA consumed. Hepatic AA levels were not significantly affected by the iron dextran. These data indicate that in the presence of excess hepatic iron, the protective effect of AA is greatly diminished. This may be due to a higher level of oxidative stress produced by the Fe loading. In conclusion, the results of this study further support the important role of AA in regulating development of uroporphyrin, but indicate that this effect can be overcome by excess iron in the liver. This work was supported by the Department of Veterans Affairs and NIH ES06263.

DETERMINATION OF PARAMETERS INDICATIVE FOR OXIDATIVE STRESS IN CARBON TETRACHLORIDE TREATED RATS.

P. Sagelsdorff<sup>1</sup> and Y. Balduchelly<sup>2</sup>. *Mechanistic Toxicology, RCC Ltd., Fuellinsdorf, Switzerland and <sup>2</sup>Chimie, HEVs, Sion, Switzerland.* Sponsor: K. Sachsse.

A role of oxidative stress has been proposed in the toxicity of numerous chemicals, in the process of ageing as well as in the pathogenesis of many diseases and carcinogenesis. Oxidative stress is known to be followed by cellular and tissue damage whereby lipids and proteins are the major targets. The aim of this study was to compare the sensitivity of different markers for oxidative stress in male Wistar rats treated with carbon tetrachloride (1 ml/kg body weight). As a measure for lipid peroxidation hepatic isoprostane F2 $\alpha$  was determined by ELISA and LC-MS/MS following solid phase extraction. Hepatic malonedialdehyde was analysed following derivatization with thiobarbituric acid by HPLC with fluorescence detection. As a measure for cellular antioxidants in the liver  $\alpha$ -tocopherol and ascorbic acid were determined by HPLC, and reduced as well as oxidized glutathione by spectrophotometry following derivatization dithio-bis-nitrobenzoic acid. Two and 6 hours after treatment, hepatic 8-isoprostane F2 $\alpha$  concentrations were maximally increased by a factor of about 40 and 13, respectively. Malonedialdehyde was increased only by a factor of 1.5.  $\alpha$ -Tocopherol and ascorbic acid concentrations in the liver were increased to 160% and decreased to 40%. The glutathione status in the liver was not influenced following treatment. In conclusion, the present study demonstrates the sensitivity of hepatic 8-isoprostane F2 $\alpha$  concentration as marker for oxidative stress induced by carbon tetrachloride.

6-HYDROXYDOPAMINE ACTIVATES THE ANTIOXIDANT RESPONSE ELEMENT THROUGH A COMBINATION OF OXIDATIVE, EXCITOTOXIC, AND STRUCTURAL FACTORS.

R. J. Jakel<sup>1,2,3</sup>, J. T. Kern<sup>3</sup>, D. A. Johnson<sup>3</sup> and J. A. Johnson<sup>1,3</sup>. *Neuroscience Training Program, University of Wisconsin, Madison, WI, <sup>2</sup>Medical Scientist Training Program and UW Medical School, University of Wisconsin, Madison, WI and <sup>3</sup>Pharmaceutical Sciences, University of Wisconsin, Madison, WI.*

Parkinson's disease (PD), a progressive neurodegenerative disorder, is characterized by loss of midbrain dopaminergic neurons. The etiology of sporadic PD is unknown; however, oxidative stress is thought to play a major role in disease patho-

genesis. The antioxidant response element (ARE) is a cis-acting enhancer element that is upstream of many phase II detoxification and antioxidant genes. Transgenic reporter mice engineered to express ARE-driven human placental alkaline phosphatase (hPAP) have been shown to be *in vivo* and *in vitro* sensors of oxidative stress. 6-hydroxydopamine (6OHDA), a mitochondrial complex I inhibitor and oxidative stressor, is a toxin used to model sporadic PD. 6OHDA-induced toxicity can be attenuated by exogenous antioxidants. Additionally, 6OHDA shares some structural similarities with hydroquinone and tert-butyl hydroquinone, two potent activators of the ARE. We hypothesized that 6OHDA would activate the ARE due to generation of ROS as well via structural activation. Primary cortical cultures prepared from ARE-hPAP mice exposed to 6OHDA demonstrate ARE activation in a dose-dependent fashion. Pretreatment with high-dose antioxidants reduced, but did not abolish ARE activation, indicating a component of ARE activation that is oxidative stress independent. Pretreatment with MK-801, an NMDA receptor antagonist, also reduced ARE-activation at low concentrations of 6OHDA suggesting that the oxidative stress caused by 6OHDA is caused, in part via an excitotoxic mechanism. When administered stereotactically to ARE-hPAP mice, 6OHDA induces ARE activity *in vivo*. The data suggest that ARE-mediated gene activity may be a mechanism to cope with oxidative stress due to 6OHDA. This work is supported by ES08089 and ES10042 from NIEHS. The authors disclose no conflicts of interest.

ACTIVATION OF TRANSCRIPTION FACTOR AP-1 IN ANILINE-INDUCED SPELENIC TOXICITY.

S. -. Kannan, J. -. Wang and M. Khan. *Pathology, University of Texas Medical Branch, Galveston, TX.*

Exposure to aniline results in selective toxicity to the spleen, leading to a variety of sarcomas on chronic exposure in rats. However, the molecular mechanism(s) by which aniline leads to tumorigenic response in spleen is not known. Previous studies have shown that aniline exposure leads to iron accumulation and oxidative stress in the spleen. We hypothesize that aniline-induced oxidative stress in the spleen causes activation of redox-sensitive transcription factor AP-1, which could regulate the transcription of genes involved in fibrosis and cell growth regulatory pathways. To test this hypothesis, male SD rats were treated with 0.5 mmol/kg/day aniline via drinking water for 30 days, and AP-1 activation was determined in the nuclear extracts of splenocytes. The binding activity of AP-1, as determined by electrophoretic mobility shift assay (EMSA) using AP-1 consensus motif, showed a significant increase in AP-1 binding in the nuclear extracts of the freshly isolated splenocytes from aniline-treated rats in comparison to the controls. AP-1 binding was also determined in the splenocytes cultured for 2 h, which showed a marked increase in binding activity in the nuclear extracts of splenocytes from aniline-treated rats as compared to the controls. The specificity of AP-1 binding for relevant DNA motifs was verified by competition EMSA assays using an excess of unlabelled consensus and mutant oligonucleotides. The wild type AP-1 motif completely inhibited the AP-1 binding, whereas the mutant AP-1 consensus motif failed to block the AP-1 binding in both control and aniline-treated splenocytes. Supershift EMSA using antibodies specific to c-Jun further confirmed the specificity of AP-1 binding activity. These observations suggest that aniline-induced oxidative stress results in the activation of AP-1, which could regulate genes that lead to fibrogenic and/or tumorigenic response in spleen.

DOW-NREGULATION OF NITRIC OXIDE AND ANTIOXIDANT SYSTEMS IN ALCOHOL-INDUCED HYPERTENSION.

K. Husain, J. Lalla and S. Kazim. *Pharmacology and Toxicology, Ponce School of Medicine, Ponce, Puerto Rico.*

Epidemiological studies show that there is link between chronic alcohol consumption and the prevalence of hypertension in humans. We have recently reported that both dose and time of alcohol ingestion is important in causing hypertension in experimental rat model. However, the cellular and molecular mechanisms implicated with ethanol-induced hypertension are not completely understood. The aim of this study was to investigate the alterations in blood pressure and cardiac nitric oxide and antioxidant systems in chronic ethanol treated rats. Male Fisher rats were given 20% ethanol (4 g/kg, p. o.) through orogastric tube daily for 12 weeks and controls received 5% sucrose through orogastric tube daily for 12 weeks. The systolic, diastolic and mean blood pressure (BP) was recorded weekly. After 12 weeks, rats were sacrificed and heart dissected and left ventricle isolated and analyzed. Results show that ethanol ingestion caused a significant increase in systolic, diastolic and mean BP ( $p < 0.001$ ) compared to control after 12 weeks. The endothelial nitric oxide synthase and vascular endothelial growth factor (VEGF-A) expressions were down-regulated leading to depletion of cardiac NO levels in ethanol treated rats compared to control. The antioxidant enzymes: CuZn-SOD, Mn-SOD, catalase and GSH-Px activities as well as protein expressions were significantly depleted in the cardiac tissue of ethanol-treated rats compared to control. Endogenous antioxidant glutathione levels in the heart tissue significantly decreased in rats treated with ethanol

compared to control. It is concluded that chronic alcohol ingestion caused hypertension which was related to the down regulation of endothelial nitric oxide generating system and antioxidants in the heart of rats(supported by NIH RCMI grant #2 G12 RR03050-19).

#### HO-1 INDUCTION CONTRIBUTES TO PCB-INDUCED OXIDATIVE STRESS IN DOPAMINERGIC CELLS.

D. W. Lee, R. M. Gelein and L. A. Opanashuk. *Department of Environmental Medicine, University of Rochester School of Medicine and Dentistry, Rochester, NY*.

Polychlorinated biphenyls (PCBs) are persistent and widespread pollutants that have been associated with disruption of dopaminergic (DAergic) pathways, leading to neurological and cognitive impairments. Previous studies in our laboratory have shown that low-level exposure to Aroclor 1254 (A1254) elicited an oxidative stress (OS) response in MN9D DAergic cells, including sustained reactive oxygen species (ROS) production, depletion of mitochondrial MnSOD, and a robust induction of heme oxygenase-1 (HO-1). HO-1 metabolizes liberated heme groups to give rise to CO, the antioxidant biliverdin, and iron (Fe), a pro-oxidant. This study tests the hypothesis that the PCB-induced cellular stress response generates a sustained induction of HO-1, thereby releasing labile iron that can participate in the Fenton reaction to generate ROS. A1254 exposure stimulated HO-1 expression and led to an accumulation of total intracellular iron after a 24h period. Pretreatment of MN9D cells with the HO-1 inhibitors, tin and zinc protoporphyrins, or desferoxamine, an iron chelator, decreased PCB-induced ROS production and protected against cell death. Cells that were infected with an HO-1 adenoviral construct had increased ROS production and were more vulnerable to cell death than those infected with anti-sense HO-1 or GFP constructs. Additionally, HO-1 protein levels were elevated to a greater extent in HO-1 over-expressing cells compared to controls following treatment with A1254. Alterations in HO-1 protein were accompanied by increased ROS production and subsequent cell death in MN9D cells infected with the HO-1 construct, while infection with anti-sense HO-1 was able to protect against PCB-induced oxidative stress and cell death. Together, these data suggest that induction of HO-1 past a critical cellular threshold can increase neuronal susceptibility to oxidative stress and lead to further DAergic cell injury and death. Supported by NIH ES00375, P30ES01247, and T32 ES07026.

#### REACTIVE OXYGEN/NITROGEN SPECIES IN ACETAMINOPHEN (APAP) TOXICITY IN FRESHLY ISOLATED MOUSE HEPATOCYTES.

A. B. Reid and J. A. Hinson. *Pharmacology, University of Arkansas for Medical Sciences, Little Rock, AR*.

APAP toxicity in freshly isolated mouse hepatocytes occurs in two phases. Despite the fact that the initial phase (0 - 2 hr) involves GSH depletion and covalent binding, it occurs with little toxicity. Toxicity occurs primarily during the second phase (2 - 5 hr). We have previously shown that the latter phase occurs with mitochondrial permeability transition (MPT), a lethal event for the cell. Since MPT may occur as a result of oxidative stress and leads to oxidative stress, we evaluated the role of oxygen/nitrogen stress in APAP toxicity. Hepatocytes were incubated with APAP (1mM) for 2 hr and subsequently washed (2x) to remove APAP and reincubated with media (2 - 5 hr). This allowed for separation of metabolic events in phase 1 from toxic events in phase 2. Addition of dichlorofluorescein (DCF), a dye converted to a fluorescent product by reactive oxygen/nitrogen species, at 2 hr resulted in a large increase in fluorescence compared to control. Inclusion of the MPT inhibitor cyclosporine A and the antioxidant N-acetylcysteine eliminated both toxicity and the increase in DCF fluorescence. To determine the role of peroxynitrite, a reactive nitrating and oxidizing species formed from interaction of superoxide with nitric oxide, proteins were analyzed by Western blot for nitrated tyrosine. Nitrotyrosine residues linearly increased in the reincubation. Inclusion of the nitric oxide inhibitor, L-NMMA (1mM), at 2 hr decreased toxicity 57% at 5 hr. Since APAP is a phenol that has been reported to scavenge peroxynitrite, the effect of APAP was determined when added back to the hepatocytes at 2 hr. APAP (1, 10, and 50 mM) decreased toxicity by 11%, 24%, and 48%, respectively at 5 hr. To determine the role of iron and oxidative stress in toxicity, the iron chelators deferoxamine (1mM) and phenanthroline (0.05 mM) were added at 2 hr. Both chelators completely eliminated toxicity. Overall, the data reveal a role for both reactive oxygen and reactive nitrogen species in APAP toxicity.

#### ACETAMINOPHEN INDUCED HEPATOXICITY IN A GCLM- NULL MOUSE MODEL.

L. McConnachie<sup>1</sup>, C. Fernandez<sup>1</sup>, I. Mohar<sup>1</sup>, R. Pierce<sup>2</sup> and T. Kavanagh<sup>1</sup>.

<sup>1</sup>*Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA* and <sup>2</sup>*Department of Pathology and Lab. Medicine, University of Rochester, Rochester, NY*.

Recent reports suggest that a substantial fraction of acute liver failure incidence in the United States is related to acetaminophen (APAP) overdose. APAP is bioactivated to a reactive intermediate, NAPQI, which is scavenged by glutathione

(GSH), an important cellular antioxidant. The rate-limiting step in GSH biosynthesis is catalyzed by glutamate cysteine ligase (GCL). This enzyme is a heterodimer composed of catalytic (GCLC) and modifying (GCLM) subunits. GCLM functions to modify the activity of GCLC by increasing its affinity for glutamate and attenuating the GSH feedback inhibition. To more thoroughly characterize the role of GCLM in GSH biosynthesis and APAP-induced liver damage, we have utilized our GCLM-null mouse model. This mouse was generated by replacing exon 1 of the GCLM gene with a b-galactosidase/neomycin phosphotransferase (b-Geo) fusion gene. Following a 12 hour fast, mice were dosed with 300 mg/kg APAP via i.p. injection and sacrificed after six hours. GSH depletion associated with APAP exposure was similar in all three genotypes, relative to vehicle treatment. Both serum ALT activity and histologic evaluation indicated hepatic damage for all three genotypes (GCLM wild-type, heterozygous and null). However, the null mice exhibited severe damage indicated by both high histologic scores and ALT activities relative to the heterozygous and wild-type mice. GCLM promoter activity in the null mice, as measured by b-galactosidase activity, was diminished, perhaps due to the high degree of hepatic damage. Collectively, these data reassert the importance of GSH in APAP-mediated hepatotoxicity. Importantly, however, these data indicate a critical role of GCLM in preventing oxidative damage. This may be clinically relevant, as the GCLM gene is polymorphic in human populations. (Supported by NIH Grants 1P42ES04696, 1R01ES10849, 1T32ES07032, and 1P30ES07033).

#### INDUCTION OF METALLOTHIONEIN SYNTHESIS MEDIATED THROUGH OXIDATIVE STRESS IN MITOCHONDRIA AND ITS BIOLOGICAL ROLE.

M. Sato. *Faculty of Pharmacy, Tokushima Bunri University, Tokushima, Japan*.

Enhanced production of reactive oxygen species (ROS) in mitochondria may contribute a variety of chronic disease and ageing. The metallothionein (MT), a cysteine rich and metal binding protein, is induced by various stress conditions. Recent study shows that MT is present in mitochondria. We previously reported that mitochondrial inhibitors such as antimycin A or 2, 4-dinitrophenol (DNP) induced MT. However, the involvement of oxidative stress in mitochondria in the induction of MT by mitochondrial inhibitors remains obscure. Administration of DNP into mice induced expression of MT mRNA in the liver and increased the MT concentration. Another mitochondrial inhibitors, sodium malonate also induced MT synthesis in mice. Addition of DNP into culture medium resulted in expression of MT mRNA in fibroblast cells, indicating that incorporated DNP in the cells induce MT synthesis. Malonate is a competitive inhibitor on succinate dehydrogenase. Pre-injection of succinate caused the reduction of malonate-induced MT synthesis, suggesting that induction of MT synthesis is mediated through inhibition of respiratory reaction and ROS production in mitochondria. Intracellular accumulation of hydrogen peroxide caused by the actions of mitochondrial inhibitors was greater in MT-null than in wild-type fibroblast cells, suggesting that MT plays a role as a radical scavenger against intracellular ROS caused by mitochondrial stress. Furthermore, ROS production by DNP was greater in wild cells than in phospholipid hydroperoxide glutathione peroxidase-overexpressed cells, which is localized mitochondrial membrane. The data suggest that mitochondrial oxidative stress induces synthesis of MT, which may contribute to regulation of mitochondrial ROS production.

#### HEPATOCYTE-SPECIFIC DELETION OF GCLC RESULTS IN PROGRESSIVE LOSS OF MITOCHONDRIAL FUNCTION.

Y. Chen, D. Shen, H. G. Shertzer, M. L. Miller, S. N. Schneider, D. W. Nebert and T. P. Dalton. *Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH*.

Hepatocyte-specific deletion of glutamate-cysteine ligase catalytic subunit (*Gclc*), encoding rate-limiting enzyme in glutathione (GSH) biosynthesis, results in growth retardation and early death in mice at approximately post-natal day (PND) 30. In these mice, the glutathione level in liver was 4% of the control. Ultrastructural examination of hepatocytes demonstrated the progressive transformation of mitochondria to become swollen with tubular cristae. This morphological transformation was prevented by the administration of N-acetylcysteine (NAC) which also prevented hepatic failure and death. GSH levels in liver mitochondria from knockout mice at PND 14, 21, 25, and 28 dropped to 42%, 19%, 16%, and 16% of age matched controls. In parallel with mitochondrial GSH loss, was a decline in cellular ATP and mitochondrial function, as measured by respiratory control ratio and membrane potential. Hydrogen peroxide liberated by respiring mitochondria increased with GSH loss. In NAC rescued mice, liver GSH levels increase to 9-14% of the control and mitochondrial levels normalize. Nevertheless, mitochondrial respiratory function did not fully recover until PND 120. We conclude that liver failure in hepatocyte *Gclc* knockout mice parallels the loss of mitochondrial function. NAC administration rescues mitochondrial function albeit with some delay. Supported in part by NIH grant R01ES012463.

A NOVEL HALOENOL LACTONE DERIVATIVE INDUCES OXIDATIVE STRESS IN HUMAN TUMOR CELLS THROUGH A GLUTATHIONE S-TRANSFERASE MEDIATED MECHANISM.

W. Wang and J. Zheng, *Pharmaceutical Sciences, Northeastern University, Boston, MA*.

Reduced glutathione (GSH) is the most prevalent non-protein thiol in animal cells. It maintains a reduced cellular environment and also acts as a nucleophile in reactions with both exogenous and endogenous electrophilic species. As a consequence, reactive oxygen species (ROS) are frequently targeted by GSH in both spontaneous and catalytic reactions. Since ROS have defined roles in cell signaling events as well as in human disease pathologies, an imbalance in expression of GSH and associated enzymes has been implicated in a variety of circumstances. A novel haloenol lactone (HEL), which we synthesized as an isozyme-selective GST-Pi inactivator, was found to deplete intracellular GSH to potentiate cytotoxicity induced by cisplatin *in vitro*. We also found HEL causes dose-dependent, time-dependent increase of intracellular ROS level at low concentrations *in vitro*. This increase of ROS was correlated to the cell viability in MCF-7 cell line. GST-Pi over-expressed transgenic MCF-7 cells showed more resistance to H2O2-induced injury than its wild type. HEL compound reverses this resistance through selective GST-Pi inhibition. GST-Pi is known as a direct inhibitor of c-Jun N-terminal kinase (JNK) *in vivo*. These results reveal that HEL may not only induce oxidative stress by depletion of GSH but also induce ROS-related apoptosis through a GST-mediated mechanism.

IDENTIFICATION AND CHARACTERIZATION OF BIOACTIVE COMPOUNDS FROM TOBACCO AS INHIBITORS OF NEURONAL NITRIC OXIDE SYNTHASE.

P. Venkatakrishnan<sup>1</sup> and T. R. Miller<sup>1</sup>. <sup>1</sup>*Graduate Center for Toxicology, University of Kentucky, Lexington, KY* and <sup>2</sup>*Graduate Center for Toxicology, University of Kentucky, Lexington, KY*.

Neuronal nitric oxide synthase (nNOS) plays a major role in cell damage and death during stroke. Specific inhibitors of nNOS would help to decrease free radical damage. Tobacco contains thousands of bioactive compounds, many of which may selectively inhibit nNOS. Our aim is to identify and isolate selective nNOS inhibitors from tobacco which do not inhibit endothelial NOS as it plays a vital role in maintaining tissue perfusion and decreasing ischemic/hypoxic damage. Several varieties of tobacco (T1565, TW109, TI464, TW88, TW152, TW87) were differentially extracted and lyophilized, ensuring for both stable storage as well as for ensuring ample supply of compound for further characterization with NOS isoforms. Increasing amounts of dried extracts from the different tobaccos (hexane, 125-755?g; methanol, 125-625?g; aqueous, 100-500?g) were included in our NOS activity assays to establish dose-response relationships for potency as nNOS inhibitors. Hexane extracts were found to be the most potent inhibitors of nNOS (65% inhibition) followed by the methanol extracts (active only at higher amounts) and lastly by the aqueous extracts. Further analysis, by analytical high performance liquid chromatography, of the hexane extracts displaying either high (TW1565), moderate (TI465), or low (TW109) nNOS inhibitory activity have revealed unique and distinct chromatographic profiles indicating differences in amounts of the chemical constituents present in different extracts and it is postulated that these differences may account for the observed differential inhibition of nNOS activity. Presently, subfractions of hexane extracts from the more potent nNOS inhibitory tobaccos are being collected to conduct both more in-depth nNOS inhibition studies, and to continue chemical characterization and identification of the active constituents by both mass-, and nuclear magnetic resonance-spectroscopy (Supported by KSEF-475-RDE-005)

DEVELOPMENT AND VALIDATION OF AN ASSAY FOR IODIDE IN SERUM USING ION CHROMATOGRAPHY WITH AMPEROMETRIC DETECTION.

E. Kaiser<sup>1</sup>, J. M. Flaherty<sup>1</sup>, M. W. Himmelstein<sup>2</sup> and J. H. Kinzell<sup>3</sup>. <sup>1</sup>*Exygen Research, Inc., State College, PA*, <sup>2</sup>*DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE* and <sup>3</sup>*Arvesta Corporation, San Francisco, CA*.

An ion chromatography method was developed and validated to assay iodide in serum sampled from rats and rabbits that had been exposed to iodomethane. Serum was prepared from whole blood collected at the time of sacrifice on wet ice and kept frozen at < -65° C. For analysis, serum samples were thawed unassisted at ambient temperature. Proteins were separated from the serum samples by ultrafiltration. A 0.100 mL filtered serum sample was then injected into the ion chromatograph without additional sample preparation. Iodide was separated in < 20 min by anion-exchange chromatography using a 25 mM nitric acid eluent. The analyte of interest was detected by pulsed amperometry using a silver working electrode. The method showed linear response over the concentration range of 100 to 5,000 ng/mL iodide

(r2 > 0.9950) with a lower limit of quantitation of 100 ng/mL iodide. The accuracy of the procedure, determined by spiked recovery measurements at 100 ng/mL iodide, was within 90-110%. The analytical procedure was applied to detect trace iodide down to 20 ng/mL in serum samples using the method of standard additions.

METHYLATION OF HEMOGLOBIN CYSTEINE AS A BIOMARKER OF EXPOSURE TO IODOMETHANE.

D. L. Nabb<sup>1</sup>, M. W. Himmelstein<sup>1</sup>, M. P. Delorme<sup>1</sup>, E. Sloter<sup>3</sup>, M. L. Gargas<sup>2</sup>, J. H. Kinzell<sup>4</sup> and R. A. Kemper<sup>1</sup>. <sup>1</sup>*DuPont Haskell Laboratory, Newark, DE*, <sup>2</sup>*The Sapphire Group, Dayton, OH*, <sup>3</sup>*WIL Research Laboratories, Ashland, OH* and <sup>4</sup>*Arvesta Corporation, San Francisco, CA*.

Iodomethane (MeI) is a water-soluble monohalomethane under review for US registration as a non-ozone depleting alternative to methylbromide in the pre-plant soil fumigation market. As part of the toxicological assessment of MeI, hemoglobin adducts were investigated as a measure of internal dose following MeI exposure. In this study, methylation of hemoglobin cysteine residues to form S-methyl-L-cysteine (SMC) was investigated. SMC formation has been used previously to estimate internal dose of methylating agents, including methylbromide. Male and female rats, and female rabbits were exposed to various concentrations of MeI for 6 hours. Whole blood was obtained 48 hrs post exposure, and globin was isolated from RBCs by acid-acetone precipitation and hydrolyzed in 6N HCl under vacuum. Deuterated SMC was added as an internal standard to account for incomplete recovery of SMC. Both liquid phase and vapor phase acid hydrolysis were examined. Hydrolysates were dried under vacuum, silylated and analyzed by GC/MS with selected ion monitoring. Preliminary data indicated that SMC was present in control rat and rabbit globin at concentrations of approximately 100 and 20 nmol/g, respectively, and that inhalation exposure to MeI produced dose-dependent increases in SMC in both species. Because of the variable recovery of SMC in hydrolysates, an alternative procedure was developed in which globin was oxidized with performic acid prior to acid hydrolysis. This procedure resulted in quantitative conversion of SMC to SMC sulfone (SMCO2), which is stable to the hydrolytic conditions used. Our preliminary results indicate that SMC formation in Hb is a useful biomarker for exposure to MeI. Data from these studies will facilitate understanding of the relationships between exposure concentration, exposure duration and internal dose for MeI.

UPTAKE OF METHYL IODIDE IN THE NASAL CAVITY OF RATS AND RABBITS.

K. D. Thrall<sup>1</sup>, A. D. Woodstock<sup>1</sup>, J. J. Soelberg<sup>1</sup>, J. H. Kinzell<sup>2</sup> and M. L. Gargas<sup>3</sup>. <sup>1</sup>*Battelle, Pacific Northwest Division, Richland, WA*, <sup>2</sup>*Arvesta Corp., San Francisco, CA* and <sup>3</sup>*The Sapphire Group, Inc., Beavercreek, OH*.

Methyl iodide (MeI) is a water soluble monohalomethane under review for US registration as a non-ozone depleting alternative to methyl bromide for the pre-plant soil fumigation market. Both acute and subchronic inhalation exposures to MeI in rats have resulted in lesions of the nasal olfactory epithelium. Efforts are underway to develop a hybrid computational fluid dynamics-physiologically based pharmacokinetic model for MeI to better describe interspecies nasal dosimetry differences, and to potentially reduce RfC uncertainty factors. Validation of this model, however, will require unique experimental data to describe the nasal absorption of MeI. To this end, a method for evaluating the uptake of MeI in the nasal cavity of the intact animal was developed. The procedure involved insertion of a small-diameter air-sampling probe in the nasal cavity to the nasopharynx region of anesthetized animals. The exterior portion of the probe was connected directly to a mass spectrometer to provide a continual real-time analysis of concentrations of MeI in the nasal cavity. A plethysmography system was used to individually monitor breathing parameters, including frequency and tidal volume for each animal. Animals were placed in a sealed glass chamber and exposed to MeI at initial chamber concentrations ranging from 1 to 50 ppm. Studies were conducted on n=3 rabbits per exposure concentration for a total of 9 animals. For rats, studies were conducted on n=6 animals at a single exposure concentration. In the rabbit, the percent of MeI absorbed in the nasal cavity ranged from 53 to 89% (average 68 ± 11) regardless of exposure concentration. Similarly, the percent of MeI absorbed in the nasal cavity of the rat ranged from 52 to 75% (average 66 ± 9). Furthermore, plethysmography results indicate that breathing parameters were unaffected by initiation of the MeI exposure for these anesthetized animals. (Supported by Arvesta Corp.).

SPECIES AND TISSUE COMPARISON OF THE GLUTATHIONE CONJUGATION OF METHYL IODIDE IN RAT, RABBIT, AND HUMAN CYTOSOL.

T. Poer<sup>1</sup>, H. Wu<sup>1</sup>, J. Soelberg<sup>1</sup>, J. Kinzell<sup>2</sup> and M. Gargas<sup>3</sup>. <sup>1</sup>*Biological Monitoring and Modeling, Battelle, Richland, WA*, <sup>2</sup>*Arvesta Corp, San Francisco, CA* and <sup>3</sup>*The Sapphire Group, Inc., Beavercreek, OH*.

Methyl iodide (MeI) is an intermediate in the manufacture of some pesticides and pharmaceuticals and it is under review for US registration as a non-ozone depleting alternative for methyl bromide in the pre-plant soil fumigation market. MeI is me-

abolized via conjugation with glutathione (GSH) and further metabolism to S-methyl cysteine and methanethiol, or via a minor CYP450 oxidation to formaldehyde. A potential mode of action for any adverse effects due to MeI exposures may involve iodide release or GSH depletion. The GSH-dependent loss of MeI from the headspace of sealed vials containing cytosol prepared from the liver and kidney of rats, human donors, female rabbits or rabbit fetuses and from rabbit olfactory and respiratory epithelium was compared. A mathematical model was developed and metabolic rate constants were determined using Simusolv (Dow Chemical Co., Midland, MI). MeI was well metabolized in most of the tissue cytosol samples, but not in blood or fetal rabbit kidney. In rabbit tissues, the relative order of the pseudo-first order rate constant (Vmax/Km) was olfactory epithelia > liver > respiratory epithelia > kidney. The metabolism in olfactory and respiratory epithelial cytosol had a Km values that were several times higher than for any other tissue (on the order of 25 mM for olfactory and 2.5 mM for respiratory), suggesting an essentially first order rate of metabolism in the nasal area. Vmax rates were similar in liver and kidney cytosol from rats and human donors (40 and 48 in liver and 68 and 55 nmol/min/mg in kidney for rat and human tissue, respectively), but were lower in rabbit tissues (10 and 4.4 in liver and kidney, respectively). The metabolism of MeI in human liver cytosol prepared from 5 individual human donors indicated a single outlier, with much less metabolism than the other human liver samples. Typically, hepatic metabolism was greater than renal and adult rabbit metabolism was greater than fetal. (Sponsored by Arvesta Corp)

## 234 IODOMETHANE: 2-DAY MECHANISTIC INHALATION EXPOSURE STUDY IN THE RAT.

M. W. Himmelstein<sup>1</sup>, M. P. DeLorme<sup>1</sup>, R. A. Kemper<sup>1</sup>, D. L. Nabb<sup>1</sup>, J. C. O'Connor<sup>1</sup>, M. L. Gargas<sup>2</sup> and J. H. Kinzell<sup>3</sup>. <sup>1</sup>DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE, <sup>2</sup>The Sapphire Group, Dayton, OH and <sup>3</sup>Arvesta Corporation, San Francisco, CA.

A previous study showed that iodomethane (MeI) caused hyperplasia of the nasal olfactory epithelium after subchronic inhalation exposure. This study investigated the mechanism of toxicity and measurement of exposure biomarker data in male Sprague-Dawley rats. MeI undergoes rapid metabolism to free iodide from the methyl group; therefore, effects on thyroid hormones, UDP-glucuronyltransferase (UDPGT), clinical pathology, and blood for S-methyl-L-cysteine (SMC) hemoglobin adducts were determined the morning after two days of 6 h/day whole body exposures to 0, 25 or 100 ppm MeI (n=10 rats/group). Additional exposure groups (n=3 rats per exposure concentration) were sampled at 0, 1, 3, 6, 9, 24, 25, 27, 30, 33, and 48 hours for quantification of inorganic serum iodide and reduced glutathione [GSH, mM] in various tissues. Results for SMC will be reported separately. GSH was analyzed in nasal respiratory and olfactory tissues, blood, liver, and kidney. Time course and exposure dependent reductions in GSH were observed in all tissues. For example, at peak exposures GSH was reduced to 17 to 40% of control concentration in nasal respiratory and olfactory tissues, and 60 to 80% of control in blood, liver and kidney. Serum iodide concentrations increased with duration and magnitude of exposure and ranged from 1, 200 to 87, 000 ng/mL, compared with 20 ng/mL in control rats. At the 48 h collection time, T<sub>3</sub> and T<sub>4</sub> were significantly reduced by 62 to 90% of control with a concomitant increase in TSH of 186-360% (p < 0.05). rT<sub>3</sub> and UDPGT were not affected. Adverse serum chemistry changes included increased serum cholesterol concentrations and decreased serum triglyceride concentrations. Clinical pathology and thyroid hormone changes suggest effects on liver enzyme and thyroid function. The results for serum iodide and GSH will be used for validation of a computational fluid dynamic physiologically based pharmacokinetic model.

## 235 EVALUATION OF RESPIRATORY PARAMETERS IN RATS AND RABBITS EXPOSED TO IODOMETHANE.

M. DeLorme<sup>1</sup>, M. W. Himmelstein<sup>1</sup>, M. L. Gargas<sup>2</sup> and J. H. Kinzell<sup>3</sup>. <sup>1</sup>DuPont Haskell Laboratory, Newark, DE, <sup>2</sup>The Sapphire Group, Dayton, OH and <sup>3</sup>Arvesta Corporation, San Francisco, CA.

Laboratory animals exposed via inhalation to iodomethane (MeI) exhibited adverse systemic CNS effects and lesions of the nasal olfactory epithelium following acute and subchronic exposures. Interactions of MeI in the nasal passage may alter systemic toxicokinetics. We used unrestrained plethysmographs to determine the MeI effect on the breathing frequency and minute volume (MV) in exposed rats and rabbits. Groups of 4 rats each were exposed to 0, 25 or 100 ppm and groups of 4 rabbits each were exposed to 0 and 20 ppm MeI for 6hrs. Breathing frequency and MV were measured, recorded and averaged on 1 minute periods over the course of the exposure. Both rats and rabbits demonstrated an approximate 35% drop in breathing frequency in the first 45 and 90 minutes of exposure, respectively, at all exposure concentrations followed by a plateau in respiratory rate. The MV measurements over the 6-hour period were summated in order to determine the total

volume of air inhaled by the animals during the course of the exposure. Rats exposed to 0 ppm inhaled 80.5 ±17.2 L (mean ± SD), while the 25 and 100 ppm groups were within 8% of the control value. In contrast, rabbits exposed to 20 ppm MeI demonstrated a 30% increase in total inhaled air volume when compared to 144 ± 54 L for the 0 ppm rabbits. Rats and rabbits exposed to MeI concentrations of up to 100 ppm, did not demonstrate a sensory irritant effect or a decreased inhalation uptake of test atmosphere. The results of this study will be integrated into a computational fluid dynamics-physiologically based pharmacokinetic model for both rats and rabbits.

## 236

### IODOMETHANE PARTITION COEFFICIENTS IN RAT AND RABBIT TISSUES AND HUMAN BLOOD.

S. Gannon<sup>1</sup>, M. W. Himmelstein<sup>1</sup>, L. M. Sweeney<sup>2</sup>, M. L. Gargas<sup>2</sup> and J. H. Kinzell<sup>3</sup>. <sup>1</sup>DuPont Haskell Laboratory for Health and Environmental Sciences, New Castle, DE, <sup>2</sup>The Sapphire Group, Dayton, OH and <sup>3</sup>Arvesta Corporation, San Francisco, CA.

Iodomethane (MeI) is a proposed non-ozone depleting alternative for methyl bromide in the pre-plant soil fumigant market. In support of physiologically based pharmacokinetic (PBPK) modeling, MeI tissue-to-air partition coefficients (PCs) were determined in rat tissues (blood, brain, fat, kidney, liver, muscle, thyroid, nasal tissue), rabbit tissues (fetal blood, maternal blood, brain, fat, kidney, liver, muscle, thyroid, placenta, nasal tissue), human blood (male and female), and saline. Weighed tissue aliquots were placed in septum-sealed vials, MeI (10,000 ppm) was added, and vials were incubated at 37°C or 30°C for nasal tissue and saline. A reference vial was prepared identically, but without tissue. Headspace MeI concentrations were analyzed at 1, 1.5, 2, 2.5 and 3 h by GC/FID. MeI headspace concentrations continuously decrease when in the presence of blood and liver, therefore, PCs were estimated by log-linear regression extrapolation to 0 h [TAP, 128:92-96, 1994]. The respective PCs for brain, fat, kidney, muscle, and nasal tissue were similar across animal species. The rabbit thyroid PC was 3 times higher than the rat thyroid PC (rabbit: 39, rat: 11). The rat liver PC was 2 times higher than the rabbit liver PC (rat: 24, rabbit 13). The rat blood PC was 2.5 times higher than the rabbit blood PC (rat: 39, rabbit: 16). The human blood PC (18) was more similar to the rabbit blood PC than the rat blood PC. There was no significant difference between male and female human blood PCs. The rabbit fetal blood PC (12) was similar to rabbit maternal blood PC (16). The measured PCs were compared with predictions derived from algorithms based on MeI solubility in oil and water. Measured PCs for rat and human blood were generally higher than the predicted PCs. The measured and predicted PCs for rat muscle and fat were approximately equivalent. Measured PCs are favored for incorporation into the PBPK models being developed to aid in MeI risk assessment activities.

## 237

### DERIVATION OF HUMAN TOXICITY REFERENCE VALUES FOR METHYL IODIDE USING PBPK MODELING.

L. M. Sweeney<sup>1</sup>, J. H. Kinzell<sup>2</sup> and M. L. Gargas<sup>1</sup>. <sup>1</sup>The Sapphire Group, Dayton, OH and <sup>2</sup>Arvesta Corporation, San Francisco, CA.

Methyl iodide (MeI) has been proposed as a replacement for methyl bromide as a pre-plant soil fumigant that does not deplete stratospheric ozone. In toxicity studies performed as part of the registration process, the three effects have been identified in animals that warrant consideration in developing human-equivalent toxicity reference values: nasal lesions (rat), acute neurotoxicity (rat), and late-term fetal resorptions (rabbit). Uncertainties in the risk assessment process can be reduced using an internal measure of target tissue dose that is linked to the likely mode of action (MOA) for the toxicity of methyl iodide when determining appropriate regulatory criteria. Physiologically based pharmacokinetic (PBPK) models have been developed for methyl iodide for this purpose. The major components of the PBPK model are submodels for MeI and iodide for adult/maternal and fetal animals, sub-compartmentalized descriptions of the nasal cavity, stomach, and thyroid anatomy, and synthesis and turnover of the metabolic co-factor glutathione (GSH) in blood and tissues. To the extent possible, species and life-stage specific parameter values (physiological, thermodynamic, and biochemical/metabolic) were identified in the literature or developed via experimentation. When parameter values were unavailable for a given species and lifestage, values from other species and lifestages were used. Model predictions were compared to a variety of experimental data from MeI-exposed rats and rabbits, including nasal uptake of MeI, whole body closed-chamber uptake of MeI, blood and tissue GSH depletion, and plasma iodide concentrations. The model was used to reduce uncertainties in the risk assessment extrapolations involved in developing human toxicity reference values (e.g. interspecies, high to low dose, exposure scenario).

## THE DISPOSITION AND PHARMACOKINETICS OF RADIOIODIDE IN PREGNANT RABBITS AND FETUSES.

J. E. Morris<sup>1</sup>, L. B. Sasser<sup>1</sup>, J. A. Creim<sup>1</sup>, L. K. Fritz<sup>1</sup>, K. D. Thrall<sup>1</sup>, J. H. Kinzell<sup>2</sup> and M. L. Gargas<sup>3</sup>. <sup>1</sup>Battelle, Pacific Northwest Division, Richland, WA, <sup>2</sup>Arvesta Corp., San Francisco, CA and <sup>3</sup>The Sapphire Group, Beavercreek, OH.

Methyl iodide (MeI) is a water soluble monohalomethane under review for US registration as a non-ozone depleting alternative for methyl bromide in the pre-plant soil fumigation market. Iodide is a metabolic byproduct of MeI metabolism and reacts with blood and tissue macromolecules. A physiologically based pharmacokinetic model exists for iodine in adult rats, pregnant rats and fetuses, and lactating rats and neonates, but not for pregnant rabbits and fetuses which have been a subject of extensive toxicity testing. Thus, a study was conducted to determine the distribution (primarily in blood and tissues containing the sodium iodide symporter) and kinetics of radioiodide in pregnant rabbits and fetuses. Time-pregnant New Zealand White rabbits received a single IV injection of 131-sodium iodide (131NaI) at either a high (10 mg/kg body weight) or low (0.75 mg/kg body weight) dose on gestation day 25. At various intervals ranging from 0.5 to 24 hrs post injection, blood and tissues (thyroid, stomach contents and skin) were collected from each doe, and blood, stomach content, thyroid and amniotic fluid were collected from a random sampling of 3 fetuses per doe per time point. Radioiodide accumulated as expected in the maternal thyroid, where concentrations were the highest tissue measured in both dose groups. Likewise, fetal samples had measurable radioiodide concentrations at all time intervals, although concentrations in amniotic fluid were low at early (0.5 and 1 hr) time points and peaked in concentration at 6 hrs post dosing. In contrast to that observed for the doe, fetal stomach contents showed the highest accumulation of radioiodide for both dose groups, followed by the thyroid. (Supported by Arvesta Corp.).

## PRENATAL DEVELOPMENTAL TOXICITY STUDIES IN RABBITS REVEAL A SUSCEPTIBLE WINDOW OF METHYL IODIDE-INDUCED FETOTOXICITY LATE IN GESTATION.

M. D. Nemec<sup>1</sup>, E. D. Sloter<sup>1</sup>, J. F. Holson<sup>1</sup>, D. G. Stump<sup>1</sup> and J. Kinzell<sup>2</sup>. <sup>1</sup>WIL Research Laboratories, Inc., Ashland, OH and <sup>2</sup>Arvesta Corporation, San Francisco, CA.

Methyl iodide (MeI), an intermediate used in the manufacture of some insecticides and pharmaceuticals, is under review for US registration as a non-ozone depleting alternative to methyl bromide in the pre-plant soil fumigation market. Previous OPPTS 870.3700 guideline developmental toxicity studies conducted at WIL showed dose-dependent increases in the mean litter proportions of late fetal deaths and postimplantation loss following inhalation exposure of pregnant rabbits to MeI concentrations ranging from 10 to 75 ppm during gestation days (GD) 6-28. The objective of the current study was to pinpoint the critical period of exposure during gestation that produced the embryo-fetotoxicity. Artificially inseminated New Zealand White female rabbits were exposed to MeI by whole-body inhalation (6hrs/day) at a concentration of 20 ppm during different windows of exposure varying from 2-23 days in duration throughout gestation (GD 6-28), early gestation (GD 6-14), mid gestation (GD 15-22) or during two-day specific intervals late in gestation (GD 23-24, 25-26 or 27-28). No maternal or developmental toxicity resulted from maternal exposure during GD 6-14, 15-22 or 27-28. However, MeI-related developmental effects, including increased mean litter percentages of late fetal deaths with or without a corresponding decrease in mean numbers of viable fetuses, were observed for females exposed during GD 6-28 ( $p < 0.01$ ), 23-24 and 25-26. Although the incidence of developmental effects observed on GD 23-24 or GD 25-26 was not statistically significant, as noted for GD 6-28, it can be deduced that the gestational window of GD 23-26 was the most susceptible time of exposure for eliciting developmental toxicity.

## METHYL IODIDE-INDUCED HYPOTHYROIDISM IN FETAL RABBITS.

E. D. Sloter<sup>1</sup>, M. D. Nemec<sup>1</sup>, R. Baumgartner<sup>1</sup>, J. F. Holson<sup>1</sup>, M. Gargas<sup>2</sup> and J. Kinzell<sup>3</sup>. <sup>1</sup>WIL Research Laboratories, Inc., Ashland, OH, <sup>2</sup>The Sapphire Group, Inc., Beavercreek, OH and <sup>3</sup>Arvesta Corporation, San Francisco, CA.

Methyl iodide (MeI) is a water soluble monohalomethane under review for US registration as a non-ozone depleting alternative to methyl bromide in the pre-plant soil fumigation market. A previous developmental toxicity study identified a window of susceptibility for MeI-induced fetotoxicity late in rabbit gestation, i.e., gestation days (GD) 23-26. To investigate a possible mode of action, the ontogeny of fetal serum chemistry, hematology, serum iodide, glutathione, hemoglobin adducts as well as thyroid structure and function was characterized in unexposed rabbits during GD21-27. Furthermore, 10 time-mated New Zealand White rabbits per group were exposed to MeI at 25 ppm by whole-body inhalation for 6 hrs/day fol-

lowing either a 2-day (GD23-24) or 4-day (GD23-26) exposure regimen. The mean incidence of late fetal deaths was 5-6% across exposure groups, compared to 1-2% in the baseline groups. T4 and T3 levels in fetal serum were 64% and 47% of baseline values, respectively, following the 2-day exposure and 21% and 105% of baseline following the 4-day exposure. TSH was 87% of baseline values following 2 days of exposure and 711% of baseline following 4 days of exposure. Increased TSH and diminished T3 and T4 serum concentrations were consistent with microscopic changes present in the thyroids of 56% and 99% of fetuses following the 2- and 4-day exposure regimens, respectively. MeI-induced changes in fetal thyroids were characterized by decreased amounts of colloid in the follicular lumen, a hypertrophic follicular epithelium and vacuolation of the epithelial cytoplasm. This window of fetal susceptibility to MeI exposure corresponded directly with the timing of critical developmental events observed in the fetal thyroids of the baseline groups, i.e., the appearance of colloid in the follicular lumen and T3 production beginning on GD22. These data implicate MeI-induced fetal hypothyroidism as a possible mode of action for late stage fetal deaths in rabbits resulting from exposure on GD23-26.

## QUANTITATIVE ASSESSMENT OF DERMAL SENSITIZATION RISK FROM TREATED ARTICLES: HEXAVALENT CHROMIUM (CRVI) AS A CASE STUDY.

T. McMahon and J. Chen. USEPA, Washington, DC.

Reporting of the potential for a pesticide to cause allergic contact dermatitis (ACD) within EPA's Office of Pesticide Programs (OPP) is typically communicated through precautionary labeling language for residential exposures, and through appropriate engineering controls or personal protective equipment in the occupational setting. In contrast to labeled pesticides, the marketing of treated articles (in which a registered pesticide is incorporated into the article to protect the integrity of the article itself) bear no such labels, and thus the public may unknowingly be exposed to potential dermal sensitizers without a means of communication of risk. Recently, the OPP, through scientific peer review and discussion, developed the foundation of a scientifically sound approach to quantitative assessment of dermal sensitization risk using hexavalent chromium in treated wood as a case study. A level of concern of 0.009 µg/cm<sup>2</sup> for hexavalent chromium was determined by the OPP to be protective against induction of ACD in non-sensitized persons as well as protective against elicitation of ACD in previously sensitized persons. This case study provides a scientifically sound basis for future risk assessments involving quantitation of risk for ACD.

## THE USE OF RISK ASSESSMENT IN EVALUATING FOOD BIOSECURITY OPTIONS.

A. M. Kadry<sup>1</sup>, C. Maczka<sup>2</sup>, P. Santiago<sup>2</sup> and L. Borghi<sup>3</sup>. <sup>1</sup>Risk Assessment Division, OPHS/USDA/FSIS, Washington, DC, <sup>2</sup>OFSEP/USDA/FSIS, Washington, DC and <sup>3</sup>Science Applications International Corporation, Germantown, MD.

For nearly a century, the US Department of Agriculture (USDA) has been protecting the nation's food supply. Food Safety and Inspection Service (FSIS) program personnel in meat, poultry, and egg product plants at ports-of-entry and at various food distribution points, work to prevent, detect, and respond to food safety emergencies. Recent world events have heightened awareness for the need to safeguard the food supply and supporting infrastructure from biological or chemical attack. In biosecurity evaluations, risk assessment helps to focus limited resources on foods, agents, and areas of greatest concern and which would likely yield the largest benefits in averting or minimizing the effects of an attack. United States regulatory agencies currently use numerous methods to evaluate the risk of a chemical or biological attack on the nation's food supply, including: Operational Risk Management Method (ORM); Risk Ranking Method (RRM); and the CARVER Method. The ORM process allows systematic risk decision-making that manages risk as part of a whole operation. There are six steps to implement ORM: Hazard Identification, Risk Assessment, Risk Control Measures, Control Decision, Risk Control Implementation and Supervision and Review. RRM is applied in four steps: Hazard Identification, Hazard Characterization, Exposure Assessment, and Risk Characterization. The CARVER Methodology considers seven factors that affect the attractiveness of a target: Criticality; Accessibility; Recoverability; Vulnerability, Effect, recognizability and shock. The purpose of this report is to provide basic information on the current procedures for evaluating the risk associated with food contaminated with chemical or biological agents.

## MYCOTOXIN RISK ASSESSMENT FOR THE PURPOSE OF SETTING INTERNATIONAL REGULATORY STANDARDS.

F. Wu. Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, PA. Sponsor: M. Karol.

The 2003 Council for Agricultural Science and Technology Mycotoxin report states that one 21st century goal is development of uniform regulations worldwide for foodborne mycotoxin contamination. This study informs that endeavor by a

risk assessment and economic analysis of two important mycotoxins: fumonisins and aflatoxins. The goals are to identify the nations that would be most heavily impacted by tighter mycotoxin regulations, examine costs and benefits as a function of regulatory stringency, and address risk-risk tradeoffs between health benefits and economic losses from compliance with those regulations. Among industrial nations, the United States would experience the heaviest economic losses from more precautionary mycotoxin standards. Environmental conditions in the developing world, however, are more conducive to mycotoxin accumulation in crops. Contrary to concerns expressed among policymakers, the less developed countries that would likely experience the greatest loss from tighter mycotoxin standards are not sub-Saharan African nations, but China and Argentina. If a fumonisin standard of 0.5 mg/kg were adopted worldwide, total export losses from fumonisins in corn may exceed \$300 million annually: threefold higher than if the less stringent US standard of 2 mg/kg were adopted. Likewise, export losses from aflatoxins in peanuts may exceed \$450 million under the current EU regulatory standard of 4 µg/kg; almost fivefold higher than if the US standard of 20 µg/kg were adopted. Stricter standards are unlikely to improve health significantly. In less developed countries such as China where hepatitis B and C are prevalent, tighter aflatoxin standards may increase health risks until improved control methods for aflatoxins are found, as high-quality crops are exported instead of being consumed domestically.

#### ASSESSMENT OF THE TOXICOLOGICAL RISK OF CHEMICAL MIXTURES AT WORKPLACE.

A. Vyskocil<sup>1</sup>, D. Drolet<sup>2</sup>, C. Viau<sup>1</sup>, F. Lemay<sup>2</sup>, G. Lapointe<sup>3</sup>, R. Tardif<sup>4</sup>, G. Truchon<sup>2</sup>, M. Baril<sup>2</sup>, N. Gagnon<sup>3</sup>, D. Begin<sup>1</sup> and M. Gerin<sup>1</sup>. <sup>1</sup>*Environmental and Occupational Health, University of Montreal, Montreal, QC, Canada*, <sup>2</sup>*IRSST, Montreal, QC, Canada* and <sup>3</sup>*CSST, Montreal, QC, Canada*.

Workers are commonly simultaneously exposed to multiple chemical agents. The regulation in Quebec, similarly to the ACGIH approach prescribes that where two or more substances are present in the work location and where they have similar effects on the same organs of the human body, the effects of these substances are considered to be additive, unless it is established otherwise. This project was undertaken to develop a toxicological database allowing the identification of possible additive or other interactive effects of mixtures present in the work environment. In the first phase of the project, standard general literature references were used to compile critical data such as target organs, effects in target organs, mechanisms of action, and toxicokinetic characteristics for each of the 668 chemical substances of the Regulation. The results of the first phase allow the prediction of potential additivity among components of a mixture. In the second phase of this project, the types of interaction for mixtures most likely to be found in workplaces and for which primary literature data are available were specified. The toxicological data were evaluated only for realistic exposure concentrations up to the STEL or ceiling value or five times the 8-h TWA PEL in humans and up to 100 times the 8-h TWA PEL or ceiling value in animals. In total, 675 studies were evaluated for 209 binary mixtures of substances. For the majority of cases where potential additivity was identified in phase 1, there is a lack of supporting toxicological data in the primary literature. In these cases, the results of the first phase will be useful for prevention purposes. The resulting database integrates the results from both phases of project. A Web-based computer tool allows the user to easily find if there is potential additivity or interaction among components of a mixture. Supported by IRSST.

#### SCIENTIFIC PEER REVIEW TO INFORM REGULATORY DECISION-MAKING: LEADERSHIP RESPONSIBILITIES AND CAUTIONS.

D. Patton<sup>1,2</sup> and S. Olin<sup>1</sup>. <sup>1</sup>*Risk Science Institute, International Life Sciences Institute, Washington, DC* and <sup>2</sup>*Consultant, Washington, DC*. Sponsor: P. Fenner-crisp.

Congress, the courts, and the public are giving increasing attention to peer review practices in federal agencies. Heightened interest carries heightened expectations for effective peer review policies and practices and, as a result, enhanced reliability and credibility for scientific and technical reports used to inform regulatory decisions. To meet these expectations, decision-makers and leaders in the federal agencies and other organizations need to know if the scientific and technical foundations of their decisions can be expected to withstand scrutiny as rulemaking products wend their way through interagency reviews, public comment and stakeholder processes, congressional oversight and judicial review. Effective peer review can provide information for this assessment. A recent ILSI Risk Science Institute report, entitled "Scientific Peer Review to Inform Regulatory Decision-Making: Leadership Responsibilities and Cautions," offers useful pointers on peer review, and potential pitfalls, with a "heads up" rather than "how to" emphasis. Without delving into the myriad technical and administrative details surrounding the peer review process, this poster highlights nine fundamental "leadership responsibilities" that determine the nature and course of peer review for any report or project. (Supported by EPA Cooperative Agreement CR-827695-01 and the ILSI Risk Science Institute)

#### A STRATEGY FOR THE SELECTION OF THE NON-RODENT IN REGULATORY PHARMACEUTICAL TOXICITY TESTING.

J. Burnett and J. Gardner. *Covance Laboratories Ltd., Harrogate, United Kingdom*. Sponsor: D. Everett.

Current regulatory practice requires safety testing to be carried out in a rodent and non-rodent mammalian species. Selection of the non-rodent species involves a strategy whereby consideration is given to the following: Similarities to human metabolic, pharmacokinetic and/or biochemical processes Similarities to human toxicity or ADME profile based on *in vivo* data Justification for numbers and species Availability of background data Previous experience with similar compounds within the same pharmacological class This poster describes how and where the use of *in vitro* and radiolabelled ADME profiling provided the basis for selection of the non-rodent species in a regulatory pharmaceutical toxicity testing programme.

**247**

#### CIRCADIAN VARIATION IN FEEDING BEHAVIOUR OF RODENTS RECEIVING POWDERED DIET ON REGULATORY TOXICITY STUDIES: 1) THE MOUSE.

D. Everett, R. Jones and F. Hallema. *Covance Laboratories Ltd., Harrogate, United Kingdom*.

During regulatory toxicity testing studies using rodents, test article is commonly administered admixed with powdered diet in order to ensure a stable plasma level. Circadian variation in feeding behaviour may result in alteration of exposure to test article. This poster reports characterisation of the circadian variation of food intake in mice maintained under typical toxicity laboratory husbandry conditions. The results are of particular use in interpreting data from investigations such as measurements of systemic exposure to test article, and helping determine the timing of such investigations during the working day.

**248**

#### ADDRESSING TOXICOLOGICAL CHALLENGES TO COMMUNITY WATER FLUORIDATION IN WASHINGTON STATE.

D. Dodge, R. C. Pleus and M. K. Peterson. *Intertox, Seattle, WA*.

Fluoride is added to thousands of public water systems in the US as a public health measure. Its primary beneficial effect is the reduction of dental caries, a health problem for nearly 80% of the world's population. The percentage of the population receiving fluoridated water in Washington State is lower than the national average; by several measures, children in Washington State lag behind other states in oral health. In order to improve the oral health of the state, the Washington Dental Service Foundation (WDSF) provides partial funding for and actively promotes water fluoridation in state communities. Despite endorsement by nearly every major public health, dental, and medical association in the nation and world, there is strong and vocal opposition to fluoridation that has made local government and the public wary of passing fluoridation measures. Recently we have assisted WDSF in addressing claims of toxicity put forth by opponents of fluoridation in several Washington communities where fluoridation measures are currently in debate. Allegations include the following: 1) health effects from fluoride itself, including skeletal fluorosis, bone fractures, cancer, and effects on the central nervous system; 2) health effects due to contaminants (e.g., arsenic, mercury) in the concentrated fluoride additive; and 3) health effects due to the leaching of chemicals (e.g., lead, aluminum) from water systems. Many of these allegations fail to recognize dose-response principles. For instance, fluoride is known to cause adverse effects at sufficient doses, but not at concentrations found in optimally treated drinking water. Risks from chemical contaminants are purported as significant simply due to their detection in concentrated solution, despite being present at levels far below toxicity and regulatory thresholds upon dilution. Still other allegations are based on poorly designed studies. We describe our experiences defending the safety of fluoride in Washington communities in the face of opposition challenges.

#### HOW STAFF GROW IN A CRO.

L. K. Earl. *Toxicology Consultancy, Huntingdon Life Sciences, Cambridgeshire, United Kingdom*. Sponsor: C. Hardy.

The benefits of providing continuous support, learning and opportunities for further development within the industrial environment are well known. Investment in staff professional development potentially leads to improved morale, feelings of self-esteem and career development opportunities. In return, highly trained, capable and motivated staff provide quality output both in respect of science and customer satisfaction. A further tangible benefit should be good staff retention. At

Huntingdon Life Sciences there is a career-long approach to learning and development supported by structured teaching programmes and appropriate support for all toxicologists within the Company. The Toxicology Education Steering Group oversees the content, direction and organisation of the programmes in place. Development of new recruits begins with an intensive induction programme and shadowing of experienced toxicologists. A foundation in the toxicological sciences is then provided and staff members are examined as a prerequisite to further promotion. Those staff meeting the criteria for taking professional examinations such as the International Diploma in Toxicology and Diploma of the American Board of Toxicology are encouraged to participate in the structured learning programme designed to prepare delegates for the examinations. In addition to in-house support, Huntingdon Life Sciences collaborates with other well established UK based industrial organisations and university toxicology departments to provide continuing education for all staff toxicologists. This holistic approach has resulted in the intellectual and professional development of staff, excellent staff retention (approximately 3% staff turnover per annum) and a high level of customer satisfaction (97% of our sponsors said performance met or exceeded their expectations).

## 250 PERCEPTION OF METHYLMERCURY RISK INFORMATION.

D. D. Petersen<sup>1,2</sup>. <sup>1</sup>ORD, USEPA, Cincinnati, OH and <sup>2</sup>Biology, University of Cincinnati, Cincinnati, OH.

Approximately 8% of American women have blood Mercury levels exceeding the EPA reference dose (a dose below which symptoms would be unlikely). The children of these women (over 300, 000 per year) are at risk of neurological deficits (lower IQ scores) primarily because of the mother's consumption of contaminated fish. Even affluent health conscious high-end fish consumers that eat swordfish or other predatory species several times a week are exhibiting symptoms of Mercury toxicity. These health risks of Persistent Bioaccumulative Toxicants (PBT) such as methyl-mercury are often underestimated because their amplification in the food chain results in toxicity, even though ambient levels of these PBTs are within seemingly acceptable limits in the water itself. Two concerns have developed from this situation (1) some of the affected groups have not been identified, and (2) means of effectively communicating the complicated risk messages to the affected groups does not readily exist. We have conducted a series of focus groups throughout the United States and have identified the primary issues surrounding how fish consumers perceive the risks. Three different formats for communicating methylmercury risk information were tested in subpopulations differing age, sex, education, risk group, occupation and locality. Written materials were preferred increasingly with age, while multimedia formats were preferred inversely with age. Web-based materials were preferred by groups seeking knowledge-level information, but not for awareness-level information. The primary factors identified, and the regional, age group and risk group differences can be used to make Mercury risk communication messages more effective by targeting the right information to the right people.

## 251 TOXICOLOGY EDUCATION - TO LEARN OR TO TEACH?

T. Malmfors. Malmfors Consulting AB, Johanneshov, Stockholm, Sweden.

A Lehman said: You too can be a toxicologist in two easy lessons, each of ten years, but he did not say how these two lessons should be spent. During the last decades many toxicology education programmes have been developed but many have also been closed down. On the other hand it is probably still a valid view that toxicologists are in great demand. How does this fit together? There are three possibilities: 1. The students recruited for the toxicology programmes do not have a suitable background. 2. The education is not conducted in an optimal way. 3. The education programmes do not deliver the right product. It is possible that the need of toxicological expertise is satisfied in other ways, e.g. by professionals with a suitable background acquiring the necessary knowledge by other means or by themselves. Furthermore, there is a need of toxicologists in developing countries. The need of toxicology knowledge in these countries is different from what the present education in the developed countries aim for. While senior toxicologist are the outermost goal in the developed countries, it is more important in the developing countries to train various experts, e.g. engineers, chemists, biologists, veterinarian and physicians, in toxicology. Thus, it would be interesting to evaluate how education programmes could serve the need of toxicologists both in developed and developing countries better by offering education to various professional groups and using training methods which are well suited to the students and what they are supposed to learn. Development of electronic communication offers possibilities for new interactive training methods as distance on-line teaching and modelling. Furthermore the facilitated access to facts makes evaluation skills even more important and has to be practised accordingly. Various interactive methods have been used at RASS and in a toxicology education programme in Estonia, Latvia and Lithuania, countries in transition. Group discussions of study cases written by the participants themselves have turned out to be a good method to train evaluation skills. In this way it is possible to cut down on the ten year lesson time.

## 252 BLOOD LEAD, ANEMIA, AND SHORT STATURE ARE INDEPENDENTLY ASSOCIATED WITH COGNITIVE PERFORMANCE IN MEXICAN SCHOOL CHILDREN.

G. G. Garcia-Vargas<sup>1</sup>, K. Kordaz<sup>2</sup>, M. Rubio-Andrade<sup>1</sup>, P. Lopez<sup>3</sup>, J. L. Rosado<sup>4</sup>, J. Alatorre Rico<sup>5</sup>, D. Ronquillo<sup>4</sup>, M. E. Cebrian<sup>6</sup> and R. J. Stoltzfus<sup>2</sup>.

<sup>5</sup>Facultad de Psicologia, UNAM, Mexico, D. F. Mexico and <sup>6</sup>Depto Toxicologia, CINVESTAV-IPN, Mexico, D. F. Mexico.

Lead exposure and nutritional factors are both associated with cognitive performance. Lead toxicity and nutritional status are also associated with each other. We examined whether nutritional status variables account for part or all of the association between cognitive performance and lead exposure. First-grade children (n = 724) ages 6–8 y, attending Mexican public schools located in the vicinity of a metal foundry were asked to participate and 602 enrolled in the study. Blood lead, iron status, anemia, anthropometry, and cognitive function were assessed. Results from 7 standardized tests are presented here. The mean blood lead concentration was  $11.5 \pm 6.1 \mu\text{g}/\text{dL}$  ( $0.56 \pm 0.30 \mu\text{mol}/\text{L}$ ) and 50% of the children had concentrations  $>10 \mu\text{g}/\text{dL}$  ( $0.48 \mu\text{mol}/\text{L}$ ). The prevalence of mild anemia ( $<124 \text{ g/L}$ ) was low (10%) and stunting ( $<2 \text{ SD}$ ) was nonexistent (2.3%). In bivariate analyses, lead was negatively associated with 4 cognitive tests and was also inversely correlated with iron status, height-for-age Z scores, and head circumference. In multivariate models, the association between lead and cognitive performance was not strongly affected by nutritional variables, suggesting that the relation of lead to cognition is not explained by lead's relation to iron deficiency anemia or growth retardation. In multivariate models, hemoglobin concentration was also positively associated with Peabody Picture Vocabulary Test and Number Sequencing performance, whereas serum ferritin was negatively related to the Coding subscale of the Wechsler Intelligence Scales for Children-Revised Mexican Version (WISC-RM). Funded by the Spencer Foundation, Chicago, IL.

## 253 LEAD EXPOSURE AS RISK FACTOR BY ALLERGY DISEASES IN MEXICAN CHILDHOOD. A PILOT STUDY.

R. Goytia-Acevedo<sup>1</sup>, G. Rodriguez<sup>1</sup>, M. Meza-Velazquez<sup>1</sup>, E. Calderon-Aranda<sup>2</sup>, G. Garcia-Arenas<sup>1</sup>, G. Rosales<sup>1</sup>, M. Rubio-Andrade<sup>1</sup>, R. Candelas<sup>1</sup> and G. Garcia-Vargas<sup>1</sup>. <sup>1</sup>Investigacion, Universidad Juarez Del Estado de Durango, Gomez Palacio, Durango, Mexico and <sup>2</sup>Toxicologia, Centro de Investigacion y de Estudios Avanzados, DF, Mexico.

A number of studies have suggested the prevalence of allergic disorders is attributable to the exposure to different environmental factors able to elicit Th2 mediated immunological responses. Lead exposure has been associated with positive modulation of Th2 responses and allergy, in human and animal models. In Torreon Coahuila, in region Lagunera-Mexico, allergy diseases are the most frequent cause of school absenteeism in children population, and exposure to lead also represents an important health problem. To evaluate lead exposure as a risk factor to allergy development in children, a pilot case-control study (28 cases and 23 controls) was performed. The clinical diagnosis of allergy, allergens contact and genetic predisposition were done through medical evaluation, skin-prick test for common allergens and a questionnaire. Total IgE level, eosinophiles were tested. Th1/Th2 cytokines profile were also evaluated in PBMC cells stimulated with ionomicine and PMA. IFN-gamma, IL-13, IL-2 and IL-4 into CD4+ cells were determined by flow cytometry. Results showed allergic rhinitis was the most frequent allergy. Allergy was positive associated to female gender, body mass index, IgE level, eosinophiles percentage and CD3+ and CD4+ cells percentage, before and after activation, respectively. Preliminary results showed Th1/Th2 cytokines response were similar in both groups; blood lead levels were under  $10 \mu\text{g}/\text{dL}$ , whereas urinary total arsenic levels (evaluated as a possible confounding factor) was under  $55 \mu\text{g}/\text{L}$ . The interaction arsenic-lead effects on allergy in children of the studied region is discussed. Sponsored by CONACYT 137610M.

## 254 DEVELOPMENT OF CHILD-SPECIFIC REFERENCE VALUES FOR SCHOOL SITE RISK ASSESSMENT.

S. Knadle<sup>1</sup>, D. W. Chan<sup>1</sup>, J. C. Carlisle<sup>1</sup>, K. E. Stewart<sup>3</sup>, C. A. Poole<sup>2</sup>, C. Vaughn<sup>2</sup>, S. Camacho<sup>2</sup> and D. M. Siegel<sup>1</sup>. <sup>1</sup>Cal/EPA, Sacramento, CA, <sup>2</sup>UC, Davis, CA and <sup>3</sup>USEPA, S.E., CA.

California law requires the Office of Environmental Health Hazard Assessment (OEHHA) in the California Environmental Protection Agency (Cal/EPA) to identify chemical contaminants at school sites that may be of concern because of child-specific exposure and child-specific physiological sensitivities. OEHHA identified 78 candidate chemicals that are known to be found, or likely to be found, at school

sites and have the potential for affecting children at lower doses than they do adults. This report is available at <http://www.oehha.ca.gov>. In order to make child-specific numerical health guidance values available, another requirement, OEHHA conducted extensive searches in the peer-reviewed literature on selected chemicals to locate quantitative studies in young animals or data from young humans. OEHHA concluded that the potential for children's sensitivity is chemical-specific. It may be due to pharmacokinetic differences in the way children's bodies absorb, distribute, metabolize, or excrete specific chemicals, or to pharmacodynamic differences in chemical/target tissue interactions, such as in the endocrine, immune, nervous, respiratory, and reproductive systems when developmental changes are occurring. When quantitative data on a critical effect specific to children can be used to determine a LOAEL, OEHHA has created a child-specific reference dose (chRD) or child-specific reference concentration (chRC) that will be used in conjunction with the "Guidance for Assessing Exposures and Health Risks at Existing and Proposed School Sites," also available at <http://www.oehha.ca.gov>. OEHHA previously reported chRDs for cadmium, chlordane, heptachlor, heptachlor epoxide, methoxychlor, and nickel. OEHHA will present chRDs for endosulfan, manganese, and pentachlorophenol, and chRCs for lead and toluene. The critical effect, citations for important studies, scientific rationale, and relationship to other existing health guidance values for each chRD or chRC will be presented.

ENVIRONMENTAL FACTORS AND PUBERTY TIMING: SUMMARY OF AN EXPERT PANEL WORKSHOP.

S. Y. Euling<sup>1</sup>, S. G. Selevan<sup>1</sup>, O. H. Pescovitz<sup>2</sup> and N. E. Skakkebaek<sup>3</sup>. <sup>1</sup>NCEA-W, USEPA, Washington, DC, <sup>2</sup>Pediatric Endocrinology/Diabetology, Indiana University, Indianapolis, IN and <sup>3</sup>University Department of Growth and Reproduction, Rigshospitalet, Copenhagen, Denmark. Sponsor: C. Kimmel.

The children's health question of whether environmental factors affect puberty timing is debated in the scientific community. The Role of Environmental Factors on the Timing and Progression of Puberty-Expert Panel Workshop was convened by Serono Symposia International to address this issue. The workshop goal was to review the data and come to consensus on three questions: 1) Are there sufficient data to suggest a secular trend in the timing of puberty markers in boys or girls from 1940 to present? 2) What are the priority research needs for environmental factors and puberty timing (for human and animal studies)? 3) What are the implications of the findings for children's public health protection? The data review, issues, and conclusions from the workshop will be presented. Major conclusions included: The majority of the panelists concluded that data for girls are sufficient to suggest a secular trend toward an earlier breast development onset and/or menarche but that data for other female pubertal markers were less reliable. Data for boys' puberty timing were considered insufficient to make a conclusion. Research recommendations included longitudinal epidemiology studies (e.g., the National Children's Study) to examine puberty markers and hormonal measurements, and the relationships between exposure to endocrine disrupting chemicals and puberty timing, and animal and human studies investigating whether precocious puberty, delayed puberty, or isolated precocious breast development are associated with outcomes later in life. Altered puberty timing was considered an adverse outcome although no agreement was reached on the magnitude of change in timing considered adverse. (Disclaimer: The views expressed are those of the author and do not necessarily reflect the views or policies of the USEPA.)

BISPHENOL A EXPOSURE AND ENDOCRINE DISORDERS IN CHILDREN.

M. Yang<sup>1</sup>, Y. Kim<sup>1</sup>, C. Shim<sup>2</sup>, S. Han<sup>3</sup> and M. Pyo<sup>1</sup>. <sup>1</sup>Pharmacy, Sookmyung Women's University, Seoul, South Korea, <sup>2</sup>Pediatrics, Seoul National University, Seoul, South Korea and <sup>3</sup>Urology, Yonsei University, Seoul, South Korea.

To clarify end points of bisphenol A (BPA)-induced health risk, we studied association between BPA exposure levels and endocrine disorders in children. To estimate BPA exposure, we analyzed urinary BPA, which was excreted as conjugated forms, with HPLC/FD. Study subjects were 84 Koreans, who answered informed consents (age, 4-16 yrs: mean, 9.2 (std, 2.1 yrs); girls, 76 %; boys, 24%): Cases (N=17) included patients who had hyperthyroid (N=7), early puberty (N=8), cryptorchidism (N=1), and varicocele (N=1); Others were hospital controls (N=67). As results, urinary BPA was detected in 76 % of subjects (range, non detectable - 311 ug/L; median, 0.31 ug/L, detection limit, 0.12 ug/L). The urinary BPA levels in cases was approx. 4 fold higher than controls (14.1 (std, 28.8 ug/L) vs. 3.79 (std, 9.51 ug/L); p=0.051). In a case of girl-endocrine disorders, such as hyperthyroid and early puberty, the above trend was more obvious (case vs. control, 14.4 (std, 33.0 ug/L) vs. 2.60 (std, 6.19 ug/L); p=0.04). Therefore, hyperthyroid and early puberty in girls are suspected as end points of BPA-induced health risk. This study was supported by NITR (National Institute of Toxicological Research)/ Korean Food & Drug Administration.

AN AGE-DEPENDENT HALF-LIFE MODEL FOR ESTIMATING CHILDHOOD BODY BURDENS OF DIBENZODIOXINS AND DIBENZOFURANS.

B. D. Kerger<sup>1</sup>, H. W. Leung<sup>2</sup>, P. Scott<sup>3</sup> and D. J. Paustenbach<sup>4</sup>. <sup>1</sup>Health Science Resource Integration, Inc., Tallahassee, FL, <sup>2</sup>Private Consultant, Danbury, CT, <sup>3</sup>ChemRisk, Pittsburgh, PA and <sup>4</sup>ChemRisk, San Francisco, CA.

This study utilized an age-dependent half life model to examine the range of childhood (ages 0-7) body burdens that correspond to selected exposure scenarios involving background dietary and environmental doses of dioxins. The scenarios examined included breast-fed and non-breast-fed infants feeding for 6 months, other dioxin uptake from foods through age 7, and exposures to urban residential soils; 50th and 95th percentile dose estimates were assessed. A simple toxicokinetic model was used which assumes that the volume of distribution for dioxins is total adipose volume and that an equilibrium exists between ingested/excreted dietary fats and the body burden of dioxins. Congener-specific half life values were estimated for the dioxin congeners that comprise the vast majority of TCDD toxic equivalents (TEQ) in human breast milk and adipose tissues, and dietary dioxin uptake estimates based on a 2001 report of the Joint FAO/WHO Committee on Food Additives were used. The model illustrates that much lower dioxin body burdens for infants and young children are generated by taking growth and fat excretion into account, resulting in lower and age-dependent effective half life estimates (0.4 to 2 years for TCDD, ages 0-7). In conjunction with observed patterns of actual body burden TEQ measurements in children, the age-dependent half life model suggests that the current tolerable daily intake estimates of 1 to 4 pg TEQ/kg-day are not likely to lead to body burdens in children that exceed background levels for adults. Due to the shorter effective half life values in young children, intake limits based on correlation of adult body burdens to animal body burdens in reproductive toxicity studies probably overstate the dioxin body burdens and associated risks per daily dose in children.

ARE THERE AGE RELATED DIFFERENCES IN CHILDRENS SUSCEPTIBILITY FOR DEVELOPING SECONDARY ACUTE MYELOGENOUS LEUKEMIA?

D. Pyatt<sup>1,2</sup>, S. Hays<sup>4</sup> and C. Cushing<sup>3</sup>. <sup>1</sup>ChemRisk, Boulder, CO, <sup>2</sup>MTEHS, University of Colorado Health Sciences Center, Denver, CO, <sup>3</sup>Exponent, Boulder, CO and <sup>4</sup>Summit Toxicology, Lyons, CO.

Secondary Acute Myelogenous Leukemia (s-AML) is a well recognized clinical entity, often the unfortunate consequence of treatment with certain classes of cytotoxic chemotherapy. Drugs known to cause AML following therapy for a primary malignancy are usually alkylating agents and/or topoisomerase II inhibitors. A variety of other potential risk factors for AML have been studied; however, only ionizing radiation, cigarette smoking and chronic high dose exposure to benzene have a sufficiently solid scientific backing to make a meaningful association. Currently, there is considerable attention being placed on childrens exposure to potential leukemogenic agents, particularly regarding benzene exposure from environmental sources. In this study, a known etiological agent for secondary acute myelogenous leukemia in children was evaluated. Specific data which allowed an evaluation of the effect of age on a childs risk of developing secondary leukemia was found in the cytotoxic chemotherapy literature. Several studies reported treatment of different aged children for the same disease with the same treatment protocols. Hodgkins disease was used to evaluate the effect of age on risk following exposure to alkylating agents, while Acute Lymphoblastic Leukemia studies reported the age specific risk of s-AML following treatment primarily with topoisomerase reactive drugs. These two classes of drugs are known to act via different mechanisms and whether or not they represent an appropriate surrogate for benzene induced AML is subject to debate. Nonetheless, the age of the child did not appear to be an independent variable for risk following treatment with either class of drug. Although the number of studies and cases is very small, the published literature on chemotherapy induced AML in children does not support the hypothesis that children will necessarily have increased susceptibility.

PBPK MODELING OF INTER-CHILD DIFFERENCES IN PHARMACOKINETICS ON THE BASIS OF SUBJECT-SPECIFIC DATA ON HEPATIC CYP2E1 LEVELS.

A. Nong<sup>1</sup>, D. G. McCarver<sup>2</sup>, R. Hines<sup>2</sup> and K. Krishnan<sup>1</sup>. <sup>1</sup>Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada and <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI.

An interindividual variability factor of 10 is used in non-cancer risk assessments to account for pharmacokinetic (PK) and pharmacodynamic (PD) differences among individuals. There has not been any effort to evaluate the inter-child variability in PK or PD of environmental agents. The objective of the present study was to incorporate experimental data on age-specific hepatic CYP2E1 content in children

(autopsy samples; 41 males and 74 females; birth to 17 years) within PBPK models for evaluating the inter-child differences in PK of toluene. The methodology involved expressing the maximal velocity for hepatic metabolism (Vmax) in terms of the CYP2E1 content in a previously validated adult PBPK model for toluene. The adult toluene PBPK model, with enzyme content-normalized Vmax, facilitated the calculation of individual-specific Vmax with knowledge of hepatic CYP2E1 protein level. The child-specific physiological parameters, except liver volume, were computed with knowledge of age and body weight, whereas physicochemical parameters were kept age-invariant based on available data. The individual-specific liver volume was included in the model. The resulting model simulated the internal dose measures for various exposure scenarios. For example, continuous exposure (12 hr) to 1 ppm resulted in an area under the arterial blood concentration vs time curve (AUC) of 0.34 to 0.41 mg/L·hr in infants under the age of a month with a low CYP2E1 concentration (<3.69 pmol/mg protein). The simulations indicate that infants under the age of one month with higher levels of CYP2E1 (4.33 to 55.93 pmol/mg protein) as well as children over a month old would have lower AUC (0.08 to 0.21 mg/L·hr). The latter values were closer to those simulated for adults (AUC 0.09 mg/L·hr). This study demonstrates the integration of data on hepatic CYP2E1 levels within PBPK models to assess the population variability of dose metrics relevant for risk assessment.

DEVELOPMENTAL EXPOSURE TO ENVIRONMENTAL ESTROGENS IS ASSOCIATED WITH OBESITY LATER IN LIFE.

E. Padilla-Banks<sup>1</sup>, W. Jefferson<sup>1, 2</sup>, R. Snyder<sup>2</sup> and R. Newbold<sup>1</sup>. <sup>1</sup>Laboratory of Molecular Toxicology, NIEHS, NIH/DHHS, Research Triangle Park, NC and <sup>2</sup>Molecular and Environmental Toxicology Department, NC State University, Raleigh, NC.

Obesity is a significant human health problem that has reached epidemic proportions in the last 2-3 decades. Obesity and overweight are associated with numerous diseases including increases in cancer rates. Commonly held causes of obesity are overeating and sedentary lifestyle imposed on a background of genetic predisposition for the disease. Although much interest has focused on these factors, the etiology of obesity remains uncertain. An emerging hypothesis is that early developmental exposure to environmental chemicals plays a role in the development of obesity later in life. Research in our laboratory has focused on effects of estrogenic compounds on differentiation. Our working premise is the developing organism is extremely sensitive to perturbation by estrogenic chemicals, and that exposure to these chemicals during critical stages of differentiation may have permanent long lasting consequences. Using diethylstilbestrol (DES) as a model chemical, we examined effects of DES on body wt.; low doses (prenatal or neonatal) caused increased body wt. and % body fat. Using PIXImus™ mouse densitometry, % fat mass was determined in 16 wk. old neonatal DES (0.001 mg/kg/day) treated mice; DES caused a significant increase over controls. Neonatal exposure to 2-OH estradiol (20 mg/kg/day) or 4-OH estradiol (0.1 mg/kg/day), doses that are approx. equal in estrogenicity to DES (0.001 mg/kg/day), caused increased body wt. showing DES is not unique. Neonatal exposure to genistein (50 mg/kg/day) caused a significant increase in body wt. Mice exposed to various estrogens are being compared to determine alterations in fat depot wt as well as hormone levels (leptin, adiponectin, etc.). Activity and feed consumption are also being measured. Our data supports the idea that brief exposure to low levels of environmental estrogens early in life is associated with increased body wt. as mice age.

PHYSIOLOGICAL PARAMETERS FOR EARLY LIFE STAGES.

S. Olin<sup>1</sup>, H. Clewell<sup>2</sup>, R. Gentry<sup>2</sup> and I. Working Group<sup>1</sup>. <sup>1</sup>Risk Science Institute, International Life Sciences Institute, Washington, DC and <sup>2</sup>ENVIRON Health Sciences Institute, Ruston, LA.

At an ILSI Risk Science Institute (RSI) workshop on assessing risks for children, the need for a comprehensive and authoritative source of physiological parameter values for early developmental life stages was noted. However, these data in humans are scattered in many different publications in the literatures of diverse disciplines and specialties, making them difficult and time-consuming to find. Over the past year an RSI expert working group has been compiling, reviewing and evaluating the available data on key physiological parameters for life stages (stages of functional maturation) from the perinatal period through adolescence, to develop a consistent and credible data set for PBPK modeling. These data have been integrated with rodent data in a pre-existent database. In this poster the database will be described, including types of data included, criteria for data selection, and approaches for summarizing data. To explore the issues associated with trying to populate the database, several case studies were conducted on selected parameters (liver weight, liver blood

flow, renal clearance, and specific enzyme systems), characterizing the nature of available data, as well as data quality issues and specific data deficiencies. For example, there is a fairly rich database on liver volume/weight over most of life, including the perinatal period, whereas data on liver blood flow is primarily flow velocity rather than flow volume. Extreme inter-individual variability of the levels of some enzymes in the perinatal period appears to result from variation in the extent of maturation. A common conclusion of the case studies was that, for the database to be useful, the data that are being incorporated must be critically evaluated, with careful consideration given to data quality and representativeness. (Supported by EPA Cooperative Agreement CR830343-01, Health Canada Contract No. H4045-03-EXSD015/4500063129 and the ILSI Risk Science Institute)

NON-CLINICAL RODENT PEDIATRIC STUDIES AT CTBR: ASSESSMENT OF MORTALITY AND GROWTH.

L. Pouliot, L. Pinsonneault, M. Adamo and K. Robinson. *Toxicology, CTBR, Senneville, QC, Canada.* Sponsor: M. Vezina.

The use of pharmaceutical and biotechnology products to treat pediatric patients requires that the conduct of pediatric animal studies be considered before clinical trials. Neonatal, weanling and juvenile rats often represent suitable models for these non-clinical studies. The most commonly used dose route in these studies is oral gavage, CTBR has conducted such studies since the 1980's with a growing number being performed since 1998. In each study, litters of rats (Sprague-Dawley or Wistar Hannover) were administered dose formulations prepared as either solutions in water or as suspensions in methyl cellulose type vehicles. Dose volumes of 4 to 10 mL/Kg/day were administered once or twice per day starting as early as Day 4 post partum (pp) for between 1 and 90 days. Typically, a standard battery of parameters (clinical observation, mortality, frequent body weight measurements, physical development, food intake post weaning, laboratory investigations, ophthalmoscopic examination, and gross and histopathological examinations) was assessed. In some studies, blood samples were obtained as early as Day 4 pp from subsets of pups for toxicokinetic profiling. Other investigations also conducted on subsets of pups were dependent upon the expected toxicology and class of compound tested and included behavioral or immunological assessments. Gradual improvement of both the pup handling procedures and modification of the dosing cannulae have contributed to mortality rates that have been comparable to those in un-dosed litters of pups from pre and postnatal studies (0 to 1% for Days 4 to 21 pp) for a number of years. Growth patterns for litters of pups dosed by gavage are similarly comparable to those of un-dosed litters. In conclusion, oral gavage dosing of rat pups does not adversely effect pup survival or growth.

**263**

AGE-RELATED DIFFERENCES IN SUSCEPTIBILITY TO TOXIC EFFECTS OF VALPROIC ACID IN RATS.

P. Espandari, T. Miller, A. Knapton, J. Zhang and J. Hanig. *CDER, USFDA, Silver Spring, MD.*

Prediction of adverse drug effects in children is a timely issue driven by recent legislation specifically mandating safe and effective drugs for children. Doses for children are often adult doses normalized to appropriate pediatric parameters in the clinic. They generally do not take cognizance of very special developmental differences that may produce significant vulnerabilities in vital target organs of children that can result in serious toxicities that are atypical in adults. Valproic acid (VPA) has been reported to cause several cases of fatal hepatotoxicity in infants and temporary increases in serum transaminases (~40% of patients). In this study, different age groups of male Sprague-Dawley (SD) rats (25, 40, 80 days old) corresponding to human toddlers, young and mature adults were treated with VPA at doses of 120, 360, 500, or 650 mg/kg i.p. injection for 4 days to determine pediatric vs. adult susceptibility. The order of sensitivity to the toxicity of VPA observed in this study was 25>80>40 days. The most dramatic toxic effects were observed in 25 day old rats at 650 mg/kg VPA: 57% survival rate, early elevations in ALT, serious G.I. disturbances, and white blood cell deficiencies. In addition, histopathology at this dose showed focal necrosis and apoptosis in the liver. Decreased serum platelet counts and diminished rate of growth were observed at all doses. In comparison, no lethality occurred in the 40 and 80 day old rat groups, and a decreased growth rate was detected in 40 day rats with all treatments. There was also an absolute weight loss in the highest dose groups at 40 and 80 days as well as the middle dose group at 80 days. This correlated with lowering of serum total protein and white blood cell counts in these age groups. Focal necrotic lesions and apoptotic cell death were observed in the liver of 80 day old rats treated with the two highest dose levels. These data indicate that the pattern of toxicity of VPA in different age groups of male SD rats is quite dissimilar. Further studies will explore these findings and its implications for pediatric drug safety.

ASSESSMENT OF HAZARD POTENTIAL AND RISK FOR ASTHMATIC RESPONSES FOLLOWING RESIDENTIAL EXPOSURE TO PHTHALATES.

R. McKee, R. David, J. H. Butala, R. Parod and L. Navarro. *Phthalate Esters Panel, Washington, DC.*

It has been hypothesized that exposure to phthalates via indoor dust inhalation may produce airway inflammation contributing to childhood asthma. Accordingly, an assessment of hazard and risk was undertaken to understand the potential for airways effects from indoor air exposure to phthalates. Phthalate esters most commonly used for indoor applications are BBP, DEHP and DINP, but lower molecular weight esters, e.g., DEP and DBP may also be present. Absent specific study designs, hazard potential was evaluated in several ways: (1) Repeated exposure studies in rats assessed the potential for airway inflammation using histologic evaluation of the respiratory tract, emphasizing the airway epithelial lining. Repeated exposure to DBP at 500 mg/m<sup>3</sup> (aerosol) produced hyperplasia and hypertrophy in nasal tissue and metaplasia in the trachea, but there were no pulmonary effects or inflammation. In previous studies of DEHP and DIDP, slight, non-specific irritation of respiratory epithelium was produced at levels > 100 mg/m<sup>3</sup>. (2) The potential for sensory irritation was obtained from studies of C6 and C10 monoesters. Exposure levels associated with 50% decreases in respiratory rate (RD50) were 525 and 187 mg/m<sup>3</sup> for the C6 and C10 monoesters respectively. (3) The potential for BBP, DEHP and DINP to influence IgE or cytokine levels was assessed in a mouse dermal application model. Total serum IgE and levels of IL-6, a cytokine associated with inflammatory responses in the lung, were not elevated. Based on measurements of phthalate levels in dust, exposure to DEHP from indoor dust inhalation would be approximately 50 ngm/m<sup>3</sup>. Thus, margins between human exposure and minimal effect levels in rodents were in the range of 100, 000 to 1, 000, 000.

BENZYL ALCOHOL: SAFETY ASSESSMENT IN JUVENILE RATS.

O. Foulon, L. Mungapen, W. Gaoua and R. Forster. *CIT, Evreux, France.*

Benzyl alcohol is used as an excipient in intravenous formulations of some pharmaceutical products, because of its antibacterial and preservative actions. It is now established that premature and newborn infants are particularly susceptible to the toxic actions of benzyl alcohol and that the use of solutions and diluents containing benzyl alcohol in newborn infants can result in "gasping syndrome" accompanied by metabolic acidosis and neurologic toxicity in newborn infants. This susceptibility probably results from differences in the metabolic and pharmacokinetic handling of benzoic acid in neonates. Regulatory measures have been taken to avoid the use of such products in newborn infants. Information is less readily available about the susceptibility of older pediatric groups (toddlers, children and adolescents) to benzyl alcohol. In order to address this question, in the present study we have examined the susceptibility of rat pups to the toxic actions of benzyl alcohol during the period from weaning to sexual maturity. Benzyl alcohol was administered by oral gavage daily to groups of 10 male and 10 female rat pups from post natal day 22 for a period of 6 weeks. Dose-levels of 100, 300 and 600 mg/kg/day were selected on the basis of published data. Control animals received vehicle only (distilled water). In addition to the evaluation of standard toxicology parameters (body weight, clinical observations, ophthalmology, haematology, blood biochemistry, urinalysis and histopathology) the study included evaluation of reactivity, learning and memory, motor activity, sexual development and respiratory function. Treatment with benzoic acid resulted in "gasping syndrome" at the higher dose-levels. A NOAEL was established for benzyl alcohol in juvenile rats.

LIPID PEROXIDATION PRODUCT INDUCED GASTRIC GROWTH IN POSTNATAL RATS BY MODULATION OF SELECTED PROTEIN KINASES.

P. C. Lee<sup>1,2</sup>. <sup>1</sup>Pediatrics, Medical College of Wisconsin, Milwaukee, WI and <sup>2</sup>Pharmacology and Toxicology, Medical College of Wisconsin, Milwaukee, WI.

Many food and food products contain the lipid oxidation product 2, 4-hexadienal (HX). Low level of exposure to HX is widespread. Long term feeding of HX led to abnormal growth of forestomach in mice and F344 rats. Our study showed that short term feeding of HX to Sprague-Dawley rats up-regulated aldehyde dehydrogenase only in their forestomachs suggesting that HX targets this tissue specifically. We examined whether short term HX feeding to young rats would affect gastric growth and whether the growth induction is accompanied by changes in specific protein kinases (PKs). Feeding rat pups for 5 days increased the mass of the fore- and glandular stomach but decreased that of the liver. The esophagus and kidney were not affected. Screening for PKs was done by Western blots using specific antibody to each of 75 selected PKs. HX feeding resulted in ~1.5 fold increase in PKC $\mu$ , CDK7 and CK2 $\alpha$ ; 2.3 fold increase in CDK9 and 1.35 fold increase in CK2 $\alpha$ . Our preliminary data indicated the trophic effect of short term HX feeding on the rat stomach is specific as it promotes growth in this organ only.

Concomitant increases in several key PKs that have important roles in cell cycle regulations were evident. Therefore, we propose that HX acts through selected PK signaling pathways in the target tissue in its growth promoting action.

GENE EXPRESSION PROFILES OF THE ARTICULAR CARTILAGE IN JUVENILE RATS TREATED WITH THE QUINOLONE ANTIBACTERIAL AGENT OFLOXACIN.

K. Goto<sup>1</sup>, K. Yabe<sup>1</sup>, S. Takada<sup>1</sup>, Y. Yamamoto<sup>1</sup>, H. Yokota<sup>2</sup>, T. Jindo<sup>1</sup> and K. Furuhama<sup>1</sup>. <sup>1</sup>Drug Safety Research Laboratory, Daiichi Pharmaceutical Co., Ltd., Tokyo, Japan and <sup>2</sup>Proteome Research Laboratory, Daiichi Pharmaceutical Co., Ltd., Tokyo, Japan.

To investigate the molecular mechanism of chondrotoxicity induced by quinolone antibacterial agents, ofloxacin (OFLX) was orally administered once at 2700 mg/kg to male juvenile (3-week-old) Sprague-Dawley rats, and then gene expression analyses in the articular cartilage of the distal femur were performed 2, 6 and 24 h after administration by using Affymetrix GeneChip Rat Toxicology U34 microarray, in conjunction with histological examination. Histopathologically, OFLX induced degeneration and/or necrosis of chondrocytes with edematous matrix and a decrease in Safranin-O staining intensity 6 h later, and cavitations 24 h later. In microarray analyses, OFLX caused up-regulation of metallothionein (MT, 2, 6 and 24 h), c-fos (6 and 24 h) and heme oxygenase-1 (HO-1, 24 h). In contrast, OFLX showed down-regulation of alpha-tubulin (Tuba1, 6 and 24 h), NADH dehydrogenase (ubiquinone) 1 alpha subcomplex 5 (Ndufa5, 6 and 24 h) and immunoglobulin heavy chain binding protein (BiP, 6 h). To further assess the expressions of these genes, quantitative real-time RT-PCR assay was conducted in the articular cartilage of juvenile rats receiving a single oral administration of OFLX at 300, 900 and 2700 mg/kg. Significantly time- and dose-dependent increases in MT-1 and -2, c-fos, HO-1 and BiP, and decreases in Tuba1 and Ndufa5 genes were observed. MT-1 and -2, c-fos and HO-1 have been reported as antioxidant response genes; Tuba1 to be related to cell proliferation and cytoskeletal organization; Ndufa5 as a component of mitochondrial respiratory chain. The above results demonstrate that the mechanisms of ofloxacin chondrotoxicity may be due to oxidative stress, followed by inhibitions of the microtubule-based process and dysfunctions of the mitochondria.

A NOVEL APPROACH TO GENERATE JUVENILE ANIMAL DATA DURING THE PRE/POSTNATAL RANGE FINDING STUDY IN THE RAT.

L. M. De Schaeprider<sup>1</sup>, G. P. Bailey<sup>1</sup>, L. M. Burns<sup>2</sup>, J. Monbaliu<sup>1</sup>, P. Annaert<sup>1</sup>, T. P. Coogan<sup>3</sup> and W. Cousensem<sup>1</sup>. <sup>1</sup>Johnson and Johnson Pharmaceutical Research & Development, Beersel, Belgium, <sup>2</sup>Sequani Limited, Ledbury, United Kingdom and <sup>3</sup>Johnson and Johnson Pharmaceutical Research and Development, Springhouse, PA.

In response to the changing regulatory environment, there has been considerable discussion on testing strategies and design of juvenile animal studies. In a desire to obtain early data on exposure and toxicity in juvenile rats, to better anticipate potential safety issues and to support prompt changes in clinical paediatric development plans, a combined range finding study has been developed. The aim of this poster is to detail the study design which is currently used in our laboratories to generate sufficient scientific data for the dose selection for both pre- and postnatal developmental toxicity studies and juvenile toxicity studies. Briefly, the combo study design can be summarized as follows: During the pregnancy/lactation study phase, 5 groups (including 2 control groups) of pregnant females are dosed from Day 6 of gestation till Day 7 of lactation. The females are allowed to litter and pups are then selected at Day 7 for the subsequent juvenile study phase. After an appropriate wash-out period, 4 groups of pups, including one of the control groups (naive animals), are dosed directly with the test material from Day 12 till Day 25 of age. Toxicokinetic data are collected from unselected pups at Day 7 (exposure via the maternal milk) and from directly dosed animals at Day 25 post-partum. The study design offers significant advantages in animal usage, cost and timing in the collection of data both from indirectly or directly dosed pups. This enables early assessment of potential safety concerns and the possibility of advancing any definitive juvenile animal study should results indicate a necessity. Further, these data may add confidence prior to initial entry into paediatric populations. In summary, the proposed combo range finding study design may play a valuable role in the pre-clinical paediatric testing strategy for some classes of pharmaceuticals.

IMPACT OF DOSE RATE ON NEUROTOXICITY OUTCOME IN CD RAT PUPS GIVEN THE N-METHYL-D-ASPARTATE (NMDA) RECEPTOR ANTAGONIST, MK-801.

M. S. Marty, J. A. Hammond, A. J. Clark, D. Rick, J. Van Fleet, A. K. Andrus and J. P. Maurissen. *Toxicology & Environmental Research, The Dow Chemical Company, Midland, MI.*

This study tested the hypothesis that a slower dose rate (small episodic doses vs. large bolus doses) would lessen the severity of MK-801 neurotoxicity in rat pups. CD rat pups (20/group) were dosed by gavage with 0, 0.2 or 0.5 mg MK-801/kg/d

from postnatal day (PND) 7-20. MK-801 was given as bolus (1x/day, 7AM) or divided doses (3x/day at 7 AM, 12 and 5 PM). Bolus pups were gavaged with water at 12 and 5 PM to control for gavage stress. Pups were monitored for clinical observations, body weight, motor activity (MA; 10/group), pre-pulse inhibition of the startle reflex (PPI; 10/group), and gross brain measurements (10/group). Clinical signs in the high-dose groups included increased activity, splayed hindlimbs, incoordinated gait, tremors (bolus only), and increased reactivity and tonic-clonic convulsions (divided only). Low-dose pups had incoordinated gait. Clinical signs were more prominent prior to PND16, but had resolved by PND20. Body weights were decreased significantly in all dose groups by PND10 with decreases of 22 and 33% in the high-dose divided and bolus groups by PND20. On PND21, MA in the low-dose divided group was decreased significantly. On PND22, PPI was decreased significantly in the high-dose bolus and divided groups (43 and 25%, respectively vs. 63% in controls) without a significant decrease in startle amplitude. This indicates a greater effect on sensorimotor gating in the divided group. Brain weights were decreased on PND22 by 11 and 8% in the high-dose bolus and divided groups, respectively. Small changes (3-5%) in cerebellar length and width were detected. These results were partially explained by kinetics data, which showed that MK-801 has a longer half-life in pups than adults, such that divided and bolus doses yielded similar MK-801 blood concentrations. Thus, dose rate impacted neurotoxicity outcome in an endpoint-dependent manner. Test material kinetics and potential exposure scenarios should be considered when designing juvenile toxicity studies.

#### COMPARATIVE DATA OF HAND-REARED AND MATERNALLY REARED INFANT CYNOLOGUS MONKEYS FOR TOXICITY STUDIES.

F. P. de Villa<sup>1</sup>, R. M. Perez<sup>1</sup>, T. Hayashi<sup>1</sup>, N. Muto<sup>2</sup>, M. Nomura<sup>2</sup> and H. Nakagawa<sup>2</sup>. <sup>1</sup>Ina Research Philippines, Inc., Binan Laguna, Philippines and <sup>2</sup>Ina Research Inc., Nagano, Japan.

Preclinical juvenile nonhuman primate toxicity studies are expected to require experimentation in a closely controlled environment so that various biochemical, behavioral and physiological parameters could be monitored as indicators of toxicity. Based on the condition that juvenile nonhuman primates were purchased from commercial breeders and separated early from their natural mothers, this prospective study was conducted to document the developmental changes according to the measurable parameters of growth, neuromotor and behavioral assessment, hematology and biochemistry measurements of twelve maternally-reared or hand-reared male and female infant cynomolgus monkeys (*Macaca fascicularis*) examined repeatedly across the first four months of life. Six (6) hand-reared infants, which were separated from their mothers within 24 hours after birth and six (6) infant macaques that continued to be nursed by their respective mothers within 2 months after birth, upon transport to the testing facility were included in the study. The available background data on these juvenile monkeys as early as two weeks of age were presented. Based on the parameters measured, our results showed that the data from the artificially reared juvenile monkeys, which experienced early maternal weaning, were comparable with those obtained from the maternally reared infants. Where toxicological research activities required that juvenile nonhuman primates be maintained early under strictly regulated conditions that would require artificial rearing, our specialized nursing and husbandry procedures were effective to produce normal growth, satisfactory health and adaptive neurobehavioral skills in these hand-reared monkeys.

#### INFLUENCE OF MATERNAL TOXICITY IN STUDIES ON DEVELOPMENTAL TOXICITY: A WORKSHOP REPORT.

F. Welsch<sup>1</sup> and E. C. Hennes<sup>2</sup>. <sup>1</sup>Orbitox, Santa Fe, NM and <sup>2</sup>ECETOC, Brussels, Belgium.

This Workshop, prepared by an Organizing Committee, was convened to explore whether the criteria to assess the influence of toxic effects induced in the maternal organism on the development of the embryo/foetus could be improved for classification purposes. Studies following OECD 414 guidelines often cause maternal toxicity because of high doses that secondarily can produce indirect effects on the progeny. Four topical presentations, followed by breakout group and plenary discussions, evaluated criteria for the interpretation of developmental effects occurring concurrent with maternal toxicity. Research needs were defined to provide better insight into the incidence of secondary effects and more precise distinctions from primary developmental toxicity. The workshop led to the following conclusions/recommendations: 1) Hazard-based classifications overlook exposure conditions. Primary developmental toxicity and secondary effects caused by chemically-induced perturbations of maternal homeostasis are not differentiated. Anticipated human exposure should be considered, and risk assessment should be entered into regulatory classifications. 2) Route and mode of dosing, dose-response data, as well as toxicokinetics/ toxicodynamics should guide study design since

toxic effects depend on how a chemical enters into the body. 3) The use of more sensitive end points (acute phase response, e.g., serum proteins; serum zinc and hepatic metallothionein concentrations; hematology; clinical chemistry/pathology) to detect the onset of maternal toxicity received solid endorsement. An experimental way forward with pilot test chemicals emerged. Such new knowledge could enter into future study design. The new data might improve the interpretation of OECD 414 study results and provide an improved scientific basis for regulatory decisions. 4) The Long-Range Research Initiative of the chemical industry that had sponsored the Workshop should consider supporting an experimental examination of the added value of expanded end points that would characterize the onset of maternal toxicity more accurately.

#### TIME-MATED RABBITS WITH VASCULAR ACCESS PORT (VAP): A NOVEL APPROACH TO THE VASCULAR SYSTEM FOR SERIAL INFUSION OR REPETITIVE BLOOD COLLECTION.

D. S. Broughton<sup>1</sup>, B. Fetter<sup>2</sup>, S. Fleener<sup>1</sup> and N. Frampton<sup>2</sup>. <sup>1</sup>Technical Services, CRP, Denver, PA and <sup>2</sup>SAD, CRP, Denver, PA. Sponsor: K. Williams.

Vascular access ports (VAPs) are currently available in a multitude of animals: rodents, lagomorphs, canines, ferrets, non-human primates and farm animals. For more than 3 years, time-mated rabbits equipped with VAPs have been available to the reproductive toxicology community. The fasted rabbit was anesthetized with a combination of Xylazine and Ketamine. Buprenorphine was administered 10 minutes prior to anesthesia, in order to reduce pain during recovery. Isoflurane was available if needed. A VAP (PMID port attached to 5F polyurethane catheter with rounded tip, devices fabricated from medical grade materials under stringent controls) was surgically implanted into one of the rabbit's jugular vein and secured caudal to the scapula. Post surgery analgesic, Buprenorphine, was administered for 2 days during recovery. The port/catheter was flushed and locked weekly prior to shipment. 380 New Zealand White (NZW) rabbits were surgically implanted with jugular VAPs by Covance Research Products (CRP), allowed 2 weeks to recover, then time-mated prior to shipment. All VAPs were patent prior to shipment and 370 remained patent after being placed on study. 360 of the 380 rabbits had viable fetus on necropsy. Animals on study were repetitively infused daily for 2 weeks. Internal and external data has provided evidence of success rates of more than 90% (i.e., animal with litter after mating, evidence of pregnancy during necropsy, patent device and no evidence of fetal anomalies in control animals). The time-mated VAP technology is an asset to researchers who investigate the effects a specific compound has on the fetus.

#### EFFECTS OF FEED RESTRICTION ON EMBRYO-FETAL DEVELOPMENT IN RATS AND RABBITS.

T. N. Lawrence, L. Tripp, M. S. Gilman, G. D. Cappon, M. E. Hurtt and T. L. Fleeman. *Pfizer Global Research and Development, Groton, CT.*

Pharmaceuticals intended to reduce appetite and promote weight loss will generate safety data that will be challenging to interpret. To aid with this, the effects of feed restriction on rat and rabbit embryo-fetal development were investigated. Groups of 20 pregnant Sprague-Dawley rats were offered ad lib, 20, 15, 10 and 7.5 g/d from GD 6-17 and groups of 15 pregnant New Zealand White rabbits were offered 150 (control), 110, 75, 55, 35 and 15 g/d from GD 7-19. Cesarean sections were performed on GD 21 (rats) or 29 (rabbits) and fetuses were examined for external, visceral and skeletal development. Maternal BW in rats at the end of the feed restriction period, GD 18, was reduced 0.88 and 0.80x control in the 20 and 15 g/d groups, respectively. Mean BW loss occurred at 10 and 7.5 g/d (0.95 and 0.85x GD 6 BW, respectively). Fetal BW was reduced 0.95, 0.93, 0.90 and 0.76x control at 20, 15, 10 and 7.5 g/d, respectively, resulting in a reduction in gravid uterine weight at 10 and 7.5 g/d. There was no increase in external or visceral anomalies. Skeletally, there was an increase in wavy ribs and a decrease in ossification only at 7.5 g/d. In rabbits at the end of the feed restriction period, GD 20, BW was 0.97, 0.98, 0.93, 0.94 and 0.86x control for the 110, 75, 55, 35 and 15 g/d groups, respectively. Only at 15 g/d was there a net BW loss (GD 20 BW was 0.93x GD 6 BW). Six does aborted in the 5 g/d group; there were no other abortions associated with feed restriction. Fetal BW was significantly reduced at 75, 55, 35 and 15 g/d (0.95, 0.90, 0.86 and 0.84x control, respectively). There was no increase in developmental anomalies. These data demonstrate that in rats, feed restriction-induced reductions in maternal BW of ~10% caused a reduction in fetal BW and up to a 15% maternal BW loss had no effect on embryo viability, but reduced fetal BW enough to cause developmental delays. Feed restriction-induced maternal BW loss in rabbits of ~7% was associated with abortion, but mild maternal BW reductions resulted in reduced fetal BW at feed levels  $\leq$  75 g/d.

## MICROARRAY-BASED ANALYSIS OF NUTRITION-ETHANOL INTERACTIONS DURING GESTATION.

K. Shankar<sup>1,3</sup>, M. Hidstrand<sup>1,3</sup>, B. Yarberry<sup>3</sup>, R. Xiao<sup>2,3</sup>, F. A. Simmen<sup>2,3</sup>, T. M. Badger<sup>2,3,1</sup> and M. J. Ronis<sup>1,3</sup>. <sup>1</sup>*Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR*, <sup>2</sup>*Physiology and Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR* and <sup>3</sup>*Arkansas Children's Nutrition Center, Little Rock, AR*.

Undernutrition markedly potentiated fetotoxicity of ethanol (EtOH) during pregnancy. To understand the mechanisms of this interaction, time-impregnated rats were fed either adequate (NRC requirements, 220 kcal/ kg<sup>3/4</sup>/d) or undernourished diets (30% less calories, 160 kcal/ kg<sup>3/4</sup>/d) via intragastric infusion containing either 12 g/kg/d EtOH or isocaloric amount of carbohydrates from gestation days (GD) 6-15. Undernourished dams had 1.6 fold greater mean urine EtOH concentrations (p = 0.007), higher complete litter resorptions (33% vs. 0%), lower litter weight and lower numbers of pups/litter (p <0.05) compared to control rats given the same dose of EtOH but fed adequate diets. Undernutrition in the absence of EtOH did not increase any parameters of fetal toxicity. Affymetrix RU34A GeneChip microarray-based comparisons were performed on maternal hepatic gene expression on GD 15. Expression of 101 genes was altered by the combination of EtOH and undernutrition as compared to only 30 genes in the rats fed an adequate diet in the presence of EtOH (p <0.05). Hierarchical clustering of gene expression data resolved the affected genes into 8 clusters. Gene ontology analysis revealed that genes associated with stress and external stimulus responses, transcriptional regulation, cellular homeostasis and protein metabolism were affected uniquely in the EtOH-nutrition group, but not by EtOH alone. Microarray data were confirmed using real-time RT-PCR. Nutritional induction of metallothionein 1, rev-erbA $\alpha$  and  $\beta$ , IGFBP-1 and 4 and repression of rPER2, and glucokinase was observed (p <0.01). Undernourished EtOH fed animals had 2-fold lower IGF1 mRNA and 10-fold lower serum IGF1 protein levels compared to undernourished controls (p = 0.0002). The present data suggest that undernutrition may potentiate the fetal toxicity of EtOH in part by disrupting IGF1 synthesis and bioavailability and zinc availability to the fetus. Supported in part by R01 AA12819 (MJR).

## DEVELOPMENTAL AND REPRODUCTIVE TOXICITY OF DI-ISOHEPTYL PHTHALATE IN RODENTS.

R. H. McKee<sup>1</sup>, K. L. Pavkov<sup>1</sup>, G. W. Trimmer<sup>1</sup>, L. H. Keller<sup>2</sup> and D. G. Stump<sup>3</sup>. <sup>1</sup>*Toxicology & Environmental Sciences, ExxonMobil Biomedical Sciences, Inc., Annandale, NJ*, <sup>2</sup>*ExxonMobil Chemical Company, Houston, TX* and <sup>3</sup>*Wil Research Laboratories, Ashland, OH*.

Di-isoheptyl phthalate (DIHP) is a branched, 7-carbon phthalate ester. Since some phthalates of similar structure have been shown to produce developmental and/or reproductive effects in rodents, an assessment of the potential for DIHP to produce developmental and reproductive toxicity was conducted. In a developmental toxicity study, female rats were given DIHP by oral gavage on gestational days 6-20. There were significant reductions in uterine weight, increased resorptions, and reduced fetal weights in the high dose group (750 mg/kg). Fetal examination revealed malformations and variations of both the skeletal system and the viscera including ectopic testes. The intermediate dose, 300 mg/kg/day, was the no effect level. In a two-generation reproductive toxicity study, DIHP was administered in the diet at 1000, 4500, and 8000 ppm. There were significant effects on indicators of male reproductive development in the high dose group. In the first (F1) generation, anogenital distance was reduced, time to balanopreputial separation was increased, there was a significant increase in thoracic nipples and testicular abnormalities; weights of testes and accessory reproductive organs were significantly reduced. Testicular sperm counts and daily sperm productions were significantly reduced. Fertility was reduced in the high dose group. In the second (F2) generation, anogenital distance was significantly reduced, and there was evidence of reduced weight gain during lactation. The overall no effect level (NOEL) in the reproductive toxicity study was in the range of 64 - 168 mg/kg/day (gestation - lactation periods). By comparison, estimated exposures in the general human population are in the range of < 1 ug/kg/day.

ASSESSING THE ROLE OF CYTOSOLIC PHOSPHOLIPASE A (cPLA<sub>2</sub>) INHIBITION IN PHTHALATE ESTER TOXICITY.

R. A. Clewell, S. M. Ross, K. W. Gaido and M. E. Andersen. *CIIT Centers for Health Research, Research Triangle Park, NC*.

Fetal exposure of rats to certain dialkylphthalate plasticizers, including dibutylphthalate and diethylhexylphthalate, cause testicular malformations. These effects are associated with inhibition of fetal testosterone (T) synthesis during gestation by the monoalkylester metabolites (MBP and MEHP). Molecular and cellular targets for phthalates in the testes are unknown, causing significant uncertainty in phthalate

risk assessments. Steroidogenesis in the adult requires both LH signaling and arachidonic acid (AA) release by cPLA<sub>2</sub>. Our research includes dose response modeling, molecular modeling of cPLA<sub>2</sub>, and *in vitro* steroidogenesis and enzyme inhibition studies. In our hypothesis, MEHP binds to cPLA<sub>2</sub>, inhibiting T production and reducing AA release from membrane phospholipids. Using *in vitro* and *in vivo* dose-response models, the concentration of MEHP required to cause 50% inhibition (IC<sub>50</sub>) in high affinity cPLA<sub>2</sub> activity in human platelets was 10  $\mu$ M. The IC<sub>50</sub> for MEHP inhibition of fetal T production (estimated with a kinetic model in the female rat) was similar (4  $\mu$ M). We also studied the effect of MEHP and the cPLA<sub>2</sub> inhibitor chloroquine (CQ) on LH-stimulated progesterone (PG) synthesis in MA-10 cells. Assays were run at a maximum stimulating LH concentration (100 ng/mL LH) with inhibitor concentrations of 1, 3, 6, 10, 30, 60 and 100  $\mu$ M. Both CQ and MEHP inhibit LH-stimulated PG production. The lowest concentration of MEHP causing inhibition was 10  $\mu$ M. This value is similar to the IC<sub>50</sub> for inhibition of cPLA<sub>2</sub> and is consistent with cPLA<sub>2</sub> inhibition having a role in phthalate toxicity. Our molecular modeling of the Ca<sup>2+</sup>-binding portion of cPLA<sub>2</sub> indicates that CQ and MEHP could compete for enzyme binding with the phosphatidyl choline head group of the phospholipid substrate. Specificity of binding to the Ca<sup>2+</sup> activated portion of cPLA<sub>2</sub> may account for the structural specificity of phthalate toxicity. Studies assessing inhibition of cPLA<sub>2</sub> from various cell types will be important for confirming cPLA<sub>2</sub> as a target of these phthalates.

## MEDIUM CHAIN CHLORINATED PARAFFIN(MCCP)-INDUCED HAEMORRHAGIC LESIONS IN NEONATAL SPRAGUE-DAWLEY RATS. A ROLE FOR ALTERED VITAMIN K DISPOSITION?

C. Elcombe<sup>1</sup>, B. Elcombe<sup>1</sup>, R. Powrie<sup>1</sup>, S. Barton<sup>3</sup> and D. Farrar<sup>2</sup>. <sup>1</sup>*CXR Biosciences Ltd, Dundee, United Kingdom*, <sup>2</sup>*Ineos Chlor Ltd, Runcorn, United Kingdom* and <sup>3</sup>*Inveresk Research, Tranent, United Kingdom*.

Previously MCCPs administered to female rats prior to pregnancy and during gestation have elicited increased pup mortality associated with internal haemorrhages. This study was designed to provide data to elucidate the mechanism of haemorrhaging. F0 rats were allocated to one control and one treated group. The treated group rats received 6250ppm MCCP (Cereclor S52, C14-17) in the diet. The F0 animals were treated for 4 weeks prior to pairing, then throughout the mating, gestation and lactation periods. On Days 1 and 4 of lactation pups were sampled and blood samples obtained. Dam milk samples were obtained on Days 1 and 4 of lactation. At study termination (day 12 of lactation) further milk and pup samples were obtained, together with maternal plasma samples. Mating performance and the duration of gestation were similar in treated and control groups. Slight differences in litter size at birth, and pup mortality from birth to Day 4 were too small to be attributed to treatment, but pup mortality after Day 4 increased substantially in the MCCP-treated group such that few pups survived until the study was terminated. Many treated group pups had severe bruising, with visible subcutaneous fluid. During lactation, treated-dam plasma levels of Vitamin K were 10% of control plasma values. This was reflected in the milk where concentrations of vitamin K in treated-dams varied from 0%-50% of control values. Although dam clotting times were unaffected, Factor VII activity was depressed (50% of control). In the pups, there were no changes in plasma Factor VII activity at day 1. However, from day 4 onwards the activity was decreased to 20% of control pup activity. A similar decrease in Factor X activity was seen. Thus, temporal decreases in plasma clotting factor activities in the pups from the MCCP-treated rats correlated with increased pup bruising and mortality. These data suggest that modulation of Vitamin K disposition may be pivotal in the neonatal toxicity induced by this MCCP.

## EFFECTS OF EXPOSURE TO 1-BROMOPROPANE IN GESTATION AND LACTATION PERIOD ON DAMS AND OFFSPRING IN RATS.

K. Furuhashi<sup>1</sup>, H. Wang<sup>1</sup>, J. Kitoh<sup>1</sup>, H. Tsukamura<sup>2</sup>, K. Maeda<sup>2</sup>, Y. Takeuchi<sup>1</sup> and G. Ichihara<sup>1</sup>. <sup>1</sup>*Nagoya University Graduate School of Medicine, Nagoya, Japan* and <sup>2</sup>*Nagoya University Graduate School of Bioagricultural Sciences, Nagoya, Japan*.

1-Bromopropane (1-BP), an alternative for ozone-depleting solvents, is known to exhibit neuro-reproductive toxicities in adult rats and humans. The present study investigated the effects of exposure to 1-BP in the gestation and lactation period on dams and offspring in rats. Experiment 1: Fifty Wistar-Imamichi adult female rats were divided into 5 groups of ten each. After confirmation of pregnancy, the 4 groups were exposed to 1-BP throughout gestation and lactation period at 0, 100, 400 and 800 ppm, respectively, for 8 h/d with a 2.5-h rest between two 4-h exposures. After delivery, the number of offspring was reduced to 4 males and 4 females. The rats were put back in their cages during an intermission between exposures to nurse their offspring after delivery. The remaining one group was not moved to chambers throughout the experiment. Experiment 2: Forty female rats were divided into 4 groups of ten each. One group was exposed daily to 1-BP at 800 ppm

throughout the gestation and lactation period, and the other 3 groups were given only fresh air in chambers. After delivery, the offspring of the exposed-group and the non-exposed group were exchanged. Offspring (Group I) of the non-exposed dams were nursed by the exposed dams, and those (Group II) of the exposed dams were nursed by the non-exposed dams. The offspring of the remaining two non-exposed groups were then exchanged (Group III and IV). In experiment 1, the survival rate up to weaning decreased dose-dependently. In experiment 2, the survival rate and body weight of offspring in Group I and II were significantly lower than in Group III and IV. The comparison of Group I and II did not show any difference in survival rate, but Group I showed significantly lower body weight gain than Group II. The results suggested that the survival rate might be affected by both exposures in the gestation and lactation period, but that the body weight gain might be affected mainly by exposure in lactation.

L-THREO 3, 4-DIHYDROXYPHENYL SERINE (DOPS) TREATMENT DURING PERINATAL DEVELOPMENT DOES NOT ALTER THE IMPACT OF DIETARY COPPER DEFICIENCY IN MICE.

J. Pyatskowit and J. R. Prohaska. *University of Minnesota-Duluth, Duluth, MN.*  
Sponsor: K. Wallace.

Alteration in catecholamine metabolism results in pathophysiological consequences. Blockage of norepinephrine (NE) synthesis in mice by deletion of the cuproenzyme dopamine beta monoxygenase (DBM) results in embryonic death. Dietary copper (Cu) deficient mice have lower NE but higher dopamine (DA) levels and poor pup survival. Might there be a connection? DOPS can be converted to NE without DBM and has been shown to rescue DBM knockout mice. Thus, perinatal Cu deficiency was induced in Swiss albino mice to investigate the effect of DOPS (a gift of Sumitomo Pharmaceuticals, Osaka, Japan) on pup survival and catecholamine levels in a 2 x 2 factorial design. Pregnant mice were placed on one of four treatments 14 days after mating. Pups were killed at postnatal day 14 (P14). Treatments were Cu adequate (Cu+) and Cu deficient (Cu-) diets with or without DOPS (1mg/mL) in the drinking water. Mortality in P14 Cu- pups was 11/24 (46%) and not significantly improved by DOPS, 14/36 (39%). Compared to Cu+ pups, Cu- mice were smaller, anemic, and had a 92% reduction in liver Cu. DOPS treatment did not alter body weight, hemoglobin, or liver Cu content in either Cu+ or Cu- mice. Catecholamine levels measured in heart and medulla/pons by LCEC showed decreased NE levels and increased DA levels in Cu- mice compared to Cu+ mice. DOPS treatment did not alter this pattern. A repeat study with ascorbic acid (2 mg/mL) added to drinking water showed increased pup mortality in Cu- mice and no effect of DOPS. Cu status markers and catecholamine levels followed the same pattern as the first experiment. DOPS was detected in heart tissue of pups in the first experiment (range 0.04-0.32 nmol/g) well below the levels of heart NE even in Cu- pups. Although DOPS was present in the pup tissue and to a greater extent in dam heart tissue, survival and catecholamine levels were not altered by the 1 mg/mL dose of DOPS; the same dose that rescued DBM knockout mice. Supported by NIH HD 39708 and 2R25-GM53421-03A1

EFFECTS OF PERFLUOROOCTANOIC ACID EXPOSURE DURING PREGNANCY IN THE MOUSE.

J. Thibodeaux, R. G. Hanson, J. M. Rogers and C. Lau. *RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Perfluorooctanoic acid (PFOA), a member of the perfluoroalkyl acids that have wide commercial applications, has recently been detected in humans and wildlife. The current study characterizes the developmental toxicity of PFOA in the mouse. CD-1 mice were mated overnight and the day on which copulatory plugs were found was designated as GD 1. Animals were given 1, 3, 5, 10, 20, or 40 mg/kg PFOA by oral gavage daily from GD2 to GD 18; controls received an equivalent volume (10 mL/kg) of water. PFOA treatment produced early, full-litter resorptions in a dose-dependent manner, leading to 100% loss in the 40 mg/kg group. Significant deficits in maternal weight gains were detected in dams of the 20 mg/kg group that carried pregnancy to term. On GD 18, some dams were sacrificed for maternal and fetal examinations while the rest were allowed to give birth for monitoring of postnatal survival, growth, and development of the pups. PFOA induced liver enlargement in the dams at all doses, but did not alter the number of implantations. In the 20 mg/kg group, the percent of live fetuses was reduced to 74% (compared to 97% in controls) the day before birth, and fetal weight ( $0.86 \pm 0.11$  g) was significantly lower than that of controls ( $1.05 \pm 0.02$  g). However, no discernable anatomical malformations were noted in any of the treatment groups. The incidence of live births was significantly lowered by PFOA in the 10 and 20 mg/kg groups (70% compared to 93% in the control group), and postnatal survival of the neonates was severely compromised in these treatment groups. Dose-dependent deficits of weight gains were detected in all PFOA-treated pups. Significant delays in eye-opening (by about 2 days) were noted in the 10 and 20 mg/kg groups, and

pubertal indices were significantly delayed (by about 3 days in males and females) in the 20 mg/kg group. These data indicate maternal and developmental toxicities of PFOA in the mouse measured as early pregnancy loss, compromised postnatal survival, and delays in postnatal growth and maturation. This abstract does not necessarily reflect USEPA policy.

281

DEVELOPMENTAL TOXICITY OF 1-BUTANOL GIVEN TO RATS IN DRINKING WATER THROUGHOUT PREGNANCY.

M. EMA<sup>1</sup>, H. Hara<sup>2</sup>, M. Matsumoto<sup>1</sup>, A. Hirose<sup>1</sup> and E. KAMATA<sup>1</sup>. <sup>1</sup>*Risk Assessment, National Institute of Health Sciences, Tokyo, Japan and*<sup>2</sup>*Ina Research, Inc., Ina, Japan.*

1-Butanol (CAS No. 71-36-3, n-butanol; n-butyl alcohol), a flammable colorless liquid with a rancid sweet odor, is widely used as an organic solvent and intermediate in the manufacture of other organic chemicals. Exposure of the general population is mainly through its natural occurrence in food and beverages and its use as a flavoring agent. The objective of this study was to evaluate the developmental toxicity of 1-butanol in rats. Pregnant rats were given drinking water containing 1-butanol at 0.2, 1.0 or 5.0% (316, 1454 or 5654 mg/kg/day) on days 0-20 of pregnancy. A significant decrease in maternal body weight gain accompanied by reduced food and water consumption was found at 5.0%. No significant increase in the incidence of pre- and postimplantation embryonic loss was observed in any groups treated with 1-butanol. Body weights of male and female fetuses were significantly lowered at 5.0%. Although a significant increase in the incidence of fetuses with skeletal variations and decreased degree of ossification was found at 5.0%, no increase in the incidence of fetuses with external, skeletal and internal abnormalities was detected in any groups treated with 1-butanol. The data demonstrate that 1-butanol is developmental toxic only at maternal toxic doses. No evidence for teratogenicity of 1-butanol was noted in rats. Based on the significant decreases in maternal body weight gain and fetal weight, it is concluded that the no observed adverse effect levels (NOAELs) of 1-butanol for both dams and fetuses are 1.0% (1454 mg/kg/day) in rats.

282

ASSESSMENT OF ISOBUTYL HEPTYL KETONE (IBHK) BY ORAL GAVAGE IN AN OECD 422 RAT REPRODUCTION/DEVELOPMENTAL SCREENING STUDY WITH SYSTEMIC AND NEUROLOGICAL ENDPOINTS.

D. M. Wilson, E. W. Carney, C. L. Zablotny, B. L. Yano and T. J. Cawley. *Dow Chemical, Midland, MI.*

Twelve CD rats/sex/group were given IBHK by daily oral gavage at 0, 100, 300, or 1000 mg/kg body weight/day (mkd). Females were dosed from 2-wk prior to breeding through postpartum day (PD) 4, then necropsied on PD 5. Males were dosed for 2-wk prior to breeding through necropsy (D39). Toxicity was assessed by daily observations, functional tests including sensory evaluation, rectal temperature, grip performance and motor activity, and terminal necropsy, organ weights, and clinical and microscopic pathology. Reproductive indices, litter size, pup survival, sex, body weight, and gross external changes were assessed. Increased salivation occurred at all doses, but was transient and in close proximity of dosing. Males had decreased hemoglobin and urinary pH at  $\geq 300$  mkd, decreased ketones at 1000 mkd, increased BUN at  $\geq 300$  mkd, and increased cholesterol, total protein, and prothrombin time at 1000 mkd; females had increased cholesterol and decreased alkaline phosphatase at 1000 mkd. Clinical pathology effects were not toxicologically significant because they were slight and near historical controls. Liver, kidney and thyroid weights were increased, with corresponding histological alterations in the liver, kidneys and thyroid of males and the liver of females. The most significant kidney lesions were degenerative, affected males  $\geq 100$  mkd, and varied in severity from very slight to moderate. Male kidney effects were accompanied by hyaline droplet formation. Hepatocellular hypertrophy occurred in the liver of males at  $\geq 100$  mkd and females at  $\geq 300$  mkd. Hypertrophy of follicular epithelial cells occurred in the thyroid of males at  $\geq 100$  mkd. There were no adverse effects on neurological function. Reproductive effects included treatment-related decreases in mean pup weights in dams given 1000 mkd. A no-observed effect level (NOEL) for general toxicity was not determined, while the NOEL for reproductive effects was 300 mkd and that for neurological effects was 1000 mkd.

283

A REVIEW OF THE ROLE OF GENOTOXICITY IN THE DEVELOPMENTAL/REPRODUCTIVE TOXICITY OF AGROCHEMICALS.

P. R. IYER<sup>1</sup> and D. W. Gammon<sup>2</sup>. <sup>1</sup>*OEHHA/RCHAS, CALIFORNIA EPA, SACRAMENTO, CA and*<sup>2</sup>*CDPR, California EPA, Sacramento, CA.*

Regulatory agencies in the USA and elsewhere require toxicity tests for agrochemicals including lifetime rodent studies to measure carcinogenicity, short-term tests to evaluate genotoxic potential, as well as developmental/reproductive toxicity studies

in laboratory animals. Compounds previously identified as causing genetic toxicity and/or cancer (as evaluated by short-term assays or lifetime rodent studies, respectively) from databases such as IARC, USEPA, CDPR and the published literature were examined for their effects in developmental/reproductive toxicity studies. Genotoxicity was assessed using the comet, Ames, chromosomal aberrations, micronucleus and UDS (unscheduled DNA synthesis) assays. Two classes of pesticides currently receiving intense regulatory scrutiny, the organophosphate insecticides and the triazine herbicides, have been included. The genotoxicity of fungicides that cause reproductive toxic effects were also examined. This investigation explores the possible role of genotoxicity in causing cancer and developmental/reproductive toxicity. Tumor sites are presented and correlations drawn, where possible, between genotoxic activity and reported oncogenicity. Similarly, correlations between genotoxicity and teratogenicity and effects on reproduction were examined. Epigenetic mechanisms are described to explain cancer and/or reproductive toxicity in the absence of genetic toxicity. For example, pesticides thought to cause cancer and/or reproductive toxicity through cytotoxicity/ mitogenic stimulation, genotoxic impurities, hormonal perturbations, enzyme induction, rodent-specific metabolites, peroxisome proliferation and hypermethylation, are provided.

#### DETERMINATION OF DART REFERENCE DOSES FOR WORKPLACE CHEMICAL EXPOSURES.

C. J. Fields<sup>1</sup>, R. J. Parod<sup>2</sup>, T. A. Lewandowski<sup>1</sup>, C. A. Bradlee<sup>2</sup>, S. L. Jasti<sup>2</sup> and E. J. Kerfoot<sup>2</sup>. <sup>1</sup>Gradient Corporation, Seattle, WA and <sup>2</sup>BASF Corporation, Wynadotte, MI.

The protection of the worker from the potential adverse effects of chemicals in the workplace is of importance to both the worker and the worker's employer. As part of a workplace program aimed at protecting workers from reproductive and developmental effects, we have been conducting screening level Developmental and Reproductive Toxicology (DART) assessments, using an approach which focuses on an individual employee's potential exposures. The DART process consists of four parts: exposure assessment, DART hazard identification, risk characterization, and risk management. The exposure assessment includes identifying chemicals to which the worker may be exposed, estimating the duration and frequency of the exposure, and a measure of the level of chemical in the workplace environment. Hazard identification involves a tiered literature search; the first source of information used is usually the American Conference of Governmental Industrial Hygienists (ACGIH) Threshold Limit Value (TLV), but if the TLV limits do not consider DART effects, other data sources such as TOXNET, Material Safety Data Sheets (MSDSs), the Environmental Protection Agency's IRIS database, and the European IUCLID database are considered. A Medline search is also performed to assure that the most recent toxicological information is included in the assessment. After a review of toxicological data, the chemical's DART potential is then classified as either Known, Suspect, Not Suspect, or Insufficient Data. For Known or Suspect chemicals, a DART Reference Dose (DRD) is calculated using either the occupational exposure limit (OEL) or animal data, whichever is more relevant. Using the individual worker's exposure data and the DRD, a hazard quotient is determined. The hazard quotient is then used by company personnel to make informed risk management decisions concerning the need for workplace exposure controls. In the first nine months of 2004, we have performed DART assessments for 15 employees and evaluated 190 chemicals, including solvents, pesticides, and pharmaceuticals.

**285**

#### DEVELOPMENT OF QSAR MODELS TO PREDICT DEVELOPMENTAL AND REPRODUCTIVE TOXICITY OF CHEMICALS.

H. Choudhury<sup>1</sup>, R. Venkatapathy<sup>2</sup> and C. Moudgal<sup>1</sup>. <sup>1</sup>NCEA, USEPA, Sodertalje, Sweden and <sup>2</sup>ORISE/NCEA-USEPA, Cincinnati, OH.

Often, there is a lack of experimental toxicity data which can be used for risk assessment for a majority of the chemicals found at contaminated sites. Generating new data would require experts in toxicology to conduct and evaluate the new studies and ethical and social issues involved with animal testing plus the cost and time for these assays would further delay remedial efforts at these sites. Predictive toxicological approaches such as Quantitative Structure-Activity Relationships (QSARs) provide a means to estimate non-carcinogenic toxicity of chemicals. Currently, a few QSAR models have been developed to predict the developmental toxicity (DT) of chemicals, while none have been developed to predict their reproductive toxicity (RT). Two commercial QSAR models (TOPKAT and Multi-Case) for DT, with LOAELs as the endpoint variables and various physicochemical properties of chemicals (descriptors) as the independent variable, have qualitative models to predict the DTs of chemicals. To meet objective, toxicity data on DT and RT for rats (74 chemicals), mice (68 chemicals) and rabbits (16 chemicals) for a total of 158 chemicals have been collected from the literature. The molecular structures were optimized to their global minimum using the CONFLEX module in CAChe (Computer Aided Chemistry) software. The descriptor generator programs

McLennan-Z, CAChe and AMPAC/CODESSA were used to generate the descriptors for the QSAR model. Initially, a single QSAR model for predicting RT and DT will be developed using Human Equivalent Dose (HED), (based on body weight scaling factors) as the dependent variable, and descriptors from the three descriptor generator programs mentioned above as independent variables. If this fails, three separate QSAR models will be developed for each end point for each species.

**286**

#### INTRODUCTION TO SYMPOSIUM: ALTERNATIVE RNA SPLICING: A MECHANISM FOR ENHANCING DIVERSITY OF GENE EXPRESSION.

C. Omiecinski. *Ctr Molec Toxicology, Penn State University, University Park, PA.*

Alternative RNA splicing is an emerging field of molecular science that has significant impact on the toxicological considerations of gene expression and protein function. The diversity of alternatively spliced transcripts has far-reaching significance in terms of understanding interindividual differences in response to xenobiotics, mechanisms of toxicity at the molecular level, tissue-specific toxicity, and the mechanisms for regulating responses to environmental and chemical challenge. This Symposium will provide an overview of basic mechanisms and toxicological significance of RNA alternative splicing, with a focus on alternatively spliced xenobiotic nuclear receptors. Importantly, the session will also address bioinformatics-related issues pertaining to the identification of splice variants, including the design of microarray and genomics platforms that facilitate variant transcript detection.

**287**

#### DISCOVERY AND TISSUE-SPECIFIC MONITORING OF ALTERNATIVE PRE-MNRA SPLICING EVENTS USING INK-JET MICROARRAYS.

J. M. Johnson, J. Castle, P. Garrett-Engele, Z. Kan, L. Lim, C. Armour, C. Raymond and E. Schadt. *Informatics, Rosetta Inpharmatics, Merck & Co., Inc., Seattle, WA.* Sponsor: C. Marcus.

To understand the biological roles, mechanism, and regulation of alternative splicing, systematic methods to monitor the splicing of exons into mature transcripts across different tissues, treatment conditions, and stages of development are needed. Microarrays offer a sensitive and parallel means to monitor transcript structure at high resolution and detect tissue-specific alternative splicing events. We have developed and optimized microarray design, sample amplification, and data analysis methods that allow tissue-specific detection of alternative splicing events using ink-jet microarrays. These tools form a robust and scalable platform we have used for discovery and analysis of alternative splicing at exons and exon-exon junctions in a systematic survey of human genes in over 50 tissues. We have used the results of these experiments to discover novel alternatively spliced isoforms of drug target genes, map the tissue distributions of known isoforms, detect changes in splicing caused by modulation of drug targets, and study the regulatory control of alternative splicing.

**288**

#### FUNCTIONALLY DISTINCT ISOFORMS OF THE FARNESOID X RECEPTOR (FXR).

P. A. Edwards, Y. Zhang and F. Y. Lee. *Biological Chemistry, UCLA, Los Angeles, CA.* Sponsor: C. Marcus.

The farnesoid X receptor (FXR) is a member of the nuclear receptor superfamily that function as ligand-activated transcription factors. FXR binds to FXR response elements together with RXR and is activated by bile acids. The single human and murine FXR genes produce multiple mRNAs as a result of the use of two distinct promoters and alternative RNA splicing. The distinct mRNAs encode four FXR isoforms that are differentially expressed in the liver, intestine, kidney and adrenals and differentially activate specific target genes. We show that the relative activation of target genes is in part dependent upon the presence or absence of four amino acids (MYTG) that lie immediately adjacent to the DNA binding domain of FXR. In order to better understand the function of the different isoforms we incubated hepatocytes, or injected mice, with adenovirus expressing specific FXR isoforms. The results reveal critical roles for FXR isoforms in regulating metabolic pathways.

**289**

#### HUMAN PXR: GENERATION OF DIVERSITY THROUGH ALTERNATIVE SPLICING AND POLYMORPHISM.

E. G. Schuetz. *Pharmaceutical Sciences, St. Jude Children's Research Hospital, Memphis, TN.* Sponsor: C. Marcus.

The pregnane X receptor/steroid and xenobiotic receptor (PXR/SXR, NR1I2) is a nuclear hormone receptor activated by the binding of many endo- and xenobiotics. PXR activates transcription of many drug-detoxification genes, leading to altered

drug clearance and to drug-drug interactions and is highly expressed in the liver and intestine. To understand whether alternative splicing contributes to individual variability and organ specific expression of PXR we analyzed PXR transcripts in 36 types of human tissue. PXR was expressed in many more human tissues than had been previously determined, including bone marrow and select regions of the brain. In each of these tissues, alternative splicing of various PXR exons resulted in transcripts that encoded distinct PXR isoforms. The most abundant alternative mRNAs lacked nucleotides in the ligand binding domain and altered PXR function. We also determined if sequence variation or alternative splicing were associated with allele specific variation in PXR expression using an allelic imbalance assay and those results will be presented. The presence of PXR in many types of human tissues and the activation of PXR by tissue-specific ligands suggest additional biological roles for this receptor.

 **290** FUNCTIONALLY DISTINCT ALTERNATIVE SPLICE VARIANTS OF THE HUMAN XENOBIOTIC RECEPTOR, CAR.

C. Omiecinski, S. Auerbach and M. Stoner. *Ctr Molec Toxicology, Penn State University, University Park, PA.*

The constitutive androstane receptor, CAR, serves as a xenobiotic sensor, especially in hepatic tissues of mammalian species, functioning to transcriptionally up-regulate a variety of biotransformation pathways, including CYP2B6 and UGT1A1. Several alternatively spliced CAR isoforms have been identified recently by our laboratory that we now show are functionally distinct. For example, CAR3 is a prominent CAR splice variant containing a 5 amino acid insertion in its ligand binding domain. Unlike the constitutively active reference form of the receptor, CAR3 displays little or no transactivation activity in the absence of ligand. However, in the presence of the specific CAR ligand, 6-(4-chlorophenyl) imidazo[2, 1-b][1, 3]thiazole-5-carbaldehyde O-(3, 4-dichlorobenzyl)oxime (CITCO), CAR3 is converted into a potent transactivator, and functions to recruit transcriptional co-activators such as SRC-1. In addition to alternatively spliced forms of the receptor, additional CAR diversity is generated through the use of internal translational start codons present in the CAR mRNA. In particular, the use of a methionine start site positioned at amino acid 76 in the receptor generates an N-terminal truncated CAR variant with unique cellular localization potential and modified capacity to activate several nuclear response elements. The diversity of structurally and functionally distinct nuclear receptors enables the expansion of the receptor repertoire, together with an enhanced xenobiotic sensing capability in mammalian systems. Supported by NIH GM66411 and GM32281.

 **291** STEROID RECEPTOR COACTIVATORS PROMOTE COORDINATE TRANSCRIPTION AND ALTERNATIVE SPLICING.

B. W. O'Malley. *Molecular & Cellular Biology, Baylor College of Medicine, Houston, TX* Sponsor: C. Marcus.

Steroid receptor coactivators, such as the SRC-1 family of molecules, are known to amplify nuclear receptor induction of gene expression, acting primarily at the initiation and re-initiation steps of transcription. Many of the currently published coactivators contain enzyme catalytic sites which are involved in chromatin remodeling and in protein modification reactions which alter the integrity of the receptor-coactivator complex at the promoter. We have searched for other applications of cell biology which might be represented by the diverse and rapidly expanding list of coactivators. We have found some novel and interesting functions. We have found that additional downstream subreactions of transcription appear to be carried out by the coactivators. For example, alternative RNA splicing appears to be regulated selectively by steroid receptors and by specific coactivators. Such findings are consistent with the current opinion that transcription and subsequent alternative splicing reactions to produce mature mRNAs are 'coupled' - and that coactivators participate in the coupling. We have tested specific coactivators and have shown them to mediate either exon inclusion or exclusion depending upon the nuclear receptor, the gene and the cell type. Using amino acid mutagenesis of the coactivator CAPERbeta, we demonstrated that specific domains in the molecule mediate the distinguishable effects on transcription initiation and RNA splicing, proving that these molecules are dual regulators of both transcription and RNA splicing. We conclude that nuclear receptor coactivators may provide the mechanism by which hormones can not only determine the quantity of gene product, but also the type of gene product. Considering that ~70% of eukaryotic genes are alternatively spliced, this mechanistic information may have important implications to many physiologic, pharmacologic, and toxicologic processes.

 **292** OVERVIEW OF DIETARY ACRYLAMIDE.

P. M. Bolger. *Center for Food Safety and Applied Nutrition, US Food and Drug Administration, College Park, MD.*

Initial investigations by Swedish researchers of fried and oven-baked foods indicated that acrylamide formation is associated with high temperature cooking processes for certain carbohydrate-rich foods, such as potatoes and cereals. Since then similar findings have been reported by researchers in other countries. The discovery of acrylamide in food is a concern because acrylamide is a potential carcinogen and genotoxin, and a known human neurotoxicant. It does not appear to be present in uncooked food and is present in low or undetectable levels in foods cooked at lower temperatures, such as by boiling. One plausible mechanism responsible for acrylamide formation in carbohydrate-rich foods cooked at high temperatures is the Maillard reaction between asparagine and certain sugars. However, not enough is known about acrylamide formation to identify safe, effective, and practical modifications to food processing techniques that will clearly prevent or reduce formation. Identifying major mechanisms of formation is an important step in identifying ways to reduce or prevent acrylamide formation during cooking. There are significant uncertainties about the impact of dietary acrylamide exposure on public health, since foods reported to contain acrylamide have been consumed for many years. While acrylamide causes cancer in laboratory animals at high doses, it is not clear whether a similar response would occur at the much lower levels found in food. Several epidemiological environmental studies of workplace and dietary exposures have failed to show an increased cancer risk with acrylamide exposure. It is also conceivable that subtle effects can occur on the developing nervous system at acrylamide doses lower than those that have been studied in animals and humans. To better assess the risk of acrylamide information is needed on dietary exposure, bioavailability from food, biomarkers of exposure, and the potential to cause cancer and neurotoxic or neurodevelopmental effects when consumed in food.

 **293** TOXICOKINETICS OF ACRYLAMIDE AND GLYCIDAMIDE IN B6C3F1 MICE AND FISCHER 344 RATS.

D. R. Doerge<sup>1</sup>, J. F. Young<sup>2</sup>, L. McDaniel<sup>1</sup>, N. C. Twaddle<sup>1</sup> and M. I. Churchwell<sup>1</sup>. <sup>1</sup>*Biochem. Toxicol., NCTR, Jefferson, AR* and <sup>2</sup>*Biometry and Risk Assessment, NCTR, Jefferson, AR*. Sponsor: P. Bolger.

Acrylamide (AA) is a widely studied industrial chemical that is neurotoxic, mutagenic to somatic and germ cells, and carcinogenic in rodents. The recent discovery of AA at ppm levels in a wide variety of commonly consumed foods has energized research efforts worldwide to define toxic mechanisms, particularly toxicokinetics and bioavailability. This study compares the toxicokinetics of AA and its epoxide metabolite, glycidamide (GA), in serum and tissues of male and female B6C3F1 mice and Fischer 344 rats following acute dosing by intravenous, gavage, and dietary routes at 0.1 mg/kg AA or intravenous and gavage dosing with an equimolar amount of GA. AA was rapidly absorbed from oral dosing, was widely distributed to tissues, was efficiently converted to GA, and increased levels of GA-DNA adducts above background were observed in liver after complete elimination from serum. GA dosing also resulted in rapid absorption, wide distribution to tissues, and produced liver GA-DNA adduct levels that were higher than those from AA. While oral administration was found to attenuate AA bioavailability from the diet and from aqueous gavage, a first-pass effect or other kinetic change resulted in higher relative metabolism to GA in both mice and rats when compared to the intravenous route. A similar effect on relative GA exposure was also evident as the administered dose of AA was reduced, which suggests that as dosing rate decreases, the conversion of AA to GA is more efficient. These findings are critical to assessment of genotoxicity of AA at low doses in the food supply, which appears to depend on total exposure to GA.

 **294** REFERENCE VALUES IN THE ACRYLAMIDE IRIS ASSESSMENT DEVELOPED BY THE USEPA.

R. S. DeWoskin. *ORD/NCEA, USEPA, Research Triangle Park, NC.*

The USEPA (USEPA) has developed an electronic database known as the Integrated Risk Information System (IRIS) that contains information on human health effects that may result from exposure to various chemicals in the environment. IRIS provides a portal to health hazard identification and dose-response assessment information. Quantitative dose-response characterization is used in conjunction with exposure data to estimate the risk to public health from exposure to a given chemical and to support risk management decisions. The on-going IRIS assessment for acrylamide contains descriptive hazard identification and quantitative information in the following categories: 1) oral reference doses and inhalation reference concentrations (RfDs and RfCs, respectively) for chronic noncarcinogenic health effects; and 2) oral and inhalation unit risks for carcinogenic effects. The noncancer reference values represent an estimate of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious noncancer effects during a lifetime. The previous IRIS assess-

ment for acrylamide (from 1988) provided quantitative estimates of carcinogenic effects from oral or inhalation exposure to acrylamide (drinking water unit risk and inhalation unit risk, respectively), and an RfD for neurological effects, but no RFC. The current assessment proposes revision to the reference values based upon more recent data from noncancer studies and an additional two-year carcinogenicity study. An RFC is also derived based upon a route-to-route extrapolation from the oral data. A number of on-going research projects are addressing data needs on the toxicokinetics and health effects of acrylamide to further improve the scientific basis of the reference values, and to reduce uncertainty. [This abstract does not necessarily reflect EPA policy.]

 **295** DIETARY ACRYLAMIDE AND RISK OF HUMAN CANCER: THE ROLE OF EPIDEMIOLOGY.

L. Mucci<sup>1</sup> and H. Adami<sup>2</sup>. <sup>1</sup>*Channing Laboratory, Harvard Medical School, Boston, MA* and <sup>2</sup>*Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden*. Sponsor: P. Bolger.

In April 2002, the Swedish National Food Administration reported the finding of elevated levels of acrylamide in commonly consumed baked and fried foods. Despite the classification of acrylamide as a probable human carcinogen, there remains a paucity of epidemiological studies examining whether dietary acrylamide could increase cancer risk. In this talk, we summarize the existing data from three case-controls studies that have examined the association between dietary acrylamide and risk of cancers of the large bowel, kidney, and bladder. We highlight results from the first two prospective studies to assess the association between dietary acrylamide and cancer risk. In the first, we assess the association between exposure to acrylamide in diet and breast cancer risk among 43,404 Swedish women aged 30-49 in the Swedish Women's Lifestyle and Health Cohort. This contributed 435,000 person-years, from which 578 breast cancer cases occurred. In the second study, we reexamine whether acrylamide in foods is related to colorectal cancer risk in the Swedish Mammography Cohort, a prospective study of 61,467 Swedish women who were followed on average for 10 years. In this cohort, 396 cases of colon cancer and 193 cases of rectal cancer occurred. Mean intake of acrylamide in the two cohorts was 26 and 25 micrograms per day, respectively. Finally, we illustrate the strengths and limitations of epidemiological studies to examine dietary acrylamide in the context of human cancer.

 **296** AN INTERNATIONAL SAFETY/RISK ASSESSMENT OF ACRYLAMIDE.

S. H. Henry. *Center for Food Safety & Applied Nutrition (HFS-308), U. S. Food & Drug Admin., College Park, MD.*

Acrylamide was the subject of an evaluation in February 2005 of an international committee of scientists the Joint Food and Agriculture Organization (FAO)/World Health Organization (WHO) Expert Committee on Food Additives (JECFA). JECFA serves as a scientific advisory body to FAO, WHO, their member states and the Codex Alimentarius Commission regarding the safety of contaminants in food moving in international trade. The conclusions of JECFA deliberations provided to the Codex influence world trade and thus have a significant economic impact on trading countries. JECFA monographs are also valuable sources of information to the international public health and scientific communities. For acrylamide, JECFA evaluated data available to date on neurotoxicity, germ cell toxicity, genotoxicity, and epidemiology, as well as studies on metabolism, biomarkers and pharmacokinetics of acrylamide in humans and rodents. The conclusions of the deliberations of the JECFA will be presented particularly regarding levels of exposure to acrylamide in human foods which may reasonably be expected to be safe as well as possible public health risks associated with these exposure levels.

 **297** ENVIRONMENTAL FACTORS AFFECTING BREAST CANCER SUSCEPTIBILITY.

S. Fenton. *USEPA, Research Triangle Park, NC.*

Breast cancer is still the most common malignancy afflicting women in the Western world. Although substantial progress has been made in elucidating some of the genetic contributors to breast cancer (i.e., the highly penetrant susceptibility genes, BRCA1 and 2), it has been estimated that only 6-12% of all breast cancer cases are due to heritable factors. Few other specific factors have been identified that contribute significantly to an individual's lifetime risk of breast cancer. It has become apparent that elements affecting cancer susceptibility (genetic or environmental components) cannot be considered separately. Environmental factors (e.g., industrial compounds, pharmaceuticals, diet, occupational hazards) have been identified in both epidemiological and rodent studies that alter breast development and tumor formation. These constituents may act as either a mutagen or as a developmental compound able to alter susceptibility to carcinogens. In addition to the contributions of environmental factors, a large percentage of cancer cases are due to sporadic mutations that may occur as a result of spontaneous genetic events, and

the interactions between gene and environmental factors. A relatively recent focus in the breast cancer field is on the interaction between genes and environment as the causal mechanism in the disease. Primary candidates for gene-environment interaction studies have been genes that encode enzymes involved in the metabolism of established cancer risk factors and those involving oxidative stress response. There are common varying forms of these genes (polymorphisms) that may directly result in impacting the risk of cancer by altering normal metabolism, circulating hormone levels, ability to respond correctly to normal stressors, or response to environmental factors. We will present data from both epidemiological and rodent studies demonstrating the importance that environmental factors play in breast cancer susceptibility. These studies will elucidate the importance of evaluating gene-environment interactions and the various environmental factors, such as diet and endocrine disrupting chemicals, on breast cancer risk assessment.

 **298** GENE-ENVIRONMENT INTERACTIONS IN THE ETIOLOGY OF BREAST CANCER.

C. Ambrosone. *Roswell Park Cancer Institute, Buffalo, NY.* Sponsor: S. Fenton.

The observation that breast cancer rates rise in women who migrate from low risk to high risk countries (e.g., from Japan to the US), and temporal and geographic patterns within the US, indicate that environmental factors are likely associated with breast cancer etiology. A role of environmental carcinogens in breast cancer is also supported by numerous animal studies. However, there has been little support in the epidemiologic literature for increased breast cancer risk with exposure to environmental factors, other than some limited data on diet. We, and others, have suggested that clear associations are masked by evaluation of heterogeneous populations, and that risk with environmental exposures may only be evident among susceptible subsets of the population, based on genetic variability in metabolic and other enzymes. The evidence for gene/environment interactions in breast cancer etiology, with examples from diet and oxidative-stress related genes and, particularly, exposure to PCBs and associated genetic variability in cytochrome P450 1A1 shall be the focus of this presentation.

 **299** INFLUENCE OF ENDOCRINE DISRUPTING COMPOUNDS (EDCS) ON MAMMARY GLAND DEVELOPMENT AND TUMOR SUSCEPTIBILITY.

S. Fenton<sup>1</sup> and J. L. Rayner<sup>2</sup>. <sup>1</sup>*Reproductive Toxicology Division, USEPA, Research Triangle Park, NC* and <sup>2</sup>*DESE, UNC, Chapel Hill, NC.*

Breast cancer risk in women is known to be influenced by genetics and prolonged exposure to estrogen. However, when known risk characteristics are considered, more than 50 percent of breast cancer cases remain unexplained. There is a growing body of evidence indicating that exposures to toxic chemicals and hormone-mimicking compounds may contribute to the development of breast cancer. Although epigenetic in nature, xenobiotics that act in an estrogenic or anti-androgenic manner may hasten development of the gland and increase the incidence of mammary tumors if they significantly alter serum estradiol levels, or if they in some way alter receptor response to endogenous estradiol levels. Nonylphenol is an example of an EDC that we have shown to hasten mammary gland (MG) development following acute *in utero* exposure. Delayed development of the MG can also be caused by *in utero* exposure to EDCs, resulting in imprinting effects in the offspring. This type of delayed glandular development could lead to increased tumor formation via an enlargement of the window of sensitivity to carcinogens. For example, a toxicant may delay MG development so that undifferentiated or dividing cells may be present for longer periods of time, thus rendering the tissue more vulnerable to a subsequent genotoxic insult. The herbicide atrazine and the polycyclic aromatic hydrocarbon, dioxin, are examples of compounds that delay MG development in rodents. These delays have been detected as early as postnatal day 4 and persist throughout sexual maturity in prenatally exposed female rats. Windows of sensitivity have been identified that lead to stunted epithelial migration and branching patterns, and extended presence of terminal end buds. These multilayered structures are sensitive to carcinogens, such as 7, 12-dimethylbenz[a]anthracene, and exposure to such agents during critical windows of susceptibility can lead to increased multiplicity or decreased latency to tumor formation. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy)

 **300** EARLY LIFE DIETARY ESTROGENIC EXPOSURES AND LATER SUSCEPTIBILITY TO MAMMARY TUMORIGENESIS.

L. A. Hilakivi-Clarke, B. Yu and M. Martin. *Oncology, Georgetown University, Washington, DC.* Sponsor: S. Fenton.

Some breast cancers may originate *in utero* as a result of an exposure to a high fetal estrogenic environment that alters normal mammary gland development and gene expression patterns. We have found that the expression of estrogen receptor (ER) -  $\alpha$  is increased in the epithelial and stromal compartments of the developing rat

mammary gland by *in utero* estradiol exposure, and this is not compensated by an up-regulation of genes that repair DNA damage, such as p53 or Brca1. We also have studied whether early life dietary exposures that modify estrogenic environment affect later breast cancer risk. For example, *in utero* dietary exposure to flaxseed that contains plant estrogens (lignans), n-Ω polyunsaturated fatty acids (PUFAs) and fiber, all of which have been previously linked to reduced breast cancer risk, surprisingly increased later carcinogen-induced mammary tumorigenesis and ER-α expression in the rat mammary glands. To identify the component in flax that may be responsible for the increased mammary tumorigenesis, we fed pregnant rats with n-Ω PUFAs or fiber. These dietary exposures reduced mammary tumorigenesis, and *in utero* exposure to fiber obtained from a whole wheat diet additionally induced a persistent up-regulation of tumor suppressors Brca1 and p53. Since the protein component of flaxseed accumulates the heavy metal cadmium to levels exceeding the maximum guidelines set by the World Health Organization, this metal might be the culprit. Cadmium and several other heavy metals bind and activate ER-α, and at human exposure levels, increase experimental mammary tumorigenesis. *In utero* exposure to heavy metals via maternal diet increases breast cancer risk in an animal model. These findings suggest that when assessing the potential effects of *in utero* dietary exposures on later susceptibility to develop breast cancer, the possibility that specific dietary components have accumulated heavy metals or contain other environmental estrogens, should be taken into account. Fetal exposure to these environmental contaminants may play a role in modifying breast cancer risk in adulthood.

### 301 DNA DAMAGE/REPAIR IN HUMAN BREAST CANCER RISK.

**J. J. Hu.** *Cancer Biology, Wake Forest U. School of Medicine, Winston-Salem, NC.*

Breast cancer accounts for nearly one-third of all cancer cases diagnosed in American women. It is estimated that about 5% of breast cancer cases are related to rare but highly penetrant genes, such as BRCA1 and BRCA2. However, low-penetrant cancer susceptibility genes may contribute to a large proportion of breast cancer cases because many of them are very common. Mammalian cells are constantly exposed to a wide variety of genotoxic agents from both endogenous and exogenous sources. Ionizing radiation, an established etiologic factor for breast cancer, and other suspected risk factors, such as chemical carcinogens, alcohol, estrogen, and diet, produce reactive oxygen species, oxidized bases, bulky DNA adducts, and DNA strand breaks. Mammalian cells have evolved distinct pathways to repair different types of DNA damage and maintain genomic integrity. Inherited reduction of DNA repair capacity may lead to deletions, amplifications, and/or mutations of critical genes that contribute to breast carcinogenesis. Previous studies have shown that deficient DNA repair and elevated DNA damage contribute to human breast cancer risk. In addition, recent data suggest that DNA-repair single-nucleotide polymorphisms (SNPs) may contribute to deficient repair function and elevated breast cancer risk. Although the functional consequences of these variant alleles may result in small changes in catalytic activity and thus a small increase in cancer risk on an individual basis, the presence of these variant alleles at polymorphic frequencies in the human population may contribute to high proportion of breast cancer cases. Furthermore, multiple DNA-repair pathways are required to maintain genome integrity, and many genes are involved in different repair pathways. For example, we provide evidence that variants of XRCC1, XRCC3, and ERCC4/XPF genes in three different repair pathways, particularly in combination, contribute to breast cancer susceptibility. In conclusion, genotypes and phenotypes in different repair pathways must be evaluated simultaneously in order to fully assess breast cancer susceptibility.

### 302 ROLE OF OXIDANT STRESS IN THE ACTIVATION OF GROWTH FACTOR SIGNALING PATHWAYS IN HUMAN BREAST EPITHELIAL CELLS BY ENVIRONMENTAL POLYCYCLIC AROMATIC HYDROCARBONS (PAHS).

**S. W. Burchiel<sup>1</sup>, A. D. Burdick<sup>2</sup>, K. F. Melendez<sup>1</sup>, F. T. Lauer<sup>1</sup> and J. W. Davis<sup>3</sup>.**  
<sup>1</sup>*College of Pharmacy, University of New Mexico, Albuquerque, NM,* <sup>2</sup>*Center for Molecular Toxicology, Penn State University, University Park, PA* and <sup>3</sup>*Worldwide Safety Sciences, Pfizer Global Research and Development, St. Louis, MO.*

There is great interest in determining mechanisms by which environmental agents contribute to the increasing incidence of human breast cancer. Benzo(a)pyrene (BaP) is an important environmental carcinogen that exerts both genotoxic and non-genotoxic actions. It is a complete carcinogen that is present in emissions from the burning of fossil fuels, woodsmoke, tobacco smoke, and in the diet where it is associated with charcoal-broiled foods. Recent work has shown that BaP exerts novel actions on the epidermal growth factor receptor (EGFR) and insulin-like growth factor (IGF) signaling pathways. Studies were performed in the human mammary epithelial cell line MCF-10A, but results have also been validated in pri-

mary cultures of normal human mammary epithelial cells (HMEC). BaP and certain AhR ligands (TCDD) protect MCF-10A cells from growth factor withdrawal-induced apoptosis. Certain metabolites of BaP, most notably BaP-quinones (BPQs) stimulate cell proliferation through an oxidant stress and redox-cycling mechanism. Stimulation of cell proliferation and inhibition of cell apoptosis are both important non-genotoxic mechanisms of tumor promotion and progression. This presentation will review the background on signaling pathways activated by PAHs and will provide new data on the toxicogenomic analysis of genes altered by BPQ treatment in MCF-10A treated cells. A conceptual basis for differential susceptibility of women to PAH-induced breast cancer will be presented based upon knowledge of polymorphisms present in PAH-activating and PAH-deactivation genes. Individual susceptibility to gene-environment interactions may be based upon these toxicogenetic differences. Supported in part by RO1 ES07925 and P30 ES012072

### 303 THE MULTI-SITE AMBIENT PARTICLE STUDY (MAPS): AN INTEGRATED APPROACH TO STUDYING HEALTH EFFECTS OF PM COMPONENTS.

**R. Devlin<sup>1</sup> and T. Gordon<sup>2</sup>.** <sup>1</sup>*USEPA, Research Triangle Park, NC* and

<sup>2</sup>*Environmental Medicine, New York University, Tuxedo, NY.*

The World Health Organization estimates that particulate air pollution (PM) is responsible for more than 500, 000 deaths worldwide each year. A large number of epidemiology studies have associated PM mass with increased mortality, and the EPA currently regulates PM on the basis of mass in different size ranges. However, recent studies suggest that PM derived from different sources may differ in toxicity and that specific PM components may serve as markers for different sources, suggesting an alternative, more efficient way of regulating PM. The overall objective of MAPS was to collect particles from several different geographical regions, characterize their physical and chemical properties, and make them available to investigators for *in vitro* and animal instillation health studies that can relate health effects with PM components and ultimately sources. Airborne particles in the ultrafine, fine, and coarse size ranges were collected in eight different locations in the US and Europe. The sites were selected to take advantage of regional differences in PM sources and components. Weekly samples were collected for a period of a month in each location, using a 3 stage particle impactor (developed at Harvard University) which is capable of collecting several mg of material during a weekly sampling interval. The particles were then assayed for a number of chemical components and made available to investigators in several different laboratories. This symposium will describe some of the studies which have characterized health effects associated with PM and PM components from each of the different geographical locations. Relating adverse health effects to specific PM size modes and specific PM chemical components is the first step towards relating these effects to PM derived from specific sources. This will ultimately allow the EPA to more effectively implement PM standards, thereby reducing not only the health impacts now associated with PM, but also their substantial impacts on quality of life and the national economy.

### 304 SAMPLE CHARACTERIZATION AND SOURCE APPORTIONMENT OF AMBIENT PARTICULATE MATTER: COMBINING ATMOSPHERIC SCIENCE AND LUNG TOXICOLOGY.

**J. M. Veranth<sup>1</sup>, G. S. Yost<sup>1</sup>, J. C. Chow<sup>2</sup> and J. G. Watson<sup>2</sup>.** <sup>1</sup>*Pharmacology and Toxicology, University of Utah, Salt Lake City, UT* and <sup>2</sup>*Atmospheric Sciences, Desert Research Institute, Reno, NV.*

**Rationale and Scope:** Ambient particulate matter (PM) chemical composition varies with time and location, and soil dust is a significant component of PM in arid regions. The USEPA and the IMPROVE network routinely measure PM composition. In principle, the PM collected at a receptor site is a linear combination of the contributions from the sources. Source apportionment by chemical mass balance is an established technique for regional airshed management. An issue is whether the observed health effects of PM are due to characteristics shared by all particles (e.g., mass, surface area, adsorbed gas-phase species) or are due to specific chemical species (e.g., metals, PAH, acids, peroxides). **Methods:** A database of dusts from over 300 soils representing various geographical locations and land uses was analyzed. *In vitro* studies are correlating cytotoxicity and cytokine release responses of lung epithelial cells (BEAS-2B) with the speciation data on soil-derived dusts. **Results:** The database analysis provided statistics on mean, S.D., and outliers for each reported chemical species. The cell culture studies indicated that some sites produced dust that induced IL-6 release 10-fold over control, while other sites produced dust that was highly cytotoxic, but that did not induce cytokine release, and other sites produced dust that appeared benign. Endotoxin did not appear to be the source of the proinflammatory signaling responses. **Conclusion:** Soil-derived particle from different sources induce different responses in a widely-used *in vitro* toxicology model. Correlating *in vitro* cell responses with PM composition data is ex-

pected to yield new insights into the relationship between pollution sources and proinflammatory signaling in the lung. This work was supported by NIEHS K25 ES011281, SERDP CP1190, and SCERP EH-03-03.

## 305 EFFECTS OF AMBIENT PM ON OXIDATIVE STRESS AND SIGNALING PATHWAYS.

L. Chen<sup>1</sup>, X. Jin<sup>1</sup>, C. Huang<sup>1</sup>, T. Gordon<sup>1</sup> and J. Hwang<sup>2</sup>. <sup>1</sup>*Environmental Medicine, NYU School of Medicine, Tuxedo, NY* and <sup>2</sup>*Statistics Institute, Academia Sinica, Taipei, Taiwan.*

Recent studies suggest that PM derived from different sources may differ in toxicity. The goal of this study is to characterize the *in vitro* effects of ambient PM and PM components from eight different locations in the US and Europe focusing on oxidative stress and related signaling pathways. Airborne particles in the ultrafine, fine, and coarse size ranges were collected in these locations for a period of a month in each location using a Harvard 3-stage particle impactor. A respiratory epithelial cell line (BEAS-2B) stably transfected with NF-κB-luciferase reporter plasmid was used in this experiment. BEAS-2B NF-κB cells were cultured in DMEM medium supplemented with 10% FBS, 100u/ml Penicillin, 100μg/ml streptomycin, 2mM L-glutamine in a 96 well plate at a density of  $9 \times 10^4$ /well and cultured up to 95% confluence. These cells were exposed to 0, 100, 300, and 500 μg/ml PM for 24 hrs. Immediately after the exposure, cells were rinsed and lysed with Luciferase Cell Cytotoxicity Reagent and the lysate analyzed for NF-κB reporter activities using a luminometer. The associations between NF-κB activity of BEAS-2B cells treated with particles and the major particle compositions were examined. Specifically, the response variable in log scale is regressed against the proportions of elemental concentrations using a mixture model. Stepwise procedures in S-PLUS were applied to find a parsimonious subset of explanatory variables to include in least square multiple regressions. The residuals from the final linear models were used to diagnose the regression model assumptions. The variations of the response variable (NF-κB activity) can be explained by the mixture of elements and amount of other compositions (mass minus the sum of all elements measured) with the adjustment of other covariates (locations and particle size fraction).

## 306 EFFECTS ON CYTOKINE PRODUCTION BY MACROPHAGES, ENDOTHELIUM AND EPITHELIAL CELLS.

J. N. Finkelstein<sup>1,2</sup>. <sup>1</sup>*Pediatrics, University of Rochester, Rochester, NY* and <sup>2</sup>*Environmental Medicine, University of Rochester, Rochester, NY.*

Using primary cultures and indicator cell lines that we have created, we have examined the effects of real world and laboratory generated particles of varying size and composition on the ability to induce gene transcription via oxidant mechanism. Mouse and human macrophages, endothelial and epithelial cells and cell lines including cell lines that have been stably transfected with an IL-8 promoter luciferase construct, were cultured in the presence of varying concentrations of coarse, fine and ultrafine size particles collected by high volume samplers at multiple sites in North America to establish a relationship between changes in gene expression and oxidant stress and size and source of ambient particles. The concentrations range from 0.5 to 19 μg/cm<sup>2</sup>. Response to these materials are assessed by measuring production of cytokines and mediators (IL-8, TNF, IL-6 MIP-2) that reflect the range of cytokine responses by these cells. Alternatively, activity of the materials was assessed by their ability to activate promoter activity of a transfected reporter. From this data we can determine the relative activity of these samples as they relate to size and composition and potential source contributions. Additionally this indicated the relative sensitivity of the different cell types to different particles. Data of this type may be helpful in comparing the role of various components of ambient PM in the induction of disease in a susceptible host. Supported by EPA Star PM Center R-827354 and P30 ES-01247.

## 307 HEALTH EFFECTS OF PARTICLES FROM TRAFFIC-RELATED AMBIENT AIR POLLUTION ON RESPIRATORY ALLERGY AND INFLAMMATION: A EUROPEAN MULTISITE STUDY.

F. Cassee<sup>1,3</sup>, T. Sandstrom<sup>3</sup> and E. Dybing<sup>2</sup>. <sup>1</sup>*Centre for Environmental Health Research (MGO), National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands*, <sup>2</sup>*Norwegian Institute of Public Health, Oslo, Norway* and <sup>3</sup>*Medicine and Allergy University Hospital, Umea, Sweden.*

Airborne particulate matter represents a complex mixture of organic and inorganic substances varying in size and composition. Particulate matter has been demonstrated to exacerbate asthma in all age groups. In addition, increases are likely in

lower respiratory symptoms and reduced lung function in children, and chronic obstructive pulmonary disease and reduced lung function in adults. Further, studies have documented an increased risk of developing lung cancer by long-term exposure to particulate matter. This paper will summarize the results of two multi site studies in Europe: Respiratory Allergy and Inflammation Due to ambient Particles (www.RAIAP.org) and Health Effects of Particles from Motor Engine Exhaust and Ambient Air Pollution (www.HEPMEAP.org). Toxicological studies show that these effects are brought about through factors such as lung inflammation, heart rate variability, changes in blood viscosity and oxygen deprivation. (1) PM2.5-10 and PM0.1-2.5 samples collected throughout Europe vary considerably in their composition and their bio-reactivity. This suggests that the PM2.5 and PM10 mass parameters are relatively crude in relationship to biological events and expected not to have strong correlations with health outcomes. (2) Though PM activities vary at a given site with time, clear regional differences in activity profiles can be identified. These differences partly relate to traffic patterns. (3) Ambient particles, at least the fine fractions, stimulate both an allergic and a non-allergic immune response. (4) Coarse and fine PM samples appear to have similar toxic activities *in vitro* and *in vivo* on a per mass unit basis, though the mechanisms and sites of action differ. The findings of the studies show clear toxicity of coarse PM, which underlines the need to consider coarse as well as fine PM in risk assessments and standard setting.

## 308 EFFECT OF SIZE FRACTIONATED AMBIENT PM SAMPLES ON INDUCTION OF PULMONARY ALLERGY IN MICE.

M. Gilmour. *NHEERL, USEPA, Research Triangle Park, NC.*

There is increasing evidence that exposure to certain air pollutants including ozone and diesel exhaust can enhance allergic sensitization to allergens. Previous work from our laboratory has shown that exposure to residual oil fly ash or its associated transition metals can enhance production of IgE antibody and T-helper 2 lymphocyte activity, resulting in increased allergic lung disease. This effect was associated with increased production of TNF-alpha in the lungs, and could be blocked with antibodies against this cytokine. We have also demonstrated that PM extracted from filters from two German cities with high and low incidence of allergic illnesses has differential effects on exacerbation of allergic biomarkers. Higher allergic responses in mice treated with the PM sample from the city with high incidence of allergies were associated with increased abundance of metal in that PM sample. Additional studies comparing the effect of two different diesel samples on the development of allergic lung disease have shown that an automotive diesel that is rich in hydrocarbons has stronger pro-adjuvant effects than a more carbonaceous diesel sample derived from a forklift truck. This presentation will describe studies investigating the relative potency of size fractionated ambient samples from cities in the U.S. and Germany to enhance induction of allergic immune responses to ovalbumin antigen in mice. Endpoints will include antigen specific and total IgE antibody in serum and lung fluid, pulmonary immune cytokines and patho-physiological markers of allergic lung disease. This abstract does not reflect EPA policy.

## 309 BROMINATED FLAME RETARDANTS: NEW FINDINGS.

L. Birnbaum<sup>1</sup> and A. J. Schecter. <sup>1</sup>*USEPA, Research Triangle Park, NC* and <sup>2</sup>*Environmental Sciences, University of Texas School of Public Health, Dallas, TX.*

The brominated flame retardants are new potential public health hazards. They resemble PCBs and are found worldwide. They can be found in carpets, styrofoam, and in household and office electrical equipment. Brominated flame retardants (BFRs), especially the common polybrominated diphenyl ethers (PBDEs) have recently been reported in humans at markedly increasing levels in blood and milk. The highest levels in humans and food worldwide have been reported in US samples. Studies of milk report 10-100 times higher levels in US than in European women. US food levels are highest in fish, then meat, and finally dairy. All human and food samples measured to date are contaminated with many of the 13 commonly reported PBDE congeners, although the congener pattern can vary in different specimens. Blood and milk levels in the USA are currently similar. PBDEs cannot be measured in 1973 blood, and are increasing markedly in humans in the USA (at the same time dioxins and PCBs are decreasing). No human health studies of these compounds have been published but cell culture and laboratory animal studies suggest certain adverse health effects, similar to those reported for PCBs which the PBDEs structurally resemble. New findings will be presented for human tissue levels and food levels in the USA and worldwide in the general population and in specially exposed workers. The uncertainty regarding toxicity of various congeners will be reviewed and compared to the dioxin toxic equivalency factor concept. No such toxicity comparison factors are available for the PBDEs at the present time

making it difficult to decide which congeners should be measured. There is currently no consensus on which to be measured; this topic will be reviewed and recommendations made. Temporal trends in human PBDE levels will be presented and compared with temporal trend for dioxins, dibenzofurans and PCBs. New toxicological findings with respect to pharmacokinetics, neurological, reproductive and developmental, endocrine, and cancer endpoints will be presented. Finally, human risk assessment will be considered.

### 310 PBDES IN US HUMANS, FOOD AND ENVIRONMENTAL SAMPLES.

A. J. Schecter<sup>1</sup>, O. Paepke<sup>2</sup>, J. Ryan<sup>3</sup>, L. Birnbaum<sup>4</sup>, D. Staskal<sup>5</sup> and K. Tung<sup>1</sup>.  
<sup>1</sup>*Environmental Sciences, University of Texas School of Public Health, Dallas, TX,*  
<sup>2</sup>*ERGO Laboratory, Hamburg, Germany,* <sup>3</sup>*Health Canada, Ottawa, ON, Canada,*  
<sup>4</sup>*USEPA, Research Triangle Park, NC and* <sup>5</sup>*UNC, Chapel Hill, NC.*

Polybrominated diphenyl ether (PBDE) flame retardants were measured in US human milk and blood, food and environmental samples. All 59 milk samples were positive for multiple congeners measured. Milk was collected beginning in 2001 from various locations in the US. PBDEs varied from 6.2 to 419 ppb lipid. In blood, we found levels from 4 to 366 in our first 39 individual analyses. In this series men had lower levels than women, although not statistically significant. Two samples of pooled blood from 100 people each had levels of 78 and 80 ppb lipid in 2003, similar to that observed in pooled serum from 100 people the same year, 62 ppb lipid. These levels are a magnitude higher than previously observed in some earlier European studies. In contrast, the concentration in a pooled archived serum sample from 100 people in 1973 was only 0.8 ppb lipid. This increasing trend is opposite to that observed for dioxins and PCBs. 44 foods of animal origin from Texas supermarkets all tested positive for multiple congeners, including the fully brominated BDE 209 congener, with highest levels in fish (especially salmon), followed by meat and then dairy. US levels are higher than published European and Japanese studies. Daily intake of PBDEs was estimated to be 163, 200 pg/kg body weight daily in US nursing infants during the first year of life and 11, 000 pg/kg daily in Germany, approximately 3, 826 pg/kg body weight for ages 2-5, and approximately 1, 300 pg/kg BW daily for ages > 19 years. Unlike dioxins and PCBs where almost all intake is from the route of consumption of animal food, it has been speculated that respiratory and dermal intake may contribute a greater portion of intake for PBDEs. Therefore, we also measured PBDEs in swipes from computer and computer monitor casings and in carpet vacuum sweepings. All samples were positive. Comparing our findings with other recent studies, we conclude that the highest levels of PBDEs in human milk, blood and in food worldwide exist in the USA. (This abstract does not reflect USEPA policy.)

### 311 TOXICOKINETICS OF BDE 47 IN MICE.

D. Staskal<sup>1</sup>, J. J. Diliberto<sup>2</sup>, M. J. DeVito<sup>2</sup> and L. S. Birnbaum<sup>2</sup>. <sup>1</sup>*UNC Curriculum in Toxicology, Research Triangle Park, NC and* <sup>2</sup>*ETD, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Polybrominated diphenylether (PBDE) congener patterns found in environmental samples and human tissue are not consistent with congener patterns found in the commercial PBDE mixtures; it is therefore essential to understand the toxicokinetic properties associated with the individual PBDE congeners. Currently, knowledge of the absorption, distribution, metabolism, and excretion is restricted to a small number of congeners which have been examined in limited *in vivo* and *in vitro* models. In general, the toxicokinetic parameters of PBDEs are dependent on the degree of bromination. With the exception of the fully-brominated congener, the PBDEs appear to be well absorbed, slowly metabolized, and distribute to lipophilic tissues. For 2, 2', 4, 4'-tetrabromodiphenyl ether (BDE 47), the major congener found in human and wildlife samples, differences in excretion rates and routes have been reported between rats and mice. In this study, the distribution and excretion of a single, oral dose (1 mg/kg) of BDE 47 was examined in adult, female C57BL/6 mice for 21 days following administration. BDE 47 was found in all tissues at all time points and distribution was dictated by lipophilicity. Elimination of BDE 47 appears to be biphasic. Highly perfused tissues have  $\alpha$  and  $\beta$   $t^{1/2}$  values of approximately 1 and 10 days, respectively. Elimination from lipophilic tissues was roughly five times slower. Although the terminal half life is long, the majority of the dose (>80%) is eliminated during the  $\alpha$ -phase. The rapid excretion of unmetabolized BDE 47 and other congeners in urine and feces suggests the presence of an active transport mechanism which may play a major role in understanding the species differences in elimination; initial results from renal transport studies support this hypothesis. Characterization of these toxicokinetic parameters will provide data needed for the development of a PBPK model which can be used in human health risk assessment. (This abstract does not reflect EPA policy. This work was partially funded by EPA NHEERL-DESE CT826513).

### 312 DEVELOPMENTAL NEUROTOXICITY OF PBDES IN MICE AND RATS.

H. Viberg, A. Fredriksson and P. Eriksson. *Environmental Toxicology, Uppsala University, Uppsala, Sweden.*

Our environment contains a vast number of contaminant including the brominated flame retardants, polybrominated diphenyl ethers (PBDEs). The PBDEs are widely found in the environment and is increasing in human milk. This means that an individual can be exposed to PBDEs during its whole lifetime, including the lactation period. We have examined the neurotoxic effects of exposure to PBDEs during a defined critical period of rapid brain development in neonatal mice and rats. The neonatal period is characterized in many mammalian species by rapid development of the immature brain. It has been shown that numerous toxicants can induce permanent disorders in brain function when administered to the neonatal mouse during the brain growth spurt (BGS). In mice and rats this period is postnatal, spanning the first 3-4 weeks of life and in the human, the BGS begins during the third trimester of pregnancy and continues throughout the first two years of life. Our studies have identified a defined critical period during the BGS in mice when the brain is vulnerable to insults of low doses of PBDEs. It has also been shown that it is the presence of PBDEs or their metabolites in the brain during this defined critical period that is crucial to evoke neurotoxic effects. Exposure to PBDEs during the short critical period of brain development leads to permanent altered spontaneous behaviour, deficits in learning and memory and disturbances in the cholinergic system, in the adult. These effects are dose-response related and tend to get worse with age. The potency of PBDEs to induce neurotoxic effects does not appear to be gender, strain or species specific, because the neurotoxic effects are induced in both male and female mice of different strains and in rats. In conclusion, the observed developmental neurotoxic effects of PBDEs are similar to the effects seen after neonatal exposure to certain PCBs and the presence of both these compounds in the environment and in human milk suggests that further attention should be focused on the neurotoxicology of PBDEs.

### 313 PBDE LEVELS AMONG US WOMEN, DAILY INTAKE AND RISK OF HARM TO THE DEVELOPING BRAIN AND REPRODUCTIVE ORGANS.

T. A. McDonald. *Office of Environmental Health Hazard Assessment, California Environmental Protection Agency, Oakland, CA.* Sponsor: L. Zeise.

The polybrominated diphenylethers (PBDEs) are a class of flame retardants widely used in electronics, furniture and textiles. PBDEs slowly migrate from these products and are now ubiquitous, measured in indoor and outdoor air, home and office dust, streams and lakes, and terrestrial and marine biota. Like PCBs and dioxins, many PBDEs are persistent and bioaccumulative, and are long lived in the body. The more bioaccumulative commercial mixtures of PBDEs have been recently banned in California, Maine and Hawaii and the European Union. Tissue levels among residents of North America are approximately 10 to 40 times higher than those of individuals in Europe or Japan, and recent data suggest that PBDE body burdens continue to rise over time in North American wildlife and humans. Five PBDEs namely, PBDE-47, 99, 100, 153, and 154, comprise more than 90 % of the PBDEs measured in US residents. The primary health concerns of PBDEs appear to be developmental effects, including harm to the developing brain and reproductive organs. PBDE levels in serum, adipose tissue, or breastmilk have been reported for individuals in six groups of women in the US. The distribution of lipid-normalized PBDE concentrations among women residing in the US was determined to be lognormal with a mean value of 87.6 ng/g and a 95th percentile estimate of 304 ng/g. Using the US body burden data and congener-specific estimates of half-lives in humans, daily intake of the sum of the five most prevalent PBDEs in people (PBDE-47, 99, 100, 153, 154) was estimated to be 4.8 ng/kg-d (median), 11 ng/kg-d (mean), and 38 ng/kg-d (95th percentile). Finally, the potential health risks posed by the PBDEs are addressed by comparing tissue concentrations in humans to estimated and measured tissue concentrations in rodents associated with developmental neurotoxicity and reproductive effects. Assuming effects in rodents are predictive of human health, the comparison suggests that the current margin of exposure is small for a significant portion of the population.

### 314 DEVELOPMENTAL TOXICOLOGY EVALUATIONS: ISSUES WITH INCLUDING NEUROTOXICOLOGY AND IMMUNOTOXICOLOGY ASSESSMENTS.

G. S. Ladics<sup>1</sup> and L. Burns-Naas<sup>2</sup>. <sup>1</sup>*DuPont Co., Newark, DE and* <sup>2</sup>*Pfizer, Inc., San Diego, CA.*

Evaluation of offspring following maternal exposures during gestation and lactation (i.e. reproductive/developmental toxicology [RDT]) has historically been a routine part of the safety assessment process. Recently, increased attention has focused on the effects of agricultural and industrial chemicals, as well as pharmaceuticals, on

the developing nervous and immune systems of the fetus and newborn. This new focus on developmental neurotoxicology (DNT) and developmental immunotoxicology (DIT) is based on the premise that the developing nervous and immune systems may be qualitatively and/or quantitatively more susceptible to chemical perturbation compared to the adult and studies conducted currently may be insufficient to protect the young. DNT studies have become common for agricultural chemicals, following the preparation of test guidelines from the USEPA (OPPTS 870.6300, 1998) and OECD (TG 426, draft). With increased DNT testing and the prospect of new DIT test guidelines, there has been considerable interest in both DNT and DIT, with many scientific workshops, roundtables, symposia, as well as sponsored research devoted to the subjects. The intent of this session is to highlight and discuss issues that are common to RDT, DNT, and DIT, including the consequences of high dose selection and maternal toxicity; the adequacy of pup exposure during lactation; whether a different dosing paradigm should be applied to RDT vs. DNT or DIT studies; whether DIT and DNT endpoints can be incorporated into a single (RDT) study for hazard identification purposes (e.g., for screening purposes, what endpoints have proven their value and should be retained). This session will provide a forum to discuss how assessment of RDT, DIT, and DNT could be integrated for hazard identification purposes and to reduce animal usage.

### 315 INTERVIEWING SKILLS FOR GRADUATE STUDENTS AND POST-DOCS.

R. J. Mitkus<sup>1</sup> and M. Pomeroy-Black<sup>2</sup>. <sup>1</sup>*Epidemiology and Preventive Medicine, University of Maryland, Baltimore, MD* and <sup>2</sup>*Biomedical Sciences and Pathobiology, Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA*.

The ability to interview well is a critical career skill, and keeping this skill up-to-date is even more important in a volatile social and economic environment. Moreover, interviewing skills that are considered important in one sector of the job market may be quite different from those in another. Therefore, it is no surprise that there are substantial differences in the expectations of employers looking to fill positions in these two areas of post-graduate employment. The purpose of this session is to expand the personal skills sets of graduate students and post-docs with regard to interviewing for post-doctoral research positions at an academic institution, faculty positions at a community college or undergraduate institution, positions in the federal government, as well as positions in the private sector. This goal will be accomplished through formal presentations on interviewing skills, followed by question-and-answer sessions. An informed presentation on interview questions that are legally permissible across all hiring sectors is an essential part of this session. Because acquiring and processing knowledge of current interviewing skills and practices is a prerequisite for putting these skills into practice, this workshop is a must for all toxicologists who are making the transition into the workforce.

### 316 INTERVIEWING FOR AN ACADEMIC POST-DOCTORAL POSITION.

M. Ehrlich. *Biomedical Sciences and Pathobiology, Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA*.

The purpose of post-doctoral training is to provide the new toxicologist with experience as a semi-independent investigator, to ease the transition to an independent investigator. Responsibilities are considerably greater than those of a graduate student, and may include exploring new frontiers for his/her mentor, managing a project (including laboratory personnel working on the project), and/or contributing to proposals that increase laboratory funding. Post-doctoral training is best done in a new environment, so the interviewer will ask why the applicant chose to do post-doctoral training, why this particular position is of interest, what the applicant can bring to the laboratory, the expectations of the applicant while employed as a post-doctoral research associate, and plans that go beyond the post-doctoral appointment. In addition to answering these questions to the best of the applicant's ability, it is important that he/she be honest about data available. To come to the interview with knowledge of current and past work of the laboratory contributes to creating a favorable impression.

### 317 INTERVIEWING SKILLS FOR A TEACHING POSITION AT AN UNDERGRADUATE INSTITUTION.

R. Resau. *Biology, McDaniel College, Baltimore, MD*. Sponsor: R. Mitkus.

There are numerous and varied colleges and universities where teaching is the primary responsibility of the faculty member and research is secondary. Some of these institutions do not expect any research effort at all. Others require research involving undergraduates, and still others expect occasional publications from the faculty member. These differences are very substantial, and require that the candidates for any given position know which alternatives they prefer, and investigate the specific characteristics of the institution offering the position. This presentation explores how to use such information to best advantage in the interview.

### 318 INTERVIEWING SKILLS FOR A POSITION IN THE FEDERAL GOVERNMENT: AN INTERVIEWER'S PERSPECTIVE.

R. J. Mitkus and A. C. Mosby. *Office of Communications and Government Relations, USEPA Region III, Philadelphia, PA*. Sponsor: R. Mitkus.

Research by the Office of Personnel Management and other organizational experts, including Dr. Paul Green, ("More than a Gut Feeling"), has determined that past performance is a valid predictor of future performance. Traditional interviewing techniques have focused on areas not directly related to the knowledge, skills and abilities required for a particular position. A newer, behavioral approach, which uses a "structured interview" process, emphasizes gaining specific examples of what a person has done in his or her education and career in order to predict future performance. This part of the workshop will discuss how the interviewer plans for and conducts the structured interview. In turn, it will allow the potential candidate to understand this process and how to prepare for a structured interview.

### 319 INTERVIEWING SKILLS FOR A POSITION IN THE PRIVATE SECTOR.

J. C. Lamb. *The Weinberg Group, Washington, DC*.

The best employers are looking for enthusiastic, informed and intelligent candidates with the ambition to grow their career. How you approach the interview can profoundly affect the impression you make. You should know to be on time, dress appropriately and most importantly, be prepared. The basic principles for a successful job search and interview in private industry are not very different from academia or government but you may have access to information on the web for private firms that can help you tremendously. There is no excuse for showing up at a job interview without knowing significant facts about the company you going to meet. The interview is a two-way communication, so be sure that you are ready to participate, not just listen. You should have a list of questions appropriate for every company you interview. Ask the personnel office what to expect at each step of the hiring process: Who will you meet? How many interviews should you expect? How long will the process take? When will they make a hiring decision? Who would your supervisor be? What is the position description? Do they have written down goals for the employee? What knowledge or skills are expected from the successful candidate? How long have others stayed in this position? Where did they go? Such questions are useful in the interview because it demonstrates your ambition to succeed. If ambition scares them, look elsewhere! Also, find out about educational assistance opportunities. There are questions you might get answered from the web that could affect your enthusiasm: How large is the firm, or the office? How long have they been in business? Are they profitable? Do their products or services interest you? Can you tell whether they have scientific problems or issues that might intrigue you, or match your training particularly well? Ask the interviewers how they see your role and your advancement potential. Check the web, go to the library, ask your friends about the firm. Do not get discouraged by an uncomfortable interview. You will learn at each one, and if it was uncomfortable at the interview, it could have been worse on the job! Good luck

### 320 WHAT INTERVIEWERS CAN AND CANNOT ASK BY LAW.

A. Mosby. *OPM, USEPA Region III, Philadelphia, PA*. Sponsor: R. Mitkus.

It is essential to ensure the development of fair and effective questions that do not violate law, when planning a logical, structured interview. This part of the workshop will raise the participant's awareness of those questions that cannot legally be asked during a structured interview. It will also address the appropriateness of other types of questions that may be asked by an interviewer during the interviewing process.

### 321 TEACHING UNDERGRADUATE TOXICOLOGY IN THE 21<sup>ST</sup> CENTURY.

T. W. Simmons<sup>1</sup> and J. B. Tarloff<sup>2</sup>. <sup>1</sup>*Department of Biology, Indiana University of Pennsylvania, Indiana, PA* and <sup>2</sup>*Department of Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA*.

Undergraduate toxicology course offerings and teaching methods for delivering these courses have dramatically changed over the last twenty years. Historically, toxicology was a discipline that was more or less restricted to graduate and postdoctoral training. This emphasis was reflected by a symposium on Some Special Toxicology Education and Training Programs that was sponsored by the National Institute of Environmental Health Sciences in 1980. The idea of undergraduate toxicology offerings was debated and discussed, and four Bachelor of Science programs were highlighted at this workshop. In 1992 a follow-up forum on Undergraduate Toxicology Coursework was convened at a Society of Toxicology annual meeting. The objective of this Forum was to reach a consensus on the content of a one-year course in toxicology to be offered at the undergraduate level by

colleges and universities. Interestingly, Dr. Donald Reed stated in his opening remarks that by the 21st century there could be tens of thousands of undergraduate students taking toxicology. Although the number of undergraduate students enrolled today in toxicology courses may not number in the tens of thousands, it is clear that a significant number of students are taking courses in major, minor and track toxicology programs. In addition, many more students are enrolled in courses offered by non-toxicology/pharmacology degree programs. Along with this increase in toxicology course offerings; topics, methods and tools for teaching toxicology have also grown. New technologies including software programs and internet resources, current events including bio-terrorism, television programming such as Crime Scene Investigation, and new teaching strategies incorporating scientific inquiry, constructivism, and reflective practice are transforming the toxicology classroom. The goal of this workshop is to provide a forum to improve teaching and learning in the toxicological sciences, by sharing experiences related to these trends.

### 322 OVERVIEW OF UNDERGRADUATE COURSE OFFERINGS: TOXICOLOGY TEACHING PROJECT.

**T. W. Simmons.** *Department of Biology, Indiana University of Pennsylvania, Indiana, PA.*

The Toxicology Teaching Project sponsored by Indiana University of Pennsylvania and the Allegheny-Erie Society of Toxicology promotes and supports undergraduate teaching of toxicology. The Project identifies colleges and universities that offer undergraduate majors, minors, tracks, and courses in toxicology; and offers an online course survey for professors to identify characteristics of these course offerings. Presently, there are at least 8 universities offering undergraduate degrees, 3 offering minors, and 1 offering a track in toxicology. Based on the responses to a survey from directors of 7 of the 8 undergraduate degree programs, the programs range in age from 19 to 30 years (X = 23); total enrollment in these programs is 260 (X = 41); and enrollment is increasing at 3 programs and remaining steady at 4 others, but 1 of these programs will be discontinued in 5 years. Approximately 36% of students graduating from these programs pursue post-undergraduate education including toxicology-related fields, and 54% obtain employment in a toxicology or pharmacology-related field. In addition, a larger number of undergraduate students are being introduced to the field in non-toxicology/pharmacology degree programs. There are at least 59 schools with undergraduate degree programs in environmental health, industrial hygiene, safety science, occupational health, environmental science, biology, entomology & plant pathology, microbiology, biochemistry, chemistry, nursing, pharmacy, food science or engineering; that offer 97 courses in toxicology. In addition, 2 community colleges have been identified with associate degree programs in environmental science or chemistry; that offer 2 courses in toxicology.

### 323 LABORATORY EXPERIENCES IN THE CLASSROOM.

**J. B. Tarloff.** *Department of Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.*

Laboratory experiences are critical for students hoping to enter industry. We have put together two laboratory courses that emphasize problem solving, report writing, and practical exercises to help students become familiar with multiple techniques. The first semester we concentrate on handling of small animals, dosing, and measurement of outcomes. We also introduce students to the concept of tissue fractionation and enzyme assays. In the second semester, students are introduced to various separation techniques (electrophoresis, high performance liquid chromatography, Western blotting, thin layer chromatography) and cell culture. Feedback from investigators who have hired our students has guided revision of these courses through the last ten years and we continue to evolve.

### 324 CURRENT EVENTS IN THE CLASSROOM.

**S. M. Ford.** *College of Pharmacy & Allied Health, Saint Johns University, Jamaica, NY.*

This presentation will describe innovative strategies to engage undergraduate toxicology students in real-life issues with respect to the social, economic, political, and scientific values that impinge on their resolution. Specific courses and curricular design will be discussed with reference to implementation and student experience.

### 325 LOBO PHARMACOKINETICS COMPUTER SOFTWARE: INTERACTIVE PHARMACOKINETIC MODELING.

**C. Marcus<sup>1</sup>, D. Godwin<sup>1</sup>, E. Danoff<sup>1</sup> and R. Galinsky<sup>2</sup>.** <sup>1</sup>*College of Pharmacy, University New Mexico, Albuquerque, NM* and <sup>2</sup>*College of Pharmacy and Pharmacal Sciences, Purdue University, W. Lafayette, IN.*

This presentation will focus on the utilization of LOBO PK, a real-time interactive pharmacokinetic modeling software package developed to teach the principles of pharmacokinetics to undergraduate and professional students in the biomedical sci-

ences. The presentation will demonstrate how this software package can be utilized in a didactic classroom milieu to illustrate basic pharmacokinetic principles, competition kinetics, and many of the underlying molecular and physiological mechanisms by which drug/drug interactions can occur and how pharmacogenomic variations in drug metabolizing enzymes can contribute to large inter-individual responses to therapeutic drugs. The presentation will also demonstrate how this software package can be utilized in a student-centered problem based learning mode in an instructional laboratory milieu as well.

### 326 DISTANCE EDUCATION: ONLINE TEACHING OF TOXICOLOGY.

**K. L. Willett and A. Bouldin.** *Department of Pharmacology, University of Mississippi, University, MS.*

The presentation will describe the development and implementation of a semester-long online, undergraduate Introduction to Toxicology course. This course has been offered at the University of Mississippi for two semesters. An expanded course evaluation was developed to assess student attitudes and perceptions of the online version of the course, along with perceived comparisons between online and traditional environments. Results of these assessments and comparison to an assessment given to students in the same course but taught in the traditional classroom setting will be presented. Finally, potential challenges associated with the online teaching delivery method along with recommendations to others considering this teaching format will be discussed.

### 327 ENVIRONMENTAL TERRORISM: DEVELOPMENT OF EVACUATION, RE-ENTRY AND RE-USE GUIDELINES FOR CHEMICAL, BIOLOGICAL AND RADIOLOGICAL AGENTS.

**M. A. Maddaloni.** *USEPA, New York, NY.* Sponsor: **A. Jarabek.**

The collapse of the World Trade Center (WTC) presented a host of challenges to the governmental agencies charged with making decisions on evacuation, re-entry and long-term re-habilitation for the impacted public in Lower Manhattan. Occupational standards, ranging from immediately dangerous to life and health (IDLH) concentrations to long-term permissible exposure limits (PELs) existed for many of the building components and combustion by-products released from the WTC disaster. However, these standards are generally not well-suited for application to the general public (i.e. residents and office workers). Conventional environmental standards and guidelines have focused on establishing long-term exposure limits for chemical contaminants in the ambient environment. That leaves a lot of poorly charted territory for assessing environmental terrorism incidents that may involve biological or radiological agents within indoor settings, as well as in the ambient environment. The anthrax bioterrorism event of October, 2001 made that abundantly clear. The environmental response to the WTC disaster involved numerous governmental agencies along with the inevitable overlapping of jurisdictions and responsibilities. A future environmental terrorism event will likely follow suit. Accordingly, this workshop will engage the key governmental agencies involved in protecting the public health from environmental terrorism. The workshop will focus on comparing and contrasting available methods for deriving short term (i.e. evacuation), subchronic (i.e. re-entry) and long-term (i.e. re-habitation) exposure criteria a for chemical, biological and radiological agents. Of particular interest will be the role of background levels, analytical detection limits, social and economic disruption, and other miscellaneous factors in the setting of exposure limits. Risk levels for the different exposure scenarios and agent classes will be evaluated for comparability. Data gaps and methodological shortcomings will be identified for representative exposure scenarios within each class of agents.

### 328 AN EPA PERSPECTIVE ON CHEMICAL CONTAMINATION CLEAN-UP.

**S. Sterling, I. P. Baumel and C. Sonich-Mullin.** *ORD/NHSRC, USEPA, Washington, DC.* Sponsor: **M. Maddaloni.**

The U. S. Environmental Protection Agency's (EPA) National Homeland Security Research Center (NHSRC) is responsible for supporting EPA field staff in the event of a terrorist incident by assisting in the development of human health risk assessments. Based on experience at the World Trade Center, USEPA field staff have identified several needs in the area of risk assessment. In response to these needs, NHSRC is compiling risk-based information for acute, subchronic and chronic exposures that would be applicable to such sites. In the case of acute exposure, NHSRC is relying heavily upon existing information such as the Acute Exposure Guideline Levels (AEGLs) to provide useful data. For subchronic exposures of one

month to two years, NHSRC has initiated an effort to develop and apply a methodology for deriving subchronic health benchmarks from existing data. For long-term exposures, NHSRC is working with other EPA offices to strengthen the methodology for developing preliminary remediation goals. This presentation will provide an update on NHSRC's efforts to make available health benchmarks for exposure to chemicals resulting from terrorist activities.

### 329 A MILITARY APPROACH TO ASSESSING HEALTH RISK.

V. Hauschild and B. Thran. *Directorate of Health Risk Management, US Army Ctr for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, Edgewood Area, MD.* Sponsor: M. Maddaloni.

Quantitative risk assessment approaches, particularly those used to assess chemical exposures, have historically resulted in the development and application of specific exposure limits or standards to protect occupational, public, or environmental settings. Despite the calculated values that represent risk in such applications, there is substantial variation in the endpoint selection and the degree of uncertainty associated with the established exposure limits. In application, use of exposure limits results in a loss of appreciation for the dose response continuum and the range of risk associated with varying exposure and human susceptibility. For certain regulatory purposes, this approach may be rationalized. In situations where risk-based goals cannot be estimated due to lack of available scientific data, or when the goals are unachievable (due to inadequate detection capabilities or mitigation/clean-up technologies), or when risk acceptance is necessary to achieve a critical goal, other approaches must be applied. The military makes use of a standardized qualitative risk characterization approach for such situations. While it is necessary to have scientific underpinnings for describing risk, this qualitative risk characterization approach can minimize the impact of variability and uncertainty. The military has successfully used this approach to facilitate rapid, systematic risk prioritization and risk communication. This presentation will discuss efforts to apply the military's qualitative risk characterization approach to two types of health hazards: chemical warfare agents and biological hazards. An example will illustrate how quantitative dose response data (that includes consideration of exposure and population variability) can be portrayed with qualitative risk ranges. The presentation will include a discussion of how a qualitative approach may be applied in response to an incident involving a weapon of mass destruction.

### 330 BIOTERRORIST THREATS TO THE US FOOD SUPPLY SYSTEM: A RISK ASSESSMENT PERSPECTIVE.

B. Hope. *Air Quality Division, Oregon Department of Environmental Quality, Portland, OR.* Sponsor: A. Jarabeck.

Since 2001, awareness of, and concerns about, terrorist use of biological agents have increased dramatically at state and federal levels and in the popular press. Vulnerability of valuable US agricultural assets to bioterrorism has received less attention. The food supply system is a key component of US agriculture. In a bioterrorism context, concerns focus on use of the system to deliver an intentionally introduced foodborne bioagent to human consumers or use of a bioagent to contaminate and disrupt system operations or to undermine confidence in the safety of the food supply. However, achieving effective agriculture security programs requires replacing such broad, and potentially intractable, generalizations with specific threat scenarios that can be evaluated, anticipated, and managed. Structured risk assessment methods can be used to provide this specificity. This point is illustrated by using fault tree analysis to undertake prospective risk assessments for two scenarios wherein human consumers are exposed to a bioagent intentionally introduced into the US food supply. This analysis suggests that the food supply system may be a less than optimal bioagent delivery mechanism, particularly if the objective is a mass casualty attack, as a number of events must occur simultaneously with reasonable probability if a bioagent is likely to be deployed effectively. In addition, an environmentally stable bioagent would be required if only the food system were used to deliver it to human consumers, but early detection of an intentional release common bioagent may be difficult absent specific intelligence or unusual epidemiological circumstances.

### 331 A PRIMER ON RADIATION ISSUES RELATED TO NUCLEAR TERRORISM.

S. L. Simon. *Radiation Epidemiology Branch, National Cancer Institutes, Bethesda, MD.* Sponsor: M. Maddaloni.

Strategies to advise authorities and the public on how to minimize individual and public harm as a result of terrorist actions that involve radiation and/or nuclear materials requires an understanding of the fundamentals of radioactivity, radionu-

clides, radiation dose, and how long-term health risks change incrementally with changes in exposure received. The similarities between exposure to radiation and exposure to chemicals or biological agents are limited primarily to exposure pathways. The types and qualities of radioactive materials, the radiations they emit, how radiation interacts with living systems and the resulting effects differ substantially from other agents. The purpose of this presentation is to provide a basic understanding of the concepts of radiation, radiation exposure, and health risk, in the context of intentionally harmful actions involving radioactive materials. A limited discussion will also be presented to explain some of the possible exposure scenarios that have been considered.

### 332 DEVELOPMENT OF OPERATIONAL GUIDELINES FOR CONSEQUENCE MANAGEMENT OF RADILOGICAL DISPERSAL DEVICE INCIDENTS.

S. Domotor<sup>1</sup>, A. Wallo<sup>1</sup>, C. YU<sup>2</sup>, D. LePoire<sup>2</sup> and S. Kamboj<sup>2</sup>. <sup>1</sup>*US DOE, Washington, DC* and <sup>2</sup>*Argonne National Laboratory, Washington, DC.* Sponsor: A. Jarabeck.

The Department of Homeland Security (DHS) is leading the development of a risk management framework for responding to and mitigating potential effects caused by terrorist use of a Radiological Dispersal Device (RDD). This initiative is being coordinated through the interagency Consequence Management Subgroup (CMS). The CMS is led by DHS and comprised of subject-matter experts in radiological and nuclear preparedness and response from a number of agencies, to include the Environmental Protection Agency (EPA), Nuclear Regulatory Commission (NRC), Department of Defense (DoD), Department of Energy (DOE), and others. The framework addresses early, intermediate, and late phases (e.g., recovery and cleanup) of response, and provides Protective Action Guides (PAGs) to aid decision makers on when to take protective actions (e.g., sheltering, evacuation, relocation) to reduce exposure to workers and members of the public from radiation or other hazards. An optimization process is provided for addressing the long-term cleanup and recovery issues from an RDD. Protective Action Guides (PAGs) are the projected doses to a reference individual, from an accidental or deliberate release of radioactive material, at which a specific protective action to reduce or avoid that dose is recommended. Operational Guidelines are derived levels of radiation or concentrations of radionuclides that can be measured by radiation detection and monitoring equipment, and then related or compared to the PAGs to quickly determine if protective actions and associated contaminant mitigation need to be implemented. For example, there may be an urgent need to make decisions on whether or not to evacuate or relocate the public, and to restore critical infrastructure services such as access to roads, medical facilities, and power, water and sewer facilities in the hours and days following the incident. Although some values already exist (e.g., derived intervention levels for food), there are many more Operational Guidelines that need to be developed.

### 333 HIGH THROUGHPUT SCREENING APPROACHES IN GENETIC TOXICOLOGY.

R. H. Schiestl<sup>2</sup> and J. Aubrecht<sup>1</sup>. <sup>1</sup>*Safety Sciences, Pfizer, Inc., Groton, CT* and <sup>2</sup>*Departments of Pathology and Environmental Health, UCLA, Los Angeles, CA.*

Recent progress in combinatorial chemistry, molecular biology, genomics, and automation has enabled identifying a relatively large number of compounds capable of reacting with intended pharmacological targets. However, 40% of drug candidates ultimately fail during clinical development due to safety related issues. The overall attrition of drug candidates due to genetic toxicology issues alone includes about 12% of drug candidates. This causes delays in the introduction of vital drugs to patients and significant economic losses. Therefore, the development of relevant mechanism-based high throughput screening technologies to assess genetic toxicity at the early stages of drug discovery with relatively limited amount of chemical is extremely important. Genetic toxicology provides the necessary information for assessment of the genotoxic risk associated with the use of drugs. Since the beginning of genotoxicity testing in the early 1970s, many different test systems have been developed and used. Since no single test is capable of detecting all genotoxic agents, the current standard *in vitro* genotoxicity testing consists of evaluating mutagenicity (bacterial reverse mutation assay) and chromosome damage (lymphocyte aberration assay or mouse lymphoma assay). Unfortunately, these standard *in vitro* assays are not amenable to high throughput testing and their application in early phases of drug discovery is not feasible. Therefore, the research and assay development efforts have been directed to developing alternative approaches, technologies and/or endpoints. The speakers in this session present emerging state-of-the-art technologies under development and/or currently used in the pharmaceutical industry. The topics covered in this symposium comprise high throughput versions of the Salmonella assay, assays for DNA deletions, chromosome aberrations, the comet assay and a gene expression reporter assay. The presentations will cover exciting developments that may spark further interest in the automation of genotoxicity assays.

**334****BIOLUMINESCENT SALMONELLA REVERSE MUTATION ASSAY: A HIGH THROUGHPUT APPROACH FOR DETECTION OF MUTAGENICITY.**

J. Aubrecht, *Safety Sciences, Pfizer, Inc., Groton, CT.*

We have developed a novel bioluminescent high throughput Salmonella reverse mutation assay applicable to the screening of large numbers of compounds including combinatorial libraries. The bioluminescent Salmonella assay utilizes genetically engineered standard Salmonella tester strains TA98 and TA100 expressing the luxCDABE operon from *Xenorhabdus luminescens*. In principle, the assay employs bioluminescence as a sensor of metabolic activities in living cells. The assay provides highly concordant data with the outcome of the standard Salmonella reverse mutation assay. Since the results of the standard Salmonella assay are required by various regulatory agencies for approval of new drugs, the bioluminescent Salmonella assay can be effectively used for prioritization of compounds in drug discovery. Because of its high throughput attributes, the assay permits effective, fast and economical screening of a large series of structural analogs enabling the investigation of structure activity relationships. In addition, the application of bioluminescent sensors for detection of metabolically active cells might have a broad application in the design of other high throughput clonogenic assays in various cell systems.

**335****BIOLUMINESCENT YEAST DEL ASSAY TO DETECT CARCINOGENS AND CLASTOGENS.**

R. Schiestl<sup>1</sup> and J. Aubrecht<sup>2</sup>. <sup>1</sup>*Pathology, UCLA, Los Angeles, CA* and <sup>2</sup>*Safety Sciences, Pfizer, Inc., Groton, CT.*

Genomic rearrangements including DNA deletions are involved in carcinogenesis. DEL assays in yeast, human cells and *in vivo* in mice that quantify DNA deletion events detect a wide variety of carcinogens, many of which are negative in other short-term genotoxicity tests. For instance, of 69 tested chemicals of known carcinogenic activity, the yeast DEL assay correctly identified 86%. In contrast, the widely used Salmonella reverse mutation assay correctly classified only 33%. Furthermore, the yeast DEL assay was also capable of correctly differentiating between carcinogen / non-carcinogen structural analogs. To assess the utility of the yeast DEL assay as a screening tool for detection of genotoxicity we have evaluated the correlation of the DEL assay with commonly used tests for mutagenicity and clastogenicity (Salmonella reverse mutation assay and the *in vitro* micronucleus assay). Our study indicates that the DEL assay is capable of accurately detecting both clastogenic and mutagenic compounds. Although the original yeast DEL assay is robust and relatively simple, the original assay format limits its utility as a screening tool. Therefore, we have developed a bioluminescent version of the DEL assay suitable for automation. The assay employs bioluminescence as a sensor of metabolic activities in living cells for visualizing cells that underwent DEL recombination events. Several chemicals have been shown to be detectable in this new bioluminescent DEL assay format, which is currently being further developed into an HTS format.

**336****APPLICATION OF A HIGH THROUGHPUT COMET ASSAY IN DRUG DISCOVERY.**

A. Hartmann<sup>1</sup> and W. Frieauff<sup>2</sup>. <sup>1</sup>*Non Clinical Safety, F.Hoffmann-La Roche Ltd., Basel, Switzerland* and <sup>2</sup>*GenSafe / Precinical Safety, Novartis Pharmacology, Basel, Switzerland*. Sponsor: J. Aubrecht.

The alkaline comet assay is a microgel electrophoresis technique which is becoming established as an *in vitro* and *in vivo* test for industrial genotoxicity screening. This assay is an indicator test that detects primary DNA lesions such as direct and DNA repair-induced strand breaks and alkaline-labile sites. DNA damage is expressed as increased DNA migration measured in individual cells in an agarose gel mounted on microscope slides. Although the genetic endpoint of the comet assay is not the induction of mutations, *in vitro* data demonstrates similar sensitivity and specificity for detection of genotoxicity as compared to clastogenicity tests such as the micronucleus test or chromosomal aberration assay. Comparative data of *in vitro* studies with various cell types commonly used for industrial genotoxicity testing will be presented. Furthermore, data demonstrating that comet assay is less prone to false-positive results related to excessive cytotoxicity - a known confounding factor for *in vitro* clastogenicity tests - will be presented. For the conduct of an *in vitro* comet assay, only very small cell sample sizes are required. Adaptations of the protocol will be discussed that utilize small scale suspension cultures of multi-well culture dishes. This approach allows the conduct of genotoxicity screening at early stages of drug development, at which usually only very limited quantities of drug candidates are available. Establishing automated image analysis aided by a robot- feeded microscope can significantly enhance the throughput of comet assay samples. New approaches will be presented which can speed up the test performance by directly

using multiwell plates for microscopic analysis replacing the time-consuming preparation of microscope slides. The comet assay is also being established for detection of *in vivo* genotoxicity in pilot toxicity studies with rodents aiming at early profiling of new drug candidates. Approaches will be discussed how the comet assay can be applied to investigate *in vivo* genotoxicity in a variety of rodent organs.

**337****A FLOW CYTOMETRIC PROCESS FOR DETECTING ANEUGENIC AGENTS *IN VITRO*.**

P. A. Muehlbauer and M. J. Schuler. *Genetic Toxicology, Pfizer Global R & D, Groton, CT.*

A major barrier in moving forward with a rapid screening platform for detecting chemical agents that induce numerical chromosomal aberrations (aneuploidy) *in vitro*, is that most test systems rely on microscopic assessment of the aneuploid effects. Typically, microscopic analysis is technically arduous and is oftentimes restricted to scoring a few test concentrations for a discrete sub-population of aneuploid cells (e.g. hyperdiploid and/or polyploid). Thus incomplete data sets are typically produced and the inter-relationships between the different aneuploid populations cannot be easily discerned. The potential to automate a screening platform for detecting aneuploid agents has been expedited with the advent of molecular mitosis specific markers and the commercial availability of antibodies to them. Using these mitosis specific antibodies in combination with 2-color flow cytometry provides a unique opportunity to discriminate the mitotic (M) population of actively dividing cells on the basis of DNA content. The reliability of this process to isolate and measure mitotic populations in chemically treated human lymphocyte cultures has been previously shown in our laboratory. Estimates of the mitotic sub-populations (i.e. hypodiploid, normal, hyperdiploid and polyploid) are realized by place region gates over the mitotic population based on DNA content and applying Becton Dickinson Cell Quest software region statistics to calculate the percent gated. The flow cytometry-based process is an automated process that detects and characterizes aneuploid agents thus it offers a tremendous timesaving advantage for investigators over methodologies that rely on a microscopic assessment. Being able to observe all the aneuploid populations concurrently provides a rare opportunity for an investigator to discern the inter-relationships between the aneuploid populations and thus gain a tremendous insight and confidence with regards to the chemical hazard characterization.

**338****HIGH-THROUGHPUT SCREENING USING STRESS-RESPONSIVE REPORTER GENE ASSAYS.**

R. Brennan<sup>1</sup> and J. D. Haley<sup>2</sup>. <sup>1</sup>*Toxicology, Iconix Pharmaceuticals Inc., Mountain View, CA* and <sup>2</sup>*Cancer Cell Biology, OSI Pharmaceuticals Inc., Farmingdale, NY.*

In recent years, the maturation of microarray technology and high-density expression data analysis tools has lead to the increasing use of whole genome expression analysis to generate highly informative predictions as to the mechanisms of compound pharmacology and toxicology. While microarrays can provide information on the expression levels of thousands of genes at a time, current platforms are not suited to rapid screening of the dozens to hundreds of compounds typical of an early stage discovery program and there remains a need to translate the predictive signature information obtained from microarray and other gene expression analyses into useful high-throughput screens that can be employed against compounds earlier in the discovery process. With this aim in mind the Discovery Technology Group at OSI Pharmaceuticals generated a panel of stably-transfected mammalian cell lines expressing luciferase reporter genes under the control of various promoters and genetic elements responsive to a broad set of cellular stresses (genotoxic, oxidative, metabolic, endocrine, etc.). Assay conditions were optimized for each cell line and methods developed for performing the assays on fully automated robotic high-throughput screening (HTS) platforms. Pilot experiments generated over 18, 000 data points per 48 h run when assaying a small library of model toxins and controls over 6 dose points in triplicate against up to 13 different cell lines in parallel. We were able to identify expression profiles characteristic of genotoxins and other toxin classes and to identify expression profiles elicited by early discovery compounds that distinguished mechanism of action from potential toxicity. Stress gene expression profiles for compounds of interest to drug discovery programs may be used to flag undesirable characteristics early in the discovery process and will assist discovery program managers in deciding which compounds or structural classes are the best candidates for progression.

**339****ELECTROCARDIOGRAPHY SAFETY EVALUATION STUDIES: NEW TECHNIQUES AND APPROACHES.**

L. B. Kinter<sup>1</sup> and D. J. Murphy<sup>2</sup>. <sup>1</sup>*Safety Assessment, AstraZeneca, Wilmington, DE* and <sup>2</sup>*Drug Safety Assessment, GlaxoSmithKline, King of Prussia, PA.*

Examination of cardiac function using clinical electrocardiography (ECG) techniques can detect potential cardiotoxic and arrhythmogenic effects of new chemical entities in animals and humans. However, application of traditional technologies in

animals not trained to accommodate collection of these endpoints can result in spurious data artifacts, and arguably contributed to failure to recognize proarrhythmic potential of some drugs subsequently associated with clinical QT interval prolongation and ventricular tachyarrhythmia. Recent advances in telemetry technologies permit collection of high fidelity ECGs from naive animals in safety pharmacology or general toxicology studies. Topics presented will include 1) ECG theory and its application in preclinical safety evaluation and human risk assessment; 2) technical considerations for implanted and non-implanted ECG systems and selection of surface, intracardiac and intravenous lead placements; 3) collection of quality ECG endpoints within safety pharmacology and general toxicity study designs; and 4) analysis and interpretation of telemetry-collected ECG data. This Roundtable Session is suggested for scientists considering and currently using telemetry systems for preclinical assessments of cardiac toxicity and arrhythmogenic potential.

#### 340 CARDIAC ELECTROPHYSIOLOGY FROM THE SINGLE CELL TO THE INTACT HEART.

R. Hamlin. *Veterinary Cardiology, Ohio State University, Columbus, OH.* Sponsor: L. Kinter.

Theory of contemporary veterinary electrocardiography (ECG) and its applications to assessments of new chemical entities for arrhythmogenic potential will be briefly reviewed. Considerations for selection species, lead placements, and analysis and interpretation of ECG data for human risk assessment will be discussed.

#### 341 TECHNIQUES AND ELECTROGRAPHIC LEAD PLACEMENTS FOR IMPLANTED ECG MONITORS.

R. Coatney. *Animal Modeling & Imaging, GlaxoSmithKline, King of Prussia, PA.* Sponsor: L. Kinter.

ECG telemetry systems come in two basic configurations, systems that are entirely implanted below the body surface using survival surgical techniques, and those that have one or more sets of components carried above the body surface, usually in a jacket or other protective covering. Technical considerations for successful surgical placement of implanted ECG telemetry components and systems will be presented, including species selections, lead and transmitter placements, and welfare considerations.

#### 342 INTRACARDIAC AND INTRAVASCULAR LEAD UTILIZATION: METHODS FOR IMPROVED DATA COLLECTION.

C. Hessler. *Safety Pharmacology, Battelle Memorial Laboratories, Columbus, OH.* Sponsor: L. Kinter.

Catheter technologies permit formulation of vascular ECG electrodes which when placed in cardiac blood vessels permit regional ECG analyses using telemetry systems. Technical considerations for application of surface and intracardiac ECG electrode placements, and construction, placement and telemeterization of intracardiac lead systems will be discussed.

#### 343 OBTAINING QUALITY ECG ENDPOINTS IN SAFETY PHARMACOLOGY AND GENERAL TOXICOLOGY STUDIES. ARE RESTRAINT AND SURGICAL INTERVENTION NECESSARY?

M. Zawada and L. B. Kinter. *Safety Assessment, AstraZeneca, Wilmington, DE.*

Traditional ECG technologies are of limited utility in preclinical safety pharmacology and toxicology studies because the restraint necessary to maintain proper lead placements usually limits the duration of ECG collection to a few minutes, and stress artifacts and high heart rates further limit the utility and interpretation of the data collected under these conditions. Advent of telemeterized systems now permits collection of high quality ECG data of nearly unlimited duration, and has greatly increased the utility of ECGs to detect acute cardiotoxicity and arrhythmogenic potential in safety pharmacology studies. However, while general toxicology studies are an excellent platform for telemetric monitor for cardiotoxic and arrhythmogenic biomarkers with subchronic and chronic exposures, prestudy surgical implantation of telemetry systems is usually inconsistent with the primary objectives and endpoints and non-implanted technologies are preferred. Considerations for and examples of applications of fully-implanted and non-implanted telemetry ECG systems in safety pharmacology and general toxicology study designs will be discussed.

#### 344

#### BIOLOGICALLY-BASED MATHEMATICAL MODEL FOR GENE EXPRESSION DUE TO JP-8 EXPOSURE TO SKIN.

J. N. McDougal<sup>1</sup>, C. M. Garrett<sup>1</sup>, C. A. Amato<sup>1</sup>, Y. Zheng<sup>2</sup>, Q. Zhang<sup>3</sup> and R. B. Conolly<sup>3</sup>. *Department of Pharmacology & Toxicology, Wright State University School of Medicine, Dayton, OH, <sup>2</sup>Department of Biomedical Engineering, Purdue University, West Lafayette, IN and <sup>3</sup>Center for Computational Systems Biology and Human Health Assessment, CIIT Centers for Health Research, Research Triangle Park, NC.*

Skin irritation is not completely understood at the molecular level. Biologically-based (toxicodynamic) models of the irritant process can be very useful for prediction of the severity and extent of the problem, as well as tools for the development of therapeutic and prophylactic interventions. The purpose of this study is to develop a biologically-based mathematical model based on results of changes in gene transcripts measured by Affymetrix Gene Array (U34A chip). After one-hour exposures to JP-8 jet fuel, we measured changes in mRNA one, four and eight hours after initiation of the exposure in rats. Among early responses, several genes related to the proinflammatory cytokine, Interleukin 1 (IL-1 $\alpha$ ), signaling pathway were increased. We developed a mathematical model for a part of the inflammatory pathway involved in these gene changes. The model captures the series of biochemical events initiated from IL-1 $\alpha$  binding to IL-1 receptor (type I) on the cell surface that activates the transcriptional factor NF-kappa B and leads to production of a responsive protein, IL-6 and an inhibitor of NF-kappa B. Using a deterministic approach, the model describes the system with a set of ordinary differential equations assembled from reaction rate laws and divides it into three compartments: the nucleus, cytosol and extracellular space. Temporal changes in protein concentrations are described by forward and backward reaction rate terms for binding, degradation, activation, translocation and synthesis. The model prediction shows qualitative agreement with gene array results. We conclude that this model is a useful tool for the future investigation and understanding of the irritant process occurring in the skin. (Supported by Air Force Office of Scientific Research and a Wright State University Major Collaboration Grant)

#### 345

#### MODELLING THE RELATIONSHIP BETWEEN NICKEL AND CHROMIUM EXPOSURE AND CONTACT DERMATITIS.

S. Franks and A. Jones. *Health and Safety Laboratory, Buxton, United Kingdom.* Sponsor: R. Conolly.

Metal induced contact dermatitis is an important occupational health problem and both chromium and nickel are known to cause both irritant and allergic responses. In an *in vitro* study conducted by the Health and Safety Laboratory, human keratinocytes were dosed with increasing concentrations of nickel and chromium ( $0.01\text{--}10^5 \mu\text{M}$   $\text{K}_2\text{Cr}_2\text{O}_7$  and  $0.01\text{--}10^4 \mu\text{M}$   $\text{NiCl}_2$  for 24hrs) to determine their effect on cell respiratory activity, viability, metal association and production of inflammatory mediators (in particular, IL-1 $\alpha$  and IL-8). Keratinocytes are the principal skin cells in the epidermis and their response to nickel and chromium was found to differ markedly. The observed amounts of metal associated with the cell, the decrease in cell viability and the release of IL-1 $\alpha$  by the keratinocytes were all much greater for chromium than for nickel at the same concentration, suggesting the former is much more cytotoxic. In order to predict the effects of nickel and chromium *in vivo*, a mathematical model describing the innate and acquired immune responses to such a toxic insult has been formulated. Mechanistically based mathematical modelling is a powerful predictive tool that effectively tests the validity of toxicological assumptions as well as helping to guide experimental work. Our model incorporates the diffusion and reaction of extracellular metal ions within the epidermis, the association of the antigen with the cells, the resulting damage to the viable keratinocytes, the release of cytokines and the influx of immune and T-cells, and provides predictions of the spatial and time evolution of these components within the epidermis. Using experimentally determined parameter values, the model was validated against the measured outputs from the *in vitro* study described above and initial results were found to agree well with the observed behaviour. Once validated, the mechanistic basis of the model allows us to extrapolate from *in vitro* to *in vivo* in order to gain insight into the relationship between metal dose and the immunological response.

#### COMPUTATIONAL MODELS FOR THE ACQUISITION OF NEOCORTICAL NEURONS IN THE DEVELOPING HUMAN, MONKEY, AND MOUSE: CROSS SPECIES COMPARISON OF TOXICODYNAMICS.

J. M. Gohlke, W. C. Griffith and E. M. Faustman. *Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.*

For interspecies extrapolation of toxicity data for risk assessment purposes, it is particularly pertinent to acknowledge the importance of the neocortex as the defining feature of human evolution. Important morphological and behavioral attributes associated with the enlarged human neocortex are absent in the rodent models used

in most toxicology studies. This necessitates quantitative research into the development and evolution of the neocortex, in order to gain the knowledge necessary for protecting our most unique and arguably most valuable feature as humans. Here we develop computational models of human neocortical development while comparing it to our previously developed rhesus monkey and rodent models. We predict the vast increase in size of the neocortex in humans by changing two key parameters, namely the cell cycle length and the length of the neurogenesis period. We compare our results to independent stereological studies estimating neocortical neuron number in adult and developing human. We have also evaluated the contribution of cell death to neocortical development in these three species. When compared to mouse, we predict cell death may play a larger role in shaping the primate neocortex. Furthermore, when applying research performed in the rat on ethanol-induced inhibition of the cell cycle during neocortical neurogenesis, our models suggest developing humans may be more sensitive to long-term neocortical neuronal deficits based on the prolonged neurogenesis period (84 days compared with 6 days in the rodent or 60 days in the rhesus monkey) during fetal development.

#### MAGNETIC RESONANCE IMAGING AND COMPUTATIONAL FLUID DYNAMICS SIMULATIONS OF RABBIT NASAL AIRFLOWS FOR HYBRID CFD/PBPK MODELING OF METHYL IODIDE.

H. E. Trease<sup>1</sup>, K. R. Minard<sup>1</sup>, L. L. Trease<sup>1</sup>, R. A. Corley<sup>1</sup>, J. S. Kimbell<sup>2</sup>, J. R. Harckema<sup>3</sup>, J. H. Kinzell<sup>4</sup> and M. L. Gargas<sup>5</sup>. <sup>1</sup>Battelle Northwest, Richland, WA, <sup>2</sup>CIIT Centers for Health Research, Research Triangle Park, NC, <sup>3</sup>Michigan State University, East Lansing, MI, <sup>4</sup>Arvesta Corp., San Francisco, CA and <sup>5</sup>The Sapphire Group, Beavercreek, OH.

Methyl iodide (MeI), an intermediate in the manufacture of some insecticides and pharmaceuticals, is under review for US registration as a non-ozone depleting alternative to methyl bromide in the pre-plant soil fumigation market. Both acute and subchronic inhalation exposures to MeI in rats have resulted in lesions of the nasal olfactory epithelium. Fetal effects have been observed in pregnant rabbits exposed to MeI vapors and the uptake of MeI by nasal tissues may impact systemic dosimetry. Computational fluid dynamics (CFD) models for nasal tissue dosimetry have been developed for rats, monkeys and humans but not rabbits. Thus, the purpose of these studies was to develop CFD models of the rabbit nasal airways that can be used in modeling MeI or other materials requiring a quantitative understanding of rabbit nasal airway dosimetry. 3D computational meshes were derived from magnetic resonance images of 3 adult female NZW rabbits for use in CFD simulations. The percentages of total airflows over the nasal respiratory and olfactory epithelium of female rabbits were calculated from these simulations under steady-state inhalation conditions. These airflow calculations are critical parameters that will be used in hybrid CFD/PBPK models that describe the nasal as well as systemic dosimetry of MeI in rabbits. Although there was considerable inter-animal variability in the fine structures of the nasal turbinates and airflows in the anterior portions of the nose (maxillary turbinate region), there was remarkable consistency between rabbits in the percentage of total inspired airflows that reached the olfactory epithelium lining the ethmoid turbinate region (~20%). These latter results were consistent with previous published estimates for the male F344 rat. (Supported by Arvesta Corporation).

#### IN SILICO PHARMACOGENETIC ANALYSIS OF R-WARFARIN METABOLISM.

Y. Guo<sup>1</sup>, P. Cheung<sup>2</sup>, J. Wang<sup>1</sup>, G. Liao<sup>1</sup>, J. Usuka<sup>1</sup>, M. Masjedizadeh<sup>3</sup>, P. Weller<sup>2</sup> and G. Petz<sup>1</sup>. <sup>1</sup>Genetics & Genomics, Roche Palo Alto, Palo Alto, CA, <sup>2</sup>DMPK, Roche Palo Alto, Palo Alto, CA and <sup>3</sup>Chemical Services, Roche Palo Alto, Palo Alto, CA.

To better understand the way in which commonly prescribed drugs are metabolized and to define their mechanism of action, we are applying a recently developed haplotype-based computational method that was shown to correctly identify the genetic basis for differences in biologically important traits among inbred mouse strains (Liao *et al.*, *Science*, 2004, in press). Warfarin is a commonly used anticoagulant with a narrow therapeutic index that has a large variation in individual dosing. Its metabolism was analyzed by administering <sup>14</sup>C-labeled R-warfarin to males of 13 inbred mouse strains. Plasma samples were collected at different time points following treatment for liquid scintillation counting and HPLC-radiometric characterization of the amount of drug and metabolites in each inbred strain. Interestingly, these inbred strains had a unique profile for warfarin and 9 identified metabolites. The pattern of variation in the amount of glucuronidated 7-hydroxylated metabolite of warfarin was computationally correlated with genetic variation found within cytochrome P450 2c29 (*Cyp2c29*). The involvement of this cytochrome in warfarin metabolism was confirmed by experiments showing that liver microsomes could biotransform warfarin to its 7-OH metabolite *in vitro*; and this biotransformation could be inhibited by a *Cyp2c* isoform specific substrate (tolbu-

tamide). In addition, expressed recombinant *Cyp2c29* also mediated the biotransformation of warfarin to its 7-OH metabolite. These results demonstrate that factors responsible for inter-individual pharmacokinetic differences for clinically important drugs can be identified by computational genetic analysis in mice. (Supported by NIH RO1 GM068885-01).

#### AN INTEGRATED QSAR-PBPK MODEL FOR SIMULATING PHARMACOKINETICS OF CHEMICALS IN MIXTURES.

K. Price and K. Krishnan. *Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada.*

Chemicals in mixtures may compete for metabolism, thereby altering their tissue dose in the organism and possibly the toxicity outcome. To predict the change in tissue dose of chemicals during mixed exposures, physiologically-based pharmacokinetic (PBPK) models are of particular use. These models integrate information on physiology, tissue and blood solubility characteristics as well as metabolism and inhibition constants to provide simulations of pharmacokinetics of chemicals in mixtures. The animal and human physiological characteristics are generally known, but the solubility and metabolic parameters for all mixture components need to be estimated and this process can be expensive and time-consuming. The present study integrated quantitative structure-activity relationships (QSARs) within PBPK models to simulate the pharmacokinetics of chemicals in mixtures. The approach involved the development of QSARs for maximal velocity of metabolism and Michaelis-Menten constant of several organic chemicals based on the group contribution approach of Gao. The Michaelis-Menten constant for each chemical was then set equal to the inhibition constant for modeling competition for enzyme binding sites. Previously published QSARs for partition coefficients were used to calculate solubility parameters for all chemicals. The adequacy of this integrated QSAR-PBPK model was evaluated by comparing the predictions with experimental data on the altered blood kinetics of dichloromethane, toluene, ethylbenzene, o-xylene, p-xylene, m-xylene, trichloroethylene and styrene in rats exposed for 4 hr to 50 ppm each of these chemicals in mixtures. The QSAR-PBPK modeling methodology provided predictions of altered pharmacokinetics of chemicals in mixtures that were within a factor of 0.8 to 1.5 of the experimental data. This study for the first time has succeeded in predicting the change in pharmacokinetics of chemicals in mixtures, on the basis of animal physiology and QSARs for chemical-specific parameters including the metabolic inhibition constants.

#### ISSUES IN THE USE OF PBPK MODELING IN THE DEVELOPMENT OF CANCER SLOPE FACTORS FOR PERCHLOROETHYLENE.

J. E. Kester, P. Gentry, T. R. Covington and H. J. Clewell. *ENVIRON Health Sciences Institute, Ruston, LA.*

The current California Environmental Protection Agency Public Health Goal (PHG) for perchloroethylene (PCE) was derived using an upper-bound estimate of the fractional metabolism of PCE in humans. This upper-bound estimate was obtained from an evaluation of the variability in human metabolism of PCE that was conducted using a physiologically based pharmacokinetic (PBPK) model in a Markov Chain Monte Carlo (MCMC) analysis. However, the data used in the MCMC analysis were limited to post-exposure concentrations of PCE in blood and exhaled air from a single inhalation study: 4-hr exposures at 72 or 144 ppm. The use of post-exposure concentrations of parent chemical for estimating metabolism in the human is problematic because PBPK model predictions of these exposures provide only an indirect indication of the amount metabolized. Recent data on the blood concentrations and urinary excretion of the major PCE metabolite, trichloroacetic acid (TCA), following exposure of human subjects to lower concentrations of PCE (10 to 30 ppm) than in previous studies, made it possible to compare the high- to low-dose extrapolation capability of several published models of PCE. We found that a model based on the work of Gearhart *et al.* (1993), which is the only model developed using data on TCA kinetics, gave the closest predictions of the TCA blood concentrations and urinary excretion observed in the low-concentration exposures. Other models overestimated metabolite excretion in this study by 5- to 15-fold. A modification of the model of Gearhart *et al.* (1993) to include metabolism of PCE to TCA in the kidney markedly improved agreement with the experimental time-course data, without altering predictions of liver metabolism. MCMC analysis of the variability in metabolism of PCE was conducted using this model together with data from three different human studies. The resulting upper 95% confidence limits of the fraction of PCE metabolized by the inhalation and oral routes were 3.4 and 7.9%, respectively, compared to 58 and 79% used in the derivation of the PHG.

Lead poisoning continues to be a public health threat for individuals in special situations and communities of people exposed to elevated levels of lead, often in their drinking water. Lead is regulated based on a safe blood concentration. Predicting the blood lead level associated with a set of exposure assumptions requires the use of a toxicokinetic model. While several lead toxicokinetic models exist, only the lead physiologically based pharmacokinetic (PBPK) model can predict blood lead levels in both children and adults, for both short (including intermittent) and long term exposures, and accommodate special circumstances like rapid rates of bone loss. Two recent public health concerns that have been assessed using the lead PBPK model include; 1) children exposed to elevated levels of lead in their school's drinking water, and 2) assessing the likely blood lead levels in astronauts who spend extended periods of time in microgravity whereby they may lose substantial amounts of bone mass. The current EPA action level for lead in school drinking water supplies is 20 ppb. Using the PBPK model, it is predicted that this level of lead in the drinking water causes an extremely small increase in blood lead levels. Likewise, substantially higher levels of lead in school water supplies have only minimal impact on blood lead levels in children. A linear relationship between school drinking water concentration and incremental increase in blood lead has been developed using the PBPK model and is provided for communicating this important issue to children and parents facing elevated levels of lead in their schools. Astronauts may lose substantial percentages of their bone mass while in microgravity. The lead PBPK model was used to simulate the potential impact that variable rates of bone loss have on blood lead levels. The results indicate that there exists the potential for significant elevations in blood lead levels with these high rates of bone loss, even after only short periods in space. Using the lead PBPK model to simulate these two scenarios has provided some valuable insight on the potential public health threats posed by each.

G. Johanson, K. Stamyr and P. Nord. *Work Environment Toxicology, Karolinska Institute, Stockholm, Sweden.*

It has been estimated that fire smoke causes 5-10, 000 fatalities per year in the US alone. Carbon monoxide is presumably the major single agent, however, the contribution of hydrogen cyanide (HCN) might be severely underestimated. HCN is released in large amounts during combustion of nitrogen containing materials, such as polyurethane foam in furniture. Fast diagnosis and treatment of intoxication may significantly reduce the number of fatalities. Aim The aim of this study was to investigate if it is possible to detect HCN poisoning by analyzing exhaled air. Modeling A PBTK-TD model for HCN was used to predict expected breath HCN levels after life-threatening exposures. The model was validated against available animal (detoxification rates, time to lethality vs dose, half times in blood and plasma etc) and human (blood and plasma cyanide levels in surviving and deceased fire victims) data. Experimental The time-course of cyanide appearance in exhaled air was measured on-line with an electrochemical detector in 10 volunteers during and after 1 min x 10 ppm HCN exposure. The study was approved by the Regional Ethical Review Board and performed according to the Helsinki Declaration. The experiment revealed an average half time of 16 (range 10-24) s in breath. These low dose experiments suggest that, even after massive peak exposures, the contribution from washout from the airways will be negligible and below the instrument (0.2 ppm) as well as the true HCN background (0.01-0.03 ppm) in breath within a few minutes. In contrast, the model suggests that acutely toxic exposures will result in elevated breath levels for several minutes. For example, a 30 min x 131 ppm (lethal within 30-60 min) exposure results in a breath level of 0.8 ppm 5 min after exposure and 0.5 ppm 30 after min. Conclusion It appears feasible to detect systemic cyanide poisoning via breath analysis (supported by the Swedish Council for Working Life and Social Research (FAS) and the Swedish National Board of Health and Welfare).

The hallmark of Aryl Hydrocarbon receptor (AhR) activation is induction of Cyp1a1 and related phase I and II metabolism genes. Because AhR can be activated by dioxin-like compounds that are linked to teratogenesis, carcinogenesis, and im-

mune and endocrine modulation, induction of AhR-related genes such as Cyp1a1 may be of significant concern for preclinical drug candidates. To study mechanisms of AhR activation, we used a large chemogenomic database (DrugMatrix) containing expression profiles from short-term, repeat dose rat studies with 600 reference drugs and toxicants. Of the 539 compounds profiled in liver, heart and kidney, 219 significantly induced Cyp1a1 in at least one tissue, many of which are approved drugs (184). Interestingly, 49 of these Cyp1a1 inducers did not induce the expression of other AhR responsive genes. This suggests possible alternative mechanisms for Cyp1a1 induction and/or AhR activation distinct from receptor binding. To evaluate whether Cyp1a1 is a suitable biomarker for AhR activation, an *in vitro* gel-shift assay utilizing rat hepatic cytosol was used to screen 150 compounds for their ability to stimulate AhR transformation and DNA binding and 24 positive compounds were identified. The results indicated 83 compounds that induce Cyp1a1 *in vivo* failed to activate the AhR *in vitro*. The *in vitro* results also identified many novel AhR ligands structurally distinct from known ligands. Using *in vivo* gene expression profiles, a support vector machine algorithm signature was derived that can distinguish between Cyp1a1 inducers that bind to and activate the AhR from those compounds that do not. These results also contribute to an improved understanding of alternative pathways of Cyp1a1 induction and its relevance to the toxic and biological effects of activators of the AhR signaling pathway.

Z. R. Master<sup>1</sup>, T. R. Sutter<sup>2</sup> and K. L. Willett<sup>1</sup>. <sup>1</sup>*Pharmacology and Environmental Toxicology Research Program, University of Mississippi, University, MS* and <sup>2</sup>*W. Harry Feinstone Center for Genomic Research, University of Memphis, Memphis, TN.*

Endometrial cancer is one of the major gynecological malignancies in women. RL95-2 endometrial cancer cells which are estrogen- and Ah-receptor positive were used for the study. After an initial screening, quercetin, amentoflavone, kaempferol, and myricetin were identified for further study. RL95-2 cells were induced with TCDD (10 nM/24 hrs) or BaP (1  $\mu$ M/48hrs). To investigate the CYP1 inhibition pattern in intact induced cells, the four selected flavonoids (0.5 – 5  $\mu$ M) were added 30 min prior to the EROD assays. Quercetin, kaempferol and myricetin inhibited EROD activity in a dose-dependent manner (TCDD/BaP-induced EROD activity: IC50= 2.49/2.25, 3.72/3.99, 2.93/2.16  $\mu$ M respectively); while amentoflavone was inactive. To determine the relative antagonism of CYP1A1 and CYP1B1 RNA expression, quantitative real time reverse transcription PCR was done. Quercetin inhibited TCDD-induced CYP1A1 mRNA levels while kaempferol (5  $\mu$ M) inhibited TCDD-induced CYP1B1 mRNA levels significantly. In western blots on cell microsomes, quercetin (5  $\mu$ M) also significantly inhibited TCDD-induced CYP1A1 protein levels, however it did not inhibit BaP-induced CYP1A1 protein. In contrast, CYP1B1 protein levels were not significantly different among various treatments. However, basal levels of CYP1B1 protein were ~12 pmol/mg as compared to ~1 pmol/mg for CYP1A1 protein. CYP1A1 message, enzyme activity and protein levels were inhibited by quercetin, and CYP1B1 message was inhibited by kaempferol in the RL95-2 endometrial cells. Because the CYP1 family has been implicated in detoxifying chemotherapeutic drugs and activating xenobiotics to genotoxic intermediates, these results suggest that quercetin and kaempferol may be effective in cancer chemoprevention. (Supported by American Association of Colleges of Pharmacy and Mississippi Functional Genomics Network, NIH/NCRR).

D. Springer<sup>1</sup>, T. I. Leakey<sup>1</sup>, R. J. Feuers<sup>1</sup>, C. Buffington<sup>2</sup>, G. S. Cowan<sup>2</sup> and J. E. Leakey<sup>1</sup>. <sup>1</sup>*OSC, NCTR, Jefferson, AR* and <sup>2</sup>*Department of Surgery, University of Tennessee, Memphis, TN.*

Although an increasing proportion of the American population is obese, there is only limited information on whether obesity or weight loss influence drug metabolism in humans. Cytochrome P450 (CYP) isoform expression is very variable in human liver samples that are used in toxicity testing and research. This variation is due to factors such as genetic polymorphism, environmental and pharmaceutical exposure to inducers and pathological and post mortem changes. It complicates the study of endogenous regulators of human CYP. Gastric bypass surgery is used in chronically obese patients as an aid to weight-loss as it both reduces food intake and absorption. Typically, once patients have lost weight a second surgery is performed to remove excess skin and muscle from the abdominal cavity. We obtained liver biopsy samples (with informed consent) from patients at both surgeries so that we could compare the effects of weight loss directly in the same patients. We investigated CYP isoform expression in these samples using isoform selective activities and western blotting. Microsomal preparations were assayed for a range of monooxygenases including acetanilide 4-hydroxylase (CYP1A2), chlorzoxazone 6-hydroxylase (CYP2E1) testosterone 6 $\beta$ -hydroxylase (CYP3A) and lauric acid 11-hydroxylase

(CYP4A) activities. Of these, CYP3A-selective testosterone hydroxylase activity was consistently increased in samples from the second surgery as compared to corresponding samples from the first (obese) surgery  $215 \pm 40\%$ ,  $P < 0.05$ ). Small increases in acetanilide and lauric acid hydroxylases were also observed ( $+52 \pm 28\%$ ,  $+35 \pm 12\%$  respectively), whereas chlorzoxazone hydroxylase activity was slightly decreased ( $-18 \pm 11\%$ ). This suggests that obesity does influence the expression of CYP3A and possibly other CYP isoforms in human liver.

#### BIPHENYL PROPARGYL ETHERS AS INHIBITORS OF CYP 1A1, CYP 1A2, AND CYP 2B1.

N. E. Hopkins<sup>1</sup>, B. Bowman<sup>2</sup>, T. Smith<sup>2,1</sup>, C. DeCuir-Charbonnet<sup>1</sup>, A. Henderson<sup>1</sup> and M. Foroozesh<sup>2</sup>. <sup>1</sup>*Cell & Molecular Biology, Tulane University, New Orleans, LA* and <sup>2</sup>*Chemistry, Xavier University, New Orleans, LA*.

Cytochrome P450 enzymes are a superfamily of hemoproteins involved in the metabolism of endogenous and exogenous compounds including many drugs and environmental chemicals. Certain aromatic acetylenes have been shown to be inhibitors of these enzymes. Size of the ring system, the location of the acetylenic moiety, and the distance of the triple bond from the ring influence the specificity, efficiency and mechanism of inhibition. Previously we found that 4-(1-propynyl)-biphenyl is a potent inhibitor of CYP 1A1 and 1A2, but 4-(1-butynyl)-biphenyl is only a moderate inhibitor. In an attempt to identify potent inhibitors of CYP 1A and 2B enzymes, we synthesized a series of mono- and di-substituted biphenyl propargyl ethers and mono-substituted biphenyl methyl propargyl ethers, including 2-biphenyl propargyl ether(2BPhPE), 4-biphenyl propargyl ether(4-BPhPE), 2, 2'-biphenyl dipropargyl ether(2, 2BPhDPE), 4, 4'-biphenyl dipropargyl ether(4, 4BPhDPE), 2-biphenyl methyl propargyl ether(2BPhMPE), and 4-biphenyl methyl propargyl ether(4BPhMPE). The presence of an oxygen atom on the substituent changes the polarity and orientation of the triple bond. The compounds were synthesized by coupling the appropriate biphenyl alcohol with propargyl bromide in the presence of sodium hydride. These compounds have been tested as inhibitors of CYP 1A1, 1A2, and 2B1 with methoxyresorufin (1A2), ethoxyresorufin (1A1), or benzyloxyresorfin (2B1) as the substrate. The preliminary results indicate that 2BPhPE is a potent inhibitor of 1A2 and 2B1 but only a moderate inhibitor of 1A1. 4-BPhPE and 2BPhMPE are potent inhibitors of 1A2 but only moderate inhibitors of 1A1 and 2B1. 4, 4BPhDPE is a moderate inhibitor of 1A1 and 1A2 but a poor inhibitor of 2B1. 2, 2BPhDPE is a moderate inhibitor of all the CYP enzymes tested. 4BPhMPE acts as a potent inhibitor of all the CYP forms tested, but may be a tight binding alternate substrate for 1A1. Experiments continue to determine the mechanism of inhibition as well as the inhibitory parameters.

#### USE OF A HUMAN HEPATOCYTE-DERIVED CELL LINE TO SIMULTANEOUSLY ASSESS CYP3A4 INDUCTION AND TIME-DEPENDENT INHIBITION.

S. L. Ripp<sup>1</sup>, K. A. Trevena<sup>1</sup>, D. R. Gibbons<sup>2,1</sup> and J. B. Mills<sup>1</sup>. <sup>1</sup>*Pharmacokinetics, Dynamics, & Metabolism, Pfizer Global Research & Development, Groton, CT* and <sup>2</sup>*Michigan State University, East Lansing, MI*.

Cytochrome P4503A4 (CYP3A4) is the major drug-metabolizing enzyme in human liver and can be subject to both induction and inhibition. Changes in CYP3A4 expression and activity are frequently associated with drug-drug interactions. We report the use of a human hepatocyte-derived cell line to simultaneously assess CYP3A4 induction and time-dependent inhibition. Fa2N-4 cells were plated and cultured for two days, then exposed to varying concentrations of test compound in cell culture medium. After 48 hours, cells were washed, then incubated with medium containing a CYP3A4 probe substrate (midazolam) in order to assess catalytic activity. Cells were then harvested, RNA isolated, and CYP3A4 mRNA measured. Replicate sets of plated cells were treated in parallel, and viability of cells assessed using a mitochondrial dehydrogenase activity assay. Treatments that affected cell viability were not used in subsequent mRNA and activity determinations. The prototypical inducers rifampicin (30  $\mu$ M) and dexamethasone (50  $\mu$ M) produced 15- and 2-fold increases in CYP3A4 mRNA in these cells after 48 hours of treatment, and 9- and 2-fold increases in enzymatic activity, respectively. In contrast, compounds that were both inducers and time-dependent inhibitors of CYP3A4, produced increases in CYP3A4 mRNA, but decreased CYP3A4 catalytic activity in these cells. For example, ethinyl estradiol (10  $\mu$ M) and ritonavir (1  $\mu$ M) each produced approximately 4-fold increases in CYP3A4 mRNA, but reduced midazolam 1-hydroxylase activity relative to control by 75% and 50%, respectively. Since compounds were washed from the cells prior to incubation with probe substrate, the decrease in CYP3A4 catalytic activity was not likely a result of competitive inhibition, but was likely due to time-dependent inhibition. These results indicate that this assay can be used for early identification of CYP3A4 inducers as well as time-dependent inhibitors of CYP3A4 in drug discovery.

#### HUMAN NAPHTHALENE METABOLISM.

T. M. Cho, R. L. Rose and E. Hodgson. *Environmental & Molecular Toxicology, North Carolina State University, Raleigh, NC*.

The polycyclic aromatic hydrocarbon naphthalene is an environmental pollutant, a component of jet fuel and since 2000 reclassified as a potential human carcinogen. Few studies of *in vitro* human metabolism of naphthalene are available, and these studies are mostly focused on lung metabolism. Therefore, the current studies were performed to characterize the metabolism of naphthalene mediated by human cytochromes P450 (CYP) using pooled human liver microsomes (pHLM) and CYP isoforms. The major metabolites from naphthalene mediated by pHLM were trans-1, 2-dihydro-1, 2-naphthalenediol (dihydrodiol), 1-naphthol (1-ol), and 2-naphthol (2-ol). Their kinetic parameters showed Km values of 23, 40, and 115  $\mu$ M, and Vmax values of 2860, 268, and 22 pmol/mg protein/min., respectively. Through human CYP isoform screening of naphthalene metabolism, CYP1A2 was identified as the most efficient isoform among those tested for producing dihydrodiol and 1-ol while CYP3A4 was the most effective for 2-ol production. Only CYP1A2 generated 1, 4-naphthoquinone from naphthalene. Metabolism studies of primary metabolites of naphthalene were also performed in order to identify secondary metabolites. While 2-ol was readily metabolized by pHLM to produce 2, 6- and 1, 7-dihydroxynaphthalene, dihydrodiol and 1-ol were inefficient substrates for pHLM. To further explore the metabolism of dihydrodiol and 1-ol, a series of human CYP isoforms was applied. 1, 4-naphthoquinone and four unknown metabolites from 1-ol were observed, and 1A2 and 2D6<sup>1</sup> were identified as the most active isoforms for the production of 1, 4-naphthoquinone. Dihydrodiol was metabolized by CYP isoforms to three unidentified metabolites with CYP2A6 having the greatest ability toward this substrate among those tested. The metabolism of dihydrodiol by CYP isoforms was lower than that of 1-ol. These studies identify both primary and secondary metabolites of naphthalene mediated by pHLM and CYP isoforms. The dihydrodiol appears to be a relatively stable biomarker of human exposure to naphthalene.

#### ROLE OF PULMONARY CYTOCHROME P450 3A1 IN 1-NITRONAPHTHALENE BIOACTIVATION AND INJURY IN ADULT AND POSTNATAL RATS.

K. C. Day, J. D. Reynolds, D. R. Morin, C. G. Plopper and M. V. Fanucchi. *University of California, Davis, Davis, CA*.

Cytochrome P450 (CYP) monooxygenases play an important role in the bioactivation of hazardous air pollutants such as 1-nitronaphthalene (1NN). Despite similar rates of 1NN metabolism in postnatal and adult rat lungs, postnatal rats are more susceptible to 1NN pulmonary injury than adults. The exact isozyme responsible for 1NN metabolism is unknown. The purpose of this study was to determine if CYP3A1, a major constituent of human liver and lung, is involved in the bioactivation of 1NN and if the amount of CYP3A1 explains the difference in susceptibility between postnatal and adult rats. We evaluated airway and liver microsomes for CYP3A1 activity using the substrate Midazolam. Seven-day old rats have lower rates of baseline Midazolam metabolism in lung and liver compared to adults. Ketoconazole, a CYP3A inhibitor, decreased total Midazolam metabolism in lung and liver microsomes from 7-day old and adult rats by at least 50%, *in vitro*. *In vivo*, ketoconazole inhibited total Midazolam metabolism by 51% in adult rat lungs, 26% in adult liver, 35% in 7-day old lungs, and 55% in 7-day old liver. To determine if ketoconazole prevents 1NN pulmonary injury, rats received an IP injection of carrier or ketoconazole prior to administration of 50mg/kg 1NN. Lungs were evaluated by high resolution light microscopy 24-hrs later. Extensive areas of vacuolated and exfoliated cells and bare basement membrane were detected in the bronchi of adult rats treated with carrier+1NN, whereas only a few vacuolated cells were detected in the bronchi of adult rats treated with ketoconazole+1NN. Ketoconazole did not significantly alter 1NN pulmonary injury in 7-day old rats as observed in adults. We conclude that pulmonary CYP3A1 is involved in the bioactivation of 1NN. We hypothesize the different injury patterns observed between adult and 7-day old rats could potentially be due to inhibition of first pass 1NN metabolism in 7-day rat liver allowing more 1NN to reach the lung. #### MODIFICATION OF PULMONARY CYP2B1 AND INDUCED CYP1A1 ACTIVITIES BY INTRAVENOUS INJECTION OF IRON DEXTRAN.

M. M. Ghanem<sup>1,2</sup>, L. Battelli<sup>1</sup>, M. Barger<sup>1</sup>, J. Nath<sup>2</sup> and A. F. Hubbs<sup>1</sup>. <sup>1</sup>*HELD, NIOSH, CDC, Morgantown, WV* and <sup>2</sup>*Genetics and Developmental Biology Program, WVU, Morgantown, WV*. Sponsor: V. Castranova.

Cytochrome P450s (CYPs) are membrane-bound heme-containing proteins (hemoproteins) that catalyze oxidation of xenobiotics producing less lipophilic substances thereby facilitating their excretion. The heme moiety of this protein is iron-

protoporphyrin IX, which plays the major role in the catalytic activity of the enzyme. We hypothesized that the bioavailability of iron modifies the activity of inducible (CYP1A1) and constitutional (CYP2B1) CYP isozymes in rat lungs. Therefore, male Sprague-Dawley rats were injected i.v. with 50 or 200 mg/kg BW iron as iron dextran. Saline was injected as a control. Eleven days later, rats were injected intraperitoneally with the classic CYP1A1 inducer, beta-naphthoflavone (BNF; 50 mg/kg BW), to induce CYP1A1. Three days after BNF injection, rats were sacrificed and the lungs were perfused by phosphate buffer saline (PBS) through the pulmonary artery to remove blood. Immediately after washing, the microsomes of the right lung lobes were freshly prepared to measure the CYP1A1-dependent enzymatic activity [ethoxyresorufin-O-deethylase (EROD)] and the CYP2B1-dependent enzymatic activity [pentoxyresorufin-O-deethylase (PROD)]. Before separation of microsomes by differential centrifugation, an equal portion of lung homogenate was freeze dried for measurement of lung iron. The results showed that pulmonary iron concentration was increased in rats receiving 50 mg/kg (310 + 31.45 µg/gm) and 200 mg/kg (796 + 37.8 µg/gm) iron compared to control (180 + 13.33 µg/gm). The activities of PROD and induced EROD were significantly decreased by injection of 200 mg/kg iron. These findings suggest that increasing rat lung iron content modifies xenobiotic metabolism in lung by decreasing the activity of CYP2B1 and inducible CYP1A1.

### 361

#### ROLE OF CYP2E1 IN THE OXIDATION OF ACRYLAMIDE (AA) TO GLYCIDAMIDE (GA) AND FORMATION OF DNA AND HEMOGLOBIN ADDUCTS.

B. I. Ghanayem<sup>1</sup>, L. McDaniel<sup>2</sup>, M. I. Churchwell<sup>2</sup>, N. C. Twaddle<sup>2</sup>, R. Snyder<sup>3</sup>, T. R. Fennell<sup>3</sup> and D. R. Doerge<sup>2</sup>. <sup>1</sup>Laboratory of Pharmacology and Chemistry, NIEHS/NIH, Research Triangle Park, NC, <sup>2</sup>NCTR, Jefferson, AR and <sup>3</sup>RTI International, Research Triangle Park, NC.

AA is a known animal carcinogen, neurotoxin, and reproductive toxin. AA is formed in baked and fried carbohydrate-rich foods such as french fries. Our earlier studies showed that CYP2E1 is the primary enzyme responsible for AA oxidation to GA. Using CYP2E1-/- (KO) mice, subsequent studies in this laboratory showed that AA metabolism to GA is required for the induction of male germ cell mutagenicity. To assess the role of CYP2E1 in the epoxidation of AA and the formation of GA-DNA adducts as well as AA and GA hemoglobin (HGB) adducts, AA was administered to KO or wild-type (WT) mice at 50 mg/kg IP. Six hours later, mice were euthanized and blood and tissues were collected. Using LC-ES/MS/MS, AA, and GA, as well as DNA and HGB adducts were measured. While the plasma levels of AA and GA were 115.0±14.0 and 1.7±0.31 µM in KO mice, respectively, they were 0.84±0.80 and 33.0±6.3 µM in the plasma of AA-treated WT mice, respectively. Dosing of AA to WT mice caused a large increase in N7-GA-Gua and N3-GA-Ade adducts in the liver, lung, and testes. Further, while traces of N7-GA-Gua adducts were measured in all three tissues from KO mice treated with AA, the levels were significantly lower than in WT mice (52- to 66-fold). Significant elevation of both AAVal and GAVal adducts was seen in WT mice treated with AA. In AA-treated KO mice, the levels of AAVal were roughly twice as high as those in WT mice. The amount of GAVal in AA-treated KO mice was low but was significantly higher than in vehicle-treated KO mice, and were  $\geq$  33-fold lower than that found in AA-treated WT mice. In conclusion, these results demonstrated that CYP2E1 is the primary enzyme responsible for the epoxidation of AA to GA, which leads to DNA adduct formation. Oxidative pathways other than CYP2E1 can lead to formation of GA and GA-DNA adducts, but the contribution of these pathways is negligible by comparison.

### 362

#### GENE EXPRESSION ALTERATIONS IN IMMUNE SYSTEM PATHWAYS FOLLOWING EXPOSURE TO IMMUNOSUPPRESSIVE CHEMICALS.

R. M. Patterson<sup>1</sup>, N. Walker<sup>1</sup>, S. Baker<sup>2</sup>, T. Dickinson<sup>2</sup>, K. White<sup>3</sup>, D. Musgrove<sup>3</sup>, S. Harrison<sup>1</sup> and D. R. Germolec<sup>1</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC, <sup>2</sup>Illumina, Inc., San Diego, CA and <sup>3</sup>VCU, Richmond, VA.

Exposure to xenobiotics can affect a number of adverse immunological outcomes, including infectious disease, hypersensitivity, and autoimmunity. It has been proposed that related disorders may share causative genetic alterations. Diethylstilbestrol (DES), Dexamethasone (DEX), Cyclophosphamide (CPS), and 2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) are immunosuppressive chemicals that can induce similar pathophysiological endpoints, however the mechanism of toxicity is different for each compound. The primary goals of these studies are to correlate changes in gene expression with alterations in functional immune endpoints, study the mechanisms of action, and evaluate the commonalities among the test compounds. Female B6C3F1 mice were treated with one of the four chemicals daily for five days. The dosages, routes and vehicles selected had been previously optimized for each compound. Splenocyte RNA was analyzed using Illumina Sentrix™ arrays and AnEx software. A dose-dependent trend was evident in differ-

ential gene expression for each of the chemicals as compared to controls. DES and TCDD induced the greatest and least number of changes in gene expression, respectively. Many of the differentially expressed genes are known to play a role in apoptosis, host defense, and cell growth, differentiation, and adhesion. The majority of gene alterations were unique to a single compound, however a number of genes were similarly altered across compounds. Alterations common to three different chemicals include upregulation of IL-18, lymphotxin B receptor, and colony stimulating factor receptor, and downregulation of RANTES and histocompatibility antigens. These findings are consistent with observed alterations in immune function. Genomic analysis revealed several gene expression changes that may be commonly associated with xenobiotic-induced immune system perturbations. However, distinct gene profiles were also found in association with chemicals that target similar immune parameters.

### 363

#### THE ROLE OF CYCLIN DEPENDENT KINASE INHIBITOR P21 IN TCDD-INDUCED THYMIC ATROPHY.

M. Fisher<sup>1</sup>, M. Nagarkatti<sup>2</sup> and P. S. Nagarkatti<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, Virginia Commonwealth University School of Medicine, Richmond, VA and <sup>2</sup>Microbiology and Immunology, Virginia Commonwealth University School of Medicine, Richmond, VA.

Thymic atrophy is a hallmark of exposure to dioxins, of which 2, 3, 7, 8-tetrachloro dibenzo-p-dioxin (TCDD) is the most potent congener. TCDD-induced thymic atrophy may be regulated by multiple pathways that are triggered following activation of the aryl hydrocarbon receptor (AhR). In the current study, we tested the hypothesis that TCDD exposure results in p21-mediated cell-cycle arrest in the thymus, and that TCDD-induced thymic atrophy results in part from a blockade of thymocyte proliferation. To test our hypothesis, p21 KO mice and age-matched wild-type mice were exposed to 10 g/kg TCDD for 48-72 hrs. We found that TCDD induced G0/G1 cell cycle arrest in thymocytes of wild-type but not in p21 KO mice. In addition, p21 KO mice were resistant to TCDD induced thymic atrophy. We also noted that lack of p21 rendered mice resistant to TCDD-induced thymocyte apoptosis. Finally, we analyzed the effect of TCDD on CD4-/CD8- (DN) thymocyte subsets, defined by expression of CD44 and CD25, which is comprised of immature progenitors that proliferate to become CD4+/CD8+ (DP) thymocytes. TCDD exposure resulted in a blockade of thymocyte maturation at the highly proliferative DN2 stage (CD44+/CD25+), as indicated by the significant increase in the proportion of DN2 thymocytes, and concomitant decrease in DN3 (CD44-/CD25+) thymocytes. In addition, the increase in DN2 thymocytes was accompanied by G0/G1 cell cycle arrest of thymocytes in the DN compartment. However, thymocytes from TCDD-exposed p21 KO mice showed no alteration in the distribution of thymocytes within the DN compartment. Taken together, these results suggest that TCDD exposure results in p21 mediated cell cycle arrest of thymocytes and that the resulting blockade of thymocyte proliferation contributes, at least in part, to apoptosis and thymic atrophy.

### 364

#### TCDD SUPPRESSES ANTIGEN-SPECIFIC INTERACTIONS BETWEEN OTII CD4 T CELLS AND OVA-LOADED DENDRITIC CELLS.

S. Navarro<sup>1</sup> and D. M. Shepherd<sup>1,2</sup>. <sup>1</sup>CEHS, University of Montana, Missoula, MT and <sup>2</sup>Biomedical & Pharmaceutical Sciences, University of Montana, Missoula, MT.

Exposure to the environmental contaminant TCDD (dioxin) causes suppressive effects on the immune system. The mechanism(s) of action at the cellular and molecular levels underlying the potent suppression of T cell-mediated immune responses is not understood. We hypothesize that TCDD exposure impedes activation of CD4 T cells due to a lack of persistent interactions with dendritic cells (DC). To test this hypothesis, C57Bl/6 recipient mice were gavaged with vehicle or TCDD (15 µg/kg), injected i.v. with OT-II ovalbumin (OVA)-specific naïve T cells, and immunized with OVA-loaded DC. The fate of both the DC and antigen-specific T helper cells in the draining lymph nodes (LN) was then evaluated on multiple days after immunization. On days 3, 4 and 6, TCDD-treated mice had significantly decreased numbers of donor DC, and on day 6 a greater frequency of these cells were PI-positive suggesting their loss was due to increased cell death. Following re-stimulation with OVA, LN cells from TCDD-treated mice produced significantly lower amounts of IL-12. Furthermore, the ability of the OVA-loaded DC to induce clonal expansion of the OT-II CD4 T cells in TCDD-treated mice was significantly suppressed on days 4 and 6 post-immunization when compared to the vehicle-treated controls. OVA-specific T cells in mice treated with dioxin were also less activated based on lower expression of CD11a and CD44, and suppressed production of IL-2 and IFN- $\gamma$  following *ex vivo* re-stimulation. Additional studies utilizing OVA-loaded DC from AhR wildtype (AhR /) and knockout (AhR -/-) mice demonstrated that the TCDD-induced loss of DC was mediated exclusively via an AhR-dependent process. However, suppression of the OVA-specific CD4 T cell

clonal expansion in TCDD-treated mice was only partially restored following the immunization of adoptively transferred mice with OVA-loaded AhR-/- DC. These results suggest that both the DC and activated T lymphocytes are directly affected following activation of the AhR- $\gamma$ ii

365

SUPERANTIGEN-PRIMED T CELLS EXPOSED TO 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) UNDERGO APOPTOSIS DURING THE FIRST ENCOUNTER AND EXHIBIT ANERGY UPON RESTIMULATION WITH THE ANTIGEN.

L. Faulconer<sup>2</sup>, I. Camacho<sup>1</sup>, M. Nagarkatti<sup>1</sup> and P. Nagarkatti<sup>2</sup>. <sup>1</sup>*Microbiology and Immunology, Virginia Commonwealth University, Richmond, VA* and <sup>2</sup>*Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA*.

In the current study, we investigated the effect of TCDD on the ability of staphylococcal enterotoxin A (SEA)-primed T cells to divide by dual-labeling the cells with 5, 6-carboxyfluorescein diacetate succinimidyl ester (CFSE) and antibodies against the specific T cell receptors. To this end, C57BL/6 wild-type mice were injected ip with TCDD (10 microg/kg body weight) followed by hind footpad injections of SEA (10 microg/footpad). The draining popliteal lymph nodes (PLN) were harvested 1-4 days post treatment, labeled with CFSE and cultured for 1-4 days without further stimulation or in the presence of the recall antigen. TCDD-exposed SEA-reactive Vbeta3+ and Vbeta11+ T cells showed decreased cell divisions upon *in vitro* culture in the absence of any stimulation, which also correlated with increased levels of apoptosis. Moreover, the recall cell-division response was also defective in SEA-reactive T cells isolated from TCDD-exposed mice. However, during the recall response, cells from TCDD-exposed mice did not exhibit a defect in apoptosis, thereby suggesting that the defective recall response may result from a state of anergy rather than increased apoptosis. Using AhR knock out (KO) mice, we found that AhR was involved in the regulation of defective cell division and apoptosis induced by TCDD. Together, these data demonstrate while TCDD-induced apoptosis may account for the decreased primary T cell proliferative response, the reduced cell division seen during subsequent exposure to the recall antigen may result from a state of anergy. The current study also demonstrates that combined use of superantigen and CFSE may offer a simple and useful tool to monitor the ability of immunotoxins to alter the proliferative responsiveness of antigen-specific T cells (This work was supported in part by NIH grants R01AI053703, R01ES09098, R01 AI058300, R01DA016545 and R01HL058641).

B CELL MATURATION AND TCDD-INDUCED MODULATION OF THE 3'α ENHANCER.

C. E. Sulentic. *Pharmacology & Toxicology, Wright State University, Dayton, OH*.

2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), a known disruptor of B cell differentiation, induces binding of the aryl hydrocarbon receptor (AhR) nuclear complex to dioxin responsive elements (DRE). Effects on B cell differentiation appear to be dependent on the AhR and the 3'α enhancer has been identified as a molecular target of TCDD. Transcriptional regulation of the immunoglobulin heavy chain gene involves several regulatory elements including the 3'α enhancer, which is composed of four distinct regulatory domains. DNA binding sites for several transcription factors, including B cell-specific activator protein, NF- $\kappa$ B and Oct have been identified within the 3'α enhancer domains and are believed to be important in regulating 3'α enhancer activity. Previous studies have focused on mature B cells and have demonstrated TCDD-induced inhibition of 3'α enhancer activity which may be, at least in part, mediated by AhR-DRE binding within the 3'α enhancer. However, one domain within the 3'α enhancer, independent of the other domains, appears to be active in pre-B cells potentially implicating a role in B cell maturation. Therefore the objective of the present studies was to determine if TCDD could modulate 3'α enhancer activity within B cell lines representing various B cell maturation states. Preliminary studies with transiently transfected luciferase reporter constructs demonstrate a TCDD-induced inhibition of LPS-activated 3'α enhancer activity within the immature B cell line, WEHI-231. These results suggest that TCDD may target B cell maturation. (Supported by the School of Medicine, WSU)

SYNTHETIC AND ENDOGENOUS PPARγ AGONISTS, GW7845, 15-DEOXY- $\Delta$ <sup>12,14</sup>-PROSTAGLANDIN J<sub>2</sub>, AND MONO-(2-ETHYLHEXYL) PHTHALATE, ACTIVATE COMPLEX CASPASE CASCADES IN PRO/PRE-B CELLS.

J. Schlezinger, J. Emberley and D. Sherr. *Environmental Health, Boston University School of Public Health, Boston, MA*.

Humans receive significant exposure to multiple PPARγ agonists, including anti-diabetic drugs (thiazolidinediones) and environmental contaminants (phthalates). Synthetic PPARγ agonists, including GW7845 and mono-(2-ethylhexyl) phthalate

(MEHP), as well as the endogenous agonist, 15-deoxy- $\Delta$ <sup>12,14</sup>-prostaglandin J<sub>2</sub> (15d-PGJ<sub>2</sub>), induce lymphocyte apoptosis, suggesting that PPARγ agonists are immunotoxins. Here, we compared the caspase cascade activated by each of these PPARγ agonists in the non-transformed pro/pre-B cell line, BU-11. A similar suite of caspases was activated by each of the PPARγ agonists; however the time required to initiate caspase activation and induce apoptosis differed. Significant apoptosis was induced within 1, 8, and 5 hr by optimal GW7845 (40  $\mu$ M), MEHP (150  $\mu$ M), and 15d-PGJ<sub>2</sub> (10  $\mu$ M) doses, respectively. Treatment with any of the PPARγ agonists resulted in the release of cytochrome c from the mitochondria, a potentially apical event in PPARγ agonist-induced apoptosis. Cytochrome c release was accompanied by mitochondrial membrane depolarization following treatment with GW7845, but not with MEHP or 15d-PGJ<sub>2</sub>. Caspases-3 and -9 appeared to be activated concurrently with cytochrome c release. In addition, treatment with any of the PPARγ agonists resulted in significant caspase-8 activation. Furthermore, formation of truncated Bid suggested a role for caspase-2 and/or caspase-8 in apoptosis. Using peptide inhibitors, we show that multiple initiator caspases may be required to fully activate the PPARγ agonist-induced apoptosis program. These data demonstrate that complex, but similar, apoptotic programs may be initiated by structurally diverse PPARγ agonists.

368

CB2 CANNABINOID RECEPTOR AGONIST, JWH015 TRIGGERS APOPTOSIS IN IMMUNE CELLS: POTENTIAL ROLE FOR CB2 SELECTIVE LIGANDS AS IMMUNOSUPPRESSIVE AGENTS.

C. A. Lombard<sup>1</sup>, M. Nagarkatti<sup>1</sup> and P. S. Nagarkatti<sup>2</sup>. <sup>1</sup>*Microbiology and Immunology, MCV Campus, Virginia Commonwealth University, Richmond, VA* and <sup>2</sup>*Pharmacology and Toxicology, MCV Campus, Virginia Commonwealth University, Richmond, VA*.

Cells of the immune system uniquely express a cannabinoid receptor designated CB2, whose precise function remains unclear. Delta-9-tetrahydrocannabinol (THC), a major psychoactive component found in marijuana and other cannabinoids that interact with both CB1 and CB2 receptors are known to induce apoptosis in immune cells and cause immunosuppression. Such studies suggested the possible use of cannabinoids as anti-inflammatory/immunosuppressive agents. However, cannabinoids that bind CB1 receptors are also psychoactive thereby limiting their clinical use. In the current study, we therefore investigated whether the synthetic CB2-selective agonist JWH015, devoid of psychoactivity, would mediate apoptosis and cause immunomodulation *in vivo*. We found that JWH015 inhibited the proliferative response of splenocytes to T and B cell mitogens *in vitro* which correlated with induction of apoptosis. In addition, JWH015 triggered apoptosis in thymocytes *in vitro*. Mechanisms of apoptosis revealed that JWH015 caused release of cytochrome c and Smac, and cleavage of caspase-8, caspase-9, caspase-3 and Bid, as well as caused loss of mitochondrial membrane potential ( $\Delta$ V<sub>m</sub>). Use of caspase inhibitors showed that JWH015 induced apoptosis through cross-talk between the extrinsic (death receptor) and the intrinsic (mitochondrial) pathways of apoptosis. Finally, administration of JWH015 into C57BL/6 mice caused thymic atrophy and apoptosis as well as decreased peripheral T cell response to mitogens. Together, this study suggests for the first time that CB2 selective agonists can induce apoptosis in immune cells and cause immunosuppression. Thus, such cannabinoids may serve as novel anti-inflammatory/immunosuppressive agents and would be ideal candidates for clinical use due to lack of psychotropic effects.

369

THE ENDOGENOUS CANNABINOID, 2-ARACHIDONYL-GLYCEROL, SUPPRESSES NF-AT NUCLEAR TRANSLOCATION AND INTERFERON- $\gamma$  PRODUCTION.

B. L. Kaplan<sup>1,2</sup>, Y. Ouyang<sup>1</sup>, C. E. Rockwell<sup>1</sup>, G. K. Rao<sup>1,2</sup> and N. E. Kaminski<sup>1,2</sup>. <sup>1</sup>*Pharmacology and Toxicology, Michigan State University, East Lansing, MI* and <sup>2</sup>*Center for Integrative Toxicology, Michigan State University, East Lansing, MI*.

2-Arachidonoyl-glycerol (2-AG), an endogenous ligand for both CB1 and CB2 cannabinoid receptors, has previously been demonstrated to modulate immune functions including suppression of interleukin-2 (IL-2) expression and nuclear factor of activated T cells (NF-AT) DNA binding activity. As NF-AT is a critical transcriptional regulator of both IL-2 and interferon- $\gamma$  (IFN- $\gamma$ ), the objective of the present studies was to investigate the effect of 2-AG on IFN- $\gamma$  expression and associated upstream signaling events. IFN- $\gamma$  expression was assessed using an enzyme-linked immunosorbent assay (ELISA) and reverse transcriptase polymerase chain reaction (PCR). Translocation of NF-AT was measured by Western analysis and calcium determinations were made with a dual excitation spectrometer. Pretreatment of splenocytes with 2-AG markedly suppressed phorbol ester plus calcium ionophore induced IFN- $\gamma$  secretion in a cannabinoid receptor-independent manner. In addition, 2-AG suppressed IFN- $\gamma$  steady state mRNA expression in a con-

centration- and time-dependent manner. Time of addition studies revealed that 2-AG treatment up to 12 hours post cellular activation still resulted in suppression of IFN- $\gamma$ , which was consistent with a time course conducted with cyclosporin A (CsA), an inhibitor of NF-AT activity. Coincidentally, 2-AG perturbed the nuclear translocation of both NF-AT1 and NF-AT2 proteins, and blocked thapsigargin-induced elevation in intracellular calcium, suggesting that altered calcium regulation might partly explain the suppression of NF-AT nuclear translocation. Taken together, these data demonstrate that 2-AG suppresses IFN- $\gamma$  expression in murine splenocytes in a cannabinoid receptor-independent manner, and that the mechanism might involve suppression of intracellular calcium signaling and perturbation of NF-AT nuclear translocation. (Supported by NIH grant DA12740).

#### CONCEPTUAL PRINCIPLES FOR UTILIZING OMIC TECHNOLOGIES IN MECHANISTIC RISK ASSESSMENT.

**C. Borgert**<sup>1,2</sup>, **P. Guiney**<sup>3</sup>, **G. Casella**<sup>4</sup> and **K. Shiverick**<sup>5</sup>. <sup>1</sup>*Applied Pharmacology Toxicology Inc., Gainesville, FL*, <sup>2</sup>*Department of Physiological Sciences, University of FL College of Veterinary Medicine, Gainesville, FL*, <sup>3</sup>*S.C. Johnson & Son, Inc., University of FL College of Veterinary Medicine, Racine, WI*, <sup>4</sup>*Department of Statistics, University of FL College of Veterinary Medicine, Gainesville, FL* and <sup>5</sup>*University of FL College of Medicine, Gainesville, FL*.

Omics technologies promise tremendous advancements for toxicology and risk assessment, including identification of more sensitive biomarkers of exposure and effect, of pre-toxicological changes, and of molecular mechanistic steps in toxicologic pathways. Omics technologies may thus help identify fundamentally similar modes of toxic action based on similar DNA, RNA, protein, or metabolic profiles and help categorize chemicals accordingly. Although some of these promises are attainable, it is important to appreciate that omics technologies alone are unlikely to elucidate the complete mechanism or mode of toxic action. To explore how best to utilize omics technologies in mechanistic research, we first considered the classic definitions of mode and mechanism of action and evaluated the types of data required to satisfy those definitions using a classic hepatotoxicity model. Our evaluation suggests several principles. Polyomic approaches will be necessary to define the sequence of molecular steps in a mechanism of toxicity. Because it is critical to understand the causal links between individual mechanistic steps and to integrate this understanding at several levels of biological organization, polyomic approaches will augment, but not replace, classical mechanistic research. Bioinformatic technology will be essential for interpreting and integrating polyomic data according to fundamental tenets of pharmacology and toxicology, such as dose-response, and in turn, to make interpretations from the data that are relevant for risk and safety assessment. It is critical to develop approaches that differentiate between pre-toxicological, compensatory, and protective responses to chemicals, and that can identify the dose-dependent transitions in mechanisms that most impact risk estimation.

371

#### USE OF GENOMICS DATA TO PREDICT MODE OF ACTION IN CHEMICAL HAZARD CHARACTERIZATION.

**I. Pagan**<sup>1</sup> and **B. Sen**<sup>2,3</sup>. <sup>1</sup>*NCEA/ORD, USEPA, Research Triangle Park, NC*, <sup>2</sup>*National Research Council, Washington, DC* and <sup>3</sup>*ECD/ORD, USEPA, Research Triangle Park, NC*.

The process of characterization of chemical hazard and human carcinogenic potential is evolving from their traditional dependence on tumor endpoints to the inclusion of data that describe the mode of action (MOA) at the cellular and molecular level. Information from gene expression profiling has the potential to greatly improve this process by predicting key mechanistic pathways involved in the chemical mode of toxicity and the human relevancy of the effects observed in animals by parallel inter-species comparisons. Hypothetical MOA(s) can then be generated for a more targeted testing protocol of the chemical of concern. Dimethylarsinic acid (DMA) will be used as an example to illustrate how gene microarray data can more rapidly provide mechanistic information comparable to that developed from years of research using more traditional toxicological endpoints. Exposure to DMA has been shown to result in rat urinary bladder tumors. Studies specifically designed to evaluate the mode of action for these bladder tumors suggest that DMA-induced cancer is associated with increased cell proliferation, generation of reactive oxygen species and cytotoxicity. Gene expression analysis of the target cell population for bladder cancer after *in vivo* exposure characterized the molecular changes involved in DMA-induced toxicity and demonstrated that oxidative stress response, cell proliferation and apoptosis are all involved in the toxicity response. The present example shows how genomics can be used as a cost- and time-effective tool to inform MOA and to generate hypothesis-driven and targeted chemical testing procedures for improved human health risk assessments. (This abstract does not reflect EPA policy).

372

#### ASSIGNING OCCUPATIONAL HAZARD CATEGORIES (OHCs) FOR MATERIALS USED AND SYNTHESIZED IN THE PHARMACEUTICAL INDUSTRY.

**F. J. Guerriero**<sup>1</sup>, **C. W. Seaman**<sup>2</sup>, **M. J. Olson**<sup>3</sup>, **M. W. Abramovitz**<sup>1</sup> and **G. L. Sprague**<sup>1</sup>. <sup>1</sup>*GlaxoSmithKline, King of Prussia, PA*, <sup>2</sup>*GlaxoSmithKline, Ware, Herts, United Kingdom* and <sup>3</sup>*GlaxoSmithKline, Research Triangle Park, NC*.

A chemical hazard categorization scheme used by a broad range of industries has been published by the UK HSE as part of the COSHH program. This scheme allows ranking of chemical hazards and targeted implementation of health-protective controls. There is no counterpart used widely across US industry, although NIOSH and other groups have coordinated recent discussions aimed at popularizing this approach. Within GlaxoSmithKline, the Occupational Hazard Category (OHC) program is recognized as a critical tool for ranking potential health hazards of chemicals. Solid materials are classified according to hazard into appropriate categories from OHC-1 (least hazardous substances) to OHC-4 (most hazardous). Notations accompanying the OHC designation include Carcinogen, Skin and Respiratory Sensitiser, Corrosive, Reproductive Hazard, etc. The OHC and notations of special hazard are linked to the GSK Exposure Control Matrix (ECM) which specifies hierarchical engineering controls as the primary means for control and containment of solid materials in order to avoid occupational exposure. Assignment of an OHC is derived from a matrix based upon the hazard classification of materials (EU R-phrase, toxicological characterization & pharmacological effect/potency). The assignment of the GSK OHC to raw materials, isolated intermediates, novel materials and pharmaceutical products supports global product development and manufacture. Externally established OELs can be converted to an OHC to aid in selection of workplace controls. Business circumstances and timing may dictate that an OHC can be established based on a limited data set. In this case, professional judgment and comparison to similar materials is used to guide the selection of an OHC. In summary, the methodology for OHC assignment currently in use by GSK is based on unifying several different approaches adopted by governmental and business groups and has been adopted for global application to the GSK product development process.

373

#### USING STRUCTURE-ACTIVITY RELATIONSHIPS FOR CHEMICAL HAZARD SCREENING UNDER THE SUSTAINABLE FUTURES PROGRAM.

**L. T. Haber**<sup>1</sup>, **A. Maier**<sup>1</sup>, **E. Becker**<sup>2</sup> and **J. Santory**<sup>3</sup>. <sup>1</sup>*Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH*, <sup>2</sup>*Consortium for Environmental Risk Management (CERM), Evansville, IN* and <sup>3</sup>*CERM, Pittsburgh, PA*.

Sustainable Futures is a voluntary EPA program with the goal of encouraging application of pollution prevention principles and the development of inherently low hazard new chemicals submitted as premanufacture notices (PMNs) under Section 5 of the Toxic Substances Control Act (TSCA). As part of the program, training and support are provided to companies in the evaluation of new chemicals, with limited available information, using EPA's hazard and risk characterization models and protocols. Physical/chemical properties, persistence, bioaccumulation, aquatic toxicity, and human health hazard from noncancer and cancer effects are identified. For this screening assessment, a broad search is conducted for relevant data on the chemical of interest. In most cases, data on the chemical are very limited, and so toxicology data on structural analogues and degradation products, as well as QSAR predictions, are used. Toxicological judgement is used to identify preferred analogs, focussing on key reactive structural groups that are likely to determine toxicity. Decision criteria for identifying potential ecological or health concerns and for selecting analogs have been developed and refined in the implementation of this program. Using these data, effect levels are identified, and combined with estimates of general public, occupational and aquatic exposure to develop risk assessments for these various scenarios and targets. This risk screening approach allows for the rapid collection and review of datasets and identification of potential toxicological and ecological concerns early in product development, and illustrates the utility of structure activity relationships for human health and risk assessment.

374

#### SCIENTIFIC CRITERIA TO TEST INGREDIENTS ADDED TO CIGARETTES.

**D. M. Byrd**, **A. Brownawell**, **M. Falk**, **R. Feldman**, **K. Lewis** and **P. Nixon**. *LSRO, Bethesda, MD*.

The Life Sciences Research Office (LSRO), a nonprofit research organization, evaluates the potential of ingredients to change the relative risk of adverse human health effects from smoking cigarettes. LSRO convened a multidisciplinary, ad-hoc advisory panel and received public comments at two open meetings in 2002 and 2003. LSRO also evaluated more than 3,800 papers and 80 books, as part of the Added Ingredients Review (AIR). LSRO's recently released initial report concluded that testing of ingredients is feasible and worthwhile. LSRO's AIR Panel held six

meetings about the second report, which LSRO is in process of publishing. In summary, this report describes the following criteria for testing. Data submitters could compare smoke from identically manufactured cigarettes containing different amounts of the ingredient. Data submitters could aim to show that neither the added ingredient (nor its pyrolysis products): (a) transfers into cigarette smoke, (b) changes the physics, chemistry, or biological activity of the smoke, or (c) alters smokers' exposures to smoke. If any of these criteria are not met, a data submitter could decrease the ingredient and retest, or provide additional data, showing that the ingredient does not change the relative risk of adverse health effects of cigarette smoking. As an alternative, epidemiological studies, comparing identically manufactured cigarettes, with and without the ingredient, could provide definitive evidence of the effects of an ingredient on human health. While predictive, such studies are generally infeasible, because of their long durations and relative insensitivities. Thus, if performed at all, epidemiological studies probably would become part of post-marketing surveillance.

375

#### AN INTEGRATED DECISION TOOL FOR EVALUATING CHEMICAL SAFETY IN LABORATORY RESEARCH STUDIES INVOLVING ANIMALS.

**A. Maier**<sup>1</sup>, J. Utrecht<sup>2</sup>, C. Pittenger<sup>4</sup>, J. Stewart<sup>3</sup> and A. Parker<sup>1</sup>. <sup>1</sup>*Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH*, <sup>2</sup>*University of Cincinnati, Cincinnati, OH*, <sup>3</sup>*Environmental Health and Engineering, Newton, MA* and <sup>4</sup>*Exponent, Inc., Cincinnati, OH*.

Toxicology and pharmacology studies using whole animal exposures remain a cornerstone of chemical and drug safety evaluation. These studies involve potential health consequences for researchers, laboratory personnel, and animal handlers. Therefore, approaches for assessing potential health concerns associated with study protocols are needed. To meet the requirements of Institutional Animal Care and Use Committees (IACUC) and other groups, we have developed an integrated approach for risk assessment of activities associated with conducting animal research experiments. This approach integrates tools to support the traditional elements of risk assessment. First, an evergreen database structure has been developed that summarizes key hazards of toxicants or drugs used in each newly evaluated protocol. This database synthesizes and provides a critical evaluation of toxicological data for each agent. Second, a decision-logic for evaluating the potential exposure has been developed based on physical and chemical characteristics, routes of administration and use scenarios, and toxicokinetic data. Third, a qualitative approach for aligning potential hazard and exposure to corresponding control strategies has been developed. This approach has been applied to over 300 laboratory use protocols, and offers a tool for increasing the consistency in defining hazards, improving the documentation for certification, and clarifying the underlying rationale for workplace control recommendations.

376

#### REAL WORLD TOXICOLOGY: A FRAMEWORK FOR EVALUATING TORT CLAIMS IN THE COURTROOM.

S. M. Bobst<sup>1</sup>, N. Zheng<sup>2</sup> and F. Thomas<sup>2</sup>. <sup>1</sup>*CERATOX, Houston, TX* and <sup>2</sup>*RAM Group Inc., Houston, TX*. Sponsor: J. Jabbour.

The United States is the most litigious society in the world, and toxic tort cases are increasing in Western Europe and developing nations as well. The toxicologist plays a critical role in evaluating evidence, and providing an opinion for a judge or jury to evaluate. Most tort claims are based on an initial perception that an exposure or environmental contamination has occurred, and liable parties are held responsible. A recent court decision, Daubert, allows the judge to act as a gatekeeper regarding the expert's opinion and supporting evidence. We present a systematic approach to evaluate any legal case involving toxicology with 5 questions. Specific examples are provided where this process has been successfully used in tort claims. This approach also provides a framework to communicate principles of toxicology in plain language easily understood by individuals without professional training or education in the field.

377

#### A FRAMEWORK/APPROACH FOR INCORPORATING PBPK MODELING INTO CUMULATIVE RISK ASSESSMENT OF CHEMICAL MIXTURES.

**R. S. Yang**<sup>1</sup>, J. E. Dennison<sup>1</sup> and **J. C. Lipscomb**<sup>2</sup>. <sup>1</sup>*Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Colorado State University, Fort Collins, CO* and <sup>2</sup>*USEPA, ORD/NCEA, Cincinnati, OH*.

Improving methods for cumulative risk assessment (CRA) of chemical mixtures has been a major goal and challenge. Toward this end, a framework/approach for incorporating physiologically-based pharmacokinetic (PBPK) modeling into CRA has

been developed, complementing existing CRA guidance, and refining its ten-step process to address PK issues. Principally, this allows the reevaluation of exposure and dose-response assessment to be transitioned from external to internal measures of exposure. PBPK modeling, as applied to chemical mixtures, can address both pharmacokinetic as well as human enzyme kinetic interactions during CRA. Doing so requires specific data. Phase I (Initial Analysis) is comprised of 5 steps culminating with the grouping of chemicals by toxic mechanism, identifying chemicals which may pose a significant amount of the mixture risk and a decision to embark on a comprehensive analysis of the mixture. PBPK analysis occurs in Phase II (Comprehensive CRA), which is comprised of 5 steps initiating with a dose-response analysis, and concluding with characterization of risk. The development of this framework/approach, not the actual CRA, utilized two model sets of chemical mixtures: Mixture 1 consists of 6 OP pesticides (methyl-parathion, parathion, chlorpyrifos, fenthion, diazinon, and fenitrothion) which share the same mode of action (acetylcholinesterase inhibition); Mixture 2 consists of 4 volatile organic chemicals (trichloroethylene, tetrachloroethylene, 1, 1, 1-trichloroethane, and chloroform) which have different modes of action and a variety of toxic endpoints. We present the advantages of integrating PBPK modeling and credible human tissue studies into CRA, as well as the methodologies involved in generating interactive PBPK models and quality human tissue studies. (Supported by USEPA Contract 3C-R102-NTEX)

#### DEVELOPMENT OF A CHILDREN'S HEALTH RISK ASSESSMENT FRAMEWORK USING A LIFE-STAGE APPROACH.

**S. Barone**<sup>1</sup>, **R. Brown**<sup>2,1</sup>, **S. Euling**<sup>1</sup>, **E. Cohen-Hubal**<sup>3</sup>, **C. A. Kimmel**<sup>1</sup>, **S. Makris**<sup>1</sup>, **J. Moya**<sup>1</sup>, **S. G. Selevan**<sup>1</sup>, **B. Sonawane**<sup>1</sup>, **T. Thomas**<sup>4,1</sup> and **C. M. Thompson**<sup>4,1</sup>. <sup>1</sup>*NCEA, USEPA, Washington, DC*, <sup>2</sup>*ASPH, Association of Schools of Public Health, Washington, DC*, <sup>3</sup>*NERL, USEPA, Research Triangle Park, NC* and <sup>4</sup>*AAAS, American Association for Advancement of Science, Washington, DC*.

The draft Framework for Children's Health Risk Assessment (CHRA) has been developed to provide a comprehensive resource for CHRA. This document is not a guideline, but rather describes the overall structure and the components considered important for CHRA. The document emphasizes the need to consider potential exposures to environmental agents during preconception and all stages of development and focuses on the relevant adverse health outcomes that may occur as a result of exposures. The framework addresses the question of why an improved CHRA will strengthen the overall risk assessment process. The value added to this approach will include: 1) a more complete evaluation of the potential vulnerability at different life-stages, 2) evaluation of potential for toxicity after exposure during all developmental life-stages, 3) integration of adverse health effects and exposure information across life-stages and 4) a focus on the underlying biological events and critical developmental periods for incorporating mode of action considerations. This framework expands upon the ILSI (2001) framework that included problem formulation, analysis, and risk characterization. The CHRA framework expands on the life-stage-specific nature of the analysis with scoping and screening level questions for hazard characterization, dose response and exposure assessment. The risk characterization step recognizes the need to consider life-stage specific risks and explicitly describes the uncertainties and variability in the data base. It is important to note that lack of data at a specific life-stage using this approach will not automatically lead to increased uncertainty in the risk assessment (*The views of the authors of this abstract do not represent Agency policy or endorsement*).

379

#### CASE STUDIES: DEVELOPING A DECISION-MAKING FRAMEWORK FOR OCCUPATIONAL HEALTH AND SAFETY CLEARANCE OF NEW CHEMICALS.

**S. Kim**<sup>1</sup>, **A. Maier**<sup>2</sup>, **P.J. Hakkinen**<sup>2,3</sup>, **A. Wullenweber**<sup>2</sup>, **D. A. Seid**<sup>1</sup> and **L. T. Haber**<sup>2</sup>. <sup>1</sup>*Applied Biosystems, Foster City, CA*, <sup>2</sup>*Toxicology Excellence for Risk Assessment, Cincinnati, OH* and <sup>3</sup>*Institute for Health and Consumer Protection, Physical and Chemical Exposure Unit, European Commission, Joint Research Centre, Ispra, Italy*.

Chemical manufacturers are expected to assess fully the potential occupational risks or hazards which could arise from the processing and/or manufacturing of new chemicals. However, in the absence of any standard or comprehensive methodology there has been room for error and/or inconsistency. Although a variety of hazard categorization and ranking schemes have been developed to remedy this gap, published approaches for expanding these into more robust occupational risk assessments are more limited. In order to remedy this gap, we have developed a comprehensive occupational hazard identification and risk assessment framework. The framework includes a decision flow chart that guides the user through specific criteria for completing the four basic steps of human health risk assessment: hazard identification, dose-response assessment, exposure assessment, and risk characterization. The procedure was designed specifically to allow for the maximum use of

the available data and current risk assessment methods. Criteria for developing toxicity and exposure potential ratings were developed drawing from a variety of published methods, with a scientific rationale presented for the selection of the recommended approaches. A set of risk characterization tools that integrate information from the toxicity and exposure assessments, as well as their interpretation was also developed. Full implementation of the procedure provided: (1) improvement in the quality of in-house risk assessment processes, (2) consistency and confidence in risk assessment output (e.g., hazard and risk ratings), and (3) strong support for safety and health decision-making for the clearance of new chemicals for use at facility operations.

**380**

A RETROSPECTIVE REVIEW OF STUDIES UTILIZING GAVAGE DOSING OF PRE-WEANING RATS DEMONSTRATES NO ADVERSE CONSEQUENCES OF DOSING PROCEDURES.

S. L. Makris<sup>1</sup>, E. Mendez<sup>2</sup> and K. C. Raffaele<sup>3</sup>. <sup>1</sup>ORD/NCEA, USEPA, Washington, DC, <sup>2</sup>OPP, USEPA, Washington, DC and <sup>3</sup>OPP, USEPA, Washington, DC.

In some studies that are conducted to assess potential hazard, dose response, and age-related sensitivity during development, it may be necessary to administer test substance directly to pre-weaning animals in order to ensure adequacy of exposure during critical early life stages. The USEPA Office of Pesticide Programs has received a number of studies that have utilized such direct dosing procedures in rats. These include 10 guideline developmental neurotoxicity (DNT) studies, performed in 5 laboratories, and over two dozen range-finding and cholinesterase inhibition studies, performed in 7 laboratories, under GLP regulations. All of the DNT studies included the following procedures: Wistar or Sprague-Dawley rats were used; pups were born in the performing laboratory; pups were dosed once daily; vehicles included water or corn oil; and dosing volume was 5 or 10 ml/kg bw. Direct doses to pups were administered between postnatal days (PND) 7 and 21, with durations of 11-15 days. An evaluation of vehicle control data across the guideline DNT studies demonstrates no adverse impact of direct gavage dosing to pre-weaning rats. DNT control group sizes ranged from 24-38 litters, resulting in 200-300 post-culling control pups (2400 pups from 294 litters). Following initiation of dosing to pups of any age, the number of mortalities per control group ranged from 1-9 (mean=3.9) during the dosing period; only seven of these deaths appeared to be due to dosing error. Except for these seven pups, there were no adverse findings attributable to gavage dosing: clinical and functional observation data, scheduled necropsy results, and mean pup body weight gain data appear normal. In conclusion, when performed by trained technical staff, direct gavage dosing of pre-weaning rat pups appears to be a valid, non-traumatic methodology for use in toxicology studies. (This abstract does not necessarily reflect the views or policy of the USEPA.)

**381**

RISK ASSESSMENT IN NEPHROTOXICOLOGY – SENSITIVITY OF RENAL TESTS.

P. A. Potnis<sup>1</sup>, A. Maier<sup>1</sup> and T. L. Guidotti<sup>1</sup>. <sup>1</sup>Environmental and Occupational Health, The George Washington University, Washington, DC, <sup>2</sup>Toxicology, Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH and <sup>3</sup>Environmental and Occupational Health, The George Washington University, Washington, DC.

The kidney is a critical target organ for many chemicals. Toxicology studies often include the evaluation of a variety of renal toxicity endpoints, including organ (kidney) weight change, histopathology as well as clinical chemistry findings. Kidney weight change is often observed at doses below those that have clear implications for functional renal deficits. As a result, the appropriate use of this endpoint for risk assessment is an area of considerable debate. To help resolve this issue existing animal toxicity findings and risk assessment interpretations were evaluated for a set of kidney toxicants. We compiled risk value data from current risk assessments for nephrotoxicants to determine the frequency at which various combinations of effects were identified as sufficiently adverse to serve as the basis for assigning critical effect levels. We also evaluated the sensitivity of kidney weight change as a marker of nephrotoxicity as compared to more traditional measures. Our results show that a significant portion of risk values are based on kidney weight change alone, suggesting that risk assessment scientists have interpreted kidney weight as an adverse effect. In our analysis of the sensitivity of kidney weight as a predictor of nephrotoxicity, we found that kidney weight change had a calculated sensitivity of 80% in predicting histopathological change or renal function impairment as measured by clinical chemistry changes. No clear relationship between specific mechanisms of action and likelihood for identifying kidney weight as an early effect marker was identified. Based on this analysis, we conclude that increased kidney weight is sufficiently predictive of more severe renal damage to be used as the basis for selecting adverse effect levels for risk assessment.

**382**

RELEVANCE OF RODENT FORESTOMACH TUMORS IN CANCER RISK ASSESSMENT.

D. Proctor and S. Hong. *Exponent, Irvine, CA.*

Studies have shown that most chemicals, which are known to be human carcinogens, also cause cancer in experimental animal models, but the converse is not as well established in that known animal carcinogens are not equally predictive of human carcinogenicity. A particularly controversial area in the use of animal data for human risk assessment is rodent forestomach tumors as a predictive tool for human carcinogenicity. Humans do not have a forestomach, but have histologically similar organs, including the oral cavity, pharynx, esophagus and glandular stomach. If tumors of the rodent forestomach are derived by a genotoxic mechanism, it is more likely that the agent is a human carcinogen as well. However, proliferative lesions in the rodent forestomach, including hyperplasia and compound-related tumors, may result from a combination of effects related to toxicokinetics, epithelial irritation, and/or dosing regimen and are less likely to be relevant for evaluating human carcinogenic potential. Hyperplasia is recognized as a preneoplastic lesion leading to forestomach papillomas and squamous cell carcinoma, but establishing the mechanism of action is critical to determining relevance to humans. We review the comparative anatomy and physiology of the rodent forestomach with human tissues and organs, forestomach tumor biology, regulatory practices and risk assessment guidance regarding the use of forestomach tumors for cancer risk assessment, examining specific chemicals, including benzo(a)pyrene, 1, 3-butadiene, epichlorohydrin, ethyl acrylate, hexavalent chromium, and mercuric chloride. A weight of evidence approach that combines criteria related to human exposure patterns, rodent tumor biology, genotoxicity, kinetics and comparative/mechanistic toxicology is proposed to evaluate human carcinogenic potential. Forestomach tumors resulting from chronic irritation associated with high-concentration drinking water and gavage dosing should not be used as the basis for determining carcinogenicity in humans or quantitative cancer potency estimates.

**383**

APPLICATION OF QSTRS TO SELECT A SURROGATE CHEMICAL FOR A CHEMICAL LACKING ORAL TOXICITY DATA.

R. M. Bruce<sup>1</sup>, R. Venkatapathy<sup>2</sup>, C. Moudgal<sup>1</sup> and H. Choudhury<sup>1</sup>. <sup>1</sup>NCEA, USEPA, Cincinnati, OH and <sup>2</sup>ORISE/NCEA-USEPA, Cincinnati, OH.

Chemicals of concern (CoCs) at hazardous waste sites are cleaned up based on their potential toxicity to humans and the ecosystem. Often, there is a lack of experimental toxicity data for developing oral reference doses (RfDs) for a CoC in the literature. This research describes a method for identifying a surrogate chemical for any given CoC using Quantitative Structure Toxicity Relationships (QSTRs). A commercial QSTR model, TOPKAT, was used to establish structural and descriptor similarity between the CoC and the compounds in the QSTR model database using the Oral Rat Chronic LOAEL model. All database chemicals within a similarity distance (Euclidean distance between descriptor values of database chemical and CoC) of  $\leq 0.200$  from the CoC are considered as potential surrogates. If the CoC fails to satisfy model considerations for the LOAEL model, no surrogate is suggested. Potential surrogates that have toxicity data on Integrated Risk Information System (IRIS) or Health Effects Assessment Summary Tables (HEAST) become candidate surrogates. If more than one candidate surrogate is identified, the chemical with the most conservative RfD is suggested as the surrogate. The procedure was applied to determine an appropriate surrogate for dichlorobenzophenone (DCBP), a metabolite of chlorobenzilate, dichlorodiphenyltrichloroethane and dicofol. 47 potential surrogates were identified that were within the similarity distance of  $\leq 0.200$ , of which only five chemicals had an RfD on IRIS or HEAST. Among the 5 potential surrogates, chlorobenzilate with an RfD of 2E-2 mg/kg-day was chosen as a surrogate for DCBP as it had the most conservative toxicity value. This compared well with surrogate selection using available metabolic information for DCBP and its metabolites or parent compounds in the literature and the provisional toxicity value of 3E-2 mg/kg-day that was developed using a sub-chronic study. In addition, 90% of 359 IRIS chemicals tested with this procedure had a surrogate chemical whose RfD was more conservative than the parent RfD on IRIS.

**384**

A HISTORICAL PERSPECTIVE ON LONG-TERM ANIMAL BIOASSAYS.

T. A. Lewandowski<sup>1</sup>, B. D. Beck<sup>2</sup>, L. A. Beyer<sup>2</sup> and L. R. Rhomberg<sup>2</sup>. <sup>1</sup>Gradient Corporation, Seattle, WA and <sup>2</sup>Gradient Corporation, Cambridge, MA.

In addition to being an academic discipline, the history of toxicology is relevant to forensic matters. For example, the history of toxicology can be a component in cases where past decisions regarding toxicological testing or data interpretation are evaluated in the context of the then-existing state of scientific knowledge. To illustrate how the state of scientific knowledge changed over time, we conducted an

analysis of chronic cancer bioassays from the 1940s to the present. Our analysis demonstrated that the cancer bioassay evolved through several stages - assays were initially used to recreate known human diseases in animal models; subsequently they were used to evaluate the safety of chemicals in foods, drugs and cosmetics; later they were used to evaluate the safety of environmental and occupational chemicals; and more recently they have been used to obtain data to calculate acceptable exposure levels. For example, in 1969 Innes et al. reported carcinogenicity data for 120 chemicals tested for the National Institutes of Health. All of the chemicals were either pesticides or chemicals with existing evidence of carcinogenicity in humans. It was not until the mid- to late-1970s that toxicologists began using data from animal tests to quantitatively estimate human cancer risks in the absence of human epidemiological data (e.g., Mantel et al. 1975, Schmahl et al. 1977). Thus, the purpose of testing changed only with an increasing level of confidence in the predictive ability of such tests for evaluating exposures outside the observable range of effects. Using lists of chronic bioassays published by the US Public Health Service since the 1950s, we have evaluated the critical events in the evolution of chronic bioassays in toxicology. By describing the "state of the art" in toxicology over time, we can place contemporaneous knowledge in an appropriate context. We also demonstrate how this analysis may be illuminating in interpreting contemporary progress made in developing and implementing methods to test for endocrine active chemicals.

**385**

THE T25 METHOD FOR CANCER HAZARD CHARACTERISATION. COMPARISON WITH HAZARD CHARACTERISATION BASED ON EPIDEMIOLOGY.

T. Sanner<sup>1</sup> and E. Dybing<sup>2</sup>. <sup>1</sup>*Institute of Cancer Research, The Norwegian Radium Hospital, Oslo, Norway* and <sup>2</sup>*Division of Environmental Medicine, Norwegian Institute of Public Health, Oslo, Norway*.

Recently we have described a simple method for quantitative risk assessment of non-threshold carcinogens based on the dose descriptor T25. In the present study quantitative hazard estimates calculated with the T25 method have been compared with results obtained using quantitative methods based on epidemiological studies. "Known" and "Likely/Probably" human carcinogens were identified from the USEPA database IRIS. In cases where the hazard characterisation was performed on the basis of epidemiological studies, the IARC monographs were used to identify animal studies by oral or inhalation exposure suitable for hazard characterisation by the T25 method. Six agents were identified: benzene, benzidine, 1, 3-butadiene, cadmium, nickel subsulfide and vinyl chloride for which USEPA had made hazard estimations based on data from epidemiological studies. Animal data suitable for hazard characterisation were also available. For comparing hazard characterisations based on epidemiological and animal data, it was pragmatically decided to do this by comparing the chronic doses expressed as those representing a lifetime cancer hazard of  $10^{-5}$  (both data sets were derived by linear extrapolation). In all cases the difference between the chronic doses determined from animal studies by the T25 method differed from those determined from epidemiological studies by a factor of less than three. Although a limited number of carcinogens were studied, the results demonstrate a very good agreement between the hazard characterisation based on epidemiological investigations and animal experiments spanning a range of more than  $10^4$ .

**386**

DOSE-RELATED ISSUES IN THE DESIGN AND INTERPRETATION OF CHRONIC TOXICITY AND CARCINOGENICITY STUDIES IN RODENTS.

L. Rhomberg<sup>1</sup>, S. Olin<sup>2</sup> and I. Working Group<sup>2</sup>. <sup>1</sup>*Gradient Corporation, Cambridge, MA* and <sup>2</sup>*Risk Science Institute, International Life Sciences Institute, Washington, DC*.

Building on a 1997 ILSI Risk Science Institute (RSI) monograph, Principles for Dose Selection in Chronic Rodent Bioassays, a 24-member multi-sectorial international working group convened by RSI has developed guidance on a number of dose-related issues in the design and interpretation of chronic toxicity and carcinogenicity studies in rodents. Among the topics covered by the working group are the role of specific study objectives in the selection of dose levels, characterization of the design decision process, key factors in study design and their implications for interpretation and assessment of studies, and perspectives on new technologies and the future of the rodent bioassay. The working group noted that chronic rodent studies should be seen as scientific experiments, designed with well-articulated objectives and conducted to address specific questions. Six possible objectives and several combined objectives are identified and discussed. The working group described a generic 7-step process for dose selection, beginning with consideration of the scientific, regulatory/risk management, and practical contexts. Optimal dose placement may differ, depending on whether the primary purpose of the bioassay is screening, dose-response characterization, NOAEL/BMD determination, or safety assessment. Factors affecting study design are discussed, ranging from kinetics to nutritional and hormonal effects to tissue pathology. Case studies illustrate the applica-

tion (or omission) of these concepts in practice. Finally, the implications of potential paradigm shifts in biology, toxicology and risk assessment for study design are considered. (Supported by EPA Cooperative Agreement R-83049601, Health Canada Contract No. H4045-03-EXSD015/4500063129, and the ILSI Risk Science Institute)

**387**

STATISTICAL PROPERTIES OF CARCINOGEN THRESHOLD ESTIMATES USING LOG-LINEAR REGRESSION.

D. A. Dankovic and M. T. Wheeler. *Risk Evaluation Branch, CDC/NIOSH, Cincinnati, OH*.

The objective of this study is to examine the statistical properties of a method that has been proposed for estimation of dose-response thresholds for carcinogens. Simulation studies have been conducted to examine the statistical properties of a method proposed by Dr. W. J. Waddell, based on log-linear regression. The simulations were based on published data sets that have been analyzed by this method. For this presentation we focus on the simulation results for an NTP study of the food additive 2, 4-hexadienal. The simulation study was done by fitting 1-stage, logistic, piece-wise linear ("hockey-stick"), and log linear regression models to the data. These models all fit the data adequately, based on a chi-square goodness of fit test using a p-value  $\geq 0.1$  as the acceptance criterion. Monte Carlo methods were used to generate sets of 2000 stochastically-varying simulated data sets. Dose-response thresholds estimated using log-linear regression were compared with the known properties of the underlying dose-response relationship, and the performance of the log-linear regression method was characterized. The primary result was that simulations based on no-threshold models (1-stage and logistic) resulted in an above-zero threshold estimate in every case, using log-linear regression. Simulations based on threshold models (log-linear regression and piece-wise linear regression) returned similar threshold estimates. However, the estimates using piece-wise linear regression exhibited considerably better precision than estimates using log-linear regression. These results suggest that the log-linear regression procedure is unreliable for determining the presence of a dose-response threshold, and sub-optimal for determining the location of the threshold in cases where the threshold is assumed to exist.

**388**

AN EMPIRICAL APPROACH TO DOSE-DURATION-RESPONSE MODELING AND TIME-SCALING.

K. G. Brown<sup>1</sup> and G. L. Foureman<sup>2</sup>. <sup>1</sup>*KBinc, Chapel Hill, NC* and <sup>2</sup>*NCEA/ORD, USEPA, Research Triangle Park, NC*.

An approach to deriving a dose-duration-response curve for dichotomous data is described with objectives of: (1) taking exposure duration, as well as exposure level, into account; (2) bringing to bear as much data as possible, of suitable quality, in a unified analysis; (3) testing co-factors that may affect response (e.g., sex, species, lab); (4) determining a time-scaling relationship (effect of a unit change in exposure level relative to a unit change in exposure duration). The idea behind the empirical approach is to extend a dose-response model that fits the data at individual exposure durations to a single model for data over all exposure durations. This is accomplished by using the duration-specific parameter estimates to determine a parametric function to explicitly incorporate duration into the dose metric, creating a dose-duration metric. The data over all exposure durations are then fit simultaneously using the dose-duration metric with addition of any co-factors to be tested. The approach is demonstrated using several studies on mortality of rats exposed to hydrogen sulfide (H2S) for durations between 10m and 6h. The resultant dose-duration metric coincides with one of the choices available in EPA's program for categorical regression (CatReg). The resultant time-scaling equation differs from the classical time-scaling equation of ten Berge et al. (1986) for concentration (C) and time (t) of the form  $C^n t = k$  (for n a parameter, k positive constant), which has been applied previously in a draft EPA guideline document on H2S. The dose-duration model with the derived metric fits the data significantly better than when a dose-duration metric consistent with the ten Berge equation is substituted. Time-scaling from the derived metric produced increasingly more conservative (i.e., lower) concentration levels than the ten Berge alternative, for comparable risk, as exposure durations decreased from 1h.

**389**

STATISTICAL METHODOLOGY FOR THE SIMULTANEOUS ANALYSIS OF MULTIPLE TYPES OF OUTCOMES IN NONLINEAR THRESHOLD MODELS.

T. Coffey<sup>1</sup>, C. Gennings<sup>1</sup> and V. C. Moser<sup>2</sup>. <sup>1</sup>*Biostatistics, Virginia Commonwealth University, Richmond, VA* and <sup>2</sup>*ORD/NHEERL, USEPA, Research Triangle Park, NC*.

Multiple outcomes are often measured on each experimental unit in toxicology experiments. These multiple observations typically imply the existence of correlation between endpoints, and a statistical analysis that incorporates it may result in improved inference. When both discrete and continuous endpoints are measured,

methodology to appropriately analyze the endpoints is scarce. We propose a new methodology to simultaneously analyze binary, count, and continuous outcomes for nonlinear threshold models that incorporates the intra-subject correlation. This methodology uses quasi-likelihood estimation and a working correlation matrix, and is therefore appropriate when the mean response of each outcome is of primary interest and the correlation between endpoints is of secondary importance. The methodology is illustrated with data collected from a mixture of five organophosphorus pesticides. Five outcomes—gait abnormality, tail pinch response, motor activity, and brain and blood cholinesterase—were analyzed using nonlinear threshold models. Compared to the individual analyses of each endpoint, the simultaneous model that incorporates the correlation between all five endpoints resulted in similar parameter estimates but had increased power to detect differences due to more precise estimates. In particular, the dose-threshold parameters for three endpoints were found to be statistically different from zero in the simultaneous analysis while none was significant in the individual analyses. Supported by T32 ES07334-01A1 (NIEHS, NIH). This is an abstract of a proposed presentation and does not necessarily reflect EPA policy or the official views of the NIEHS, NIH.

**390**

TOXICITY ESTIMATION OF LOW LEVEL SHORT-TERM EXPOSURES TO CHEMICAL MIXTURES.

M. M. Mumtaz<sup>1</sup>, C. T. De Rosa<sup>1</sup>, H. Pohl<sup>1</sup>, D. Moffett<sup>1,2</sup>, H. A. El-Masri<sup>1</sup> and B. A. Fowler<sup>1</sup>. <sup>1</sup>Division of Toxicology, ATSDR, Atlanta, GA and <sup>2</sup>US Public Health Service, Atlanta, GA.

The recent national report on human exposure to environmental chemicals indicates that over 100 chemicals have reached detectable levels in the U. S. human population. Thus, concerns exist that low level exposure to environmental chemical mixtures may adversely affect human health and wildlife. Health hazards assessment from exposure to chemical mixtures are most often performed using the hazard index approach that uses potency weighted dose or response addition. The Agency for Toxic Substances and Disease Registry (ATSDR) has developed a mixtures research program that supports targeted experimental research coupled with *in vitro* and limited *in vivo* testing to detect subtle health effects and verify or resolve built-in assumptions in the assessment methods for chemical mixtures. Mixtures of polycyclic aromatic hydrocarbons, polychlorinated biphenyls, and dioxins have been evaluated using the toxicity equivalency factor method that is based on the principle of additivity. Meta-analysis of recent experimental studies supported by ATSDR, with mixtures of chloro-organic hepatotoxicants, neurotoxicants, and metals using standard toxicological endpoints did not demonstrate deviations from expected toxicity based on additivity at the lowest dose level tested. These findings suggest the need for further research into more sensitive molecular biomarkers-based parameters in order to detect possible ongoing cellular effects.

**391**

PURITY ANALYSES FOR TOXICOLOGY STUDIES - A CASE STUDY WITH ANTHRAQUINONE.

S. Graves<sup>1</sup>, N. South<sup>1</sup> and C. Smith<sup>2</sup>. <sup>1</sup>Toxicology Columbus, Battelle, Columbus, OH and <sup>2</sup>NIEHS, Research Triangle Park, NC.

Anthraquinone is used as an intermediate in the manufacture of dyes and pigments, an additive in the kraft pulping process in the paper industry, a catalyst in the isomerization of vegetable oils, an accelerator in nickel electroplating, and as a bird repellent. The National Toxicology Program conducted studies of the chemical in feed for 14 weeks and 2 years in male and female F344/N rats and B6C3F1 mice. In response to questions regarding the purity of this material raised by a supplier of the anthraquinone made by a different synthesis route, work was done to identify and quantify small impurities seen in the original analysis. The original analyses indicated an overall purity of 99.4% with a gas chromatographic (GC) analysis using flame ionization detection indicating a purity of 99.9% with one impurity of 0.1% and a high performance liquid chromatographic (HPLC) analysis using ultraviolet detection indicating a purity of 99.5% with two impurities (one of 0.2% and one of 0.3%). Beyond quantitation by peak area percent, these impurities were not further characterized during the original analyses. The current work identified the two impurities as 9-nitroanthracene and anthracene by mass spectrometry and retention time matching using both GC with flame ionization detection and HPLC with UV detection. They were found to be present at concentrations of 0.06 and 0.05 (anthracene) and 0.11 and 0.09% (9-nitroanthracene) by HPLC and GC respectively. In addition anthrone and phenanthrene were found to be present at 0.002% or less. The chemical was also checked for the presence of several other suspected impurities with structural similarities to anthraquinone. No other impurities were found.

THE TCDD TEQ IN HUMAN BLOOD FROM DIETARY VS. ANTHROPOGENIC DIOXINS: A DIETARY STUDY.

M. A. Harris<sup>1</sup> and B. Finley<sup>2</sup>. <sup>1</sup>Exponent, Houston, TX and <sup>2</sup>Exponent, Santa Rosa, CA. Sponsor: L. Haws.

Numerous naturally occurring compounds in the human diet can bind to the Ah receptor (AhR). The purpose of this study was to provide data for evaluating whether dietary Ah receptor binding compounds are contributors to the non-

PCDD/F and PCB blood TCDD TEQ (2, 3, 7, 8-tetrachlorodibenzo-p-dioxin toxicity equivalent quotient). Ten human volunteers were enrolled in the study only after giving full informed consent. The study protocol was reviewed and approved by an external Institutional Review Board. Volunteers maintained a specified (vegetable free or vegetable rich) diet over the course of two 4-day periods. Two volunteers participating in the study continued the vegetable-rich diet for an additional two-day period, while also ingesting an I<sup>13</sup>C extract. Meals were to be consumed at specified times. One 100 mL blood sample was taken before commencing the controlled diets, which was used for GC/MS analysis of PCDD/Fs and PCBs. During the four-day baseline diet, two blood samples were collected. During the four-day endodioxin-rich diet, four blood samples were collected. Bioassay analyses of the whole blood samples were carried out using a reporter gene bioassay assay for Ah receptor ligands. The mean analytical TCDD TEQ values calculated for the group of participants ranged from 0.022 to 0.119 ppt. In participants eating a vegetable-free diet, the bioassay TCDD TEQs ranged from 13 to 66 ppt. For participants eating an vegetable-enriched diet, the bioassay TCDD TEQs were 18 to 133 ppt. For participants eating an vegetable-enriched diet and taking I<sup>13</sup>C supplements, the bioassay TCDD TEQs were 62 to 218 ppt. The results of this study indicate that PCDD/Fs and PCBs comprise a very small fraction of the total TCDD TEQ in human blood and that modifications to the diet influence the TCDD TEQ. Substances that could be responsible for the vast majority of the blood TCDD TEQ are naturally-occurring Ah receptor binding compounds found in the diet, endogenous Ah receptor ligands and/or other anthropogenic compounds (besides PCDD/Fs and PCBs).

RELATIVE POTENCIES OF THREE DIOXIN CONGENERS BASED ON LIVER FOCI FORMATION ASSAY AND LIVER CONCENTRATIONS IN RAT AND HUMAN ESTIMATED BY PBPK MODELS.

W. Maruyama and Y. Aoki. Research Center for Environmental Risk, National Institute for Environmental Studies, Tsukuba, Japan.

In the health risk assessment of dioxins, WHO-TEF (toxic equivalency factor) is presently used to express the relative potencies (REP) of 29 dioxin-like compounds. In WHO-TEF, the same TEFs are set for rodents and humans without consideration of interspecies differences, although the half-lives for rats (20 days) and humans (6.9 years) are different, as are the body sizes and organ weights. For Japanese people in general, 2378- tetrachlorodibenzo- p- dioxin (TCDD), 12378-pentachlorodibenzo- p- dioxin (PeCDD) and 23478- pentachlorodibenzofuran (PeCDF) are three large contributors to total toxic equivalency (TEQ), according to their TEFs and daily uptake levels. The relative contribution of 2378-TCDD, 12378-PeCDD and 23478-PeCDF were 8.4, 14.4, and 12.7 % of total TEQ. We tried to determine new REPs of these three dioxins for rats and humans based on a specific endpoint and the concentration in the target organ. In this study, we focused on the formation of hepatic foci as a marker of the tumor promotion activity of dioxins. Rats were initiated with diethylnitrosoamine (DEN) and a 70% partial hepatectomy was followed by repeated oral administration of dioxins. Foci formation in the liver was quantified by staining with anti-glutathione-S-transferase P1 (GSTP1) antibody. The observed relative foci formation activities of 2378-TCDD, 12378-PeCDD and 23478-PeCDF were 1.0, 0.9 and 0.6, respectively. For interspecies extrapolation of the toxicity of dioxins, we developed physiologically based pharmacokinetic (PBPK) models for humans. Interindividual differences among Japanese adults were also analyzed with a Monte Carlo simulation. These methods and the results obtained are useful for the quantitative risk assessment of dioxins.

**394**

VARIABILITY AND UNCERTAINTY DISTRIBUTIONS FOR THE CARCINOGENIC POTENCY OF 2, 3, 7, 8-TCDD.

E. Crouch. Cambridge Environmental Inc., Cambridge, MA. Sponsor: L. Green.

There are ten long-term carcinogenicity bioassays using 2, 3, 7, 8-TCDD, in male Syrian Golden hamsters, male and female Osborne Mendel rats, male and female B6C3F1 and B6C3 mice, and two in female and one in male Sprague-Dawley (SD) rats. Carcinogenic potency estimates and their approximate uncertainty distributions were obtained from each experiment using likelihood methods applied to a linearized multistage dose-response curves. Maximum likelihood estimates (MLE) for the carcinogenic potency range from zero to 40, 000 kg-d/mg using the metric of applied dose, and 95th percentile upper confidence limits (UCL95) on potencies in rats and mice appear to be lognormally distributed, but the hamster is a low outlier. Applying a lognormal between-experiment variability distribution to the rat and mice data leads to a MLE for the median of 1, 100 kg-d/mg, with an uncertainty UCL95 on the UCL95 of the variability distribution (the 95/95 point) of 15, 000 kg-d/mg. Constraining the between-experiment variability to have the geometric standard deviation (a factor of 10) previously observed (Crouch, 1996) in animal-to-human extrapolations, and including the hamster data also, leads to an extrapolated median estimate of 80 kg-d/mg for potency in humans, but a 95/95

point of 30, 500 kg-d/mg. Using the same methods but the EPA approach of extrapolation using the 1/4 power of bodyweight ratios gives a median estimate of human potency of 7, 000 kg-d/mg with 95/95 point of 52, 900 kg-d/mg (rat and mouse data only). A better dose metric for extrapolation to humans may be the lifetime average concentration in the body. This metric was estimated for two experiments with measured concentrations (both in female SD rats) based on the dosimetric model of Carrier (1995). The MLE for carcinogenic potency are 0 and 0.46 per  $\mu\text{g}/\text{kg}$ , but these are not significantly different. The combined uncertainty distribution has median 0.18 and UCL95 0.41 per  $\mu\text{g}/\text{kg}$ . All uncertainty and variability distributions are available in tabulated and parametric form.

### 395

#### COMPARING ENVIRONMENTALLY RELEVANT PCBs TO TCDD IN CYP1A2 NULL AND WILDTYPE MICE.

D. E. Burgin<sup>1,2</sup>, J. J. Diliberto<sup>3</sup> and L. S. Birnbaum<sup>3</sup>. <sup>1</sup>National Center for Environmental Economics, USEPA, Washington, DC, <sup>2</sup>Toxicology, University of North Carolina, Chapel Hill, NC and <sup>3</sup>ORD/NHEERL/ETD, USEPA, Research Triangle Park, NC.

The role of CYP1A2 on the interactions of TCDD (2, 3, 7, 8-tetrachlorodibenzo-p-dioxin, dioxin), dioxin-like (DL) and non-dioxin-like (NDL) polychlorinated biphenyl (PCBs) was compared in multiple responses of different laboratory-defined mixtures, based on mass ratios found in food, using *Cyp1a2* null (KO) and C57BL/6J wildtype (WT) male and female mice. The chemical groups were TCDD alone, DL Mix A, NDL Mix B, and combination Mix C and the doses ranged from 0.0, 0.001, 0.01, 0.1, 1.0, and 10.0  $\mu\text{g}$  TEQ/kg body weight for Mix A, B and C, and the same plus 100.0  $\mu\text{g}$  /kg for TCDD. Liver weight was increased only in Mix C in both male and female, WT and KO. No effects were observed in the KO mice on markers of oxidative stress. Both male WT and KO showed greater decreases in levels of total triiodothyronine (TT3), while Mix A and Mix C resulted in a 50% reduction in levels of total thyroxine (TT4) in all groups. With exposure to TCDD or DL mixes, but not to NDL PCBs, there was an increase in ascorbate levels. Based on these findings, there does not appear to be a strain difference in response to chemical exposure, indicating CYP1A2 is not required for these biochemical responses. However, there does appear to be a gender difference between the both the knockout and wildtype, reflecting a possible endogenous estrogenic component to maintenance of TT3 and ascorbic acid cycling levels. Based on these findings, it appears that CYP1A2 does play a role in the processes leading to increased liver weight, increased enzymatic induction, and disruption of thyroid homeostasis, but does not appear to play a role in responding to oxidative insult. Neither in the presence nor absence of CYP1A2 can the TEQ approach predict all effects measured when DL and NDL PCBs are present. (This abstract does not reflect EPA policy. DB supported by EPA CT902908 and NIEHS T32-ES07126)

### 396

#### CANCER POTENCY ESTIMATION FOR ACRYLAMIDE.

M. S. Sandy, T. A. McDonald and L. Zeise. Office of Environmental Health Hazard Assessment, California EPA, Oakland, CA.

A widely-recognized carcinogen, acrylamide produces tumors at multiple sites in rats and mice. Sources of exposure to acrylamide include cigarette smoke, the diet (i.e., formation occurs during high temperature cooking of many plant-based foods), and occupational uses. A thorough evaluation of the available evidence on the carcinogenic mode of action indicated that a genotoxic mechanism was most likely operative. Thus, a low-dose linear approach to dose-response characterization was taken. In addition, the analysis explicitly took into account the difference between humans and rats in the conversion of acrylamide to its DNA-reactive epoxide glycidamide, the longer half lives of acrylamide and glycidamide in humans than rats, and interspecies differences in pharmacodynamics. Calculation of the cancer potency of acrylamide was based on data from multiple acrylamide-responding tumor sites observed in four long-term drinking water studies in male and female rats. For each experiment, a probabilistic Monte Carlo procedure was used to derive a multisite cancer potency distribution, which combined dose-response relationships for each acrylamide treatment-related cancer site. The multisite potency distributions were used to obtain a geometric mean of potencies from the four studies, using Monte Carlo techniques. The upper 95 percent confidence bound of the geometric mean distribution was taken as the cancer potency for acrylamide. This potency estimate for acrylamide is lower than the value currently used by California EPA and USEPA. Also discussed are sources of interindividual variation in sensitivity to acrylamide-induced cancer due to variability in activation and detoxification enzymes, age, and co-exposures to other carcinogens or promoters. Finally, the cancer potency estimate based on the rat bioassays was compared with a cancer potency estimate based on pancreatic tumors observed among acrylamide-exposed workers, as a measure of the quantitative consistency and plausibility of the rat-derived estimate.

### 397

#### ACRYLAMIDE TOXICITY - IS A REAPPRAISAL NECESSARY?

C. Siegers<sup>1</sup> and J. B. Schulze<sup>2</sup>. <sup>1</sup>Institute of Experimental and Clinical Pharmacology and Toxicology, Luebeck, Germany and <sup>2</sup>Office of the Dean, Medical Faculty, Frankfurt, Germany.

Acrylamide has long been considered an exclusively man-made chemical. In biomonitoring studies however, even unexposed persons displayed a background level of DNA adducts specific for acrylamide exposure. In 2000 acrylamide formation in foodstuff has been detected, which may explain this level in biomonitoring studies. Risk assessment for acrylamide exposure has been based both on animal experiments and epidemiological studies; besides neurotoxicity the carcinogenic potency in animals has been led to the classification of acrylamide as a probable human carcinogen. Based on food exposure and comparison of likely acrylamide uptake in low and high food exposure groups the carcinogenic risk of acrylamide to humans should be reevaluated. Studies in industrial plants do not unanimously indicate an increase in human tumor incidence. Animal experience did not show a specific organ or organ group preference in high exposure groups, as opposed to specific acting carcinogens. Specifically, at 2  $\text{mg}/\text{kg}$  bw, i.e. close to a toxic concentration female Fischer rats developed tumors in the mammary gland, uterus, thyroidea and CNS, at nearly equivalent rates. Studies addressing the mutagenicity resulted in divergent phenomena - not mutagen but clastogen. Although these studies usually are interpreted as evidence for a specific carcinogenic potential also at low doses the following results favor a toxic mechanism with carcinogenicity likely due to cell toxicity: diverse tumor organs; weight loss as toxic phenomenon at the effect level; relevant incidence of spontaneous tumors in control animals. Whereas for a purely technical chemical prudence should prevail a different view on relevance may be necessary for compounds present in the natural environment. We will reassess epidemiological data with regard to human toxicity of acrylamide and background acrylamide exposure from foodstuff.

### 398

#### DOSE-RESPONSE MODELING OF IN VIVO GENOTOXICITY DATA: ITS RELEVANCE TO RISK ASSESSMENT ILLUSTRATED BY AN APPLICATION TO ACRYLAMIDE.

B. Allen<sup>1</sup>, E. Zeiger<sup>2</sup>, M. Friedman<sup>3</sup> and A. Shipp<sup>4</sup>. <sup>1</sup>Environ Health Sciences Institute, Chapel Hill, NC, <sup>2</sup>Errol Zeiger Consulting, Chapel Hill, NC, <sup>3</sup>UNDMJ, Newark, NJ and <sup>4</sup>Environ Health Sciences Institute, Ruston, LA.

Genetic toxicity results are typically summarized as being either positive or negative, with no further consideration of the dose-response patterns that can be estimated from such studies. This analysis explores the use of two possible modeling approaches that extend the utility of such data: Poisson regression of counts of genetic effects per cell and dynamic modeling of the time-course of micronucleus production and loss as a function of exposure. Benchmark doses and predictions of response rates for predetermined doses of interest can be used to assess the relevance and role of the genetic toxicity results in a risk assessment. With respect to the acrylamide case study, the results suggest that the doses at which genetic damage is predicted to occur do not appear to be consistent or congruent with the major tumor endpoints (in the thyroid) observed in two long-term bioassays in rats; at doses equivalent to the highest bioassay dose level (where there was a 16% incidence of thyroid tumors) the model-predicted changes in chromosome aberration or micronucleus rates were less than 5%. Benchmark doses derived from the genetic toxicity data base do not appear to be the critical ones for acrylamide risk assessment. The benchmark doses derived from multigeneration reproductive studies were between 3 and 14  $\text{mg}/\text{kg}$  whereas those derived using the genotoxicity data ranged from 14 to 847  $\text{mg}/\text{kg}$ . This analysis suggests that issues associated with dose metric selection, extrapolation from one type of study to another and from one species to another, and mathematical modeling approaches need careful consideration.

### 399

#### ISSUES RELATING TO THE DERIVATION OF ORAL TOXICITY VALUES FOR CHLORDECONE.

J. A. Stickney<sup>1</sup>, M. H. Follansbee<sup>1</sup>, D. W. Wohlers<sup>2</sup>, P. R. McClure<sup>2</sup>, M. Odin<sup>2</sup> and P. M. McGinnis<sup>3</sup>. <sup>1</sup>Environmental Science Center, Syracuse Research Corp, Scarborough, ME, <sup>2</sup>Environmental Science Center, Syracuse Research Corp, Syracuse, NY and <sup>3</sup>Environmental Science Center, Syracuse Research Corp, Philadelphia, PA.

Chlordecone (Kepone®) insecticide production in the United States ended in 1975 due to severe intoxication from industrial exposure at a Hopewell, VA facility. The primary noncancer health effects of oral exposure in humans and animals include liver and kidney effects, neurotoxicity, and male reproductive toxicity. Other reproductive effects (i.e., persistent vaginal estrus, impaired reproductive success) and developmental effects were observed in laboratory animals at higher doses. Some of these effects may be related to the endocrine disrupting properties of chlordecone. Renal toxicity (i.e., proteinuria and glomerulosclerosis) occurred at the lowest

chronic dose in animal studies. Noncancer toxicity values (e.g. RfDs or ADIs) could be derived using benchmark dose modeling of the renal data and application of appropriate uncertainty factors. No data on the carcinogenicity of chlordcone in humans are available. A single chronic dietary study provides evidence for carcinogenicity following high-dose exposure in rats and mice but lacks appropriate dose-response data. Therefore the study is considered to be limited in its usefulness for low-dose extrapolation and assessment of human cancer risk. The available data suggest that chlordcone is not genotoxic, but acts as an epigenetic carcinogen and a tumor promoter. Because the mode of action for carcinogenicity has not been completely elucidated, both linear and nonlinear approaches could be applied to dose-response assessment. A time-to-tumor approach could be utilized to adjust for the significant mortality in the bioassay. A nonlinear approach would consider the available data for precancerous liver hyperplasia that has been associated with subsequent liver tumor formation. (The views expressed in this abstract are those of the authors only and do not necessarily reflect the views or policies of the USEPA.)

#### RE-EVALUATION OF THE RISK OF LUNG CANCER FROM DIESEL EXHAUST EXPOSURE.

T. W. Hesterberg<sup>2</sup>, W. B. Bunn<sup>2</sup> and C. A. Lapin<sup>1</sup>. <sup>1</sup>Lapin and Associates, Glendale, CA and <sup>2</sup>International Truck and Engine Corp, Warrenville, IL.

In the past several years, important developments have occurred (and are ongoing) that call for a critical review of the database on the association between exposure to diesel exhaust (DE) and lung cancer. Indeed, several assessments of DE exposure and epidemiological data are ongoing, and should provide a greatly improved database for DE within the next few years. For instance, these assessments should provide more definitive data regarding the potential carcinogenic risks from historical and current DE, and some will be particularly relevant for assessing the impacts of future advancements in diesel technology. With respect to the current diesel database, changes in diesel engine technology have significantly changed the composition of DE such that the epidemiological studies evaluating the effects of diesel engines in the 1950s through the 1980s, many of which are cited in contemporary assessments of DE, will not accurately predict the carcinogenic potential of current or future DE exposures. Further, a reevaluation of the available epidemiological and toxicological databases demonstrate that they are, in fact, insufficient to support a connection between exposure to DE and lung cancer. As several noted researchers have recently concluded, the significant deficiencies in the epidemiology studies make them inadequate to link DE to increases in lung cancer. In fact, new data demonstrate that DE and gasoline exposures are inseparable in all industries except mining. Thus, studies in miners present the best data for evaluating the potential linkage between DE and lung cancer. Finally, a contemporary assessment of the available evidence demonstrates that the toxicological database does not provide an adequate basis for finding an association between DE and lung cancer, that data regarding the mutagenicity of DE extracts have limited utility for conducting an assessment of the association between exposure DE and lung cancer, and that meta-analyses are unsuitable for evaluating the potential linkage between DE exposure and lung cancer.

**401**

#### IMPORTANCE OF PEROXISOME PROLIFERATION IN UNDERSTANDING POTENTIAL MODE(S) OF ACTION FOR TCE AND ITS APPLICATION IN RISK ASSESSMENT.

N. Keshava<sup>1</sup> and J. C. Caldwell<sup>1</sup>. <sup>1</sup>Office of Research and Development, USEPA, Washington, DC and <sup>2</sup>Office of Research and Development, USEPA, Washington, DC.

Peroxisome proliferators include a variety of chemicals such as phthalates, chlorinated paraffins, chlorinated solvents such as trichloroethylene and perchloroethylene, certain pesticides and hypolipidemic pharmaceuticals. These chemicals can be of concern to regulatory agencies if their potential for carcinogenic action is indicated by long-term carcinogen bioassays using rodents. The purpose of this presentation is to discuss the current state of knowledge for known peroxisome proliferators, including the scientific controversies, and describe how this information could be used in assessing human health risk for trichloroethylene (TCE). Peroxisome proliferators have often been thought to elicit their effects without causing mutation of DNA or chromosome damage. They are heterogeneous in action and the receptors they activate are extremely pleiotropic. Studies have demonstrated that peroxisome proliferator-activated receptors (PPARs), particularly activation of PPAR alpha, may be an obligatory factor in peroxisome proliferation in rodent hepatocytes. Recent studies in human and rodents, however, have reported that there are also other actions of PPAR alpha activation. TCE and two of its metabolites (trichloroacetic acid and dichloroacetic acid) have been shown to induce peroxisome proliferation in rodents though each has a different toxicity profile. Understanding the responses of PPAR alpha agonism for the determination of a key event or as a possible mode of action for TCE effects is crucial for its risk assessment. (Disclaimer: The views expressed in this abstract are those of the authors and do not represent the policy of the USEPA).

#### INCORPORATION OF TRICHLOROACETIC ACID PLASMA BINDING IN HUMAN AND MOUSE IN TRICHLOROETHYLENE RISK ASSESSMENT.

D. A. Keys<sup>1</sup>, M. H. Lumpkin<sup>2</sup>, J. V. Bruckner<sup>1</sup> and J. W. Fisher<sup>1</sup>.

<sup>1</sup>Interdisciplinary Toxicology Program, University of Georgia, Athens, GA and <sup>2</sup>Clayton Group Services, Inc., Kennesaw, GA.

Trichloroacetic acid (TCA) is a metabolite of the solvent trichloroethylene (TCE), which remains an important risk assessment issue because of its carcinogenic potential. PBPK-model generated TCA dose metrics were employed in the most recent draft TCE risk assessment by USEPA (2001). Subsequently, Lumpkin et al. (2003) found that the proportion of bound TCA to free TCA is substantially higher in human plasma than mouse plasma. TCA binding equations were incorporated into 2nd generation PBPK models for TCE and TCA for mice (Abbas and Fisher, 1997) and humans (Fisher et al., 1998). Cancer bioassay conditions (NTP, 1990; NCI, 1976) were simulated using the 2nd generation mouse model (with binding), and average daily liver, total blood, and free blood AUC and peak TCA concentrations were calculated. All TCA AUC values were very similar when binding was incorporated into the PBPK models using either a single, saturable binding equation or using interpolation of the binding data. This finding indicates that the low dose predictions of the TCE PBPK models are robust to alternative descriptions of TCA plasma binding. The linear multistage model was fit to PBPK generated internal dose-metrics vs. liver tumor incident rates in male B6C3F1 mice. Mouse internal dose ED10 and LED10 values were extrapolated to human external doses with the 2nd generation human model that included TCA binding in plasma. Human ED10 and LED10 estimates based on TCA AUC in liver exceeded those based on liver dose metrics calculated previously (without TCA binding in plasma) (EPA, 2001; Rhomberg, 2000) by one to two orders of magnitude. Calculations of risk (e.g. incremental risk per mg/kg/day) would, thus, decrease by 10 to 100 times (Supported by DOE Coop. Agreement DE-FC09-02CH11109).

**403**

#### USE OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR CHLOROFORM TO EVALUATE BIOMONITORING DATA.

K. H. Liao<sup>1</sup>, R. B. Conolly<sup>1</sup>, A. M. Mason<sup>2</sup> and Y. Tan<sup>1</sup>. <sup>1</sup>Center for Computational Systems Biology & Human Health Assessment, CIIT Centers for Health Research, Research Triangle Park, NC and <sup>2</sup>Chlorine Chemistry Council, Arlington, VA.

Biomonitoring data are evidence of exposure to environmental chemicals but do not, by themselves, say anything about the risk of adverse health effects. Physiologically based pharmacokinetic (PBPK) modeling can be used to estimate exposures consistent with biomonitoring data. Exposure estimates and knowledge of exposure-adverse effect and tissue dose-adverse effect relationships do, however, provide a basis for risk estimation. In anticipation of the need to evaluate biomonitoring data for chloroform, three published data sets describing blood and exhaled breath levels in people exposed to chloroform under controlled conditions were evaluated with an existing PBPK model. Model predictions agreed well with the measured data. We then defined a plausible exposure regimen combining inhalation, oral and dermal exposures associated with residential use of water containing low levels of chloroform. The following inputs to the PBPK model were chosen to reflect realistic exposure scenarios: (1) water concentration (0 - 80 ppb), (2) water intake (927, 2016, 3588 mL/day), (3) shower/bath duration (3, 10, 15, 60 min), (4) ambient concentration in air (1.2, 2.1, 4.1 ppb), and (5) water-air mass transfer coefficient (2.5, 8.9, 21 L/min). Time-course predictions of exhaled breath and blood levels using these inputs showed that inhalation and dermal exposures, and drinking tap water could each contribute substantially to total chloroform exposure when showering was considered. PBPK modeling of variability in the input parameters, as indicated above, predicted that variability in drinking water intake would, by itself, be expected to have little effect on the overall exhaled breath and blood levels. In summary, this study indicates that (a) multiple routes of exposure to chloroform should be considered during the evaluation of biomonitoring data and (b) PBPK modeling will be useful in the analysis of biomonitoring data for chloroform and other halomethanes.

#### MONTE CARLO ANALYSIS OF SOURCES OF VARIABILITY IN CHLOROFORM-INDUCED HEPATIC CYTOLETHALITY AND REGENERATIVE PROLIFERATION IN B6C3F1 MICE.

Y. Tan and R. B. Conolly. Center for Computational Systems Biology & Human Health Assessment, CIIT Centers for Health Research, Research Triangle Park, NC.

Characterization of sources of interindividual variability in toxic responses supports population-based risk assessment and helps to define how responses should be extrapolated from laboratory animals to humans. Physiologically based pharmacokinetic (PBPK) modeling can be used to study how PK behavior differs between individuals in a population and among species, as in the extrapolation from

laboratory animals to people. We extended a PBPK model for chloroform to describe a plausible mechanism of hepatic cell killing and regenerative proliferation, which is a risk factor in carcinogenesis (*Toxicol. Sciences* 75, 192-200, 2003). This pharmacodynamic (PD) extension allowed simulation of labeling index (LI), which is a measure of regenerative cellular proliferation in response to cytotoxicity. In the current study we analyzed sources of variability in LI data from female B6C3F1 mice that inhaled chloroform for 7 consecutive days (*Toxicol. Sciences* 66, 201-208, 2002). A Monte Carlo implementation of the PBPK/PD model was developed in which PK parameters and the control rate of hepatic cell division were varied. This analytical approach tests the hypothesis that the measured interindividual variability in LI is due to a combination of PK variability and variability in the control rate of hepatic cell division. The distributions, means, and standard deviations (SD) for the PK parameters were obtained from literature; the distribution, mean, and SD of the control cell division rate were calculated from 10 control LI data points. Monte Carlo simulations were compared to measured data by plotting measured and predicted mean LI against measured and predicted variance of the LI. With 1,000 iterations of the Monte Carlo model, all measured values fell within the cloud of predicted data points. Extension of these studies to male B6C3F1 mice and to rats will help to define appropriate treatment of interindividual and interspecies variability in human health risk assessments for chloroform.

DOSE-RESPONSE MODELING AND BENCHMARK CALCULATIONS FROM SPONTANEOUS BEHAVIOR DATA ON MICE NEONATALLY EXPOSED TO 2, 2', 4, 4', 5 - PENTABROMODIPHENYL ETHER.

S. Sand<sup>1</sup>, D. von Rosen<sup>2</sup>, P. Eriksson<sup>3</sup>, A. Fredriksson<sup>3</sup>, H. Viberg<sup>3</sup>, K. Victorin<sup>1</sup> and A. Falk Filipsson<sup>1</sup>. <sup>1</sup>*Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden*, <sup>2</sup>*Biometry and Informatics, Swedish University of Agricultural Sciences, Uppsala, Sweden* and <sup>3</sup>*Environmental Toxicology, Uppsala University, Uppsala, Sweden*.

In this work the benchmark dose (BMD) method was introduced for spontaneous behavior data observed in 2-, 5-, and 8-month-old male and female C57Bl mice exposed orally on postnatal day 10 to different doses of 2, 2', 4, 4', 5 - pentabromodiphenyl ether (PBDE 99). Spontaneous behavior (locomotion, rearing, and total activity) was in the present work quantified in terms of a fractional response defined as the cumulative response after 20 minutes divided by the cumulative response produced over the whole 1h test period. The fractional response contains information about the time-response profile (which differs between the treatment groups) and has appropriate statistical characteristics. In the analysis male and female mice could be characterized by a common dose-response model, i.e. they responded equally to the exposure to PBDE 99. As a primary approach, the BMD was defined as the dose producing a 5 or 10 % change in the mean fractional response. According to the Hill model, considering a 10 % change the lower bound of the BMD for rearing, locomotion, and total activity was 1.2, 0.85, and 0.31 mg PBDE 99 / kg body weight, respectively. A probability based procedure for BMD modeling was also considered. Using this methodology the BMD was defined as corresponding to an excess risk of 5 or 10 % of falling below cut-off points representing adverse levels of fractional response.

**406**

ADVANTAGES AND LIMITATIONS OF BENCHMARK DOSE MODELING AND THE NOAEL/LOAEL APPROACH IN PERFORMING DOSE-RESPONSE ASSESSMENT BASED ON SMALL STUDIES: SUBCHRONIC RFD FOR CHLOROBENZENE AS A CASE STUDY.

M. Odin, P. McClure and P. McGinnis. *Environmental Science Center, Syracuse Research Corp, Syracuse, NY*.

Benchmark dose modeling has advantages over the traditional NOAEL/LOAEL approach for dose-response assessment when suitable data are available. However, the benchmark dose methodology is highly sensitive to certain characteristics of the data to be modeled. One such character is group size. In the benchmark dose methodology, a benchmark response (BMR) of 10% is conventionally used for quantal data. USEPA guidance notes that 10% response is at or near the limit of sensitivity in a typical cancer bioassay. Group sizes in such studies are usually 50 or more animals. Yet, the benchmark dose methodology and 10% BMR have frequently been applied in assessments based on data from subchronic studies, which may include 10 or fewer animals per group. Application of the benchmark dose methodology and 10% BMR to small studies such as these can be problematic. A case study in which a subchronic RfD is derived for chlorobenzene is used to illustrate the issues involved. The critical study for this assessment was a 13-week study in dogs (4/sex/group). The point of departure for the subchronic RfD was derived by both benchmark dose modeling with a 10% BMR and by the NOAEL/LOAEL approach, and the results contrasted. Limitations of both approaches in handling

small group sizes are discussed. This case study suggests that the NOAEL/LOAEL approach is less sensitive to small group sizes than benchmark dose analysis using the 10% BMR. This is because the NOAEL/LOAEL approach requires less resolution from its statistical analysis, and because it can incorporate a weight-of-evidence analysis based on multiple endpoints simultaneously. Risk assessors have underappreciated the difficulties associated with application of benchmark dose methodology and 10% BMR to small studies, and should consider carefully whether group sizes are sufficient to support benchmark dose modeling in their assessments.

**407**

BENCHMARK DOSE MODELING OF DEVELOPMENTAL RESPONSES IN OFFSPRING OF RATS EXPOSED TO TRICHLOROACETIC ACID.

L. H. Moilanen<sup>1</sup>, P. McClure<sup>1</sup>, D. Wong<sup>2</sup> and P. McGinnis<sup>1</sup>. <sup>1</sup>*Environmental Science Center, Syracuse Research Corp, Syracuse, NY* and <sup>2</sup>*Office of Research & Development NCEA/IRIS Program, USEPA, Washington, DC*.

Trichloroacetic acid (TCA) is formed in drinking water as a byproduct of disinfection with chlorine. Selected fetal and litter data from a developmental study in Long-Evans rats (Smith et al. 1989) were analyzed by benchmark dose (BMD) modeling as part of the EPA effort to update information on health effects of TCA for IRIS. Pregnant rats were exposed to 0, 330, 800, 1200, or 1800 mg/kg-day of TCA by oral gavage on gestation days (GD) 6-15 and sacrificed on GD 20. Incidence data for fetuses with visceral malformations (levocardia was the principal lesion) and continuous data for fetal body weight (BW) and fetal crown-rump length (CRL), converted into quantal form, were modeled. Conversion of BW and CRL data involved 1) an assumption of normal distribution and 2) the use of the estimated distribution of the controls to define a response (BW or CRL decreased more than 1 SD below the control mean). Converted data for fetal BW and CRL were analyzed using three models, each of which included dose and litter size as explanatory variables and accounted for intralitter correlation by assuming a beta-binomial distribution for individual fetal responses. The TERALOG, TERAVAN, and TERAMOD programs (ICF Kaiser International, Ruston LA) were used to fit these models by maximum likelihood methods to the available data. Litter incidence data for levocardia were modeled using all available quantal models in the EPA BMDS program (v. 1.3.1). Overall, the most sensitive modeled responses were fetal BW and litter incidence of levocardia. The 95% lower confidence limits on the BMD values for these endpoints were 28 mg/kg-day (average from three models) and 31.3 mg/kg-day, respectively, for a benchmark response of 5% extra risk. These values are similar to the NOAEL of 32.5 mg/kg-day obtained for hepatic effects in F344 rats exposed to TCA in drinking water for two years. (Opinions expressed in this abstract are the authors and do not necessarily represent EPA policy.)

EMPIRICAL EVALUATION OF SUFFICIENT SIMILARITY FOR A MIXTURE OF NINE HALOACETIC ACIDS (HAA'S) ON CHINESE HAMSTER OVARY CELL CHRONIC CYTOTOXICITY USING A FIXED-RATIO RAY DESIGN.

L. G. Stork<sup>1</sup>, C. Gennings<sup>1</sup>, W. Carter, Jr.<sup>1</sup>, R. Johnson<sup>1</sup>, D. Mays<sup>2</sup>, R. Carchman<sup>3</sup>, J. Simmons<sup>4</sup> and M. Plewa<sup>5</sup>. <sup>1</sup>*Biostatistics, Virginia Commonwealth University, Richmond, VA*, <sup>2</sup>*Statistical Sciences and O. R., VCU, Richmond, VA*, <sup>3</sup>*Solveritas, LLC, Richmond, VA*, <sup>4</sup>*ORD/NHEERL, USEPA, Research Triangle Park, NC* and <sup>5</sup>*Crop Sciences, University of Illinois at Urbana-Champaign, Urbana, IL*.

Ray designs based on relevant fixed-ratio rays are useful for testing hypotheses of additivity for large numbers of chemicals. Relevant ratios of chemicals in industrial or environmental processes may not remain constant. While ray designs decrease experimental effort, all possible rays cannot be experimentally evaluated. Interest may be focused on statistical two-sided equivalence tests for additivity or one-sided equivalence tests for lack of synergy along an observed reference ray, and whether the same inference applies to an unobserved candidate ray. Borrowing ideas from the statistical equivalence literature, we have developed methodology that permits us to claim equivalent inference from an observed reference ray to an unobserved relevant candidate ray. Based on this methodology, equivalence margins associated with biologically meaningful deviations are chosen. A confidence region is computed for the reference ray and for the candidate ray based on the variability from the observed data. If both confidence regions are completely contained within the equivalence margins then the candidate ray may be concluded to be sufficiently similar in inference to the reference ray. The regions of equivalence are depicted graphically for interpretation. The cytotoxic effects of nine HAA's formed during disinfection of drinking water were evaluated in Chinese hamster ovary cells using single chemical concentration-response curves and a reference mixing ratio. Based on the observed reference ray, which shows lack of synergy, the graphical methods described above are used to illustrate that a mixing ratio from another disinfection process is sufficiently similar in inference as defined by selected equivalence margins. (This abstract does not reflect USEPA policy).

## EVALUATION OF PROPOSED THRESHOLD DOSES FOR CHRYSOTILE EXPOSURE AND RESPIRATORY DISEASE.

B. Finley<sup>1</sup>, F. Mowat<sup>2</sup>, R. Richter<sup>3</sup>, G. Brorby<sup>4</sup>, V. Craven<sup>1</sup> and P. Sheehan<sup>4</sup>. <sup>1</sup>Exponent, Santa Rosa, CA, <sup>2</sup>Exponent, Menlo Park, CA, <sup>3</sup>Exponent, Irvine, CA and <sup>4</sup>Exponent, Oakland, CA.

Some researchers have suggested that a cumulative chrysotile exposure of approximately 25 f/cc\*year is a minimum threshold dose for increased risk of lung cancer and asbestos. However, to our knowledge, the scientific merits of this suggested threshold have not been tested via a comparison to occupational doses derived from individual exposure data. Brake mechanics provide a unique opportunity to conduct such an analysis, because 1) they are exposed to the chrysotile form of asbestos only, 2) there is a substantial amount of published industrial hygiene data characterizing asbestos exposures in brake servicing facilities, and 3) numerous epidemiology studies have consistently demonstrated that brake mechanics are not at an increased risk of developing asbestos-related respiratory diseases. In this analysis, we developed distributions of occupational tenure data for automobile mechanics and 8-hour TWA concentration data from long-term personal samples collected by NIOSH in brake service garages in the US (more than 80 samples were collected during the years 1976 through 1987 at 22 brake repair facilities). A Monte Carlo analysis was used to derive an upper bound (95th percentile) cumulative asbestos exposure of approximately 3 f/cc\*year for brake mechanics in the US. This upper bound is below the 25 f/cc\*year threshold and, therefore, our exposure analysis is consistent with the negative epidemiology data for lung cancer and asbestososis in auto mechanics. Although a chrysotile threshold dose has not been suggested for mesothelioma (indeed there is considerable debate in the scientific community as to whether chrysotile asbestos is a causative factor in mesothelioma), numerous studies have consistently concluded that brake mechanics are not at an increased risk of developing mesothelioma and therefore the upper bound cumulative exposure estimate of 3 f/cc\*year for brake mechanics could serve as a preliminary estimate of a minimum threshold chrysotile dose for mesothelioma.

## CHRYSOTILE ASBESTOS EXPOSURE ASSOCIATED WITH REMOVAL OF AUTOMOBILE EXHAUST SYSTEMS (CIRCA 1946-1970).

D. J. Paustenbach<sup>1</sup>, A. Madl<sup>1</sup>, K. Clark<sup>1</sup>, K. Fehling<sup>1</sup> and T. Lee<sup>2</sup>. <sup>1</sup>ChemRisk, Inc., San Francisco, CA and <sup>2</sup>Carolina EHS, Lake Wylie, SC, SC.

For decades, asbestos-containing gaskets were used in almost every mechanical application. A gasket is a sealing device which frequently must be resistant to extreme temperatures and pressures. Prior to the mid-1970s, some automobile exhaust systems contained asbestos gaskets either at flanges along the exhaust pipes or at the exhaust manifolds of the engine. Additionally, a limited number of automobile mufflers briefly contained asbestos paper inside the muffler. Recent claims have suggested that there might be appreciable health risks associated with asbestos exposure during the repair of automobile exhaust systems. A simulation study was conducted to characterize personal and bystander exposures to asbestos during the removal of automobile exhaust systems (circa 1946-1970) containing asbestos gaskets. Personal, area, bystander, and area background samples were collected for about one hour during the repair work. Sixteen pre-1974 vehicles with old or original exhaust systems were studied. Air samples were analyzed by NIOSH PCM and TEM methods and bulk samples were analyzed by PLM and XRD. Results showed eighteen of thirty air samples collected on the lapel of the worker showed PCM results below the limit of detection (0.003-0.13 f/cc). TEM analysis indicated that only two lapel samples showed asbestos in which concentrations were 0.02 f/cc for chrysotile. Thirty-three of fifty-one area bystander samples were below the limit of detection (0.004-0.093 f/cc for PCM) and TEM analysis indicated that six bystander samples showed asbestos in which the highest concentration was 0.02 f/cc for chrysotile. Under a worst-case scenario where a mechanic might repeatedly conduct exhaust work over an eight-hour workday, these results indicate that exposure to asbestos from work with automobile exhaust systems containing asbestos gaskets was substantially below 0.1 f/cc, the current PEL for chrysotile asbestos.

## EXPOSURE RECONSTRUCTION OF HISTORICAL AIRBORNE BENZENE CONCENTRATIONS: CASE STUDY OF A DECK CREWMAN ON BOARD CRUDE OIL AND CHEMICAL TANKERS.

A. Madl<sup>1</sup>, K. Unice<sup>3</sup>, P. Scott<sup>3</sup>, K. Robinson<sup>2</sup>, P. Scarameda<sup>1</sup>, D. Pyatt<sup>2,4</sup> and D. Paustenbach<sup>1</sup>. <sup>1</sup>ChemRisk, Inc., San Francisco, CA, <sup>2</sup>ChemRisk, Inc., Boulder, CO, <sup>3</sup>ChemRisk, Inc., Pittsburgh, PA and <sup>4</sup>University of Colorado Health Sciences Center, Denver, CO.

High benzene exposures on board tankers transporting cargo containing benzene have been reported. Several factors influence the degree of benzene exposure under this occupational setting including the type of loading/unloading tasks performed

and the ventilation systems present. A reconstruction of historical airborne benzene exposures associated with deck work on board two tankers was conducted (one crude oil and one chemical). Work history of a shipmate was used as a basis for this case study. Parameters considered in the exposure model, included quantity of benzene-containing cargo, time involved with specific tasks (loading/unloading, manual gauging, transport, tank cleaning), voyage information including transit time at sea, and general conditions on board the tankers. Exposure estimates for specific operations believed to be comparable to the cargo and conditions on board these tankers were identified from the scientific literature. Monte Carlo methods were then used to characterize the plausible range of airborne benzene exposures a deck crewman might have historically experienced on board these tankers. Based on the specific work history of this case study, exposure model results showed that cumulative benzene exposures to a deck crewman on board tankers transporting crude oil and chemical cargo with less than five percent benzene were relatively low (less than one ppm/year). Tank cleaning operations provided the opportunity for the highest potential benzene exposures and appeared to drive the exposure estimates. Under the assumptions used in this case study, a worker exposed for a forty-year working lifetime would have a cumulative exposure to benzene well below levels shown to be associated with an increased risk of disease. These findings suggest that benzene exposure under the conditions modeled in this assessment do not pose a health risk to deck crewmen.

## DIESEL-RELATED BENZENE EXPOSURES DURING REFUELING OPERATIONS AT TWO GROCERY DISTRIBUTION CENTERS.

M. J. Fedoruk<sup>1</sup>, T. Smalstig<sup>1</sup>, J. Tran<sup>1</sup>, M. Shum<sup>1</sup>, R. O. Richter<sup>1</sup>, R. Bronstein<sup>1</sup> and B. D. Kerger<sup>2</sup>. <sup>1</sup>Exponent Inc., Irvine, CA and <sup>2</sup>Health Science Resource Integration, Inc., Tallahassee, FL.

Airborne benzene exposures were assessed during diesel refueling of tractor trailer trucks and generator fuel tanks for refrigerated trailers used for food transportation. Fuel was dispensed from a fuel truck tank by a nozzle with no vapor recovery system. Benzene samples included near-source levels before refueling, approximate 1-min breathing zone levels while refueling, integrated breathing zone levels for an industrial hygienist shadowing a refueler, background air levels, and diesel fuel concentrations. Summa canisters were analyzed by EPA-TO-15 and passive dosimeter badges by NIOSH 4500. Airborne benzene levels above the tank openings immediately after cap removal averaged 16.0 + 7.9 ppb (mean + S.E., n = 3) for tractor tanks and 4.3 + 1.1 ppb (n = 6) for generator tanks. Breathing zone levels obtained for about 1 min while the refueler was dispensing fuel averaged 38.7 + 19.7 ppb (n = 3) for tractor tanks and 11.8 + 7.1 ppb (n = 6) for generator tanks. Integrated breathing zone levels for the industrial hygienist shadowing the refueler averaged 8.8 + 5.3 ppb (n=2) while refueling tractor and generator tanks. Yard area samples including locations downwind from the entrance where diesel trucks entered the facility averaged 2.0 + 0.04 ppb (n = 7). Benzene concentration in the diesel fuel averaged 0.0034 + 0.0010 wt.‰ (n=3). These data suggest that airborne benzene exposures during diesel refueling are lower than levels associated with gasoline. Benzene levels in the yard with diesel traffic were similar to regional historical averages and suggest that diesel exhaust is not a significant source of benzene exposure to yard workers. Average workday exposure levels to refuelers of tractor trucks in open areas could be higher if diesel refueling operations involved more vehicles, but it seems unlikely that benzene exposure would exceed the OSHA Permissible Exposure Limit of 1.0 ppm (8-hour time-weighted average).

## OCCUPATIONAL PESTICIDE EXPOSURE DURING SEED CORN PRODUCTION IN MICHIGAN.

B. Hughes<sup>1</sup>, L. Olsen<sup>2</sup>, P. Hite<sup>3</sup> and P. Bills<sup>2</sup>. <sup>1</sup>PPPM, MI Department Ag., Lansing, MI, <sup>2</sup>Ent., MSU, East Lansing, MI and <sup>3</sup>Lab., MI Department Ag., East Lansing, MI.

A dermal exposure and work activity assessment was conducted to determine if the EPA's occupational risk assessment methodologies adequately protect workers from pesticide exposure in seed corn production. Seed corn is a crop that requires significant amount of hand labor, often conducted by sensitive subpopulations such as adolescents and migrant workers. A variety of practices such as rogueing (removing genetically undesirable plants) and detasseling are unique to this crop and can be considered high-risk from previously applied pesticides. Therefore, the purpose of the study was to determine: 1) dislodgable foliar residues, 2) dermal exposures, and 3) a generic transfer coefficient for risk assessments on tall/row crops for Tilt® (propiconazole) and Warrior® ( $\lambda$ -cyhalothrin). A 152-acre field used for seed corn production was sprayed with Tilt® (4 ounces/acre) and Warrior® (3 ounces/acre). Leaf samples were taken at Days 0 through 7 after application for dislodgable foliar residue pesticide analysis. The residue dissipation curves displayed typical first order decay; the R-squared was 0.84 and 0.86 for Warrior® and Tilt®, respectively. On day 2, the field was reentered by 15 volunteers wearing inner/outer whole body

dosimeters to determine the amount of leaf residue transferable to the participant. All volunteers roged for a 4-hour period after which the inner/outer dosimeters were divided into lower and upper leg, lower and upper arm, and front and back torso sections and submitted for pesticide analysis. The majority of the pesticide residues were distributed on the upper leg, lower leg, and lower arm. Residue penetration from the outer to the inner dosimeter was 5.3% and 7.2% for Warrior® and Tilt®, respectively. Day 2 foliar residues were used to calculate transfer coefficients (TC) for each section of the dosimeter. The average overall TC for Tilt® and Warrior® were 7800 and 6800, respectively. A preliminary estimate indicates that the margin of exposure for this crop and activity far exceeds EPA's target of 100 for occupational risk.

**PESTICIDE EXPOSURE ASSESSMENT: MOISTURE ENHANCES MALATHION TRANSFER TO HARVESTER GLOVES AND CLOTHING, BUT DOES NOT INCREASE ABSORBED DOSE.**

**R. I. Krieger, X. Zhang, T. Dinoff, Y. Chou and S. Acevedo.** *University of California Riverside, Riverside, CA.*

When strawberries are protected from pests with insecticides, fungicides, miticides, or molluscicides, field entry intervals are an important means to minimize harvester exposures. Establishment of safe entry intervals requires knowledge of dosages that produce experimental adverse effects and field measurements of harvester exposure. The influence of morning dew on harvester exposure was studied using latex glove and cotton forearm dosimeters (ug per harvester), and urine biomonitoring. Using a crossover design groups of 12 workers harvested malathion-treated in either the morning or in the afternoon during a 10-day period. Worker production during the day did not differ. The dislodgable foliar residues ranged from 0.22 to 0.014 ug/cm<sup>2</sup>. This abstract reports the first 3 d of 10 that are included in this report. Latex gloves in the morning retained 5.3 ± 1.1 mg malathion and 1.2 ± 0.66 mg malathion in the afternoon. A similar pattern of residue retention was found on the forearm dosimeters: morning residues were 1.2 ± 0.61 and 0.28 ± 0.81 during the afternoon harvest. Urine specimens normalized for daily creatinine excretion were obtained for measurement of malathion mono- and diacids. Even though the gloves and shirtsleeves represented morning: afternoon ratios of about 4 (day 3-5 post malathion application), the excreted malathion acids following morning exposures (0.95 ug/kg-3d) and afternoon exposures (1.26 ug/kg-3d) did not differ (>0.05). Based upon these observations, morning dew enhanced pesticide transfer from treated foliage, but it did not increase malathion absorption of harvester. Pesticide exposure estimates based upon external dosimeters may be excessive in the presence of moisture e.g., dew, rain, and perhaps perspiration. Supported in part by the California Strawberry Commission and DB Specialty Farms, Santa Maria, CA.

**CHEMICAL EXPOSURE ASSESSMENT: SURFACE DEPOSITION OF ENVIRONMENTAL TOBACCO SMOKE (ETS).**

**J. J. Keenan, X. Zhang and R. Krieger.** *Environmental Toxicology Program and Department of Entomology, University of California, Riverside, CA.*

ETS is commonly regarded as a source of bystander exposure to mainstream and sidestream smoke. Dermal exposures may be more important than inhalation to semivolatile (< 10<sup>-3</sup> mm Hg) chemicals in ETS. Nicotine was used as an exposure marker due to its concentration in ETS, stability, suitability for sensitive biological and environmental analysis, and toxicity. Nicotine is readily absorbed from inhaled air, ingestion, and skin contact. Dermal contact may be an important route of exposure for non-smokers, and this exposure may begin early in life. Carpet swatches were placed for 1, 2, and 4 weeks in 9 homes of cigarette smokers. Transferable carpet residue (TCR; µg nicotine/cm<sup>2</sup>) was sampled with a cotton cloth pressed beneath a 30-lb. roller. Nicotine was measured via GC/MS following Soxhlet extraction of carpet swatches with ethyl acetate. Nicotine concentrations in carpet swatches contained as much as 4.3 µg/cm<sup>2</sup> with a mean deposition of 1.29 µg/cm<sup>2</sup>. Carpet deposition increased about 0.3 µg/cm<sup>2</sup>/week. Mean nicotine concentrations after a four-week exposure were 1.7 µg/cm<sup>2</sup>. Potential daily dose (µg/person) is the product of TCR x TC x exposure hours. TCRs (TC; cm<sup>2</sup>/h) are used by the USEPA to evaluate and re-register pesticides for residential use. Assuming 10% nicotine transferability and the USEPA TC of 8700 cm<sup>2</sup>/hr, a potential daily dermal dose of 1, 500 µg/person-h. Assignment of dose is tentative since the transferable carpet residue is more tightly bound than organophosphate and pyrethroid pesticides that have been studied in this laboratory. Transferable surface residue to a cotton cloth utilizing a 30 lb roller was unsuccessful (LOQ 5 µg/ml). Dermal absorption could contribute significantly to ETS exposure measured using biomarkers such as cotinine and attributed to inhalation exposure (e.g. Jurado et al. 2004 and Kim et al., 2004). Many persons object to the irritancy of ETS in indoor settings, but primary exposure to tobacco smoke constituents, may result from dermal contact rather than inhalation.

**VALIDATION OF A SURROGATE MIX TO DETERMINE CONCENTRATION OF INDIVIDUAL COMPONENTS OF JP-8 IN AEROSOL AND VAPOR SAMPLES BY GC/MS.**

**K. Dietzel<sup>1</sup>, J. Campbell<sup>1</sup>, M. Bartlett<sup>2</sup>, M. Witten<sup>3</sup> and J. Fisher<sup>1</sup>.**

<sup>1</sup>*Interdisciplinary Toxicology Program, University of Georgia, Athens, GA,*

<sup>2</sup>*Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA and*

<sup>3</sup>*Pediatrics, University of Arizona, Tucson, AZ.*

JP-8 is a kerosene-based jet fuel containing several hundred hydrocarbons and is used in a variety of military vehicles, including aircraft. The chemical complexity of JP-8 makes analysis of individual components difficult. The objective of this study was to develop an analytical method, with an accuracy and precision of 20% or better, for JP-8 aerosol and vapor samples using gas chromatography/mass spectrometry (GC/MS). Preliminary analysis of the hydrocarbon composition of aerosol and vapor samples of JP-8 collected from a nose-only mouse exposure chamber at the University of Arizona was undertaken. Thirty-four of the primary components detected in the atmosphere were used to create a surrogate mixture for GC/MS analysis. Our surrogate mixture contained n-alkanes ranging from n-octane to n-heptadecane, toluene, n-ethylbenzene, xylenes, n-substituted cyclohexanes, 3-ethyltoluene, 2-methylnonane, trimethylbenzenes, indene, methyldecanes, 1, 2, 3, 4-tetrahydronaphthalene, naphthalene, methylnaphthalenes, and dimethylnaphthalenes. Three separate runs containing a standard curve, ranging from 1.25 µg/mL to 250 µg/mL, and six replicates each of the surrogate at concentrations of 1.25 µg/mL, 4.0 µg/mL, 75 µg/mL, and 200 µg/mL were analyzed. The average precision obtained for the thirty-four components was 8% or better, while the average accuracy was 13.5% or better. The precision of the standard curves was 18% or better at all concentrations of each of the components. Based on these results, we attained our desired precision and accuracy and have thus developed a suitable method for analyzing JP-8. This method will be used in the future to determine the concentration of major components in JP-8 samples acquired from the nose-only exposure chamber at the University of Arizona. Funded by AFOSR [grant no F49620-03-1-0157].

**PHYSICOCHEMICAL CHARACTERISATION OF COMBUSTION PARTICLES FROM RESIDENTIAL WOOD SMOKE AND VEHICLE EXHAUST.**

**A. Kocbach<sup>1</sup>, K. E. Yttri<sup>2</sup>, P. E. Schwarze<sup>1</sup> and E. Namork<sup>1</sup>.** <sup>1</sup>*Environmental Medicine, Norwegian Institute of Public Health, Oslo, Norway and* <sup>2</sup>*Department for Chemical Analysis, Norwegian Institute for Air Research, Kjeller, Norway. Sponsor: E. Dybing.*

Air pollution is associated with negative health effects. The particle characteristics responsible for these effects are still debated, but size, surface area and chemistry seem to influence the potency of the particles. This work is part of a VISTA\* project investigating possible relationships between physicochemical characteristics of particles and their biological effects. Since residential wood smoke and vehicle exhaust are the primary sources of particulate air pollution in Norway, combustion particles collected from a traditional Norwegian wood stove and in a road tunnel were compared. In this study, the morphology of the particles was characterised by transmission electron microscopy (TEM) and the ratio of organic to total carbon content (OC/TC) was determined by thermal-optical transmission analysis. The only combustion particles observed in the samples were carbon aggregates of different sizes, consisting of spherical primary particles with diameters between 20 and 60 nm. The mean diameters of primary particles from wood smoke was 39 ± 11 nm, whereas the diameter for vehicle exhaust from the road tunnel sample was 26 ± 7 nm. The OC/TC ratios for wood smoke and vehicle exhaust were 0.43 ± 0.04 and 0.65 ± 0.03, respectively (4 measurements). For equal particle masses, a decrease in particle diameter results in an increase in surface area. In the comparison of combustion particles from the two sources, vehicle exhaust particles were found to have a larger surface area per unit mass and a higher content of organic material, as compared to wood smoke particles. Increases in surface area and organic carbon content have been associated with increases in certain biological effects. Based on these parameters, combustion particles from vehicle exhaust may be considered more harmful than particles from residential wood smoke. \* VISTA - The Norwegian Academy for Science and Letters and Statoil. **COMPARISON OF TRACER METHODS USED TO MEASURE IN-VEHICLE CONCENTRATIONS.**

**M. D. Easter<sup>1</sup>, R. Ireson<sup>2</sup>, T. Hesterberg<sup>3</sup>, M. Lakin<sup>1</sup> and C. Lapin<sup>4</sup>.** <sup>1</sup>*EnSIGHT, Walnut Creek, CA,*  <sup>2</sup>*AQM Consulting, Greenbrae, CA,*  <sup>3</sup>*International Truck & Engine Corporation, Chicago, IL and* <sup>4</sup>*Lapin & Associates, Los Angeles, CA.*

Two studies<sup>1</sup> used different tracer methods to estimate diesel particulate matter (DPM) inside school buses attributable to bus exhaust. One used continuous monitors for black carbon, PM2.5, PAH, and SF<sub>6</sub> (a tracer gas released into the school

bus exhaust pipe). Objectives included characterizing student exposures, and conditions associated with high concentrations. It provides in-bus concentrations for several buses over a range of conditions. However, instrument instability due to sample line switching and tracer release rates that didn't vary with emission rate resulted in inconsistent, and in some cases, unrealistic estimates of self pollution. Based on correlations between SF<sub>6</sub> and other species, the study reports that about one-fourth of in-bus DPM concentrations, or 2-5 µg/m<sup>3</sup>, were due to bus exhaust. Regressions were inconsistent, and the few showing statistical significance may indicate only that DPM from other sources is entering the bus at the same time as the tracer. The second study focused exclusively on self-pollution, using iridium (Ir) tracer in the fuel. The DPM:Ir emission ratio was measured on a dynamometer; in-bus integrated samples were collected for Ir and PM2.5. DPM from the bus was detected with a sensitivity of 0.001 µg/m<sup>3</sup>. The average concentration was 0.22 µg/m<sup>3</sup>, 10-25X lower than the SF<sub>6</sub> self-pollution estimate. This difference appears to arise from the SF<sub>6</sub> study's inability to distinguish the bus's emissions from those of other sources. The iridium tracer method is specific and highly sensitive. Continuous data for SF<sub>6</sub> and other species improve the ability to identify conditions affecting concentrations, but are less sensitive and non-specific. Design of future studies should insure that adequate sensitivity for all parameters is achieved, and that bus exhaust contributions can be explicitly distinguished from on-road background. <http://www.arb.ca.gov/research/schoolbus/schoolbus.htm>; [http://www.greendieseltechnology.com/tracer\\_091003.html](http://www.greendieseltechnology.com/tracer_091003.html)

#### SIMULATION AND ASSESSMENT OF OCCUPATIONAL EXPOSURES TO ISOCYANATES AND VOCs DURING APPLICATION OF A URETHANE PRODUCT SUITE UNDER WORST-CASE CONDITIONS.

**M. H. Lumpkin<sup>1</sup>, V. Runnion<sup>1</sup>, R. Lieckfield<sup>1</sup>, S. D. Paul<sup>1</sup> and R. D. Harbison<sup>2</sup>.**  
<sup>1</sup>*Clayton Group Services, Inc., Kennesaw, GA and*<sup>2</sup>*Environmental & Occupational Health, College of Public Health, University of South Florida, Tampa, FL.*

Some reports claim health effects for workers exposed to isocyanates and VOCs while applying sprayed-on paint and urethane coatings. However, no exposure data are available for workers using troweled-on urethane putty and associated cleaners and primers in confined work spaces such as coal mines. Therefore, laboratory tests and work simulations were performed to assess the potential, worst-case occupational exposure to VOCs and isocyanates resulting from the use of a urethane product suite to repair rubber conveyor belts typically used in the coal mining industry. Tests were conducted in small chambers to identify airborne chemicals that could be measured during belt repair simulations. A method was also developed to assess potential dermal exposure to isocyanates using treated cotton sleeves as a surrogate skin surface. A series of six belt repair simulations were performed by an experienced belt repair technician in a walk-in exposure chamber. These simulations were designed to quantify potential exposure to isocyanates and VOCs while using the product suite to repair a rubber conveyor belt. A target list of 24 compounds, including 3 isocyanates, was developed from the small chamber data and the product's MSDSs. These compounds were sampled during the belt repair simulations. No airborne isocyanates were detected. The measured average airborne VOC concentrations were well below established occupational exposure limits. Low and intermittent levels of isocyanates were detected in dermal sleeve samples. These dermal exposures resulted from incidental self-application by the worker while wearing gloves having surface residues of uncured urethane putty. The results of the laboratory tests and large chamber simulations suggest that the normal and intended use of the urethane product suite is not likely to result in VOC or isocyanate exposure to workers at levels sufficient to produce adverse health effects

#### OCCUPATIONAL EXPOSURE TO ULTRAFINE PARTICLES AND POLYCYCLIC AROMATIC HYDROCARBONS FROM CANDLE EMISSIONS.

**D. Silver and R. D. Harbison.** *University of South Florida, Tampa, FL.*

Recently attention has been focused on occupational exposures to ultrafine particles (UFPs). Exposure to UFPs may include candle emissions in restaurants, spas and churches. Recent environmental studies indicate that there may be an increased risk of cardiovascular disease and pulmonary distress associated with exposure to UFPs in urban environments. Environmental concentrations of UFPs in urban environments is much greater than rural environments due to soot generated from vehicles, power plants and other fuel sources. Previous claims have been made that candle soot contains polycyclic aromatic hydrocarbons (PAHs). Comparatively, using candles for a limited time period exposes a person to less UFPs than ambient outdoor air of a typical city. A single candle and groups of 5 and 10 candles were burned inside a test room. Candles were selected based on the types typically used in churches, restaurants and spas. To accurately measure submicrometer-sized particles, a condensation nucleus counter was used. PAHs were sampled and analyzed according to OSHA Method 58. These data were extrapolated to churches, restaurants and spas using modeling equations. Candle emission data shows that the exposure to UFPs from candle use is not much different than that inhaled during an outdoor 24 hour time period. PAH analysis demonstrates that airborne concentrations are below detectable limits and do not impact lifetime cancer risk. Moderate use of candles is not a risk in occupational and residential settings because of transient and infrequent exposures and low levels of air constituents. Lifetime daily average dose (LADD) of ultrafine particles (adjusted for alveolar deposition) from ambient sources such as parking lots and roadways ranged between 0.775-1.10 E9 particles, inside shops 3.46 E8 particles and inside restaurants with secondary sources and the absence of candles, 5.82 E9 particles. LADD calculations for candle soot in occupational workplaces where candles are burned ranged from 1.86-9.36 E9 particles. The increased exposure to candle soot is not a measurable public health hazard.

#### EXPOSURE ASSESSMENT FOR PERCHLORATE IN MILK.

**D. Proctor.** *Exponent, Irvine, CA.*

Perchlorate has been measured in nearly 100% of commercial milk samples collected in Texas and California from three separate studies. It is presumed that perchlorate occurs in cow's milk because it concentrates in the leaves of alfalfa consumed by dairy cows. The alfalfa contains perchlorate because it is grown with perchlorate affected irrigation water. The measured levels of perchlorate in milk are low ranging from 1.5 to 10.6 ppb, with a mean for all three surveys of 3.6 ppb. However, analytical data validation information are not available for most of these samples. We calculated the dose of perchlorate for the US population, children ages 1 to 6 years, females of childbearing age, and pregnant or nursing females using USDA food consumption survey data, and considered all forms of liquid cow's milk and buttermilk. The fetus and neonate may be more sensitive to perchlorate than adults. In the survey, 67 percent of the US population reported consuming milk, whereas 92 percent of children, age 1 to 6 years, and 83 percent of pregnant and/or nursing women consumed milk. Using the mean concentration of perchlorate in milk reported in the three studies, the dose of milk for each population was calculated for the mean, and 50th and 90th percentiles of milk consumption rates. Body-weight adjusted doses were highest for children, ranging from 0.086 at the 50th percentile to 0.17 µg/kg-day at the 90th percentile of milk consumption rates. Doses for pregnant or nursing women were approximately 30% higher than those for all women of childbearing age (14 to 49 years), and ranged from 0.017 at the 50th percentile to 0.039 µg/kg-day at the 90th percentile of milk consumption rates. The dose to pregnant and nursing women does not exceed either the USEPA draft perchlorate reference dose (RfD) of 0.03 µg/kg-day or the RfD used by CalEPA to determine a perchlorate public health goal of 0.37 µg/kg-day. The dose to children does not exceed the CalEPA RfD, but exceeds the draft USEPA RfD by a factor of 2 (at the 50th percentile) and 6 (at the 90th percentile). These doses are lower than the dose which causes inhibition of iodide uptake in adults, a known precursor to thyroid dysfunction.

#### CURRENT ALCOHOL USE IS ASSOCIATED WITH A REDUCED RISK OF HOT FLASHES IN PERI-MENOPAUSAL WOMEN.

**C. Schilling<sup>1</sup>, L. Gallicchio<sup>2</sup>, S. Miller<sup>2</sup>, J. Babus<sup>1</sup>, L. Lewis<sup>1</sup>, H. Zacur<sup>2</sup> and J. A. Flaws<sup>1</sup>.**  
<sup>1</sup>*University of Maryland, Baltimore, MD and*<sup>2</sup>*Johns Hopkins University, Baltimore, MD.*

Hot flashes are one of the most common physiologic symptoms reported by women transitioning to menopause. Previous studies indicate that hot flashes are precipitated by low levels of endogenous estrogens. While many factors are associated with low estrogen levels, a few studies suggest that alcohol use may be associated with low estrogen levels in peri-menopausal women. Thus the purpose of this study was to examine the relation between current alcohol use, estrogen levels, and hot flashes in peri-menopausal women using a case-control study design. Cases were peri-menopausal women who reported ever experiencing hot flashes (n=317). Controls were peri-menopausal women who reported never experiencing hot flashes (n=222). Each participant completed a questionnaire and provided a blood sample that was used to measure estradiol and estrone levels by enzyme-linked immunosorbent assay. The results indicate that current alcohol users had lower odds than non-users of experiencing any hot flashes (odds ratio (OR): 0.63, 95% confidence interval (CI): 0.42, 0.93), independent of age, race, obesity and smoking habits. Also, the hot flashes experienced by current alcohol users were not any more severe (OR: 0.7, 95% CI: 0.46, 1.08), or any more frequent (OR: 0.56, 95% CI: 0.31, 1.02) than those experienced by non-users. In addition, current alcohol users had similar levels of estradiol (geometric mean: users 95.9 pg/ml, non-users 91.8 pg/ml; p<0.3) and estrone (geometric mean: users 117.5 pg/ml, non-users 112.2 pg/ml; p<0.3) compared to non-users of alcohol. These data suggest that current alcohol use is associated with a reduced risk of hot flashes in peri-menopausal women by a mechanism that may not include changes in estrogen levels. Supported by NIH AG18400.

ENVIRONMENTAL EXPOSURE TO CADMIUM AT A LEVEL INSUFFICIENT TO INDUCE RENAL TUBULAR DYSFUNCTION DOES NOT AFFECT BONE DENSITY AMONG FEMALE JAPANESE FARMERS.

F. Kayama<sup>1,2</sup>, H. Horiguchi<sup>1,2</sup>, E. Oguma<sup>1,2</sup>, S. Sasaki<sup>3</sup>, K. Miyamaoto<sup>1</sup>, Y. Ikeda<sup>1</sup> and M. Munehito<sup>1</sup>. <sup>1</sup>*Environmental Medicine, Jichi Medical School, Kawachi-Gun, Tochigi, Japan*, <sup>2</sup>*CREST, JST, Kawaguchi, Saitama, Japan* and <sup>3</sup>*National Institute of Health and Nutrition, Tokyo, Tokyo, Japan*. Sponsor: T. Yoshida.

Some recent researches suggest that environmental exposure to cadmium (Cd), even at low levels, may increase the risk of osteoporosis and that the bone demineralization is not just a secondary effect of renal dysfunction induced by high doses of Cd as previously reported. To investigate the effect of exposure to Cd at a level insufficient to induce kidney damage on bone mineral density and bone metabolism, we conducted health examinations on 1,380 female farmers from five districts in Japan who consumed rice contaminated by low-to-moderate levels of Cd. We collected peripheral blood and urine samples and medical and nutritional information, and measured forearm bone mineral density. Analysis of the data for subjects grouped by urinary Cd level and age-related menstrual status suggested that Cd accelerate the increase of urinary calcium excretion around the time of menopause and the subsequent decrease in bone density after menopause. However, multivariate analyses showed no significant contribution of Cd to bone density or urinary calcium excretion, indicating that the results mentioned above were confounded by other factors. These results indicate that environmental exposure to Cd at levels insufficient to induce renal dysfunction does not increase the risk of osteoporosis, strongly supporting the established explanation for bone injury induced by Cd as a secondary effect. This research protocol was approved by the Committee on Medical Ethics in Jichi Medical School.

HEALTH EFFECTS REPORTED IN TEXAS HOMES WITH VISIBLE MOLD AND/OR WATER DAMAGE.

J. Gandy<sup>1,2</sup> and A. J. Harris<sup>1</sup>. <sup>1</sup>*Center for Toxicology and Environmental Health, Little Rock, AR* and <sup>2</sup>*College of Public Health, Department of Pharmacology and Toxicology, University of Arkansas School for Medical Sciences, Little Rock, AR*.

Although the presence of indoor mold has been associated with allergy symptoms, there is inadequate data quantifying the airborne mold in homes reporting health effects in the occupants. In order to determine the average mold spore levels in homes with reported health effects, a retrospective analysis was performed of indoor air quality investigations conducted in Texas homes from the years 2001 to 2003 in response to homeowner complaints of visible mold and/or water damage. As part of the investigations, homeowners were questioned about symptoms that were present in the home occupants. These data describe the reported health effects, as well as the indoor and outdoor spore concentrations in 94 investigated homes. Airborne mold spores were collected using Zefon Air-O-Cell spore traps collected for five minutes at a flow rate of 15 liters per minute. The samples were analyzed by direct microscopy to determine the genus of the molds and the concentration of spores was calculated (spores/m<sup>3</sup>). The mean indoor and outdoor airborne spore levels were 3,014 spores/m<sup>3</sup> (range 160-20, 352 spores/m<sup>3</sup>) and 9,315 spores/m<sup>3</sup> (75-156, 323 spores/m<sup>3</sup>), respectively. *Stachybotrys* was found in 21 homes (mean = 227 spores/m<sup>3</sup>). Symptoms were reported in 72% of the homes with visible mold and/or water damage. The most commonly reported symptoms were allergies (42%), upper respiratory problems (19%) and asthma (13%). There were no significant differences between the indoor airborne spore concentrations of homes with or without reported symptoms. However, the mean outdoor spore concentration was significantly higher outside homes that reported allergies (3-fold, P<0.01), respiratory problems (4-fold, P<0.01) or asthma (7-fold, P<0.05) than in homes that reported no adverse health effects. In summary, the mean outdoor spore concentration was significantly higher for homes that had occupant reported health effects than in those with no reported symptoms.

AN INVESTIGATION OF HOME DAMPNESS AND ADVERSE HEALTH EFFECTS ON A NATIVE AMERICAN RESERVATION.

A. L. Stock, K. Davis, C. Brown, J. Sarisky and C. Blanton. *NCEH, Centers For Disease Control and Prevention, Atlanta, GA*.

Over the past 15 years, indoor dampness and mold have been perceived as a growing public health issue. Home dampness has been implicated in a variety of health effects including asthma, upper respiratory disease, and allergic rhinitis. It is still unclear what mold contributes to the risk of respiratory disease associated with damp houses. In 2001, we conducted a cross-sectional study of Native Americans who lived in flooded rental homes on the Turtle Mountain Reservation. Households were randomly selected for the study (N=137) which included visual

inspection, environmental sampling and responses to a health questionnaire. We used non-parametric and logistic regression analyses to look for relationships among environmental factors, demographic and lifestyle factors, home dampness, presence of molds and adverse health symptoms. Nearly all (98.5%) homes had one or more factors that contributed to home dampness and 67.7% had living space relative humidities above the EPA recommended range (30%-50%). Inspectors found visible mold in the living spaces of most homes (71.4%). The amount of mold in these areas was significantly correlated with the number of dampness contributors ( $\beta=0.33$ ,  $p<0.001$ ) found. Most study participants (93.7%) reported experiencing at least one adverse health symptom, with an average of 5.2 symptoms. The average number of self-reported health symptoms increased with the number of dampness contributors in the home ( $\beta=0.24$ ,  $p<0.001$ , trend line  $R^2=0.65$ ). Dampness contributors were significantly correlated with the total number of respiratory symptoms ( $\beta=0.28$ ,  $p<0.001$ ) and rhinitis symptoms ( $\beta=0.26$ ,  $p<0.001$ ). Living in a cluttered home ( $\beta=0.30$ ,  $p<0.001$ ) or having a pet indoors ( $\beta=0.30$ ,  $p<0.001$ ) were associated with the total number of self-reported symptoms. Logistic regression modeling demonstrated that *A. versicolor* in household dust samples was the mold most often associated with adverse health symptoms. More discriminate strategies are needed to assess the individual and synergistic contributions of these factors on adverse health outcomes.

UNIVOCAL DECISION RULES FOR THE ASSESSMENT OF CHRONIC SOLVENT-INDUCED ENCEPHALOPATHY; A PROPOSAL.

M. Verberk<sup>1</sup>, J. van der Hoek<sup>4</sup>, E. Wecking<sup>3,2</sup>, M. van Hout<sup>5,2</sup>, G. Hageman<sup>3,2</sup> and G. van der Laan<sup>2</sup>. <sup>1</sup>*Coronel Institute for Occupational Medicine, Academic Medical Center, Amsterdam, Netherlands*, <sup>2</sup>*Netherlands Center for Occupational Diseases, Academic Medical Center, Amsterdam, Netherlands*, <sup>3</sup>*Psychiatry, Academic Medical Center, Amsterdam, Netherlands*, <sup>4</sup>*Neurology, Medical Spectrum Twente Hospital Group, Enschede, Netherlands* and <sup>5</sup>*Clinical Psychology, Medical Spectrum Twente Hospital Group, Enschede, Netherlands*. Sponsor: P. Bogaard.

The two current 1985 international classification systems for chronic solvent-induced encephalopathy (CSE) lack univocal criteria. Our purpose was to develop univocal decision rules for patient data, based on the principles of these systems. We scrutinised our diagnostic methods, which were derived from the 1985 systems. Subjective procedures were replaced by objective ones as much as possible. Present implicit decision rules were refined and explicitly formulated for the following fields: (1) test-based neuropsychological impairment, (2) cognitive and somatic symptoms, (3) symptoms of disturbed mood and well-being, (4) the extent of solvent exposure, (5) differential diagnosis, and (6) the combination of these five fields to a final CSE diagnosis, in which three stages of deficit are discerned. By applying these rules to the data that we collected in the evaluation of 1543 alleged patients, 14% were diagnosed as CSE-only and 5% as CSE combined with another disease. We consider this proposal as a feasible example of the necessary elaboration of the 1985 classification systems. The proposed system keeps its transparency if cut-off criteria are set at a different level. We hope that it will contribute to an improved and internationally acceptable classification for CSE.

MATERNAL DDE SERUM LEVELS AND NEUROLOGICAL DEVELOPMENT IN INFANTS. PRELIMINARY FINDINGS.

L. Torres-Sanchez<sup>1</sup>, L. Lopez-Carrillo<sup>1</sup>, L. Schnaas<sup>2</sup>, E. Osorio<sup>2</sup>, M. Hernandez<sup>2</sup>, R. Garcia<sup>3</sup> and M. Cebrian<sup>3</sup>. <sup>1</sup>*INSP, Morelos, Mexico*, <sup>2</sup>*IN Perinatologia, Mexico City, Mexico* and <sup>3</sup>*Toxicology, CINVESTAV-IPN, Mexico City, Mexico*.

Experimental studies have shown that pp-DDE (DDE) has the potential to alter neurodevelopment. However scarce human evidence is available. From an ongoing cohort study, 87 pregnant women with no delivery complications and their infants were identified in Morelos, Mexico, whose Southern area used to be endemic for malaria. Mental and psychomotor development was evaluated in the infants at one month of age by the Neonatal Behavioral Assessment Scales (NBAS) and the Bayley Scales of Infant Development (BSID-II) and at three months of age by the BSID-II only. The BSID-II included indices of mental development and psychomotor development. Serum samples from the mothers were obtained during the first trimester of their pregnancy to determine DDE and other organochlorine pesticides by electron capture gas-liquid chromatography. The median of maternal DDE levels was 1,460.17 ng/g (range 95-11,445.). The median DDE level in serum is common in Mexican women living in similar areas and was comparable to that observed in women residing in California in 1971. Better scores for mental and psychomotor indexes at first month of age were observed in breastfed children independently of DDE maternal levels. A borderline significant reduction in the psychomotor index at three months of age ( $\beta=-2.09$ ,  $p=0.08$ ) was observed among breastfed children whose mothers had DDE levels higher than the median during

the first trimester of pregnancy, as compared to breastfed children whose mothers had DDE levels below the median. Data were adjusted by maternal IQ and home scale. Our preliminary results suggest a negative interaction between DDE exposure and breastfeeding on the motor development of infants at three months of age. Further studies in larger populations are needed to confirm the magnitude and the reversibility of this finding. #### ASSESSING THE PUBLIC HEALTH IMPACTS OF THE 1991 GULF WAR IN SAUDI ARABIA: A QUALITATIVE RISK ASSESSMENT APPROACH.

H. I. Williams<sup>1</sup>, A. Wiman<sup>1</sup>, C. Williams<sup>1</sup>, C. Stineman<sup>2</sup>, R. Freeman<sup>3</sup>, R. V. Lee<sup>4</sup>, M. Bell<sup>5</sup>, M. J. Symons<sup>6</sup>, S. Kim<sup>6</sup>, R. White<sup>6</sup>, J. Samet<sup>6</sup> and P. Breysse<sup>6</sup>. <sup>1</sup>*Ecology and Environment, Inc., Tallahassee, FL*, <sup>2</sup>*Ecology and Environment, Inc., Chicago, IL*, <sup>3</sup>*TERRA, Inc., Tallahassee, FL*, <sup>4</sup>*School of Medicine and Biomedical Sciences, State University of New York at Buffalo, Buffalo, NY*, <sup>5</sup>*Yale School of Forestry and Environmental Studies, New Haven, CT* and <sup>6</sup>*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*.

During the 1991 Gulf War, Iraqi military forces invaded and occupied Kuwait, deliberately contaminating the State's natural resources. The burning of oil wells, release of oil into the Arabian Gulf, and disruption of the desert surface by troop movements also impacted Kuwait's neighbor, Saudi Arabia. These activities contributed to increased levels of oil residues in seafood, and combustion products, soot, and airborne particulate matter (PM) in the atmosphere. As part of a larger program to evaluate the health impacts in Saudi Arabia from the war and its aftermath, a qualitative risk assessment was performed to identify populations experiencing adverse health effects from exposure to pollutants, stressful situations, or trauma. This assessment was also designed to determine relevant exposure pathways and contaminants of concern, and to identify war-related health effects; all for the purpose of designing a large-scale Exposure and Health Survey. Environmental monitoring data were obtained from a number of sources including air monitoring and modeling efforts and other published sources. Analyses of these data indicated that much of the eastern half of the Kingdom was impacted by air pollution, primarily airborne PM, which was a complex mixture of oil fire soot, soot-contaminated dust, and vehicle exhaust. Shoreline and seafood contamination data were obtained from previously published studies that measured trace metal and hydrocarbon concentrations in sediment and/or biota. Overall findings of the analysis established that health outcomes of concern could be broadly categorized as follows: cardiovascular, respiratory, systemic, and post-traumatic stress disorder (PTSD).

#### GETTING THE LEAD DOSE-RESPONSE CURVE RIGHT: IMPLICATIONS FOR PUBLIC HEALTH AND POLICY.

S. J. Rothenberg<sup>1</sup>, J. C. Rothenberg<sup>2</sup> and D. A. Fox<sup>3</sup>. <sup>1</sup>*Instituto Nacional de Salud Pública, Cuernavaca, Morelos, Mexico*, <sup>2</sup>*University of Sydney, Camperdown, NSW, Australia* and <sup>3</sup>*University of Houston, Houston, TX*.

Population lead study researchers sample a range of lead exposure and often frame blood lead as a continuous independent variable, against which they regress the health effect. Publications sometimes use natural log transformed lead, sometimes linear lead with no formal testing of the functional form best describing the dose-response curve for lead-health effect. We use data from a pooled analysis study of blood lead on child IQ (N=1333) and a study of blood lead on elevated blood pressure in pregnant women (N=1735) to show that untransformed blood lead and natural log transformed blood lead are both highly significant predictors of the health effects. We use diagnostic tests (J-test and generalized additive models with spline fitting) to show that natural log transformed blood lead describes the drop in child IQ with increasing lead significantly better than the linear lead function (J-test, p=0.009) and that the log-linear dose-response curve is not due to residual confounding by improperly specified control variables. The same procedure for the blood lead-systolic blood pressure function shows marginally significant improvement in the dose-response function using the log-linear form (J-test, p=0.053). We compare linear-linear and log-linear dose-response functions for blood lead-IQ in a published economic benefits model showing dollar savings from the US nationwide blood lead reduction between 1976 and 1999. The log-linear dose-response function for lead-IQ showed 2.2 times the economic savings (\$319 billion) predicted by the linear-linear dose-response function (\$149 billion). A log-linear dose-response function for lead on IQ implies that 70% of the decrease in child IQ (12.4 IQ points) measured over the study lead range of 0.1-71.7 µg/dL (17.8 IQ points) occurs from 0.1-10.0 µg/dL. The 10 µg/dL CDC action limit for children does not prevent the majority of damage to child intelligence. We can duplicate the economic benefit already achieved by further reducing national blood lead to 0.2 µg/dL.

430

#### MECHANISMS OF METAL-ASSOCIATED VASCULAR DISEASE.

E. K. Silbergeld, A. Navas-Acien, B. S. Schwartz, R. Sharrett, E. Sharrett and E. Guallar. *Johns Hopkins University Bloomberg School Public Health, Baltimore, MD*.

There is increasing evidence associating several toxic metals and cardiovascular outcomes. However, it is generally assumed that these risks involve high exposures and often renal toxicity. We have reported that small increments in blood lead in adults (from 1 µg/dL to 3 µg/dL) are associated with significant increases in risks of hypertension and premature mortality due to cardiovascular disease and stroke. To explore mechanisms by which low level lead (Pb) and cadmium (Cd) exposures may increase risks of peripheral arterial disease (PAD), we used data from two National Health and Nutrition Examination Surveys conducted from 1999-2000 and from 1999-2002. There was a dose-effect relationship of blood Pb with increased odds of PAD among US adults as levels increased from below 1 to approximately 5 µg/dL. For Cd, blood levels above 0.7 µg/L and urine levels above 0.24 µg/L (along the full dose range) were associated with increased odds of PAD. These associations were not confounded by biomarkers of lipid or renal function, arguing against a major role of these mechanisms in the observed effects of Pb or Cd. Elevations in blood Pb were also strongly correlated with elevations in serum homocysteine (HC) at levels as low as 1.6-2.2 µg/dL. Our analysis indicates that Pb may confound the observed associations between HC and vascular disease. It is possible that HC may be a biomarker of Pb-induced oxidative stress. We also examined gene-environment interactions for Pb and vascular disease, to test the role of nitric oxide-related pathways. In a study of Pb-exposed workers in Korea, the nitric oxide synthase gene G→T 894 polymorphism was not associated with blood pressure nor modified the Pb-blood pressure relation. These results demonstrate the utility of epidemiological studies in hypothesis generation for mechanistic toxicology. In addition, they support the need for research on metal-induced vascular dysfunction at levels within the range of current exposures. *Research supported by American Heart Association, CDC, NHLBI, and NIEHS.*

431

#### CATEGORIZATION OF THE ASSOCIATIONS BETWEEN EXPOSURE TO THE HERBICIDES USED IN VIETNAM OR THEIR CONTAMINANTS AND HEALTH OUTCOMES.

J. Cohen and M. Catlin. *The National Academies, Washington, DC*.

Between 1962 and 1971 military forces sprayed herbicides over Vietnam. In 1991, because of ongoing uncertainty about the long-term health effects on Vietnam veterans of the herbicides sprayed, Congress passed the Agent Orange Act of 1991. That legislation directed the Secretary of Veterans Affairs to request the National Academy of Sciences, a non-profit organization that provides independent, objective advice on scientific issues, to perform a comprehensive review and evaluation of scientific and medical information regarding the health effects of exposure to Agent Orange, other herbicides used in Vietnam, and the various chemical components of those herbicides, including dioxin. In assessing the evidence of an association between exposure to the herbicides and their components and a health outcome, the committees responsible for the reports review the available literature and categorize the evidence as 1) sufficient of an association; 2) limited or suggestive of an association; 3) inadequate or insufficient to determine whether an association exists; or limited or suggestive of NO association. In addition, conclusions regarding the biological plausibility of the health effects and the risk to Vietnam veterans are also made. Biennial updates are produced; the latest of those reports is *Veterans and Agent Orange: Update 2004*, which will be released in December 2004. The assessments in the reports are used by the Department of Veterans Affairs to make policy decisions regarding compensation to veterans for service-related illnesses. The methods used by the committee as well as the most recent conclusions made by the committee will be discussed.

432

#### THE IMPACT OF REDUCTION OF THE OCCUPATIONAL EXPOSURE LIMIT FOR FORMALDEHYDE IN QUEBEC: A RE-EVALUATION OF HEALTH RISKS.

N. Noisel, M. Bouchard and G. Carrier. *Sante Environnementale & Sante Au Travail, Universite de Montreal, Montreal, QC, Canada*.

As part of a study on the impact of a reduction of the occupational exposure limit (VEA) for formaldehyde (FM) in Quebec, which value is currently 2 ppm, the health risks related to occupational exposures to FM was re-evaluated. A critical analysis of the available literature data following acute, subchronic or chronic exposure was conducted. Specific criteria were used to select and classify most pertinent studies. This analysis showed that exposure to concentrations near the VEA should not induce adverse effects on the respiratory system, such as asthma. Also, with the

CIIT model, the probability of FM-induced cancers in the 143, 491 Quebec workers exposed to 1 ppm for 40 years was calculated to be less than one case. In the range of concentrations of the VEA, the critical biological effects appear to be nose, throat and eyes irritations; preventing these effects should avoid the appearance of other effects. To assess the impact of a reduction of the VEA, a dose-response relationship was thus established between exposure to FM and the occurrence of irritations as a critical effect. This was best achieved by quadratic regression rather than linear regression on raw irritation data combined from selected published human studies, and compiled by concentration ranges and by degree of severity. Results showed that at concentrations below to 0.75 ppm, there is little probability for FM-induced irritations to occur. Between 0.75 and 1 ppm, 6.3% of exposed individuals could experience mild eye irritations, 1.6% mild nose and throat irritations and none severe eye irritations. Between 1 and 2 ppm, 10.1% and 0.8% of exposed individuals could manifest mild and severe eye irritations respectively, and 4.5% mild nose and throat irritations. The application of this risk assessment to the context of the 143, 491 Quebec workers potentially exposed to FM shows that a decrease of the actual exposure limit towards 1 ppm could prevent mild irritations for 300 to 400 workers and severe eye irritations for 50 workers. This research was funded by the IRSST.

EFFECTS OF INHALED COMBUSTION-DERIVED PARTICULATE MATTER ON INDICES OF CARDIAC, PULMONARY, AND THERMOREGULATORY FUNCTION IN SPONTANEOUSLY HYPERTENSIVE RATS.

L. B. Wicher<sup>1</sup>, W. H. Rowan<sup>2</sup>, J. P. Nolan<sup>2</sup>, U. P. Kodavanti<sup>2</sup>, M. J. Schladweiler<sup>3</sup>, A. D. Ledbetter<sup>3</sup>, D. L. Costa<sup>2</sup> and W. P. Watkinson<sup>2</sup>. <sup>1</sup>SPH, UNC, Chapel Hill, NC and <sup>2</sup>ORD/NHEERL/ETD/PTB, USEPA, Research Triangle Park, NC.

Epidemiological studies have shown a positive relationship between elevated levels of ambient particulate matter (PM) and rates of morbidity and mortality; these correlations are further strengthened when limited to individuals with preexisting cardiopulmonary diseases. While similar effects have been demonstrated in animals, the mechanism(s) by which these effects are mediated are unresolved. To further investigate this phenomenon, we examined the cardiac, pulmonary, and thermoregulatory effects of a combustion-derived PM (HP12), a particle with a more relevant metal profile ( $\uparrow$ Zn,  $\downarrow$ V) and bioavailability than the residual oil fly ash used in many previous studies. Spontaneously Hypertensive (SH) rats were surgically implanted with radiotelemeters capable of continuously monitoring electrocardiogram (ECG), heart rate (HR), systemic arterial blood pressure (BP), and core temperature ( $T_{co}$ ). Animals were divided into air and HP12 groups and exposed via inhalation (0 and 11 mg/m<sup>3</sup>, respectively) for 6hr/dx4d while inside whole-body plethysmograph chambers. This methodology permitted continuous, simultaneous monitoring and acquisition of cardiac and pulmonary physiological parameters in unanesthetized, unrestrained animals. Rats underwent blood collection and were sacrificed to obtain bronchoalveolar lavage (BAL) at 7 days post-exposure. We observed no changes in HR, BP, or  $T_{co}$  with exposure to inhaled HP12. However, ECG abnormalities, consisting of general rhythm disturbances and premature contractions, were observed in  $\approx$ 50% of HP12-exposed rats. There were slight increases in select blood and BAL indices, while there were only minor effects of HP12 on respiration parameters. Thus, this study demonstrated minimal deficits in cardiac function in SH rats after inhalation exposure to a low-metal content, "ambient-like", combustion-derived particle. (Abstract does not represent USEPA policy. This research was supported by EPA CT826513.)

**434**

CARDIOPULMONARY EFFECT OF PARTICULATE MATTERS ON DIABETIC RATS: FROM CAPS TO ULTRAFINE PARTICLES.

Y. Lei and T. Cheng. College of Public Health, National Taiwan University, Taipei, Taiwan. Sponsor: T. Ueng.

The association between ambient particulate matter (PM) and cardiovascular diseases has been demonstrated in epidemiological studies. Recent studies suggest that diabetic patients are at greater risk for PM-associated cardiovascular events. However, the biological mechanism remains unclear. In this study, we used concentrated ambient particles and ultrafine carbon black particles to examine the cardiopulmonary effect of particles on diabetic rats. First, streptozotocin-induced diabetic and healthy rats were intratracheally administered with PM2.5 collected from traffic busy area in a dose of 200 $\mu$ g. Cell and differential counts as well as protein and LDH activity were determined in BALF. 8-OHdG, ET-1 and NO, as well as CRP, IL-6 and TNF- $\alpha$  in peripheral blood were also determined. Our results showed that diabetic rats were associated with increased 8-OHdG, IL-6, ET-1 and decreased NO. In non-diabetic rats, PM exposure was also associated with increased 8-OHdG, IL-6, TNF- $\alpha$ , CRP and decreased NO. Interestingly, increases of

8-OHdG and ET-1 after PM exposure were more prominent in diabetic rats as compared to non-diabetic rats. General linear model further indicated that there were interactions between diabetes and PM on 8-OHdG ( $p<0.01$ ) and ET-1 ( $p=0.08$ ). Subsequently, we exposed diabetic and non-diabetic rats to 0, 125 and 500 $\mu$ g ultrafine carbon black particles (ufCB). The results revealed that ufCB caused significant in lung inflammation and plasma IL-6 in diabetic and non-diabetic rats. We also observed significant alteration in plasma ET-1 and NO in diabetic rats exposed to ultrafine carbon black while, similar finding were not observed in non-diabetics. We concluded that ambient fine particles may enhance the risk of cardiovascular diseases in diabetics through the interaction between PM and diabetes that results in excess ROS generation and endothelial dysfunction. The results also suggest that inert ultrafine particles may induce cardiovascular toxicity in diabetics. We also found that STZ-diabetic rats may be a useful model for PM toxicity study.

TOXICOGENOMIC EXPRESSION PROFILES OF SPONTANEOUSLY HYPERTENSIVE RATS EXPOSED TO CONCENTRATED AMBIENT PARTICLES.

Y. Lei and T. Cheng. *Public Health, National Taiwan University, Taipei, Taiwan.* Sponsor: T. Ueng.

Particulate air pollution has been associated with morbidity and mortality of cardiopulmonary disease. However, the mechanism remains unclear. The goal of this study is to use cDNA microarray technology to examine the global gene expression patterns of different target organs in diseased animal models exposed to concentrated ambient particles (CAPs). Six male spontaneously hypertensive rats (SHR) were exposed to CAPs in a traffic busy EPA supersite at Hsing-Chung area, Taipei. Five male SHR without CAPs exposure were prepared as controls. After 6 hr/day, 1 day/week CAPs exposure for 10 weeks, rats were sacrificed and the lung, heart and aorta tissue were collected and prepared for total mRNA extraction. cDNA microarray were performed in triplicate experiments using Rat Chip 8K. The ratio of means of each target organ was calculated for analysis. In our study, we observed differential gene expression profiles in lung, heart and aorta tissue. Higher expressions of IL-1 $\beta$ , IFN, MIP-1 $\gamma$ , ICAM-1, and MnSOD were observed in lung in SHR after CAPs exposure. Interestingly, we found several genes related to blood pressure control, systemic inflammation, coagulation and atherosclerosis were significantly expressed in aorta among cardiovascular compromised SHR. In aorta, higher expression of ANP, IFN, MIP-1, MCP-1, TGF- $\beta$ , VEGF, VCAM-1, fibrinogen-like protein, and PAI-1 were observed. These expression profiles may represent manifestations of PM-related thrombosis formation and subsequent cardiovascular outcome, especially in susceptible populations. Furthermore, these markers may be used in elucidating ambient PM toxicity.

**436**

TIME-COURSE OF INFLAMMATION AND TISSUE DAMAGE IN THE MOUSE LUNG CAUSED BY FINE PARTICULATE MATTER FROM SIX EUROPEAN CITIES (PAMCHAR).

M. S. Happo<sup>1,2</sup>, R. O. Salonen<sup>1</sup>, A. I. Halinen<sup>1</sup>, P. Jalava<sup>1,2</sup> and M. Hirvonen<sup>1</sup>. <sup>1</sup>Department of Environmental Health, National Public Health Institute, Kuopio, Finland and <sup>2</sup>University of Kuopio, Kuopio, Finland. Sponsor: M. Viluksela.

In contrast to epidemiological findings, coarse particles have had after 16 to 48-h exposures a higher inflammatory potency in the animal lung than fine particles. We investigated the time-course of different inflammatory markers using fine particles (PM<sub>2.5-0.2</sub>) collected with an optimized high volume cascade impactor during selected seasons in six European cities: Duisburg (autumn), Prague (winter), Amsterdam (winter), Helsinki (spring), Barcelona (spring) and Athens (summer). Healthy C57BL/6J mice were intratracheally exposed to the PM samples (10mg/kg) using three exposure durations: 4h, 12h and 24h. At the end of the exposures, the lungs were lavaged and the bronchoalveolar lavage fluid (BALF) was assayed for indicators of inflammation and tissue damage: cell number microscopically, total protein and lactate dehydrogenase (LDH) spectrophotometrically and cytokines (TNF- $\alpha$ , IL-6 and KC) immunochemically. After 4-h exposures, the PM<sub>2.5-0.2</sub> samples increased all the cytokine concentrations with large potency differences between cities. After 12-h exposures, the BALF cytokine concentrations were no longer increased with these samples, but the total cell number and total protein concentration most often peaked at this time point. In line with earlier reports, after 24-h exposures, none of the PM<sub>2.5-0.2</sub> samples induced significant changes in BALF cytokine concentrations and the total cell numbers and total protein concentrations were only slightly higher than the basal levels. In contrast, the coarse PM<sub>10-2.5</sub> samples induced clear increases in all of these parameters at 24 h. In conclusion, exposure times longer than 12 h seem inappropriate for the assessment

of inflammatory activity and tissue damage in the healthy mouse lung after a single intratracheal instillation of urban air fine particles. Grants: EC-FP5 contract QLK4-CT-2001-00423 and The Academy of Finland and TEKES.

#### EXPOSURE TO CONCENTRATED AMBIENT PARTICLES DOES NOT AFFECT ENDOTHELIAL VASOMOTOR FUNCTION IN PATIENTS WITH ISCHEMIC HEART DISEASE.

N. L. Mills<sup>1</sup>, D. E. Newby<sup>1</sup>, S. D. Robinson<sup>1</sup>, D. Anderson<sup>1</sup>, E. Freney<sup>1</sup>, D. Robert<sup>1</sup>, N. A. Boon<sup>1</sup>, W. MacNee<sup>1</sup>, K. Donaldson<sup>1</sup> and F. Cassee<sup>2</sup>. <sup>1</sup>Centre for Cardiovascular Science, ELEGI Colt Research Laboratories or Department of Chemistry, University of Edinburgh, Edinburgh, United Kingdom and <sup>2</sup>Centre for Environmental Health Research, National Institute for Public Health and the Environment, Bilthoven, Netherlands.

There is extensive evidence of endothelial dysfunction in patients with atherosclerosis, systemic inflammation, and in cigarette smokers. We hypothesised that exposure to concentrated ambient air particles will cause systemic inflammation and have detrimental vascular effects. Twelve male patients with stable ischemic heart disease and 12 age-matched non-smoking volunteers were recruited. These individuals were exposed to concentrated ambient urban fine + ultrafine particles (CAP) in Edinburgh, Scotland or filtered air (FA) during 2 hrs of intermittent exercise. Bilateral forearm blood flow and inflammatory markers were measured 6-8 hrs after CAP or FA exposure in response to intra-brachial acetylcholine (5-20  $\mu$ g/min), sodium nitroprusside (2-8  $\mu$ g/min) and bradykinin (100-1000 pmol/min). Pulmonary inflammation following CAP and FA exposure was assessed in 8 subjects using exhaled breath condensate. Average exposure concentrations  $190 \pm 37.2$   $\mu$ g/m<sup>3</sup>. Levels of 8-isoprostone in exhaled breath increased 6 hours after exposure to CAP (CAPs  $16.9 \pm 8.5$  pg/ml vs FA  $4.9 \pm 1.2$  pg/ml,  $p < 0.05$ ). There was no difference in whole blood leukocyte count, serum C-reactive protein concentration, or resting forearm blood flow following exposure to CAP or FA. Although there was a dose dependent increase in blood flow with each vasodilator ( $p < 0.001$ ), both endothelium-dependent and independent vasodilation were unaffected by CAP or FA in either group. A 2 hour exposure to Edinburgh urban CAP, low in combustion-derived component, causes pulmonary oxidative stress but not systemic inflammation. On average a 6-fold increase over ambient air, exposure to Edinburgh urban ultrafine + fine CAP did not affect vascular function in either middle-aged healthy volunteers or patients with stable ischaemic heart disease.

#### EXPOSURE TO CONCENTRATED AMBIENT PARTICLES IN DETROIT ALTERS HEART RATE VARIABILITY IN SPONTANEOUSLY HYPERTENSIVE RATS.

J. G. Wagner<sup>1</sup>, L. B. Wicher<sup>2</sup>, M. Morishita<sup>3</sup>, A. C. Rohr<sup>4</sup>, G. J. Keeler<sup>3</sup> and J. R. Harkema<sup>1</sup>. <sup>1</sup>Michigan State University, East Lansing, MI, <sup>2</sup>USEPA -NHEERL, Research Triangle Park, NC, <sup>3</sup>University Michigan, Ann Arbor, MI and <sup>4</sup>Electrical Power Research Inst, Palo Alto, CA.

Elevations in airborne particulate matter (PM) are linked to increased mortality and morbidity in humans with cardiopulmonary disease. Clinical studies show that PM is associated with altered heart rate variability (HRV) and suggests that loss of autonomic control may underlie cardiovascular toxicity. To assess the effect of PM on HRV in a rodent model of cardiovascular disease, we exposed spontaneously hypertensive rats (SH) and Wistar-Kyoto (WKY) rats to concentrated air particulates (CAPs) generated from ambient air in urban Detroit. Rats ( $n=4$ /group) were exposed to CAPs or filtered Air for 8h/day (7am-3pm), for 13 consecutive days inside a mobile laboratory equipped with whole body exposure chambers and a Harvard type fine concentrator that enriches fine PM (<2.5  $\mu$ m). Rats were implanted with radio transmitters and electrocardiograms were recorded by telemetry. Beat to beat intervals were used to calculate SDNN and RMSSD as determinants of HRV. Average mass concentration of CAPs was  $502 \pm 272$   $\mu$ g/m<sup>3</sup> (range:103-918). SDNN increased in CAPs/SW rats on Day 1 compared to Air/SW controls (13.5 vs. 15.6 ms; air vs. CAPs), but decreases in SDNN were observed in CAPs/SW rats during successive exposures and were consistent through Day 13 (17.5 + 1.5 vs. 14.9 + 0.5 ms). In CAPs-exposed SH rats, a trend for decreased SDNN in the early morning hours and in the early days of exposure was evident compared to baseline (0.8 - 2.7ms decrease). Conversely, decreased SDNN in the afternoon hours was not present early, but developed by Day 13 in CAPs-SH rats (2.3 ms decrease). CAPs-induced decreases in RMSDD occurred in later exposure days in SH rats. Changes in HRV were not dependent on PM mass. No consistent changes in SDNN or RMSDD were present in CAPs/WKY rats. These data suggest that CAPs-induced changes in HRV in rats with systemic hypertension are dependent on the length and frequency of exposure. Research supported by EPRI.

#### EXPOSURE TO CONCENTRATED AMBIENT PARTICLES IN DETROIT, MICHIGAN CAUSES HEART RATE AND THERMOREGULATORY CHANGES IN SPONTANEOUSLY HYPERTENSIVE AND WISTAR-KYOTO RATS.

A. C. Rohr<sup>1</sup>, J. G. Wagner<sup>2</sup>, M. Morishita<sup>3</sup>, G. J. Keeler<sup>3</sup> and J. R. Harkema<sup>2</sup>. <sup>1</sup>EPRI, Palo Alto, CA, <sup>2</sup>Michigan State University, East Lansing, MI and <sup>3</sup>University of Michigan, Ann Arbor, MI.

Cardiovascular effects have been reported in rats exposed to concentrated ambient particles (CAPs) in different regions of the United States. The objective of this study was to evaluate the cardiovascular effects of CAPs in a region dominated by mobile source emissions. We stationed a portable particle concentrator in an area heavily impacted by diesel emissions in Southwest Detroit, MI. Spontaneously hypertensive (SH) and Wistar-Kyoto (WKY) rats were exposed to CAPs 8 hours/day for 13 consecutive days. Animals were implanted with telemeters, and heart rate (HR) and temperature (T) data were collected continuously. Four groups of animals were studied: SH-CAPs, SH-sham (filtered air), WKY-CAPs, and WKY-sham ( $n=4$  in each group). Extensive exposure monitoring was conducted, including gaseous pollutants and particulate matter (PM) components. CAPs exposure concentrations were  $103-918 \mu\text{g}/\text{m}^3$  (mean= $502 \mu\text{g}/\text{m}^3$ ). We observed a significant reduction in HR over the exposure period in CAPs-exposed SH and WKY compared with sham animals. Mean HR in CAPs and sham SH rats was  $300 \pm 13$  bpm and  $292 \pm 11$  bpm, respectively ( $p=0.001$ ). CAPs-exposed WKY and sham animals had mean HRs of  $312 \pm 8$  bpm and  $305 \pm 7$  bpm, respectively ( $p < 0.0001$ ). There was a suggested negative association between HR and CAPs concentration, with  $R^2$  values of 0.18 ( $p=0.15$ ) for SH and 0.21 ( $p=0.12$ ) for WKY. Core body T in WKY rats decreased with CAPs exposure, although this effect did not reach statistical significance ( $p=0.15$ ). As with HR, there was a suggested trend toward reduced T with increasing CAPs concentration ( $R^2=0.25$ ;  $p=0.08$ ). These results are important in light of the small sample size studied, and suggest that CAPs exposure causes cardiovascular and thermoregulatory changes in rats. Additional analyses incorporating detailed exposure characterization and source apportionment data from this study will provide valuable insight into the CAPs components associated with these changes.

#### SUBCHRONIC EFFECTS OF CONCENTRATED AMBIENT PARTICLES (CAPS) IN SENESCENT MICE (AKR).

Q. LI and L. Chen. Environmental Health, NYU School of Medicine, Tuxedo, NY.

The objectives of this subchronic (3 months) CAPs inhalation study in senescent mice (AKR) was to determine the effects of CAPs on the progressive changes in cardiac function and heart-rate regulation in an animal model of a susceptible human population. AKR mice ( $n=8$ /group) were exposed to northeastern regional background CAPs or filtered air for 6 hr/d, 5d/wk. from Feb. to May 2004. Six died during experiment (two from control group, four from exposure group). Ten second ECG, body temperature, and activity data were sampled from each mouse every 5 minutes using implanted DSI transmitters throughout the study. In the surviving mice, daily average of the 5-minute heart rate (HR) was decreased in both exposure (52 bpm) and control (23 bpm) groups during the experiment. Most mice exhibited very strong circadian rhythm in their daily standard deviation of normal to normal beat (SDNN, a measure of heart rate variability, HRV), which had a very strong negative correlation ( $R=-0.9$ ) with body temperature and activity counts. The differences of the 24 hr average of non-exposure weekend day SDNN between CAPs exposed and filtered air controls were significant after three weeks of CAPs exposure, and the difference continually widened until the end of the study. Differences of daily 24hr average SDNN between CAPs and control in the first six weeks are 0.01, 0.02, -0.06, -0.07, -0.3, -0.25 respectively. The results of this study suggest that CAPs exposure significantly altered cardiac autonomic function in senescent mice.

441

#### CARDIAC INJURY FROM LONG-TERM EPISODIC EXPOSURE TO PARTICULATE MATTER (PM): SOLUBLE COMPONENTS OR SOLID PARTICLES?

U. P. Kodavanti<sup>1</sup>, M. C. Schladweiler<sup>1</sup>, A. D. Ledbetter<sup>1</sup>, J. McGee<sup>1</sup>, P. S. Gilmour<sup>2</sup>, W. P. Watkinson<sup>1</sup>, D. C. Christiani<sup>3</sup>, D. L. Costa<sup>1</sup>, R. H. Jaskot<sup>1</sup>, J. H. Richards<sup>1</sup> and A. Nyska<sup>4</sup>. <sup>1</sup>ETD/NHEERL/ORD, USEPA, Research Triangle Park, NC, <sup>2</sup>CEMALB, UNC, Chapel Hill, NC, <sup>3</sup>HSPH, Boston, MA and <sup>4</sup>NIEHS, Research Triangle Park, NC.

Long-term exposure to PM has been associated with cardiac injury in rats. The purpose of this study was to investigate if cardiac injury was due to soluble metals (i.e., zinc), insoluble PM, or pulmonary injury/inflammation. Male Wistar Kyoto rats ( $n=8$ ) were exposed intratracheally (IT), once/wk x 8 wks to either saline, Mount

St. Helens ash (MSH, no soluble metals) - 2.3 mg/kg/wk, environmental combustion particles (PM, zinc as soluble metal) - 1.15 or 2.3 mg/kg/wk, the saline-leachable fraction of PM (PM/L) - 2.3 mg/kg/wk or ZnSO<sub>4</sub> (Zn) - 33.4 µg/kg/wk (equivalent soluble zinc in PM). Another group of rats was exposed to half the concentration of all components above but for 16 wks. All exposures, except saline, caused marked lung inflammation including MSH. Lavage fluid protein, albumin, and LDH also increased in all groups relative to saline. PM high dose demonstrated the greatest effects. No changes were apparent among the hematological parameters. Four sections of each cardiac tissue were examined microscopically. Lesions were scored in a blinded manner for extension (e.g., focal or multifocal) of inflammation, fibrosis and myofiber degeneration. Minimal to no lesions were noted in controls. Mild to moderate myocardial lesions were noted in all other groups including MSH; the mean severity was highest in PM high dose group. Subepicardial and random myocardial lesions were characterized by inflammation with fibrotic degeneration. Gene expression arrays are being evaluated to understand potential differential roles of the PM components. In summary, long-term episodic IT exposure to insoluble PM or Zn causes persistent pulmonary inflammation/injury as well as varying degrees of cardiac lesions. These findings support the hypothesis that both soluble and insoluble components may cause cardiac injury. (Does not reflect USEPA policy. Supported in part by #CR829522 between EPA and UNC).

**442 HEART RATE CHANGES IN 24-MONTH OLD FISHER 344 RATS EXPOSED TO CONCENTRATED PARTICULATE MATTER (PM2.5) CLOSE TO A FREEWAY IN DIAMOND BAR, CA.**

A. K. hamade, T. Lam and M. T. Kleinman. *University of California, Irvine, CA.* Sponsor: H. Hamadeh.

High incidences of mortality and morbidity from cardiovascular-related diseases exist in the United States. A portion of those incidents has been associated with air pollution episodes according to a good number of epidemiological studies, especially in the geriatric population. Epidemiological studies serve as a starting point and strongly support the need for additional research. Thus we see the need for using geriatric rats as susceptible-population experimental models. Eight 24-month old Fisher 344 rats were implanted with telemetry-based EKG monitors. The rats were used as their own controls. In week one the rats were exposed to a particle-free and gas-free atmosphere. In week two, the same rats from week one were exposed to concentrated fine particulate matter (PM2.5). Each week exposures ran for three days for four hours each day. Exposures took place in Diamond Bar, CA downwind of a major freeway in our mobile exposure vehicle and utilizing a particle concentrator. We observed an increase in heart rate in the rats when exposed to PM2.5 as compared to purified air. This increase might result from pulmonary irritation induced autonomic nervous system stimulation or proinflammatory cytokine induction of autonomic neural reflexes affecting the heart. These results suggest potentially serious effects on susceptible individuals in the geriatric population if exposed to elevated levels of inhaled particulate matter.

**443 EFFECTS OF ON-ROAD AEROSOLS IN AGED RATS.**

A. Elder<sup>1</sup>, N. Corson<sup>1</sup>, P. Mercer<sup>1</sup>, R. Gelein<sup>1</sup>, J. Finkelstein<sup>2</sup>, P. Hopke<sup>3</sup>, W. Watts<sup>4</sup>, D. Kittelson<sup>4</sup> and G. Oberdorster<sup>1</sup>. <sup>1</sup>*Environment Med., University of Rochester, Rochester, NY*, <sup>2</sup>*Ped., University of Rochester, Rochester, NY*, <sup>3</sup>*Chem. Eng., Clarkson University, Potsdam, NY* and <sup>4</sup>*Mech. Eng., University of Minnesota, Minneapolis, MN*.

Ambient particulate pollution has been associated in epidemiological studies with adverse health effects in elderly individuals with cardiopulmonary diseases. We hypothesize that inhaled ultrafine particles (UFP) and their gaseous co-pollutants contribute to these effects, especially when vehicle passengers are exposed directly to freshly-generated, concentrated highway aerosols. To test this hypothesis, we exposed old rats (20-22 mo, F-344) to freshly-generated highway aerosols (particles (<1µm)/gas phase, gas phase only, or filtered air) using an on-road tractor-trailer exposure system. Inlet pipes at the end of the trailer allowed sampling of the diluted engine exhaust plume emitted from the front of the tractor. Rats were treated with inhaled endotoxin or instilled influenza virus either before or after on-road exposures to prime respiratory tract cells. Controls were treated with saline. Exposures (6 hr; 1 or 3 days in a row) in compartmentalized whole-body chambers occurred while driving between Rochester and Utica (NY I-90). Endpoints related to lung inflammation, inflammatory cell activation, and acute phase responses were measured after exposure. The primary particle size was 13-19 nm and the number concentration was 1.6-4.3 x 10<sup>6</sup>/cm<sup>3</sup>. The expected significant changes in response due to priming agent (endotoxin, virus) were observed. Exposure atmosphere had no effect on lavage PMN percentage, cell oxidant release, or biochemical indices of cytotoxicity. However, a significant increase in total lavage cell number, increases in macrophage intercellular adhesion molecule-1 expression, a decrease in the percentage of blood PMNs, and changes in plasma fibrinogen were due to the particle/gas

phase mixture. Some of these changes were evident three days after exposure. These results show that freshly-generated exhaust aerosols have significant effects on the pulmonary and cardiovascular systems in compromised, old rats.

**444 COLLECTION, AEROSOLIZATION, AND CHARACTERIZATION OF PAVED ROAD DUST FOR AN INHALATION TOXICITY STUDY.**

J. McDonald, E. Barr and J. L. Mauderly. *Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM.*

Resuspended dust, including paved road dust, contributes to both PM10 and PM2.5 in ambient air. Although studies on the toxicity of inhaled road dust are limited, recent work (Wellenius et al., 2003) has shown associations between cardiovascular response to concentrated ambient particles and the concentration of silica, an indicator of resuspended dust. In order to characterize the respiratory and cardiovascular toxicity of inhaled dust directly, a collection, processing, suspension, and characterization strategy has been developed and tested. The collection strategy evaluates a modified indoor surface sampler versus a commercial street sweeper. Samples were processed by sieving to 40 microns and resuspended by a Wright Dust feeder into a rodent inhalation chamber. Particle size, metals, carbon, inorganic ions, and fungal/bacterial content were characterized. The composition of the resuspended dust in the inhalation chamber was consistent with previous laboratory studies used to define resuspended dust composition.

**445 CHEMICAL, MICROBIOLOGICAL AND TOXICOLOGICAL CHARACTERIZATION OF FINE PARTICULATE MATTER (PM2.5) FROM AN INDOOR ENVIRONMENT IN PUERTO RICO.**

A. Gioda<sup>1</sup>, E. Fuentes-Mattet<sup>2,1</sup>, B. Bolanos<sup>2</sup> and B. D. Jimenez-Velez<sup>2,1</sup>. <sup>1</sup>*Center of Environmental and Toxicological Research-UPR Medical Science Campus, San Juan, PR, Puerto Rico* and <sup>2</sup>*Biochemistry, UPR Medical Science Campus, San Juan, PR, Puerto Rico*.

Fine atmospheric particles (PM2.5) were sampled at an indoor working environment consisting of 3 analytical laboratories located in the same building. The objective of this study was to determine the individual composition of particulate matter and to evaluate its chemical, toxicological and microbiological characteristics. We compare our results with that of the immediate surrounding outdoor environment and with other published indoor studies. All samples were digested for metal analyses including their appropriate field blanks. Six metals were analyzed in this study (As, Cd, Fe, Ni, Pb and V) by means of Atomic Absorption. Some of the filters were expended for the determination of fungi. Fungi were grown in malt extract agar and glycerol agar culture media. Aqueous extracts from particulate matter were evaluated by a immuno-toxicological assay (Bio-Plex Cytokine Array System) in human lymphocytes. The amount of PM2.5 indoor ranged from 4.5-12 µg/m<sup>3</sup> as compared to 21.5 µg/m<sup>3</sup> outdoor. Although the levels of PM2.5 were higher outdoor the concentration of metals per mass of PM2.5 was greater indoors. The metals per mass in the indoor air ranged from 7.1- 172, 195 µg/g. All metal analyzed were significantly higher indoor when compared to outdoor with an I/O ratio as high as 10 for Ni. These indoor metal concentrations are high when compared to other studies. The main fungi species found in the indoor environment was Aspergillus versicolor. The concentrations of these fungi were relatively low as 2 CFU/m<sup>3</sup>. The Aqueous extracts significantly increased the release of IL-8, IL-17 and MCP-1 by human lymphocytes. Relative increases in IL-5 and IL-13 were also observed for these extracts. This research provides the tools for studying the effects of specific components in indoor air particulate matter on immune response.

**446 HIGH NO<sub>2</sub>/NO<sub>X</sub> RATIO IN DIESEL ENGINE EMISSION AEROSOL MAY REPRESENT A MORE IMPORTANT ACUTE TOXIC TRIGGER THAN PARTICULATE MATTER (PM) FOR LUNG TISSUE.**

J. MORIN<sup>1</sup>, A. Bion<sup>1,2</sup>, V. Keravec<sup>2,1</sup> and F. Dionnet<sup>2</sup>. <sup>1</sup>*INSERM U644, Rouen, France* and <sup>2</sup>*CERTAM, Saint Etienne du Rouvray, France*. Sponsor: R. FORSTER.

We assessed the PM and gas phase respective contributions to lung toxicity profile induced by Diesel engine emission aerosols. Organotypic cultures of rat lung tissue were exposed to continuously sampled and diluted Diesel engine emission aerosols. PM content and size distribution were measured using an AVL415 and SMPS respectively. CO, NO, NO<sub>2</sub>, and HC were monitored using a Horiba Mexa 7000 analyser. Filtration of diluted emissions through a silicon carbide monolith removed >99% PM from the emissions and did not alter the gas phase pollutant content. Engine was operated at different speeds and loads with various fuels (Sulphur and aromatics), and after treatment devices to quantitatively modulate pollutant

emissions. Endpoints for Inflammatory reaction (TNF $\alpha$ ) and oxidative stress (GSH, Catalase, GPx, SOD, 8-oxoguanine) where assessed in lung tissue and/or culture medium. Beside the wellknown inflammatory impact of PM emission evidenced at low NO<sub>2</sub>/NO<sub>x</sub> ratio (<0.1) (Bion et al. CBT 2002;18:301-14), we have identified that aerosol gas phase was responsible for oxidative stress. We could correlate oxidative injury to increasing NO<sub>2</sub>/NO<sub>x</sub> ratio in the exhaust which varied from less than 0.1 up to more than 0.55, with almost no variation of total NO<sub>x</sub>. Neither CO nor HC were assignable for these effects. For NO<sub>2</sub>/NO<sub>x</sub> ratio >0.2, emission filtration could no more modify the toxic response pattern suggesting a predominant impact of the gas phase over the PM phase. For high NO<sub>2</sub>/NO<sub>x</sub> ratios >0.4, we observed lung tissue cytotoxicity and cell necrosis. Oxidant enzyme profiles varied with increasing NO<sub>2</sub>/NO<sub>x</sub> ratio, suggesting a modulation of ROS profile according to the experimental combination. We suggest that NO<sub>2</sub>/NO<sub>x</sub> ratio could be a good marker of the pro-oxidative potential of combustion engine emission aerosols and thus be considered as a useful tracer of lung detrimental biological potential of these emissions. Supports from EC QLK4-CT62002-02357 MAAPHR program and Region Haute Normandie are greatly acknowledged

#### 447 EFFECTS OF DIESEL EXHAUST ON TLR3 SIGNALING IN RESPIRATORY EPITHELIAL CELLS.

J. M. Ciencewicki<sup>1</sup>, M. Madden<sup>3,1</sup> and L. Jaspers<sup>2,1</sup>. <sup>1</sup>*Curriculum of Toxicology, University of North Carolina, Chapel Hill, NC*, <sup>2</sup>*Pediatrics, University of North Carolina, Chapel Hill, NC* and <sup>3</sup>*Human Studies Division, USEPA, Chapel Hill, NC*.

There are a variety of intrinsic as well as extrinsic factors, such as exposure to air pollution that can affect the pathogenesis of respiratory infections. Diesel exhaust (DE) emissions can significantly contribute to air pollution levels and exposure to DE can alter host defense and immune responses. Double stranded RNA (dsRNA), a by product of viral infections, is a ligand for toll-like receptor 3 (TLR3). In this study, we examined the effects of DE extract (DEE) on dsRNA-induced responses in respiratory epithelial cells. A549 cells were exposed to DEE for 2 hours, subsequently challenged with polyribonucleic acid:polyribocytidyl acid (poly I:C), a synthetic form of dsRNA, and 24 hours post-exposure analyzed for the expression of IL-6 and IFN-beta. We found that pre-exposure of epithelial cells to DEE significantly increased the expression of IL-6 and IFN-beta in response to poly I:C. Flow cytometric analysis showed that TLR3 is predominantly expressed in the cytoplasm of A549 cells. Exposure to DEE increased TLR3 mRNA levels in these cells. In addition, we examined the expression of the TLR3 adaptor protein Toll/IL-1 receptor domain containing adaptor inducing interferon- $\beta$  (TRIF) in response to DEE exposure. We found that exposure to DEE caused an increased expression of TRIF within 3-4 hours post-exposure. Upon activation of TLR3, TRIF associates with TNF receptor-associated factor 6 (TRAF6). TRAF6 is an intracellular signaling protein required for the TLR3-dependent activation of NF- $\kappa$ B and Interferon regulatory factor 3 (IRF3), which regulate the expression of IL-6 and IFN-beta, respectively. Overexpression of a dominant negative version of TRAF6 reversed the effects of DEE on poly I:C-induced IL-6 expression. Taken together these results indicate that exposure of respiratory epithelial cells to DE could potentially alter the response to viral infections by increasing the expression of components involved in the TLR3-dependent signaling cascades.

#### 448 NEUROTROPHIN RECEPTOR BLOCKADE ATTENUATES DIESEL EXHAUST PARTICULATE MATTER (DEP) ENHANCEMENT OF ALLERGIC RESPONSES.

A. K. Farra<sup>1,2</sup>, N. Haykal-Coates<sup>2</sup>, A. D. Ledbetter<sup>2</sup>, P. A. Evansky<sup>2</sup> and S. H. Gavett<sup>2</sup>. <sup>1</sup>*Molecular and Biomedical Sciences, North Carolina State University, Raleigh, NC* and <sup>2</sup>*Experimental Toxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC*.

Recent investigations have linked neurotrophins including NGF, NT-3, and BDNF to allergic airways diseases. Antibody blockade of NGF attenuates airway resistance associated with allergic airway responses in mice. Mice administered an antibody against the low affinity pan-neurotrophin receptor p75, or p75 knockout mice have reduced pulmonary airway inflammation. DEP has been linked to asthma exacerbation in many cities with vehicular traffic congestion. Cell types affected by DEP, including eosinophils, macrophages, lymphocytes and the airway epithelium, also produce neurotrophins and/or express neurotrophin receptors. We tested the hypothesis that DEP-induced enhancement of the hallmark features of allergic airway disease in a murine model is dependent on p75 function. Nonallergic (NA) and ovalbumin (OVA)-allergic C57BL/6J mice were intranasally instilled with an antibody against the p75 receptor or saline alone 1 hour before OVA challenge. The mice were then exposed nose-only to the PM<sub>2.5</sub> fraction of SRM2975 DEP (0.85 mg/m<sup>3</sup>) or air alone for five hours, 1 hour later (n=9/group). Two days later, air exposed OVA-allergic mice developed increased levels of bronchoalveolar lavage fluid eosinophils, macrophages, neutrophils and IL-4, enhanced serum OVA-specific

IgE, and had a small but insignificant increase (22%) in methacholine (Mch)-induced airway obstruction (PenH; Buxco), relative to air-exposed NA mice. DEP-exposed OVA-allergic mice had a significantly greater degree of airway obstruction than all other groups (68% greater vs. air-exposed NA mice). Instillation of anti-p75 significantly reduced mean PenH values in DEP-exposed OVA-allergic mice to levels similar to NA mice. The data demonstrate that neurotrophins play a role in DEP exacerbation of allergic responses, particularly airway obstruction, and may be relevant to human DEP exposure (Supported by NCSU/USEPA CT829470. This abstract does not reflect EPA policy).

#### YM1/2 CHITINASE PROTEINS IN MURINE NASAL EPITHELIUM AFTER A 13-WEEK INHALATION EXPOSURE TO ULTRAFINE CARBON BLACK PARTICLES.

J. R. Harkema<sup>1</sup>, P. Santhanam<sup>1</sup>, J. G. Wagner<sup>1</sup>, L. A. Bramble<sup>1</sup>, A. P. Elder<sup>2</sup> and G. Oberdorster<sup>2</sup>. <sup>1</sup>*Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI* and <sup>2</sup>*Environmental Medicine, University of Rochester, Rochester, NY*.

Mice exposed for 13 wk to airborne, ultrafine carbon black particles (Cb) develop nasal lesions including chronic rhinitis, mucous cell metaplasia in respiratory epithelium (RE), degeneration of olfactory epithelium (OE), and accumulations of an unique eosinophilic protein in both RE and OE. The purposes of the present study were to identify the Cb-induced eosinophilic protein and determine the exposure-response relationship for Cb exposure and protein expression in murine nasal epithelium. Female mice were exposed to 0, 1, 7, or 50 mg/m<sup>3</sup> Cb for 6 h/day, 5 days/wk for 13 wk. Mice were sacrificed 1 day, 13 wk, or 11 mo post-exposure (PE). Cb aerosols had a primary particle size of 17 nm with aerodynamic diameters ranging from 1.2-1.6 microns. Nasal airways were processed for light microscopy and immunohistochemically stained for Ym1/2 chitinase proteins (Ym). Morphometry was used to determine the volume density of Ym in RE and OE. No or scant amounts of Ym were present in RE or OE of mice exposed to 0 or 1 mg/m<sup>3</sup> Cb. Mice exposed to 7 mg/m<sup>3</sup> Cb and sacrificed 1 day and 13 wk PE had mean values of 3.4 and 5.3 nl Ym/mm<sup>2</sup> basal lamina at 1 day and 13 wk PE, respectively. Mice exposed to 50 mg/m<sup>3</sup> had three fold more Ym in RE than 7 mg/m<sup>3</sup> Cb-exposed mice at similar times PE. Only 50 mg/m<sup>3</sup>-Cb-exposed mice had marked amounts of Ym in sustentacular cells of OE at 1 day PE, and an 18-fold-Ym increase in OE, compared to air controls, at 13 wk PE. No Cb-induced increases of Ym in RE or OE were found at 11 mo PE. These results indicate that inhaled, low toxicity, ultrafine particles may cause marked and persistent increases of Ym expression in murine nasal epithelium. The role of mammalian chitinase proteins in particle-induced airway epithelial injury and repair in mice or humans is yet to be determined. (Research sponsored by the International Carbon Black Association).

#### 450

#### PARTICLE SURFACE AREA AND PARTICLE NUMBER, BUT NOT PARTICLE MASS, PREDICT THE ADJUVANT EFFECT OF PARTICLES ON ALLERGIC RESPONSES IN MICE.

U. C. Nygaard, M. Samuelsen, A. Aase and M. Lovik. *Environmental Immunology, Norwegian Institute of Public Health, Oslo, Norway*. Sponsor: E. Dybing.

Airborne particles have been shown to enhance allergic responses in humans and mice. Traditionally, particle exposure has been monitored as mass concentration of PM<sub>10</sub> or PM<sub>2.5</sub>. Large particles strongly influence the mass concentration, thus particle mass is a poor measure for characterizing the amount of the small, possibly more biologically potent particles. The aim of this study was to examine whether fine particles exert a stronger adjuvant effect on allergic responses than coarse particles, and if so, whether particle surface area or particle numbers predict the increased IgE responses better than particle mass. We used polystyrene particles (PSP) ranging in diameter from 0.0588 to 11.14  $\mu$ m, carbon black (CB) and diesel exhaust particles (DEP), to study the adjuvant effect of particles on the immune responses to the allergen ovalbumin (OVA) after subcutaneous injection into the footpad of BALB/c mice. At a given mass per mouse, the small particles (0.0588 and 0.202  $\mu$ m PSP, CB and DEP) increased the OVA-specific IgE serum levels to a higher degree than the larger particles (1.053, 4.64 and 11.14  $\mu$ m PSP). Furthermore, during the primary response to OVA in the draining popliteal lymph node, the particles' synergistic effect increased with decreasing particle size, measured as cell numbers, expression of surface markers (CD19, MHC class II, CD86 and CD23) and *ex vivo* production of IL-4 and IL-10. Linear regression analyses indicated that the IgE response was predicted by the total particle surface area ( $R^2=0.64$ ), number of particles ( $R^2=0.62$ ) and particle diameter ( $R^2=0.58$ ), but not by particle mass ( $R^2=0.06$ ). This conclusion was confirmed by linear regression analyses for the cellular parameters. To conclude, ultrafine and fine particles had

stronger adjuvant effects on allergic responses than larger particles at equal administered mass. Accordingly, the total particle surface area and particle number, but not the currently used particle mass, predicted the adjuvant effect of particles on allergic responses.

#### CHEMICAL CHARACTERISTICS AND TOXICITY OF POLAR ORGANIC EXTRACT OF DIESEL EXHAUST PARTICLES.

T. Kobayashi<sup>1</sup>, H. Shima<sup>1</sup> and E. Koike<sup>2</sup>. <sup>1</sup>*Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Ibaragi, Japan* and <sup>2</sup>*PM2.5 and DEP Research Project, National Institute for Environmental Studies, Tsukuba, Ibaragi, Japan*. Sponsor: S. Hirano.

Previous studies show that diesel exhaust particles (DEP) induce inflammatory responses. Chemical characteristics such as oxidative capacity may be related to the responses. The present study was designed to elucidate the relationship between chemical characteristics of organic extract of DEP and toxicity. DEP were collected with quartz filter. The organic compounds of DEP were extracted using dichloromethane. The organic extracts (OE-DEP) were fractionated into n-hexane soluble fraction (H-SOL) and n-hexane insoluble fraction (H-INSOL). GC-Mass, IR, and NMR spectra of OE-DEP, H-SOL and H-INSOL were measured. Oxidative capacity was measured using dithiothreitol (DTT) consumption. Induction of heme oxygenase-1, as a marker of oxidative stress, in alveolar epithelial cells was measured by ELISA. Cytotoxicity was assessed by LDH release. Induction of inflammatory response was evaluated the number of neutrophils infiltrated into peritoneal cavity of BALB/c mice 24 h after administration of the extracts. IR spectra show that H-INSOL not H-SOL has functional groups related to oxygenation such as hydroxyl, ketone, aldehyde, carboxyl groups. Relative intensity of these peaks were H-INSOL>OE-DEP>H-SOL. DTT assay also showed that relative oxidative capacity was H-INSOL>OE-DEP>H-SOL. Induction of heme oxygenase-1, by H-INSOL is also stronger than those of OE-DEP or H-SOL. H-INSOL injured alveolar epithelial cells concentration dependently. The relative strength of the cytotoxicity was H-INSOL>OE-DEP>H-SOL. The analysis of the number of the infiltrated neutrophils in the intraperitoneal cavity also showed that H-INSOL caused inflammation dose dependently. The induction of the inflammatory responses by H-INSOL was stronger than OE-DEP or H-SOL. These results suggest that polar organic extract, H-INSOL, contains oxygenated compounds. Some of them have oxidative capacity. They may be responsible for the induction of oxidative stress and inflammatory responses.

#### ORGANIC EXTRACT OF DIESEL EXHAUST PARTICLES STIMULATES EXPRESSION OF IA AND COSTIMULATORY MOLECULES ASSOCIATED WITH ANTIGEN PRESENTATION IN RAT PERIPHERAL BLOOD MONOCYTES BUT NOT ALVEOLAR MACROPHAGES.

E. KOIKE<sup>1</sup> and T. KOBAYASHI<sup>2</sup>. <sup>1</sup>*PM2.5 and DEP Research Project, National Institute for Environmental Studies, Tsukuba, Ibaraki, Japan* and <sup>2</sup>*Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Ibaraki, Japan*. Sponsor: S. Hirano.

Diesel exhaust particles (DEP) consist of carbonaceous cores that adsorb many organic compounds. DEP and organic compounds in them were shown to induce oxidative and inflammatory effects. Previous reports have been shown that DEP induce allergic asthma. Our present study is designed to clarify whether DEP may affect 1) the expression of Ia and B7 molecules in alveolar macrophages (AM) as a mature cell or peripheral blood monocytes (PBM) as an immature cell, 2) the antigen-presenting (AP) activity of PBM. The organic extract of DEP (OE-DEP) was prepared using dichloromethane. AM and PBM were prepared from normal male Wistar rats (8-10 weeks). T cells for use in the experiments of the AP activity were prepared from lymph nodes of ovalbumin-sensitized rats. AM and PBM were exposed to whole DEP, OE-DEP or residual particles from DEP (washed DEP) for 24 hrs. The expression of cell surface molecules associated with antigen presentation was measured by flow cytometry. AP activity was assessed by ovalbumin-specific T cell proliferation. Whole DEP and OE-DEP significantly increased the expression of Ia and B7 molecules in PBM but not in AM concentration dependently. The effect of washed DEP was not observed in this study. Low concentration of organic extract also increased AP activity of PBM. These results suggest that DEP may enhance AP activity in immature APC and the effect contributing to the organic compounds rather than the residual carbonaceous particles of DEP. Furthermore, our recent study shows that OE-DEP had ability to induce oxidative stress (induction of heme oxygenase-1) in pulmonary cells equivalent to whole DEP, but the activity of washed DEP was low. Thus, the oxidative stress may be a key component causing the exacerbation of allergic reaction by DEP.

#### WOOD SMOKE PARTICLES INCREASE ALLERGIC RESPONSES IN MICE, BUT LESS THAN DIESEL EXHAUST PARTICLES (DEP).

M. Samuelsen, U. C. Nygaard and M. Lovik. *Norwegian Institute of Public Health, Oslo, Norway*. Sponsor: E. Dybing.

There is ample evidence that ambient air particles increase the severity of asthma and allergic diseases. In this project financed by VISTA\* we have used well-characterized combustion particles to study the relationships between particle properties and their capacity to increase allergic responses. Diesel exhaust particles (DEP) and chemically and physically characterized particles from wood smoke and road traffic were used to study the adjuvant effect of combustion particles on the immune responses to the allergen ovalbumin (OVA). OVA, particles with and without OVA and vehicle alone (HBSS), were injected into one hind footpad of BALB/cA mice. Particles together with OVA significantly increased the level of OVA-specific IgE in serum, as compared to the groups given OVA or particles alone, although wood smoke particles with OVA induced significantly lower IgE levels compared to the other particles. However, wood smoke particles with OVA induced higher levels of OVA-specific IgG2a than DEP and road traffic particles. The primary responses to particles with or without OVA, were studied using cells in the draining popliteal lymph node. As compared to OVA and particles alone, all particles with OVA increased cell numbers, cell proliferation, *ex vivo* secretion of IL-4 and IL-10 after Con A stimulation and expression of several cell surface molecules (CD19, MHCII, CD86 and CD23). Overall, DEP with OVA seemed to be most potent in inducing primary cellular responses, and wood smoke particles induced somewhat higher responses than road traffic particles. In conclusion, all combustion particles tested had the capacity to enhance allergic sensitization, although to different degrees. DEP was the most potent allergy adjuvant, while the potency of wood smoke and road traffic particles depended on the parameters measured. The antibody experiments indicated that while DEP was a clear Th2 adjuvant, wood smoke and road traffic particles appeared to give a mixed Th1/Th2 associated response. \* The Norwegian Academy for Science and Letters and Statoil

#### COMPARISON OF PULMONARY TOXICITY BETWEEN HEALTHY SPRAGUE-DAWLEY RATS AND SPONTANEOUSLY HYPERTENSIVE RATS EXPOSED TO DIESEL EXHAUST PARTICLES.

W. Chang, Y. Lei and T. Cheng. *College of Public Health, Institute of Occupational Medicine and Industrial Hygiene, Taipei, Taiwan*. Sponsor: T. Ueng.

Epidemiologic studies have demonstrated an association between ambient particulate matter and cardiopulmonary morbidity and mortality. Diesel exhaust particles (DEP), a major contributor to ambient particulate matter, have also been reported to be associated with lung cancer and cardiopulmonary diseases. It has been proposed that the reactive oxygen species (ROS) may contribute to the cardiopulmonary toxicity of particulate matter including diesel particles. Spontaneously hypertensive (SH) rats, a model with antioxidant deficiency, have been used in many studies investigating PM toxicity. Here, we compare the pulmonary and systemic inflammation and oxidative DNA damage of DEP between healthy Sprague-Dawley (SD) rats and SH rats. Both SD rats and SH rats were administered with different doses of DEP (SRM 2975, NIST) (0, 125, 500 µg per animal) via intratracheal instillation. After 24 hours, cell and differential counts as well as total protein were determined in bronchoalveolar lavage fluid. Plasma 8-OHdG, IL-6 and TNF- $\alpha$  were also determined in peripheral blood. After DEP exposure, significant lung inflammation and injury with dose-response relationship were observed in both SH rats and SD rats. However, there is no difference on these parameters between SD rats and SH rats. We conclude that diesel exhaust particles may cause lung inflammation and injury, which may not be mediated through ROS production. Further studies are needed to clarify above findings.

455

#### APOE MOUSE MODEL OF ATHEROSCLEROSIS CONFER SUSCEPTIBILITY TO EXTRAPULMONARY EFFECTS OF DIESEL EXHAUST.

M. J. Campen, J. Seagrave, L. Blair, S. Lucas, A. Gigliotti, M. Reed and J. McDonald. *Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM*.

Particulate matter air pollution (PM) has been associated with increased incidence of cardiovascular mortality. Analysis of specific cause of death suggests that coronary artery disease (CAD) represents a major susceptibility trait. To test the hypothesis that CAD confers vulnerability to adverse PM health effects, we used a mouse model of hyperlipidemia and atherosclerosis, the ApoE knockout mouse fed a high fat diet for 16 weeks. During the 15th week of the high fat diet, ApoE mice and their genetic control (C57BL/6J) were implanted with radiotelemetry device to permit the acquisition of electrocardiographic (ECG) signals. After 7 days of recovery, mice (n=5 per group) were exposed to filtered air or diesel exhaust (0.5 or

5.0 mg/m<sup>3</sup>) for 6 h/d  $\times$  3 d. Raw ECG traces were recorded digitally to enable post hoc analysis. Mice were euthanized 18 hours following cessation of the final exposure. Lipid staining of the aortas confirmed the increased severity of atherosomatous disease in ApoE mice compared to C57BL/6J mice. Bronchoalveolar lavage analysis indicated significant pulmonary inflammation only in mice (both strains) exposed to the highest diesel concentration. Significant ECG findings, primarily decreases in heart rate ( $\Delta$ max = 70 bpm below filtered air-exposed mice), were present in ApoE mice but not C57BL/6J mice exposed to the high concentration of diesel. Measures of systemic oxidative stress (oxidized low-density lipoproteins) were also elevated (>5-fold) in the high concentration-exposed ApoE mice. These findings support the use of the ApoE mouse to investigate mechanisms of PM-associated adverse cardiovascular health effects. (This study was funded by an EPA STAR grant #R830839-010. This abstract does not necessarily reflect EPA policy.)

#### RELATIVE EFFICACY OF COMBUSTION EMISSION PARTICULATE MATTER TO ADSORB THE NEUTROPHIL-ATTRACTING CHEMOKINE IL-8.

J. Seagrave and C. Knall. *Lovelace Respiratory Research Institute, Albuquerque, NM.*  
Previous data indicated that when diesel exhaust (DE) particulate matter (PM) was incubated with a solution of IL-8, the ELISA-detectable activity in the supernatant of the suspension was depleted. Furthermore, the particles then gained the ability to activate neutrophils, suggesting that the IL-8 became adsorbed to the surface of the particles and remained in a bioactive form (Seagrave et al., 2004). These results suggested that inhaled PM could locally concentrate the neutrophil chemokine, potentially causing a strong localized inflammatory responses. We have extended these studies to examine the mechanisms of adsorption, determine whether other forms of PM had similar IL-8-adsorptive capacities, and quantify the neutrophil activating potential of the DE-PM-associated IL-8. Radiolabeled IL-8 associates with the particles, confirming that the loss of ELISA-detectable IL-8 is not loss of immunoreactive epitopes. Binding to DE-PM does not seem to be through either ionic or hydrophobic mechanisms, but is blocked weakly by larger proteins and somewhat more strongly by smaller proteins, suggesting intercalation into micropores. Dissociation of the chemokine is very slow in protein-free buffer, but is increased in the presence of competing proteins, suggesting rapid re-binding. We examined a wide range of particles including DE-PM from 5 sources, 2 types of gasoline engine emissions PM, 3 types of ambient PM, woodsmoke PM, and 3 forms of carbon black. Results showed a wide range of adsorptive capacity, even among the various types of DE-PM. DE-PM-bound IL-8 appeared to be slightly less effective in activating neutrophils than equivalent amounts of soluble IL-8. These data support the hypothesis that IL-8 adsorption to inhaled PM could contribute to localized inflammatory responses in regions of high PM deposition. This work was supported by the Health Effects Institute and the National Institutes of Health.

#### DIESEL EXHAUST PARTICLES SUPPRESS LPS-STIMULATED PRODUCTION OF PGE2 IN HUMAN ALVEOLAR MACROPHAGES: ROLE OF P38 MAPK AND ERK PATHWAYS.

M. C. Madden<sup>1</sup>, S. Becker<sup>1</sup> and S. Mundandhara<sup>2</sup>. <sup>1</sup>*ORD, NHEERL, HSD, Clinical Research Branch, USEPA, Chapel Hill, NC* and <sup>2</sup>*CEMALB, University N. Carolina, Chapel Hill, NC.*

Studies have reported associations between exposure to ambient particulate matter (PM) and adverse health effects, including respiratory and cardiovascular effects. Diesel exhaust particles (DEP) compose a significant fraction of PM in some areas. Alveolar macrophages (AM), the key players in lung host defense mechanisms against bacteria, function by releasing soluble mediators such as cytokines and prostanglandins (PG). This study was designed to investigate the effect of DEP on human AM responsiveness to LPS by monitoring the release of PGE2 and also to study the signal transduction pathways involved in the expression of cyclooxygenase 2 (COX2). AM were exposed *in vitro* to Standard Reference Material (SRM) 2975, SRM 1650, SRM 1975 (dichloromethane extract of SRM 2975) (SRMs from NIST) or carbon black (CB) for 24hr, and subsequently incubated with LPS (1ng/ml) for 24hr. DEPs, but not CB, suppressed the release of PGE2 by LPS-stimulated AM. This suppression is significant after 4h of LPS stimulation. mRNA expression of COX2 was not affected by all DEP treatment at 2h of LPS treatment, but there was a decreased COX2 mRNA expression (>50%) after 4h of LPS treatment, suggesting a feedback inhibition. However, COX2 protein levels were equivalent in vehicle and DEPs exposed AM. Further studies to investigate the effect of DEPs on p38 MAPK and ERK signaling pathways showed that DEPs alone (24 hr) did not inhibit the phosphorylation of p38 or p42. However, DEP exposure in-

duced a decrease in phosphorylated p38 and p42 (vs vehicle) with LPS stimulation. The data indicate DEPs suppress the ability of AM to produce PGE2 in response to LPS, despite having no effect on the COX-2 protein expression. The data suggest that organic extract was capable of inducing these responses without the particle core. Alteration of macrophage signaling pathways may play a role in some PM-induced health effects. #### SULFORAPHANE, A POTENT PHASE 2 INDUCER, INHIBITS THE ADJUVANT EFFECT OF AEROSOLIZED DIESEL EXHAUST PARTICLES IN A MURINE MODEL FOR OVALBUMIN SENSITIZATION.

M. J. Whitekus, S. A. Ritz and D. Diaz-Sanchez. *UCLA School of Medicine/Division of Clinical Immunology and Allergy, UCLA, Los Angeles, CA.*

Human epidemiological studies suggest a correlation between exposure to ambient particulate matter and adverse health effects while animal studies indicate diesel exhaust particle (DEP) exposure can enhance asthma-like symptoms. One mechanism whereby DEP is thought to exacerbate endpoints associated with asthma is by oxidative stress. Our previous studies show that antioxidants can mitigate increases in antigen specific IgG1 and IgE levels caused by DEP. Here we show that D, L-sulforaphane (broccoli extract), a potent phase 2 inducer, was able to mitigate antigen specific increases in IgG1 and IgE caused by DEP. 24 balb/c mice were treated with 4.5 umol/mouse/day D, L-sulforaphane and 24 were treated with olive oil (vehicle) by gavage for 7 days prior to a 10-day inhalation treatment, the D, L-sulforaphane treatment continued through the 10-day inhalation treatment. The mice were placed into 4 different inhalation exposure groups (6 mice/group), saline (20 minute/day), ovalbumin (OVA, 20 minutes/day), DEP (60 minutes/day) and DEP+OVA and treated by inhalation for 10 days. Sera samples were taken 4 days after the last inhalation treatment. Mice that did not receive D, L-sulforaphane treatment presented the typical pattern of OVA-specific IgG1 induction, i.e., DEP+OVA treated mice showed high levels of OVA-IgG1 (307 ng/ml) while saline, OVA only and DEP only treated mice all had OVA-IgG1 levels below 100 ng/ml. However, mice treated with D, L-sulforaphane prior to DEP+OVA treatment showed a decrease in OVA-IgG1 levels (20ng/ml). This same pattern held true for OVA-IgE levels, i.e., OVA+DEP treated mice presented high OVA-IgE levels compared to mice treated with saline, OVA only or DEP only and mice pre-treated with D, L-sulforaphane prior to DEP+OVA treated had significantly reduced OVA-IgE levels. This data suggests that induction of phase 2 enzymes can be protective against the adjuvant effects of DEP.

#### THE INCREASE IN TOTAL IGE IN SERUM OF FEMALE MICE AFTER INTRANASAL EXPOSURE OF CARBON BLACK PARTICLES WITH POLLEN.

K. Kobayashi<sup>1</sup>, K. Itoh<sup>1</sup>, Y. Inoue<sup>1</sup>, Y. Kudo<sup>1</sup>, M. Tsunoda<sup>1</sup>, T. Satoh<sup>1</sup>, C. Yashiro<sup>2</sup>, Y. Sugita-Konishi<sup>2</sup> and Y. Aizawa<sup>1</sup>. <sup>1</sup>*Preventive Medicine and Public Health, Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan* and <sup>2</sup>*Division of Microbiology, National Institute of Health Sciences, Setagaya-ku, Tokyo, Japan.*

Carbon black particles (CB) have been widely used for commercial products. The risk of allergic diseases induced by inhalation of carbon black particles is a growing concern. We evaluated allergic effects of CB in an intranasal exposure model in BALB/c mice. CB (Mitsubishi Kasei) and purified pollen were suspended in PBS. Female BALB/c mice, 6-8 weeks of age, were intranasally instilled by pipetting a total volume of 10  $\mu$ l of the suspensions for three consecutive days. The amount of CB administered for each group was 0, 33.5, 100 and 300  $\mu$ g, and that of pollen for the groups was 5  $\mu$ g. For additional groups, one group was administered 300  $\mu$ g of CB only, and the other group was administered PBS only. Ten days after administration, each mouse was intranasally instilled suspended 5  $\mu$ g of pollen in PBS. At 15 days after the first administration, blood was collected from a tail of each mouse. Serum total IgE and pollen-specific IgE were determined by ELISA. The mean value of total IgE of the group administered 100, or 300  $\mu$ g of CB with pollen was significantly higher than that of the group administered pollen only. The means of total IgE of the high-dose groups were also significantly higher than that of the group administered PBS. The mean value of total IgE of the group administered CB only was slightly higher than that of the group administered pollen or PBS only. The mean values of pollen-specific IgE of the groups administered CB and pollen were higher, however, it did not reach the significant level. The administration of CB with pollen by instillation increased total IgE at the levels of 100  $\mu$ g and over. Since the mean values of pollen-specific IgE was not different significantly among the groups, CB may have a direct effect of increasing IgE. High dose exposure of CB may be related to allergic diseases.

DIESEL AND HARDWOOD SMOKE EMISSIONS DIFFERENTIALLY AFFECT CLEARANCE AND INFLAMMATION OF INTRATRACHEALLY INSTILLED PSEUDOMONAS AERUGINOSA.

M. Reed<sup>1</sup> and K. S. Harrod<sup>2</sup>. <sup>1</sup>Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM and <sup>2</sup>Infectious Disease Program, Lovelace Respiratory Research Institute, Albuquerque, NM.

Diesel exhaust (DE) and wood smoke are contributors to indoor, outdoor, and occupational air pollution. Of the many cardio-respiratory health outcomes associated with episodic and long-term exposures to air pollution, respiratory infection is a major contributor to morbidity and mortality. As part of a larger health assessment of multiple anthropogenic source emissions, mice were exposed to DE and hardwood smoke (HWS) and instilled with an inoculum of a common respiratory pathogen, *Pseudomonas aeruginosa*. Bacterial clearance and pulmonary inflammation were assessed. DE was generated from a 2000 model Cummins 5.9L, turbo diesel engine operated on national average certification fuel on a modified version of the EPA heavy-duty test cycle. HWS was generated by burning consistent weights and sizes of oak in an uncertified stove operated on a 3-phase cycle: kindling, high-burn, and low-burn. DE and HWS were diluted to particulate matter (PM) mass concentrations of 30, 100, 300, and 1000  $\mu\text{g}/\text{m}^3$  respectively. Young C57Bl/6 mice were exposed to DE and HWS for 6h/d, 7d/ wk, for 1wk and 6mo, instilled with bacteria, and sacrificed after 18h in clean air. Colony counts of serial diluted lung homogenate and histopathology were assessed. HWS had no overall effect on bacterial clearance or inflammatory histopathology at either time point. Consistent with our previous observations in a model of respiratory syncytial virus infection, DE decreased bacterial clearance and exacerbated inflammatory histopathology. These results indicate that resistance to respiratory bacterial infection is differentially affected by PM-containing pollutant mixtures from different sources. This abstract is funded by the National Environmental Respiratory Center (NERC) with support of multiple government and industry sponsors including the USEPA. This work is not intended to represent the view of any NERC sponsor.

SAFETY EVALUATION OF AEROSOLIZED CYCLOSPORINE IN RATS AND DOGS.

T. Wang<sup>1</sup>, R. Steigerwalt<sup>1</sup>, M. Lynch<sup>2</sup>, R. Kovelesky<sup>1</sup>, C. Rodriguez<sup>1</sup> and K. Sprugel<sup>3</sup>. <sup>1</sup>Drug Assessment and Development, Chiron Corporation, Emeryville, CA and <sup>2</sup>Toxicology, Battelle, Columbus, OH.

Lung transplantation treated by current systemic regimens has the highest rate of rejection associated with any current transplant procedure. Local immunosuppressive therapy with aerosolized Cyclosporine Inhalation Solution (CyIS) has the potential to improve survival after lung transplants by delivering high concentrations of cyclosporine to the site of rejection while reducing systemic drug exposure and side effects. The objective of these studies was to evaluate the potential toxicity of CyIS when given by nose-only inhalation to rats and dogs for 28 consecutive days followed by a recovery period. Sprague-Dawley rats received total inhaled doses of 0 (air control), 0 (vehicle, propylene glycol), 7.4, 24.3 and 53.9 mg cyclosporine/kg/day. Daily administration of CyIS did not result in any observable accumulation in blood or lung tissue. Treatment-related effects were observed in all dose groups including mortality (high dose only), clinical observations, body weight, food consumption, and clinical and anatomic pathological parameters. Systemic effects were consistent with those known for cyclosporine. There were no respiratory or systemic effects of high doses of the propylene glycol vehicle relative to air control. A NOAEL of 24.3 mg cyclosporine/kg was established for local effects of CyIS in the respiratory tract. In a separate study, beagle dogs were exposed to 0, 4.4, 7.7 and 9.7 mg cyclosporine/kg/day. Minimal, focal laryngeal ulceration was observed in the mid dose males on Day 29 and the high dose males after recovery. There were no adverse effects in clinical observations, body weights, food consumption, electrocardiograms, ophthalmic examinations, respiratory function, or clinical and anatomic pathology. The NOEL is 4.4 mg cyclosporine/kg in the dogs. Toxicokinetics from the rat study showed that the exposure of cyclosporine was ~18 times higher in the lung tissue compared to the blood. These studies support the use of CyIS for prophylaxis of lung rejection in patients receiving allogeneic lung transplants.

TOXICITY OF A SELECTIVE INHIBITOR OF LCK IS DUE TO INHIBITION OF LCK AND IS NOT CHEMOTYPE-RELATED.

R. F. Stachlewitz<sup>1</sup>, A. J. Schwartz<sup>1</sup>, B. Bettencourt<sup>1</sup>, J. Syed<sup>1</sup>, D. Conlon<sup>1</sup>, J. E. Erickson<sup>1</sup>, E. O'Connor<sup>1</sup>, D. J. Calderwood<sup>2</sup> and G. C. Hirst<sup>2</sup>. <sup>1</sup>Discovery Safety, Metabolism & Pharmacokinetics, Abbott Bioresearch Center, Abbott Laboratories, Worcester, MA and <sup>2</sup>Chemistry, Abbott Bioresearch Center, Abbott Laboratories, Worcester, MA.

Lck, a Src family tyrosine kinase involved in the activation of T cells, is a potential target to prevent acute rejection of transplanted organs. We have developed potent inhibitors of Lck that block T cell activation and prevent acute rejection in the rat

heterotopic heart transplantation model. However, a src-family selective Lck inhibitor showed extensive toxicity when dosed at 10 X efficacious AUC in 14-day rodent toxicity studies. Histologic changes caused by this compound included mixed inflammatory infiltrate and focal necrosis in the heart, lymph nodes, eye and harderian gland, tubular necrosis in the kidney, sperm granuloma in the epididymis, and thymic and splenic atrophy. This Lck inhibitor also caused significant loss of body weight, lymphopenia, neutrophilia and decreases in plasma proteins and serum albumin. We needed to determine whether the toxicity of these inhibitors was due to inhibition of the target Lck or was linked to the chemotype. Structure-activity analysis showed the critical nature of a methoxy group of this compound for activity against Lck; hence we synthesized a structurally close desmethoxy analog of this LCK inhibitor. As expected, the desmethoxy analog was 15-fold less potent against Lck compared to the parent compound but exhibited relative similar potency against other Src family members tested and analogous PK characteristics. Doses of both compounds were administered that gave similar exposure in a 14-day rat toxicity study to compare the toxicology of the two compounds. The desmethoxy analog did not show any of the same toxicity as parent compound. It is concluded that the toxicity of this Lck inhibitor is a result of inhibition of Lck and is not linked to the chemotype of these compounds. Thus, the inhibition of Lck as a therapeutic modality appears to be limited by mechanism-based toxicity.

THE IMMUNOHISTOCHEMICAL EXPRESSION OF UROPLAKIN III IN RAT BLADDER TISSUE.

S. Grainger. Covance Laboratories Ltd., Harrogate, United Kingdom. Sponsor: D. Everett.

This poster presents the results of an investigation into the immunohistochemical staining pattern of the differentiation marker, uroplakin III, and its correlation with the proliferation marker Ki67 in urothelial lesions. Several current drug development strategies involve the assessment of PPAR (peroxisome proliferator-activated receptor) agonists as potential therapeutics for the treatment of Type II (matute-onset) diabetes and dyslipidaemias. Histopathology in preclinical rodent toxicity studies on this class of compounds has revealed multi-organ pathology, including an increased incidence of pre-neoplastic and neoplastic bladder lesions. Ninety percent of the apical surface of mammalian urothelium is covered by rigid looking proteinaceous plaques, known as asymmetric unit membranes (ASMs). As the principal differentiation product of urothelium they are believed to play a role in urothelial structure and function. ASMs contain four major sub-units of uroplakins, of which uroplakin III possesses domains accessible for use in immunolocalisation studies. Retrospective samples of bladder were obtained from in-house rat carcinogenicity studies to include normal tissue, and bladder showing hyperplastic, benign and malignant lesions as observed by H&E histopathology. Immunohistochemical staining patterns using an antibody against uroplakin III in these tissues were assessed. Uroplakin III expression was also correlated with expression of Ki67, a general cell proliferation antigen.

BORTEZOMIB (VELCADE®) DOES NOT INDUCE THE FORMATION OF PROTEINASE K-RESISTANT PRION PROTEIN IN MURINE AND HUMAN NEURONAL CELL LINES *IN VITRO*.

V. G. Sasseville<sup>1</sup>, A. Raczyński<sup>1</sup>, V. Csiszmadia<sup>1</sup>, W. Riordan<sup>1</sup>, J. Ironside<sup>2</sup>, M. Rolfe<sup>1</sup> and P. Bouchard<sup>1</sup>. <sup>1</sup>Millennium Pharmaceuticals, Inc., Cambridge, MA and <sup>2</sup>University of Edinburgh, Edinburgh, United Kingdom. Sponsor: C. Alden.

Prion diseases are associated with the conversion of cellular prion protein (PrP<sup>C</sup>) to a protease-resistant isoform (PrP<sup>Sc-like</sup>). A PrP<sup>Sc-like</sup> form accumulated when PrP transfected cells were subjected to complete proteasome inhibition, suggesting a potential theoretical link between proteasome inhibition and the pathogenesis of prion disease. However, these findings were not duplicated in nontransfected, but normal wild-type PrP-expressing neuronal cell lines and primary neurons. This discrepancy has been attributed to the potential of proteasome inhibitors to selectively induce transcription from expression constructs carrying a heterologous viral promoter. We determined if pharmacologically relevant concentrations of bortezomib resulted in the accumulation of proteinase K resistant forms of PrP in nontransfected mouse (N2A, GT-1) and human (NT-2) neuronal cells. Cells were exposed to bortezomib and other unrelated proteasome inhibitors (lactacystin, epoxomicin, and MG 132) for 16 hours and were examined by Western. Verification of functional proteasome inhibition was shown by accumulation of c-jun after exposure of each cell line to the proteasome inhibitors. All cell lines had abundant normal PrP<sup>C</sup> expression and no indication of an increase in the amount of endogenous PrP<sup>C</sup> or the conversion of it into a PrP<sup>Sc-like</sup> form upon treatment with any of the proteasome inhibitors. In

conclusion, this study and recent literature indicates that *in vitro* studies with non-transfected neuronal cell lines expressing wild-type PrP exposed to bortezomib do not show increased levels of PrP, nor the formation of proteinase-resistant forms. Previous preclinical studies with bortezomib indicated that it does not appreciably cross the blood-brain barrier, and in toxicity studies, there has been no evidence of prion-related disease pathology. Thus, the experimental data indicates that there is negligible risk associated with proteasome inhibition and prion-related disease.

#### PHARMACOLOGY AND TOLERABILITY OF INS50589, A REVERSIBLE P2Y<sub>12</sub> RECEPTOR ANTAGONIST WITH ANTI-PLATELET AGGREGATION ACTIVITY, ADMINISTERED BY CONTINUOUS INTRAVENOUS INFUSION IN RATS AND DOGS.

M. S. Cowlen, C. S. Crean, R. Krishnamoorthy, P. S. Watson, J. L. Boyer, W. M. Peterson and S. A. Anderson. *Inspire, Durham, NC.*

The objective of this study was to evaluate the pharmacology and tolerability of INS50589 when administered by continuous intravenous infusion to Sprague-Dawley rats and Beagle dogs. Animals were infused for up to 24 hours with INS50589 at concentrations from 0.3 to 30 mg/kg/h in rats and 0.03 to 1.5 mg/kg/h in dogs. Blood was collected for assessment of ADP-stimulated *ex vivo* platelet aggregation and determination of drug plasma levels. Platelet counts were determined by standard hematology. Tolerability to treatment was assessed by clinical observations and serum chemistry. The results indicate that infusion of INS50589 produced a rapid, dose-dependent inhibition of *ex vivo* platelet aggregation in rats and dogs. No treatment-related changes in platelet count were observed in either species. In rats, infusion of INS50589 at doses from 3 to 20 mg/kg/h resulted in 70-100% inhibition of platelet aggregation at all time points. Half-maximal inhibition of platelet aggregation was observed at plasma levels of INS50589 of approximately 185 nM. No adverse clinical signs were observed during or after infusion of rats with INS50589 at doses up to 10 mg/kg/h for 24 h. In dogs, maximal inhibition of platelet aggregation was observed at doses between 0.3 and 1.0 mg/kg/h. The inhibitory effect reached steady state within 30 minutes, was maintained for the duration of infusion at all concentrations tested, and reversed rapidly after the end of infusion. Half-maximal inhibition of platelet aggregation was attained at plasma levels of INS50589 of approximately 63 nM. The plasma half-life of INS50589 was 7 minutes in dogs. INS50589 was well tolerated in dogs when infused at a dose of 1.5 mg/kg/h for 24 hours. In conclusion, intravenous infusion of INS50589 induced rapid, reversible inhibition of platelet aggregation, and was well tolerated at doses up to 1.5 mg/kg/h in dogs and 10 mg/kg/h in rats.

466

#### RANGE-FINDING TOXICITY STUDIES WITH SQ109, AN ANTI-TUBERCULAR AGENT, IN RATS AND DOGS.

E. Glaze<sup>1</sup>, Y. Chen<sup>2</sup>, L. Alex<sup>2</sup>, R. Morrissey<sup>3</sup>, L. Jia<sup>1</sup>, P. Noker<sup>4</sup> and J. Tomaszewski<sup>1</sup>. <sup>1</sup>NIH, Rockville, MD, <sup>2</sup>University of Illinois, Chicago, IL, <sup>3</sup>Pathology Associates, Chicago, IL and <sup>4</sup>Southern Research Institute, Birmingham, AL.

Pre-clinical range-finding studies were conducted with SQ109 (N-adamantan-2-yl-N'-[3, 7-dimethyl-octa-2, 6-dienyl]-ethane-1, 2-diamine dihydrochloride) to determine its relative toxicity. Doses of 0, 7.2, 36, and 54 mg/m<sup>2</sup>/d i.v., and 0, 144, 360 and 900 mg/m<sup>2</sup>/d p.o. (gavage) were given to male Fischer 344 rats (3/group) for up to 14 days. Lethality occurred with doses  $\geq$ 360 mg/m<sup>2</sup>/d p.o. (Days 3-9). Microscopic evaluation of tissues from these rats showed hypertrophy and glycogen depletion of liver, depletion or necrosis of lymphoid tissue and bone marrow, necrosis of GI tract and hyperplasia of urinary bladder. Hyperplasia of urinary bladder was also observed for 1/2 rats surviving to Day 15. Dose-dependent lymphopenia ( $\geq$ 360 mg/m<sup>2</sup>/d p.o.) and liver toxicity (900 mg/m<sup>2</sup>/d p.o.) could be identified early with clinical pathology analyses. No toxicity was seen with 144 mg/m<sup>2</sup>/d p.o. or  $\leq$ 54 mg/m<sup>2</sup>/d i.v. Male and female Beagle dogs (1/sex/group) received SQ109 doses of 0, 100, 200, 240 (female) and 400 mg/m<sup>2</sup>/d i.v., and 0, 100, 400 and 1200 mg/m<sup>2</sup>/d p.o. (gavage) for up to 28 days. Dogs receiving  $\geq$ 400 mg/m<sup>2</sup>/d p.o. were also given ondansetron to prevent emesis. Both dogs in the 400 mg/m<sup>2</sup>/d i.v. group were euthanized moribund on Day 2. The male dog had moderate inflammation of the lung and minimal to mild degeneration of liver, kidney and heart, hemorrhage in gall bladder, and necrosis or depletion of lymphoid tissues upon microscopic evaluation. Hepatobiliary and kidney toxicity were identified with clinical pathology analyses prior to euthanasia. Toxicologically relevant changes in body weights and clinical pathology were not observed with  $\leq$ 240 mg/m<sup>2</sup>/d i.v. or  $\leq$ 1200 mg/m<sup>2</sup>/d p.o. SQ109 was present in plasma at all oral doses administered, and plasma concentrations increased with repeated dosing. The MTD for SQ109 is  $\geq$ 54 (i.v.) and  $\sim$ 144 (p.o.) mg/m<sup>2</sup>/d for rats, and NOAEL is 240 (i.v.) and  $\sim$ 1200 (p.o.) mg/m<sup>2</sup>/d for dogs (N01-CM-87103 and N01-CM-07110).

#### SAFETY ASSESSMENT OF A NOVEL P38 INHIBITOR IN CYNOMOLGUS MONKEYS FOLLOWING DAILY ORAL DOSING.

S. L. Wild<sup>1</sup>, T. Pabst Marra<sup>1</sup>, G. Jang<sup>1</sup>, W. Min<sup>1</sup>, R. House<sup>3</sup>, A. Mould<sup>2</sup> and M. Cosenza<sup>1</sup>. <sup>1</sup>Amgen Inc., Thousand Oaks, CA, <sup>2</sup>Covance Laboratories Inc., Madison, WI and <sup>3</sup>DynPort Vaccine Company LLC, Frederick, MD.

Inhibitors of the p38 MAP kinase enzyme are thought to be a viable agents for the treatment of inflammatory diseases. A small molecule inhibitor of p38 MAP kinase (e.g. AMG 548) has been evaluated in a repeated dose toxicology study in cynomolgus monkeys. Monkeys (4/sex/group) were dosed orally for at least 28 consecutive days with doses of 0 (control article was 1% Tween® 80 and 2% hydroxypropyl methylcellulose), 3, 25, and 75 mg/kg/day. Recovery animals (2/sex) were included for the control and high dose levels and were evaluated following a 4-week recovery period. Animals were evaluated for clinical observations, body weight, food consumption, clinical pathology, electrocardiography, ophthalmology, pharmacodynamic effects, toxicokinetics, and histopathology. Several animals had clinical observations of watery, liquid stool throughout the study that appeared to be related to treatment. In extreme cases the liquid stool resulted in dehydration, lack of food consumption, and morbidity. Minor, reversible effects on clinical pathology were noted and the gastrointestinal tract was the target organ. There were no test-article related effects noted on electrocardiographic measurements, ophthalmic examinations, body temperatures, or body weights. AMG 548 had a pharmacodynamic effect to inhibit lipopolysaccharide (LPS)-induced production of tumor necrosis factor alpha (TNF- $\alpha$ ) and interleukin-1 beta (IL-1 $\beta$ ). No accumulation or consistent sex difference in exposure was observed; exposure on day 26 increased greater than dose-proportionally across the dose range. Based upon clinical observations, clinical pathology, and histopathology, a no observed adverse effect level (NOAEL) was considered to be 3 mg/kg/day (male) and 25 mg/kg/day (female) following 28 days of repeated oral dosing in cynomolgus monkeys.

468

#### CYTOFLAVINE REDUCES HYPOXIA CAUSED BY SEVERE ALCOHOLIC INTOXICATION AND MILD HEAD TRAUMA.

A. D. Tsvinsky<sup>1,3</sup>, B. V. Batotsyrenov<sup>2</sup>, T. N. Savateeva<sup>1</sup>, V. E. Marusanov<sup>3</sup> and A. L. Kovalenko<sup>1</sup>. <sup>1</sup>Institute of Toxicology, St.Petersburg, Russian Federation, <sup>2</sup>Regional Poison Center, St.Petersburg, Russian Federation and <sup>3</sup>Postgraduate Medical Academy, St.Petersburg, Russian Federation. Sponsor: J. Waksman.

**Background:** Severe alcoholic intoxication is accompanied by hypoxia, which may be worsened even by mild head trauma. Cytoflavine (C) is a novel antioxidant; each 10ml vial of it contains succinate (1g), N-methylglucamine (1.65g), riboflavin (0.02g), nicotinamide (0.1g) and inosine (0.2g). It can reverse hypoxic damage via improvement of mitochondrial function. The aim of our study has been to assess C influence on parameters of oxygen transfer and consumption. **Methods:** 21 patients (pts) with blood ethanol level more than 0.25g/dl sustaining head trauma were included into single blind study of C. All of them were comatose and mechanically ventilated. 12 pts received C (0.15ml/kg b.i.d. IV). Arterial and venous blood and expired air were assessed for O<sub>2</sub> and CO<sub>2</sub> content. According to Fick's principle the parameters of ventilation, circulation, oxygen transfer and consumption were calculated. The data are presented as means $\pm$ SEM. **Results:** The admitted pts had dead space to tidal volume ratio increased up to 0.54 $\pm$ 0.04 (compared with normal values 0.32 $\pm$ 0.04), and increased right to left shunt to 13% $\pm$ 2% of cardiac output. Oxygen consumption and extraction parameters were non-significantly decreased. By the 3rd day the oxygen consumption and extraction restored in C group. In the control group the oxygen consumption progressively decreased to 104 $\pm$ 12ml/min\*m<sup>2</sup> (normal values 149 $\pm$ 16). Oxygen extraction has also been reduced to 19 $\pm$ 2ml/l in the control group (normal values 37.8 $\pm$ 0.4). There was a trend to reduction of right to left shunt in C group, but it remained disturbed in the control group. A trend to decreased duration of coma and incidence of complications was found in pts received C. **Conclusion:** Cytoflavine restores oxygen transfer and utilization in severe alcoholic intoxication complicated with mild head injury. The mechanism includes succinate-dependent improvement of mitochondrial respiration described earlier.

469

#### TEMPO ATTENUATION OF DICLOFENAC ADDUCTION AND ENTEROPATHY.

L. Kaphalia<sup>1</sup>, J. F. Aronson<sup>1</sup>, K. A. Nethery<sup>1</sup> and M. Treinen Moslen<sup>1,2</sup>. <sup>1</sup>Pathology, University of Texas Medical Branch, Galveston, TX and <sup>2</sup>Internal Medicine, University of Texas Medical Branch, Galveston, TX.

**Background:** Therapy with diclofenac and other non-steroidal anti-inflammatory drugs (NSAIDs) is occasionally complicated by small intestinal permeability and other indicators of enteropathy. One strategy reported to protect against NSAID enteropathy is pretreatment with Tempo (2, 2, 6, 6-tetramethyl-1-piperidinyloxy),

a nitroxide radical scavenger (Davies and Jamali, 1997). Objective: We investigated the unknown mechanism responsible for the protective effect of Tempo pretreatment using our established rat model of diclofenac enteropathy where addition of enterocytes by the reactive acyl glucuronide metabolites of diclofenac appears to be a causal factor in small intestinal ulceration. Experimental Design: Sprague-Dawley rats were pretreated at 1 hr with Tempo (100 mg/kg) or vehicle and then treated with diclofenac (50 mg/kg). Extent of enteropathy was measured by counting ulcers and assessing intestinal leakage by measuring serum protein at 3, 12 or 24 hours. Patterns of diclofenac addition to proteins in liver and intestinal tissues were assessed by western blot analysis and immunohistochemistry. Serum concentrations of diclofenac were determined by HPLC. Results: Compared to rats treated with diclofenac alone, which typically had ~90 intestinal ulcers by 12 hrs, Tempo pretreated rats had < 5 ulcers at 12 hrs and showed sustained protection against intestinal leakage at 24 hrs. At 3 hr, Tempo pretreated rats had 65% lower serum concentration of diclofenac and markedly less drug-protein addition in liver and intestine. Conclusions: Possible effects on diclofenac uptake, distribution or bioactivation could explain why the observed protection against diclofenac enteropathy in Tempo pretreated rats was associated with lower systemic drug levels and less tissue addition. (Supported by NIH DK 56494, DK56338, and NIEHS ES06676)

ENDOSCOPY STUDY OF THE GASTROINTESTINAL TOLERANCE OF STRONTIUM RANELATE IN CYNOMOLGUS MONKEYS.

C. Fisch<sup>1</sup>, M. Attia<sup>1</sup>, F. Dargent<sup>1</sup>, S. de Jouffrey<sup>1</sup>, I. Dupin-Roger<sup>2</sup> and J. Claude<sup>3</sup>. <sup>1</sup>*CIT, Evreux, France*, <sup>2</sup>*Laboratoires Servier, Courbevoie, France* and <sup>3</sup>*Paris V University, Paris, France*.

The objective of this study was to evaluate the digestive tolerance of strontium ranelate, a new antiosteoporotic drug, and to compare it to that of another strontium salt, strontium chloride. Strontium ranelate, strontium chloride or placebo were administered orally in capsules to three groups of two male and two female cynomolgus monkeys once daily for 7 days at a dose-level of 2g/day, which is the recommended dose in therapeutic use. Endoscopic examination of the esophagus, stomach and the first part of the duodenum was performed in fasted animals approximately 3 hours after the first (Day 1) and last dosing (Day 7). Where lesions were found on Day 7, further examinations were performed on Days 8 and 14 to assess recovery. Treatment with placebo and strontium ranelate did not result in any visible damage in the gastric mucosa, esophagus or first part of the duodenum. In contrast, acute superficial gastric damage was noted in all animals receiving strontium chloride, consisting of hemorrhagic and erosive lesions (ulceration in one male and marked congestive arthritis in one female). These effects were reversible after cessation of treatment. Microscopic examination of biopsy samples from the site of these gastric lesions revealed moderate granulocyte infiltration, indicating a local irritative origin of the lesions. It is concluded that oral administration of strontium ranelate is well tolerated by the gastric mucosa of cynomolgus monkeys while strontium chloride induces reversible superficial gastric lesions. This good gastrosophageal tolerance has been confirmed during the clinical trials of strontium ranelate.

TC 1734-112: PRECLINICAL SAFETY ASSESSMENT OF A SELECTIVE  $\alpha 4\beta 2$  NICOTINIC ACETYLCHOLINE RECEPTOR AGONIST.

V. M. Traina, G. J. Gatto and M. Bencherif. *Toxicology, Targacept, Inc., Winston-Salem, NC*.

TC-1734-112 is an agonist of the central  $\alpha 4\beta 2$  nicotinic acetylcholine receptor with a high binding affinity to membrane preparations from rat brain. The compound is currently under development in our laboratories in Phase 2 clinical trials for the treatment of AAMI indication. To support safety, TC-1734-112 has been tested in preclinical animal models including acute, subacute 2- and 4- week studies, subchronic 90 day studies, chronic 6-month, Segment 2 reproductive, mutagenicity, and safety pharmacology studies. TC-1734-112 was well tolerated in all repeat dose studies in the rat and dog and changes were observed at high treatment doses and blood levels: 1) bradycardia in the dog at 10 and 30 mg/kg; 2) testicular and accessory sex organ pathologies in the rat at 150 and 200 mg/kg; mild centrilobular hypertrophy with alkaline phosphatase elevations in the rat at 50, 150, and 200 mg/kg; and alveolar histiocytosis in the rat at 150 mg/kg. Dosages of 3 mg/kg in the dog and 5 mg/kg in the rat were considered the NOEL. There were no ophthalmoscopic or electrocardiogram alterations. TC-1734-112 was not mutagenic or teratogenic. For the toxicokinetics, the absorption of TC-1734 was rapid with a Tmax at about one hour. The Cmax and the AUC were generally greater for females than males and there was a general trend for values to increase as the study proceeded. Accordingly, if the maximum clinical dose is projected at about 1 mg/kg, a sufficient margin of safety exists to support long term clinical trials.

OPIOIDS: OCCUPATIONAL CONTACT DERMATITIS AND THE LOCAL LYMPH NODE ASSAY (LLNA).

M. J. Olson<sup>1</sup>, F. J. Guerriero<sup>2</sup>, M. Cunningham-Hill<sup>2</sup> and N. Tapscott<sup>2</sup>. <sup>1</sup>*GlaxoSmithKline, Research Triangle Park, NC* and <sup>2</sup>*GlaxoSmithKline, Philadelphia, PA*.

Allergy to some opioid phenanthrene derivatives, including morphine and codeine, is recognized as a hazard in health care and pharmaceutical workers handling these materials. Retrospective assessment of human cases of occupational allergy by patch test has been used to categorize a limited number of opioids as dermal allergens. However, very little information is available on the use of laboratory assays to prospectively assess the allergenic potential of specific opioids. Recent trends in opioid chemistry suggest that this gap should be addressed in evaluating the potential impact of less well characterized opioids on occupational health. For example, *Papaver somniferum* (opium poppy) strains have been selectively developed to express high levels of the phenanthrene derivatives thebaine and oripavine as a means to provide raw materials for synthesis of newer medically important opioids. In addition, chemical syntheses yield stable, isolated substances such as 14-hydroxynormorphinone (NHM) from bioactive, native opioids. NHM is non-analgesic and relatively safe to transport and process, but can be readily chemically converted to medically useful opioid antagonists. As an initial step in quantifying the allergenic potential and potency of materials such as NHM, thebaine, and oripavine, we have assessed these materials in the LLNA. In addition, since opioids can trigger histamine release, these materials have been assessed for potential to irritate eye and skin in the GSK tiered worker safety test battery. The LLNA predicts NHM as a sensitizer with concentration-dependent increases >3-fold in stimulation index observed at applied concentrations of 10% and 25% and a <3-fold SI at 5%. NHM was non-irritant to skin but was a mild eye irritant. NHM has also been identified recently as a human dermal allergen. Very similar LLNA and dermal/ocular irritation findings for oripavine have also been obtained. In summary, the LLNA used in conjunction with assays for direct irritant potential provides useful data for prospectively assessing occupational hazards of opioids.

USE OF NALTREXONE TO PREVENT ADVERSE EFFECTS OF SUFENTANIL IN BEAGLE DOGS.

M. Soloviev<sup>1</sup>, M. J. Taylor<sup>2</sup>, T. R. Edwards<sup>1</sup>, J. Culwell<sup>2</sup>, C. R. Rampersand<sup>2</sup>, J. A. Felice<sup>2</sup>, D. Argonza<sup>2</sup>, M. Calimlin<sup>2</sup>, R. Ordonio<sup>2</sup>, R. Afan<sup>2</sup>, T. J. Siacotos<sup>2</sup> and G. J. Schaefer<sup>1</sup>. <sup>1</sup>*WIL Research Laboratories, Ashland, OH* and <sup>2</sup>*Durect Corporation, Cupertino, CA*.

Sufentanil citrate is a potent analgesic used in the maintenance of balanced general anesthesia. It is also used in a proprietary drug formulation for an implantable drug delivery device, which is expected to be valuable in the treatment of chronic pain. Performance testing of such devices requires implantation in different animal species including non-rodents. The beagle dog is widely used in non-clinical safety studies. The lethal dose for IV administration in male beagle dog is approximately 10  $\mu$ g/kg. In order to evaluate the final human configuration of the device, which carries a high concentration of Sufentanil, purpose-bred adult male beagle dogs were each subcutaneously implanted with five CHRONOGESIC® Sufentanil osmotic pumps (DURECT Corp, Cupertino, CA) and carefully observed for more than one month. Animals were treated with naltrexone to minimize adverse effects of Sufentanil. Each osmotic pump delivered Sufentanil at 320  $\mu$ g/day. Animals (body weights 11.2 and 13.3 kg) received 1600  $\mu$ g/day total; daily dosage levels were 142 and 120  $\mu$ g/kg. Starting one day prior to implantation, animals were given tablets of naltrexone HCl (50 mg, b.i.d. at 6 a.m. and 3 p.m., orally). No clinical signs of Sufentanil overdose were observed. Animals showed only minor decreases in body weight (mean 0.4 kg) during the first week after implantation, followed by steady gains of 0.1, 0.4, and 0.2 kg during the following three weeks. Food consumption (mean 398 g/day before treatment) was also slightly decreased during the first week (255 g/day) and then showed a steady increase of 314, 323, 346 g/day during the following weeks. Thus, the used naltrexone treatment regimen was effective in prevention of the adverse effects of otherwise lethal doses of Sufentanil in beagle dogs.

FLORIDA RED TIDES: MOLECULAR THERAPEUTICS FROM A SEA OF RED.

D. Baden<sup>1</sup>, A. J. Bourdelais<sup>1</sup> and W. Abraham<sup>2</sup>. <sup>1</sup>*Center for Marine Science, UNCW, Wilmington, NC* and <sup>2</sup>*Division of Research, Mt Sinai Medical Center, Miami Beach, FL*.

Florida red tides produce potent neurotoxic chemicals known as brevetoxins. Brevetoxins also induce severe pulmonary effects, including bronchoconstriction and inhibition of tracheal mucus velocity when inhaled. Recently, an antagonist known as brevenal has been isolated from both field samples and laboratory cultures. Brevenal is a trans-syn polyether material possessing 5 rings in a 67677

motif. A number of active derivatives of brevenal are found naturally. Brevenal displaces brevetoxin binding on voltage-gated sodium channel site 5, antagonizes the acute animal toxicity of brevetoxins, and reduces or eliminates both the inhibition of tracheal mucus velocity and the bronchoconstrictor effects of brevetoxin exposure by inhalation. The antagonistic effects elicited by brevenal occur at picomolar to nanomolar concentrations, which makes them equipotent with the brevetoxin molecules whose effects they antagonize. Brevenal, when applied at picomolar concentrations alone in a sheep pulmonary system, increases mucociliary transport as evidenced by roentgenographic techniques. The effects of brevenal on TMV occur at approximately 1 million-fold lower concentration than for amiloride with nearly equal duration of effect. The discovery of brevenal is a step forward in the discovery of therapeutic agents to counteract seafood poisonings due to brevetoxins and pulmonary effects encountered during Florida red tides. More important, the brevenal structure may provide insight into development of therapeutics for mucociliary diseases including cystic fibrosis. Sponsored by P01 ES10594 funded by NIEHS, NIH, DHHS.

**475**

EFFICACY OF PIROXICAM IN ALLEVIATING TETRACYCLINE-INDUCED MUSCLE DAMAGE.

J. Jahun<sup>1</sup> and H. M. Lantum<sup>2</sup>. <sup>1</sup>Faculty of Vet. Medicine, Amadou Bello University, Zaria, Nigeria and <sup>2</sup>African Society for Toxicological Sciences (ASTS), Rochester, NY.

Oxytetracycline long-acting (TLA) is used in the treatment of canine ehrlichiosis. Intramuscularly (IM) administered TLA produces a severe pain and muscle damage. This study evaluates the efficacy and safety of piroxicam in alleviating adverse effects of an IM therapeutic dose of TLA in six healthy dogs. The dogs were administered TLA alone and, after a two-week interval, were injected with TLA and piroxicam concurrently. All the dogs were physically examined after each injection. Blood samples were collected 24h pre- and at 0, 0.5, 1, 3, 6, 9, 12, 24, 48, and 96h post-treatment for serum creatinine kinase (CK) activity. Swelling was noticed at the injection site of TLA in all six (100%) dogs and all were reluctant to move due to muscle stiffness, and lost appetite. Five dogs (83%) felt pain at the injection site. Four were unable to use the injected legs temporarily. Injecting TLA and piroxicam concurrently suppressed all the signs except for muscular stiffness, which was observed in two (33%) of the dogs for 12h. Transient increases in CK activities were observed after both treatments. Mean muscle damage was  $14.95 \pm 8.78$  g after IM TLA. Muscle damage was not significantly elevated ( $27.57 \pm 17.2$  g;  $P \geq 0.05$ ) after injecting TLA and piroxicam concurrently. These data show that piroxicam suppressed the side effects of an IM dose TLA but did not suppress muscle damage.

**476**

THE EFFECTS OF CONTINUOUS INTRAVENOUS INFUSION OF SALINE ON BODY WEIGHT GAIN, FOOD INTAKE AND CLINICAL PATHOLOGY IN THE GÖTTINGEN MINI PIG.

M. Mus and C. Copeman. IPN, CTBR Bio-Research Inc., Senneville, QC, Canada. Sponsor: M. Vezina.

The Göttingen minipig has frequently been used as a non-rodent model for pre-clinical intravenous infusion safety studies at CTBR. Data from non-catheterized animals (oral and dermal routes) ranging from 4 to 8 months of age were evaluated to determine any effects of the presence of a femoral catheter and continuous intravenous infusion on the body weight gain, food consumption and clinical pathology parameters. The animals were surgically prepared with an indwelling medical grade catheter, placed in the vena cava via the femoral vein. The catheter was then brought subcutaneously to the exteriorization point on the animal's back. The catheter was connected to a clinical grade infusion pump via a tether and jacket system. The pigs were infused with 0.9% Sodium Chloride for Injection U.S.P. continuously for 26 weeks at a rate of 4 mL/hour. Body gains, food consumption and clinical pathology were unaffected when compared with historical control values for non-catheterized animals. It is concluded that in our laboratory the presence of an indwelling catheter and continuous intravenous infusion of saline in pigs had no adverse effects on the animals when compared to non-catheterized pigs.

**477**

BACKGROUND INCIDENCE OF EXPERIMENTAL DESIGN-RELATED EVENTS ON INTRAVENOUS INFUSION STUDIES.

C. Copeman and M. Vezina. IPN, CTBR Bio-Research Inc., Senneville, QC, Canada.

Intravenous (IV) infusion has become a common route of administration, in particular with the expansion of the biotechnology industry. Conducting IV infusion in preclinical laboratory species can present procedure-related difficulties that require close control to avoid impacting the outcome of a study. Background inci-

dence of such events plays an important role in the overall interpretation of a study. Compilation of the historical incidence of experimental procedure-related deaths, catheter repairs and rate of infection at the infusion site in rat, dog and primate IV infusion studies of up to 6 months duration conducted over the past 15 years was extracted from an average of 30 rat, 15 dog and 8 primate studies/year. Procedure-related deaths at the time of surgical cannulation or during post-operative maintenance has been maintained at or below 1 to 2 % for rats and <1 % for dogs and primates. During the conduct of the studies, experimental-related deaths associated with infusion (or inability to progress with the infusion to study termination), in saline infused animals is  $\leq 1\%$ . Repair of catheters is anticipated in infusion studies, however the frequency for saline-infused animals remains low, at <1 % for all species. The use of appropriate sterile procedures during the surgical cannulation and additional precautions used during the conduct of the study to minimize bacterial infiltration have permitted maintenance of a <1% infection rate at the site of infusion. These success rates are also feasible with other relatively innocuous vehicles (eg. 5% Dextrose in Water, USP, phosphate buffered saline). The rates/volume and duration of infusion will greatly influence the success of the infusion. Infusates with extremes of pH or osmolality or that are irritant for other reasons will also negatively influence the success of the infusion. Based on this background data, it is considered that the low incidence of infusion-related adverse events does not interfere with the outcome of short or long-term infusion studies in our laboratory.

**478**

VALIDATION OF A NEWLY INVENTED PORT CATHETER SYSTEM FOR CONTINUOUS INFUSION STUDIES.

P. Nowak, S. Korte, F. Vogel and W. Mueller. Covance Laboratories GmbH, 48163 Muenster, Germany. Sponsor: G. Weinbauer.

For continuous infusion studies in restrained or unrestrained rodent and non-rodent species, the choice of the appropriate port model is pivotal. Available vascular access ports (VAP) are being used depending on the selected species and the method of application. We developed a new modular multi-functional titanium port of unique shape, reduced size and adaptability to different applications. For initial validation, two male and two female cynomolgus monkeys (*Macaca fascicularis*, 3.8 - 6.4 kg and 4 - 8 years of age) were subcutaneously implanted with the new Covance VAP (patent pending). Due to the rocket-like shape and particularly due to smaller size, the incrustation process and post surgery recovery were accelerated in comparison with other ports, commonly available on the market. The small holes around the modular device facilitated the subcutaneous fixation. The catheter of choice for nonhuman primates was connected to the port and the animals will be administered intravenously for 13 weeks with 0.9% NaCl at 0.25 mL/kg, using the Pegasus Infusion Pump, stored in a back pack, and connected either by Gripper or SFN-port needles. Clinical signs, neurological evaluations, determination of body temperature, food consumption, 4-weekly clinical pathology, x-ray imaging using a contrast medium and a full macro- and microscopic evaluation were recorded. The sc port and the silicone membrane could easily be palpated and required less frequent needle exchanges than conventional ports. Clinical signs observed were a reddish and slightly swollen area at the port, isolated episodes of low food consumption and occasionally irregular feces. These observations were considered as incidental background findings. Body weight development was normal. One animal was terminated on study day 55. X-ray diagnostic in week 8 confirmed the proper VAP location and the free-flow into the vena cava caudalis. In conclusion, these preliminary results demonstrate that the new multi-functional VAP system appears well tolerated and should be suitable for various applications due to its modular design.

**479**

CONTINUOUS SUBCUTANEOUS INFUSION IN RODENTS AND NON RODENTS.

M. Stilianesis, S. Groom and C. Copeman. Toxicology, CTBR, Senneville, QC, Canada. Sponsor: M. Vezina.

Intravenous infusion pre-clinical safety studies have been routinely performed at CTBR for close to 20 years on a wide-range of pharmaceutical and biotechnology products and in several species of laboratory animals. The subcutaneous route is often used for drug administration in humans. Continuous subcutaneous infusion has been developed to provide an alternative to intravenous infusion and subcutaneous injection and can assess the potential biological effects of compounds having a short half-life. Subcutaneous infusion was selected as the route of delivery for various drug types intended for the treatment of rheumatoid arthritis, auto-immune and inflammatory diseases, anti-obesity, and type II diabetes. Continuous subcutaneous infusion in rodents as well as non-rodents was successfully performed for up to 3 months. This method allows for higher infusion volumes to be administered, with an expected accuracy of delivery within  $\pm 10\%$  of the nominal dose. Infusion

rates as high as 1.0 mL/kg/h for rodents and 0.208 mL/kg/h for non-rodents have been employed using saline as the preferred vehicle. These rates correspond to approximate daily dose volumes of up to 0.6 mL for a 23 g mouse, 7.2 mL for a 300 g rat, 15 mL for a 3 kg monkey and 50 mL for a 10 kg dog. Advantages of such a system include low risk of infection, low stress to the animals, and unhindered animal activity. Since the pump and infusate remain external to the cage, the potential for the animal to interfere with the infusion is eliminated and handling of the animals during daily dosing procedures is minimized. Furthermore, the set-up does not interfere with daily study-related activities such as clinical observations, body weights, food consumption, blood sampling, etc. Overall, our method of infusion has been demonstrated to be both well-tolerated and without biologically significant effects on clinical pathology or pathology, which were generally transient in nature.

480

#### A METHOD FOR LONG-TERM CONTINUOUS SUBCUTANEOUS INFUSION IN RATS AND DOGS.

G. Washer, S. Jerat, M. Landry, S. Vachon, N. Galliard, J. Laliberte, P. Ha and J. Hooson. *ITR Laboratories Canada Inc., Baie d'Urfe, QC, Canada.*

Continuous subcutaneous infusion is occasionally employed as a route of administration in humans. In order to mimic this route for nonclinical development of such drug candidates our laboratory developed a surgery and dosing technique in rats and dogs. The procedure involved an incision in the mid-scapular region, followed by insertion of the catheter in a caudal-lateral direction (approximately 1 inch for rats and 3 inches for dogs) by means of a trocar. In the case of dogs the surgery employed only a local anesthetic, while in rats general isoflurane anesthesia was used. The external portion of the catheter was connected to a cage-mounted infusion pump by means of a jacket and tether and infusion of control or test article was initiated at rates of up to 0.13 mL/kg/hour. Depending on the irritant nature of the test material, the catheters were replaced at intervals of 1 to 2 weeks, and the newly inserted catheters were directed away from the previous catheter path. Rats and dogs were maintained on continuous infusion for 6 months, during which time the following toxicological parameters were assessed: clinical condition, body weight, food intake, clinical pathology, ophthalmology, ECGs (dogs only) and toxicokinetic sampling. At the end of the treatment period animals were subject to terminal examinations, including organ weights and histopathology. Evaluation of data from controls (6 dogs/sex and 24 rats/sex) infused by this method for 6 months revealed minor, transient infusion site findings, but no effect on general physical condition, body weight gain or food intake, no ophthalmological changes, no ECG changes, and no changes in clinical pathology parameters relative to normal values. Histopathological findings of mild to moderate fibrosis and inflammation were seen in the tissue in the area of the catheter, but were considered to reflect a normal reaction to the presence of a foreign material. In conclusion, this technique was considered to be suitable for use with drugs to be administered by long term subcutaneous infusion.

#### SUCCESSFULL PREVALIDATION OF AN *IN VITRO* RECONSTITUTED HUMAN CORNEA MODEL TO ASSESS THE EYE IRRITATING POTENTIAL OF CHEMICALS.

B. De Wever<sup>1</sup>, F. Van Goethem<sup>2</sup>, F. Straube<sup>3</sup>, N. Alepee<sup>4</sup> and E. Adriaens<sup>5</sup>.

<sup>1</sup>*SkinEthic Laboratories, Nice, France*, <sup>2</sup>*Johnson & Johnson Pharmaceutical R&D, Beerse, Belgium*, <sup>3</sup>*Novartis Pharmacology, Basel, Switzerland*, <sup>4</sup>*Pfizer Global R&D, Amboise, France* and <sup>5</sup>*University of Ghent, Ghent, Belgium.*

This multi-centre study aimed at evaluating the reliability (reproducibility) and relevance (predictive power) of a new commercially available human corneal epithelial (HCE) model (SkinEthic Laboratories, Nice, France) to assess acute ocular irritation. A prevalidation approach (protocol optimisation, transfer and performance) was followed and at each of the 4 participating laboratories, 20 reference chemicals, covering the whole range of irritancy, were tested. The compounds were applied topically to the HCE cultures and the level of cytotoxicity (tissue viability and histological analysis) was determined. Once a standardized protocol was established, a high level of reproducibility between the laboratories was observed. In order to assess the capability of the HCE model to discriminate between irritants (I) and non-irritants (NI), a classification prediction model (PM) was defined based on a viability cut-off value of 60%. The obtained *in vitro* classifications were compared with different *in vivo* classifications (e.g. Globally Harmonized System) which were calculated from individual rabbit data described in the ECETOC data bank. Although an overall concordance of 80% was obtained (sensitivity = 100% and specificity = 56%), the predictive power of the HCE model substantially increased when other sources of *in vivo* and *in vitro* data were taken into account.

482

#### *IN VITRO* SKIN IRRITATION : STRONG REPRODUCIBILITY FOR 50 CHEMICALS TESTED ON THE SKINETHIC RECONSTITUTED HUMAN EPIDERMAL MODEL.

B. De Wever<sup>1</sup>, C. Tornier<sup>1</sup>, H. Maibach<sup>2</sup>, E. Adriaens<sup>3</sup> and M. Rosdy<sup>1</sup>.

<sup>1</sup>*SkinEthic Laboratories, Nice, France*, <sup>2</sup>*University Center of San Francisco, San Francisco, CA* and <sup>3</sup>*University of Ghent, Ghent, Belgium.*

Evaluation of the irritancy potential to human skin of any chemical or formulation used in the chemical, pharmaceutical, and cosmetics industries is a necessity. Most of the available data come from the rabbit Draize test, but its reproducibility is questionable. Toxicologists develop tests on various skin models but the emergence of new tools such as reconstituted human skin tissues offers the most promising future to alternative methods. We have tested fifty chemicals (20 compounds chosen by ECVAM and 30 products previously tested in a human *in vivo* patch test) with two *in vitro* skin irritation test protocols. One is a direct topical application test and the other an *in vitro* patch test. Both protocols were performed using multiple endpoint analysis including cell viability (MTT reduction), histology, and IL-1 $\beta$  release. A prediction model is proposed to classify the chemicals as irritant or non irritant, and the results are compared to available rabbit and human data. The strong reproducibility observed by endpoint, and by compound, combined with the enhanced convenience and the reduced costs obtained by the use of reconstituted human epidermis prove all the usefulness and the potential of this tool.

483

#### DETERMINATION OF THE DOSE-RESPONSE RELATIONSHIP FOR SURFACTANTS USING THE BCOP.

S. Yan and E. Choudhury. *Limited Brands, Paramus, NJ.*

The Bovine Corneal Opacity And Permeability Assay (BCOP) is a very sensitive assay in which it determines a safe allowable use for different types of surfactants (i.e. anionic, cationic). With this assay, we are able to determine an acceptable amount of surfactants to balance into the formula of our bubble bath products to avoid irritant potential. This method enables us to guide in the development of final product formulas when formulating with surfactants. There were multiple series of bubble bath formulas with surfactants at different concentrations tested in 1% and 10% dilutions in sterile, deionizer water. A set of four corneas was incubated in the presence of the test article at 32 ± 1°C for 60 minutes. A set of three corneas was incubated in the presence of the positive control at 32 ± 1°C for 10 minutes. After the 10 and 60-minutes exposure times, the control or test article treatments were removed. The epithelial side of the corneas was washed at least three times with the Complete MEM and an opacity measurement was performed. The corneas exposed to the positive control (10-minutes exposure) were returned to the incubator for approximately 2 hours. The corneas exposed to the negative control and test articles (60-minute exposure) were returned to the incubator for 1 hour. After the designated post-exposure incubation times, a final measure of opacity was obtained. The optical density at 490 nm (OD<sub>490</sub>) was determined using a Molecular Devices Vmax kinetic microplate reader. A 360  $\mu$ L sample of each 1:5 dilution was transferred to the specified well on the 96-well plate. The plate was read again and the final reading was saved. After results were calculated and graphed, a range was then determined from non-irritating to mildly irritating effects of surfactant levels. Whereby from this relationship a safe use level for the surfactants can be recommended in experimental formulations.

484

#### EVALUATION OF A SOLUBILITY PROTOCOL FOR *IN VITRO* CYTOTOXICITY TESTING.

J. Strickland<sup>1,2</sup>, M. Paris<sup>1,2</sup>, W. Stokes<sup>1</sup>, S. Casati<sup>3</sup>, R. Tice<sup>1,2</sup>, H. Raabe<sup>4</sup>, C. Cao<sup>5</sup>, R. Clothier<sup>6</sup>, J. Harbell<sup>7</sup>, G. Mun<sup>4</sup>, A. Sizemore<sup>4</sup>, G. Moyer<sup>4</sup>, J. Madren-Whalley<sup>4</sup>, C. Krishna<sup>5</sup>, M. Owen<sup>6</sup>, N. Borne<sup>6</sup>, M. Wenk<sup>7</sup> and M. Vallant<sup>8</sup>. <sup>1</sup>*NICEATM, NIEHS, Research Triangle Park, NC*, <sup>2</sup>*ILS, Inc., Research Triangle Park, NC*, <sup>3</sup>*JRC, ECVAM, Ispra, Italy*, <sup>4</sup>*IVVS, Gaithersburg, MD*, <sup>5</sup>*ECBC, USArmy, Aberdeen Proving Ground, MD*, <sup>6</sup>*University of Nottingham, Nottingham, United Kingdom*, <sup>7</sup>*BioReliance, Rockville, MD* and <sup>8</sup>*NIEHS, Research Triangle Park, NC*.

A standardized solubility protocol was tested as part of a NICEATM and ECVAM multi-laboratory validation study to evaluate the usefulness of two *in vitro* basal cytotoxicity assays for estimating rodent and human acute systemic toxicity. The intent of the protocol was to guide the selection of solvent for 72 coded chemicals and to evaluate the interlaboratory variation in solvent selection. Chemicals were tested in each of four labs for solubility in culture medium, dimethyl sulfoxide (DMSO), and ethanol (ETOH) in a hierarchical solubility protocol that favored the order listed. Solubility in DMSO and ETOH was tested at concentrations 100X greater than medium to adjust the solubility test concentrations of all solvents to equivalent concentrations to be used in the cytotoxicity assays. Chemicals were tested at

successively lower concentrations that differed by fixed intervals. The criterion for solubility was a clear solution with no evidence of precipitate after vortexing, sonating, and mild heating, as necessary. All four labs agreed on the solvent for 52 (72%) chemicals, and on both solvent and maximum concentration for 42 (58%) chemicals. For 7 of the remaining 20 chemicals, three of four labs agreed on the solvent and maximum concentration. For the remaining 13 chemicals, at least two labs agreed on the solvent, but not necessarily the highest concentration. The final solvents selected were media for 37 chemicals, DMSO for 35 chemicals, and ETOH for 0 chemicals. These data show that the protocol provided good interlaboratory reproducibility for most chemicals, but that differences in solvent selection may occur that could affect the maximum tested concentration and study outcome. Supported by: N01-ES-35504, N01-ES-75408; EPA IAG DW-75-93893601-0; European Commission 19416-2002-04 F2ED ISP GB

#### INTEGRATED DISCRETE MULTIPLE ORGAN CULTURE: A NOVEL *IN VITRO* EXPERIMENTAL SYSTEM FOR TOXICITY STUDIES.

A. P. Li<sup>1,3</sup>, Y. Sakai<sup>1</sup> and C. Bode<sup>2</sup>. <sup>1</sup>Advanced Pharmaceutical Sciences, Inc., Columbia, MD, <sup>2</sup>Tissue Transformation Technologies, Inc., Edison, NJ and <sup>3</sup>The ADMET Group LLC, Rockville, MD.

Multiple organ interactions may play an important role in the effects of a toxicant *in vivo*. A toxicant may be biotransformed in the liver, and the metabolites may be toxic to a distant organ such as the central nervous system. To model the *in vivo* multiple organ interactions, a novel cell culture system, the Integrated Discrete Multiple Organ Culture (IdMOC; patent pending) system, has been developed in our laboratory. The system applies a wells-in-a-well concept (several "inner wells" within a single "containing well"), where cells from multiple organs are cultured in the inner wells, with each cell type cultured in a separate well. After culturing, the multiple cell types are "integrated" via an overlying medium that covers all the inner wells in the containing well. The system thereby models an organism with multiple organs, with the organs situated physically separated from each other, but connected via the circulatory system. The advantages of the IdMOC includes the following: 1. Simultaneous treatment of multiple cell type can be achieved via the addition of the toxicant into the overlying medium, allowing the assessment of differential cytotoxicity under virtually identical experimental conditions. 2. The presence of cells from multiple organs allows the assessment of total metabolites and effects as *in vivo*. 3. The effects of treatment on individual cell types can be evaluated with relevant (e.g. pharmacology or toxicity) endpoints. The application of IdMOC is demonstrated with tamoxifen, a known anticancer agent for the treatment of breast cancer, via the co-culturing of normal human cells (hepatocytes, astrocytes, aortic endothelial cells, renal proximal tubule cells, small airway epithelial cells) and a cancer cell (MCF-7 breast adenocarcinoma cells). Tamoxifen, while toxic to all cell types, was most toxic towards the MCF-7 cells. IdMOC with human cells models human *in vivo* and represents a useful experimental system for drug development.

#### EFFECTS OF NANOSPHERES ON THE ADHESION AND CELL VIABILITY OF ASTROCYTES.

C. Au<sup>1</sup>, L. Mutkus<sup>2</sup>, A. Dobson<sup>2</sup>, J. Riffle<sup>3</sup>, J. Lallli<sup>3</sup>, R. Claus<sup>3</sup> and M. Aschner<sup>1</sup>. <sup>1</sup>Pediatrics, Vanderbilt University Medical Center, Nashville, TN, <sup>2</sup>Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC and <sup>3</sup>NanoSonic Inc., Blacksburg, VA.

In recent years, there has been an increasing interest in the potential of using magnetic nanoparticles as carriers for drug delivery by pharmaceutical companies. However, data concerning the effects of these nanospheres on the nervous system is still limited. This study tested the hypothesis that magnetic carriers, nanospheres, (1) can inhibit adherence of astrocytes to culture plates and (2) cause cytotoxicity or termination of growth. Astrocytes were obtained from the cerebral cortices of newborn Sprague-Dawley rats. Using light microscopy, changes in plating pattern were determined by visual assessment. Cell counting 4 days after plating revealed a significant decrease in the number of viable cells in treated groups ( $p < 0.0001$ ). To determine the cytotoxic effects of nanospheres, astrocytes were allowed to adhere to culture plates prior to treatment. Membrane integrity and mitochondrial function were measured using colorimetric analysis of lactate dehydrogenase (LDH) and 3-[4, 5-Dimethylthiazol-2-yl]-2, 5-diphenyltetrazolium bromide (MTT), respectively. Treatment with nanospheres did not significantly alter astrocytic LDH release ( $p = 0.27$ ) in controls ( $100\% \pm 1.56$ ) versus treatment ( $97.18\% \pm 2.03$ ). However, a significant increase in MTT conversion ( $p = 0.01$ ) between control ( $100\% \pm 3.65$ ) and treated groups ( $112.8\% \pm 3.23$ ) was observed. The latter could be interpreted as possible mitochondrial uncoupling. These data suggest that nanospheres impede the attachment of astrocytes to substratum. However, once astrocytes are attached to a substratum and grow to confluence, nanospheres may cause mitochondrial stress, but not direct cell death. Supported by a grant from NanoSonic to MA

#### IN VITRO MODEL OF PENETRATION AND ACTIVE DECONTAMINATION OF A CORROSIVE.

L. MATHIEU<sup>1</sup>, C. Godard<sup>1</sup>, H. Coudouel<sup>1</sup> and A. H. Hall<sup>2</sup>. <sup>1</sup>Scientific Researches, Prevor, Toulouse, France and <sup>2</sup>Scientific communications, TCMTS Inc., Elk Mountain, WY.

The aim of this study is to show by *in vitro* experiments the penetration of a corrosive such as sodium hydroxide (NaOH) and to evaluate the interest of a rinsing with an active solution. *In Vitro* studies were performed: 1) Penetration of NaOH through the tissues was simulated through a semi-permeable membrane depending on the concentration. A volume of NaOH is put at the surface of the membrane and the evolution of the pH is measured in a compartment containing sodium chloride (420 mosmoles/Kg). 2) A model of semi-permeable membrane was used to simulate a complete rinsing of 2N NaOH exposure. Comparison was made between a water rinsing and an active rinsing solution such as Diphtherine. Two times of exposure was tested, 20 seconds and 1 minute. The penetration of sodium hydroxide depends on its osmotic pressure. For 0.1N and 0.2N NaOH concentrations, the penetration was delayed and a final pH value after 900s was respectively about 9 and 10. When the NaOH concentration is 1N, the penetration is faster due to a higher osmotic pressure than cornea ; the final pH value after penetration is 11.5 at 900s. For 2N and 5N concentrations, the penetration is really higher than for 1 N concentration and a final pH value is respectively 12 at 900s and 12.3 at about 600s. The complete rinsing showed better efficacy with Diphtherine rinsing versus water rinsing at all times of exposure. For a 20 seconds time of contact and after 3 minutes of rinsing, the external pH value was respectively about 9 for Diphtherine and about 12.8 for water. After 45 minutes, the internal pH value is about 9 with Diphtherine rinsing and 11.5 with water rinsing. For one minute of contact, the curves of pH are similar with a delayed decrease of pH. This *in vitro* model has shown to be depending on the concentration of the corrosive and the balance of osmotic pressure. The simulation of a complete rinsing showed better efficacy with an active rinsing solution versus water rinsing after NaOH exposure.

#### TESTING CASCADE TO PREDICT THE POTENTIAL OF DRUG DISCOVERY COMPOUNDS TO INDUCE MITOCHONDRIAL DYSFUNCTION.

L. D. Marroquin, G. J. Stevens and Y. Will. Safety Sciences, Pfizer, San Diego, CA.

Mitochondrial toxicity has been suggested as a pharmacotoxicological effect with a variety of therapeutics. For example, adverse effects associated with certain antiviral agents, lipid-lowering drugs, and certain cancer chemotherapeutics are attributed to mitochondrial dysfunction. In the case of antiviral therapy with AZT, mitochondrial toxicity is confirmed by monitoring the extent of mitochondrial DNA depletion. Some fibrates, used to treat hyperlipidemia, have been shown to inhibit complex I (NADH-cytochrome c reductase) of the electron transport chain *in vitro*. Doxorubicin causes mitochondrial dysfunction by selectively abstracting electrons from complex I through a redox cycling mechanism. Although progress has been made in identifying the mechanisms of mitochondrial toxicity, the ideal situation is to avoid drugs with the potential of causing mitochondrial toxicity. Some chemical compound classes can be predicted to target mitochondria such as redox cycling compounds or weak carboxylic acids. With other compound classes, the potential may not be as obvious. We are interested in developing a systematic testing cascade that would allow us to predict if any of our new chemical entities have the possibility to cause mitochondrial dysfunction and to address possible mechanisms. We used well-documented model compounds such as rotenone, doxorubicin, metformin, valproic acid and several fibrates in our studies. We tested each compound in the following assays: 1. The commercially available MitoScan, which identifies inhibitors of the electron transport chain; 2. potential of compounds to inhibit complex I-IV activities, 3. effect of compounds on respiration using glutamate/malate and succinate/rotenone as substrates; 4. ability of compounds to induce the mitochondrial permeability transition and 5. the effect of compounds on mitochondrial membrane potential. We present our findings and discuss advantages and limitations of each testing regimen. We provide recommendations for what we believe could be a useful testing cascade for new drug candidates that are suspected to have the potential to cause mitochondrial dysfunction.

489

#### PREDICTION OF TOXICITY PARAMETERS OF AMINO- AND NITROBENZENE DERIVATIVES.

K. Kabirov and A. Lyubimov. Toxicology Research Laboratory, University of Illinois at Chicago, Chicago, IL.

It is necessary to have information about the approximate toxicity of chemical substance on a stage of toxicological study design. Such information can be received by means of Quantitative Structure-Activity Relationships (QSAR) analysis. One hundred and fifty equations for prediction of a number of toxicity parameters were received on the basis of several physicochemical descriptors ( $\log P$ , Hammett parameter  $\delta$ , and molecular refractivity) for a class of amino- and nitrobenzenes. The

following quantum mechanical molecular characteristics were the most valuable for toxicity prediction: energy of the highest occupied molecular orbital (HOMO), energy of the lowest unoccupied molecular orbital (LUMO), total energy, energy of activation, maximal index of free valence (Nmax), the maximum charge of a carbon atom not bound to a functional group/substitute (Qmax), the difference between a sum of charges of a carbon atom in a benzene ring and its derivative ( $\Delta Q$ ). Toxicity parameters included acute oral and inhalation toxicity, cumulative properties, thresholds of acute, chronic and embryotoxic activity. The received multiple regression models had a high level of reliability ( $P<0.05$ ,  $R>0.7$ ). The validation of the equations has shown coincidence between actual and calculated values of acute oral and inhalation toxicity, cumulative properties, thresholds of acute activity for more than half of amino- and nitrobenzenes which were not used for a training set in obtaining these equations. Absence of sufficient experimental data limited validation of the models for prediction thresholds of chronic and embryotoxic activity. All physicochemical and quantum mechanical molecular descriptors can be calculated based on the structural formula of a new chemical. Thus, the suggested models allow predicting several toxicity properties of amino- and nitrobenzene compounds during the design of new chemical entities even prior to their laboratory synthesis.

#### THE USE OF LASER SCANNING CYTOMETRY (LSC) AS A POTENTIAL TOOL FOR QUANTITATIVE ANALYSIS OF CYPs IN LIVER TISSUE SECTIONS.

V. Kostrubsky<sup>1</sup>, S. Kulkarni<sup>1</sup>, A. Shen<sup>2</sup>, S. Schomaker<sup>2</sup>, I. Pruijboom-Brees<sup>2</sup>, D. Amacher<sup>2</sup> and D. Brees<sup>2</sup>. <sup>1</sup>WWSS, Pfizer, Ann Arbor, MI and <sup>2</sup>WWSS, Pfizer, Groton, CT.

We investigated if LSC can be used for quantitation of CYP induction in liver sections from animals treated with CYP inducers. Rats were treated with phenobarbital (PB) at 10 and 100 mg/kg or dexamethasone (DEX) at 5 and 50 mg/kg administered by gavage for 4 days. Livers were collected and microsomal fractions and formalin-fixed paraffin-embedded sections were prepared. Sections were processed for immunohistochemistry, stained with CYP3A or CYP2B antibody, visualized with fluorescent detection and analyzed by LSC. Microsomal CYP3A and CYP2B were analyzed by Western blot (WB) using the same antibodies as for LSC detection. Microsomal samples were assayed for pentoxysresorufin O-deethylase (PROD) and ethylmorphine N-demethylase (EMD) activity, indicators of CYP2B and CYP3A, respectively. Treatment with PB or Dex resulted in a dose-dependent increase in CYP2B (PB treated) and CYP3A proteins expression (Dex or PB treated), increases in liver weight and biochemical activities. Expression of CYP2B increased by 2.3 to 4.5-fold in PB treated groups compare to control with 2-fold increase observed between the low and high dose groups as was detected by WB analysis. PROD increased 4.7 to 9.5-fold in PB treated groups compared to controls with a 2-fold increase observed between the two groups. Two fold increase has been observed between treated groups by LSC. Induction of CYP3A by PB ranged from 1.5 to 4-fold by WB. A 2.6 and 2.9-fold increase was found between a low and high dose groups as measured by WB and LSC, respectively. EMD increased 1.9 to 2.8-fold in PB treated groups with a 1.5-fold increase observed between the two dose groups. CYP3A protein increased up to 2-fold by DEX compare with untreated animals with corresponding changes detected by LSC. EMD was also increased 1.7 to 3.4-fold in DEX treated groups compared to controls with a 2-fold increase observed between the two groups. These data indicate that LSC procedure can be used for analysis of CYP levels.

#### METABONOMICS COMES INTO THE COLD: COMPARISON OF SENSITIVITY AND REPRODUCIBILITY OF CRYOGENIC PROBES VERSUS INCREASED FIELD STRENGTH.

M. J. Santostefano<sup>1</sup>, B. C. Sweatman<sup>2</sup>, S. Castellino<sup>3</sup>, A. W. Nicholls<sup>2</sup>, S. A. Ringeissen<sup>2</sup>, B. F. Hamilton<sup>1</sup>, H. L. Jordan<sup>1</sup>, T. L. Schehl<sup>4</sup> and J. N. Haselden<sup>2</sup>. <sup>1</sup>SA, GlaxoSmithKline, Research Triangle Park, NC, <sup>2</sup>IPT, GlaxoSmithKline, Ware, United Kingdom, <sup>3</sup>DMPK, GlaxoSmithKline, Research Triangle Park, NC and <sup>4</sup>Randstad, Research Triangle Park, NC.

Metabonomics is gaining acceptance as a tool for distinguishing metabolic perturbations resulting from drug administration [1]. The aim of this work was to compare the metabonomic results from 1H NMR spectroscopic data acquired at 700 MHz on a conventional probe with that at 600 MHz from a cryogenic probe. Male rats were administered a single dose of hydrazine, a hepatotoxicant with a well-defined metabonomic profile [2] at 10, 40, or 75 mg/kg, and urine was collected over the next 72 h. Two sets of samples were prepared by robotics and analyzed at the 2 field strengths. The resulting NMR spectral data were analyzed using multivariate statistics. In-life and clinical pathology findings reflected previous literature data [2]. Irrespective of field strength, metabonomic analysis of urine spectral data demonstrated substantial modulations in urinary metabolites that were entirely consistent with published observations [2, 3]. Treatment-related changes consisted

of decreases in citrate, 2-oxoglutarate, creatinine, hippurate, and succinate with an increase in 2-amino adipate, beta-alanine, creatine, taurine, and argininosuccinate. Direct analysis of the signal-to-noise ratio of the fumarate resonance showed that greater sensitivity was observed using a cryogenic probe at 600 MHz (260-390:1) compared to the data obtained on a conventional probe at 700 MHz (88-186:1). The overall interpretation of the metabolic profile of hydrazine toxicity was the same regardless of the field strength. Enhanced dispersion at the higher frequency provides value for the identification of novel metabolic markers, but for initial marker discovery, the better sensitivity of the cryogenic probe technology provides a rapid cost-effective improvement for metabonomic analyses. <sup>1</sup>Lindon et al, *Toxicol. Appl. Pharmacology*, 187:137, 2003; <sup>2</sup>Nicholls et al, *Chem. Res. Toxicol.*, 14:975, 2001; <sup>3</sup>Keun et al, *Chem. Res. Toxicol.*, 15:1380, 2002

#### EFFECTS OF REPEAT INTRAMUSCULAR DOSING OF KETAMINE FOR 14-DAYS IN CYNOMOLGUS MONKEYS.

K. Moore<sup>1</sup>, J. Mandsager<sup>1</sup>, S. Roesch<sup>1</sup>, P. Franklin<sup>1</sup>, J. Jabbour<sup>1</sup>, W. Congdon<sup>1</sup>, S. Meyer<sup>1</sup> and R. Nagata<sup>2</sup>. <sup>1</sup>Safety Assessment, SNBL USA, Ltd., Everett, WA and <sup>2</sup>Shin Nippon Biomedical Laboratories, Ltd., Kagoshima, Japan.

Ketamine is a dissociative anesthetic and analgesic agent that is widely used as an adjunct to biomedical procedures performed in drug safety studies in nonhuman primates because of its capacity to rapidly produce a profound and transient state of sedation without significant loss of normal reflexes. Little was known, however, of the effects of sedative levels of ketamine on parameters commonly assessed in safety assessment studies in these species. In this study the effects of ketamine administration in the sedative range doses were assessed on body weight, food consumption, hematology, coagulation, serum chemistry, urinalysis, and organ weights in cynomolgus monkeys (*Macaca fascicularis*). Ketamine was administered by intramuscular injection at dose levels of 0, 5, or 20 mg/kg once daily for 14 consecutive days to cynomolgus monkeys (3 animals/sex/dose level). The resulting data indicates that ketamine administration had negligible effects on food consumption, body weight, serum chemistry, hematology, coagulation, ionized calcium and organ weights in this species when compared to pre-dosing baseline and concurrent control data. In conclusion, daily intramuscular administration of sedating levels of ketamine appears to have no impact on drug safety assessment parameters in a non-human primate model; and because the routine use of ketamine minimizes risk to personnel associated with collection of data from unrestrained animals, as well as effectively minimizes any influence restraint may contribute to the study parameters assessed, provides a very valuable adjunct to the conduct of nonhuman primate safety assessment studies.

#### A CANINE MODEL FOR SAFETY EVALUATION OF PERCUTANEOUS INTRAHEPATIC INJECTION OF 10% ROSE BENGAL.

R. Jones<sup>1</sup>, E. Wachter<sup>2</sup>, D. Griffin<sup>1</sup>, K. Davis<sup>1</sup> and N. Foster<sup>1</sup>. <sup>1</sup>Toxicology, Charles River Laboratories - DDS - Arkansas Division, Redfield, AR and <sup>2</sup>Provectus Pharmaceuticals, Inc., Knoxville, TN.

Haepatocellular carcinoma (HCC) accounts for 90% of liver tumors and over 1 million deaths annually. Detection of the disease has been improved by advances in medical imaging techniques. The most common method of treatment is ablative therapy conducted by ultrasound guided microwave coagulation or small molecule injection. Surgical treatment may be limited or complicated by liver disease or anesthetic risk. Percutaneous administration has been reported to have similar patient survival times and response rates as invasive surgical catheter placement for colorectal liver metastases. Rose Bengal is a stable, small molecule with potential cytotoxic effects against HCC that is excreted unmetabolized via the bile, with secondary excretion by the kidneys. For safety evaluation, the canine model was selected based on considerations of anatomy, physiology and previous toxicity data. One male and one female adult dog were premedicated with ketamine/xylazine then anesthetized with isoflurane. The xypoid area was surgically prepared and a single 20 mg/kg dose of 10% Rose Bengal (w/v) in sterile saline was given by percutaneous intrahepatic injection. Hematology, coagulation and clinical chemistry parameters were measured at pre-dose and four days post-dose prior to sacrifice, and liver was collected for histopathology. Results included clinical observations of purple discolored emesis, urine and feces. On day four, there were biologically relevant increases in alanine aminotransferase and alkaline phosphatase. Histologically, the treated liver lobe of each animal was characterized by a band of subcapsular degeneration and necrosis of hepatocytes that contained small numbers of neutrophils and macrophages and subjacent sinusoidal congestion. It was concluded that the canine percutaneous intrahepatic model was appropriate to evaluate the clinical indication of this test article.

## CHARACTERIZATION OF NOVEL BIOMARKERS OF PERCHLORATE EXPOSURE IN ZEBRAFISH.

S. Mukhi<sup>1</sup> and R. Patino<sup>2</sup>. <sup>1</sup>Department of Environmental Toxicology, Texas Tech University, Lubbock, TX and <sup>2</sup>Texas Cooperative Fish and Wildlife Research Unit, Lubbock, TX.

Perchlorate inhibits iodide uptake by thyroid follicles and lowers thyroid hormone production. Although several effects of perchlorate on the thyroid system have been reported, the utility of these pathologies as markers of environmental perchlorate exposures has not been adequately assessed. This study examined time-course and concentration-dependent effects of perchlorate on thyroid follicle hypertrophy, colloid depletion, and angiogenesis; alterations in whole-body thyroxine (T4) levels; and somatic growth and condition factor of subadult and adult zebrafish. Changes in the intensity of the colloidal T4 ring previously observed in zebrafish were also examined immunohistochemically. Three-month-old zebrafish were exposed to ammonium perchlorate at measured perchlorate concentrations of 0, 11, 90, 1131 and 11480 ppb for 12 weeks, and allowed to recover in clean water for 12 weeks. At 2 weeks of exposure, the lowest observed effective concentrations (LOECs) of perchlorate that induced angiogenesis and depressed the intensity of colloidal T4 ring were 90 and 1131 ppb, respectively; other parameters were not affected (whole-body T4 was not determined at this time). At 12 weeks of exposure, LOECs for colloid depletion, hypertrophy, angiogenesis and colloidal T4 ring were 11480, 1131, 90 and 11 ppb, respectively. All changes were reversible, but residual effects on angiogenesis and colloidal T4 ring intensity were still present after 12 weeks of recovery (LOEC, 11480 ppb). Whole-body T4 concentration, body growth (length and weight), and condition factor were not affected by perchlorate. The sensitivity and longevity of changes in colloidal T4 ring intensity and angiogenesis suggest their usefulness as novel markers of perchlorate exposure. The 12-week LOEC for colloidal T4 ring is the lowest reported of any perchlorate biomarker in aquatic vertebrates.

## CROSS-TISSUE BIOMARKERS THAT PREDICT AND CHARACTERIZE THE ACUTE PHASE RESPONSE.

S. Tugendreich. *Iconix Pharmaceuticals, Mountain View, CA.* Sponsor: K. Kolaja.

We have developed a large library of microarray biomarker sets (Drug Signatures™) for important toxicities, pathologies, and pharmacological mechanisms of action to optimize compound selection during drug development. The signatures were derived from a comprehensive chemogenomic reference database (DrugMatrix™) that ties gene expression values from compound-treated rats in short term studies to pharmacological, toxicological, and pathological effects of the administered compounds. The database contains data from 600 compounds using over 15, 000 microarray gene expression arrays coupled to the clinical chemistry, hematology, and histopathology of the treated rats. We have generated drug signatures using a specialized Support Vector Machine (SVM) algorithm, and until now have specifically trained them on gene expression values derived from one particular tissue. For example, we currently have approximately 180 liver-specific signatures that can predict various endpoints such as ALT elevation or bile duct hyperplasia from microarray data. In the present experiment, we investigated whether it is possible to create signatures from microarray data from many tissues simultaneously. The ultimate goal is to identify biomarkers that can be used broadly in many different tissues as well accessible tissues such as whole blood. Since all tissues that are profiled for microarrays contain residual blood, and/or contain resident cells derived from blood cell lineage, pan-tissue signatures are likely to contain blood-borne markers. As a starting point, we made pan-tissue signatures that detect a compound-induced acute phase response within hours of compound administration — earlier than hematological perturbations, such as fibrinogen levels or WBC counts. The signature uses genes such as calgranulin B or lipocalin 2 known to be expressed in WBCs in response to inflammatory signals. Cross-tissue signatures will further expand our ability to form conclusions about mechanisms of toxicity and pharmacology from microarray experiments in under-represented tissues, and possibly allow selection of biomarkers to use in human whole blood.

## THE CHANGE IN FINGER OVAL AREA IN A NON-HUMAN PRIMATE COLLAGEN-INDUCED ARTHRITIS MODEL AND ITS CORRELATION WITH BIOCHEMICAL PARAMETERS.

N. Horai, H. Horai, H. Tsubaki, H. Tokado, K. Fukuzaki and R. Nagata. *Shin Nippon Biomedical Laboratories, Ltd., (SNBL), Kagoshima, Japan.*

We prepared a collagen-induced arthritis (CIA) model by sensitizing with an emulsion of type II bovine collagen to cynomolgus monkeys, and have assessed its efficacy by monitoring the change of swelling of the joint which is an important site. In this study, we assessed the correlation between swelling of the finger oval area and biochemical parameters including bone metabolic parameters. Male cynomol-

gus monkeys were used and the 1st sensitization was conducted following 1-week acclimation. The 2nd sensitization was conducted 3 weeks after the 1st sensitization. During this period, score of swelling, body weight, urinalysis, hematology and serum biochemistry were examined sequentially. Finger oval area was measured on the interphalangeal (IP) joints of 16 fingers except for the thumbs of all limbs, and score of swelling was observed on 64 major movable joints in the distal areas including knee and elbow joints of all limbs. When compared with the mean IP area, 29 of 40 animals showed 105% or greater after the sensitization period. However, 38 of 40 animals showed swelling at one site or more in the score of swelling. The correlation between IP area and score of swelling was high ( $R=0.800$ ), and those with serum ALP and urine NTx were high. The coefficient of correlation with ESR and CRP which were well known as the inflammatory markers were  $R=0.313$  and  $0.262$ , respectively. The clinical significance of bone metabolic markers in rheumatoid arthritis has not been unclear, because there are insufficient evidences. However, IP oval area showed high correlations with serum ALP and urine NTx, and this suggests that bone metabolism is the type of high metabolism rotation. Additionally, it is expected that score of swelling, serum ALP and urine NTx which showed high correlation with IP oval area would be available parameters for evaluation of drug efficacy.

## EFFECTS OF BRIEF ENVIRONMENTAL TOBACCO SMOKE (ETS) AND PROPIONIC ACID EXPOSURES.

J. C. Walker, D. B. Walker, R. Whitt, J. C. Suarez, K. W. Winship, M. Russo and N. J. Walker. *Sensory Research Institute, Florida State University, Tallahassee, FL.* Sponsor: C. Smith.

Little is known concerning relationships among severity and duration of brief contaminant exposures and magnitude of impacts over time. To generate descriptive data needed for eventual mechanistic understanding, we exposed 20 healthy never-smokers to 8 conditions, each presented in a 100-min session conducted in a 10m<sup>3</sup> environmental chamber (ETS: 0, 15, 100 and 800  $\mu\text{g}/\text{m}^3$  RSP; PA: 0, 1, 10 and 15 ppm). Perceptual, breathing and blood pressure responses were recorded at different times. Odor, nasal irritation and eye irritation ratings indicated that: i) the ranges of the PA and ETS stimuli are approximately equal in perceived intensity; ii) 15  $\mu\text{g}/\text{m}^3$  ETS-RSP is peri-threshold after ~50 minutes of exposure; and iii) odor is the most sensitive endpoint and shows the clearest evidence of adaptation. Continuous breathing measurements showed that: i) overall, breathing responses appear at least as sensitive as perceptual endpoints; ii) PA causes a decline in breathing frequency due to increased inhalation duration but, because of a marked increase in inhalation volume, an increase in minute ventilation; and iii) with ETS, the slowed breathing (also due to increased inhalation duration) and a drop in inhalation volume accounted for a concentrated-related drop in minute ventilation. Blood pressure was altered by only the highest ETS concentration, which caused a decrease in systolic and an increase in diastolic pressure. Although it is difficult to measure a variety of responses from the same individuals repeatedly under different well-controlled conditions, this approach may be a critical step in generating the comprehensive quantitative data needed for understanding exposure situations representative of actual environments. As part of an effort to probe neural mediation of responses, anosmic (lacking olfactory input to brain) individuals will be tested next in this paradigm. Supported in part by Philip Morris USA Inc.

## RESPONSES OF MRP2-DEFICIENT TR RAT TO REPEATED DICLOFENAC EXPOSURE.

V. Ramirez-Alcantara<sup>1,2</sup>, L. Kaphalia<sup>1</sup>, J. F. Aronson<sup>1,3</sup>, M. F. Kanz<sup>1</sup> and M. Treinen-Moslen<sup>1,3</sup>. <sup>1</sup>Pathology, UTMB, Galveston, TX, <sup>2</sup>CINVESTAV-IPN, D.F. Mexico and <sup>3</sup>Internal Medicine, UTMB, Galveston, TX.

Background: Mrp2 exporter-deficient TR rats have previously been found resistant to the enteropathy produced by a single dose of diclofenac, a widely prescribed NSAID. This resistance is attributed to their limited capacity for biliary delivery of reactive acylglucuronide metabolites of this NSAID to the intestine. However, this resistance might be overcome with repeated exposure to diclofenac if other mechanisms — not involving acylglucuronide exposure — contribute to the enteropathy of chronic NSAID treatment. Objective: We tested the hypothesis that potential changes in the response of TR rats to repeated diclofenac exposure could involve a shift in ulcer location or a disassociation of ulceration from metabolite adduction of enterocytes. Experimental Design: Male TR rats and Wistar rats were treated with diclofenac po for 5 days at a low pharmacological dose of 10 mg/kg or at a high dose of 50 mg/kg. Enteropathy was defined by measuring declines in serum albumin and assessing ulcer number and location. Adduction was assessed by immunohistochemistry. Results: TR rats were relatively resistant to the low pharmacological dose (no decline in serum albumin and <5 ulcers) which caused substantial enteropathy in Wistar rat (averaging a 23% decline in serum albumin and 67 ulcers

that were located predominately distally). However, the high dose did cause enteropathy in TR rats as indicated by an average 22% decline in serum albumin and ~20 ulcers that were predominately proximal located and associated with very sparse immunohistochemically detectable adduction, particularly at the brush border of the enterocytes. Conclusions: Thus, Mrp2-exporter deficient rats responded to repeated low diclofenac doses with a resistance to enteropathy but developed enteropathy after repeated high doses that was shifted proximally in location and accompanied by only sparse adduction of enterocytes. EVALUATION OF THE EFFECTS OF INTRANASAL ADMINISTRATION OF IL-4 TO MICE AND INHIBITION OF THESE EFFECTS BY A MURINE IL-4 RECEPTOR ANTIBODY.

M. Horner<sup>1</sup>, L. L. Carlock<sup>1</sup>, J. Tocker<sup>1</sup>, B. He<sup>2</sup> and J. L. Bussiere<sup>1</sup>. <sup>1</sup>Amgen Inc., Thousand Oaks, CA and <sup>2</sup>Gene Logic Laboratories Inc., Gaithersburg, MD.

Inhibition of IL-4 receptor is being evaluated for the treatment of asthma. The ability of a murine IL-4 receptor antibody (muIL-4R Ab) to inhibit effects of IL-4 intranasal administration and to affect serum IgE levels were evaluated. A pilot study was conducted to determine the optimal dose of IL-4 to use as a challenge. Five groups (4 female BALB/c mice/group) received a single intranasal administration of saline or IL-4 at 30, 50, 100, or 300 ng/animal. All animals were sacrificed on Day 2 and lungs were harvested for ClCa3 mRNA analysis (ClCa3 is a calcium activated chloride channel associated with excessive mucus production in asthma). Intranasal IL-4 administration produced a dose-dependent increase in ClCa3 lung expression levels. A safety study was conducted to determine toxicity, toxicokinetics (TK), and pharmacodynamics (PD) of a muIL-4R Ab, when administered weekly for 4 weeks by intravenous (IV) or subcutaneous (SC) injection to BALB/c mice, and to evaluate recovery following a 4-week treatment free period. Five groups of mice (15/sex/group for toxicity, 15-36/sex/group for TK, and 5/sex/group each for IL-4 challenge and IgE analysis) were dosed at levels of 0, 4, 20, or 100 mg/kg IV or 100 mg/kg SC. Mortality, clinical signs, body weights, clinical pathology (hematology, serum chemistry and urinalysis), organ weights, gross and microscopic pathology, TK, antibody analysis, and PD effects were evaluated. There were no test article-related effects on clinical signs, body weights, clinical pathology, organ weights, gross pathology, or histopathology. The administration of muIL-4R Ab by either IV or SC did not elicit an antibody response. Administration of muIL-4R Ab over a 4-week period significantly reduced intranasal IL-4 induced ClCa3 mRNA expression in the lung and reduced total serum IgE levels. Based on the results of the study, weekly IV or SC treatment with muIL-4R Ab for 4 weeks in BALB/c mice was well tolerated and pharmacodynamic activity was observed.

CYSTEINYLMERKATIN 1 AND 10 PROTEIN ADDUCTS OF BENZENE OXIDE AND NAPHTHALENE-1, 2-OXIDE FOR QUANTIFICATION OF DERMAL EXPOSURE TO BENZENE AND NAPHTHALENE.

L. A. Nylander-French<sup>1</sup>, D. Fox<sup>1</sup>, K. Jayara<sup>1</sup>, D. G. Klapper<sup>2</sup>, A. Gold<sup>1</sup>, L. M. Ball<sup>1</sup> and J. E. French<sup>3</sup>. <sup>1</sup>Environmental Sciences & Engineering, UNC-CH, Chapel Hill, NC, <sup>2</sup>Department of Microbiology and Immunology, UNC-CH, Chapel Hill, NC and <sup>3</sup>Laboratory of Molecular Toxicology, NIEHS, Research Triangle Park, NC.

Epoxide metabolites of naphthalene and benzene are generated by cytochrome P450s in the liver and the skin where they can form protein adducts. Likely nucleophilic protein targets for adduct formation in the skin are the sulphydryl groups of cysteine residues in the head region of keratin-1 (K1) and keratin-10 (K10) proteins. We have developed polyclonal antibodies to adducts of epoxide metabolites of naphthalene and benzene and keratin proteins. S-phenyl-, S-(1-naphthyl)-, and S-(2-naphthyl)-cysteines were synthesized and incorporated by FMOC chemistry into oligopeptide sequences of K1 or K10. Antisera were collected from rabbits immunized with each of these synthesized adducts and purified by immunoaffinity chromatography with S-aryl modified K1 and K10 oligomers linked to an amino-containing resin. Antibodies purified in this manner were cross-reactive with K1 or K10 proteins, thus, they were further purified through a column containing either the K1 or K10 oligomer linked to an amino-containing resin to remove non-epitope specific antibodies. The resulting antibodies showed high specificity for a specific adduct and low cross reactivity with other adducts. Immunoaffinity purified antibodies generated, with high specificity and low cross reactivity, will be used to develop an ELISA to measure these adducts extracted from dermal tape-strip samples collected from persons occupationally exposed to naphthalene and benzene. This will allow us to determine if these adducts are formed in the skin and to quantify dermal exposure. Supported by NIEHS P42-ES05948.

GLYCOPROTEOMIC ANALYSIS OF RAT PLASMA FOLLOWING PROTEIN PHOSPHATASE INHIBITION BY MICROCYSTIN-LR.

C. R. Wilson<sup>1,3</sup>, F. E. Regnier<sup>2</sup> and S. B. Hooser<sup>1,3</sup>. <sup>1</sup>Animal Disease Diagnostic Laboratory, Purdue University, West Lafayette, IN, <sup>2</sup>Chemistry, Purdue University, West Lafayette, IN and <sup>3</sup>Vet. Path, Purdue University, West Lafayette, IN.

Microcystin-LR (MCLR), a peptide toxin produced by freshwater blue-green algae, is a potent inhibitor of hepatic protein phosphatases 1 and 2A, and induces massive liver injury *in vivo*. Using targeted glycoproteomics profiling, a method has been developed to isolate and quantify changes in plasma mannosylated proteins relevant to MCLR-induced hepatotoxicity. In this study, male Sprague-Dawley rats were treated with MCLR (500 ug/kg, ip) or saline (control) and necropsied at 6h. Mannosylated glycopeptides were isolated and quantified in plasma samples (control and MCLR-treated) using lectin affinity chromatography and a global isotope coded labeling agent (GIST). Briefly, this procedure involves the following: 1) plasma proteins from each sample were tryptically digested into peptides, 2) the resultant tryptic peptides from the plasma samples were GIST-labeled with acetoxysuccinimid (control sample) and deuterated-acetoxysuccinimid (treated sample), then mixed together, 3) mannosylated, labeled peptides were lectin affinity selected using concanavalin A-agarose, 4) the isolated mannosylated peptides were separated using HPLC with UV detection, 5) changes in these peptides, from control and treated plasma, were quantified using MALDI-TOF mass spectrometry. MALDI-TOF mass spectrometry of GIST-labeled peptides identified approximately 60 mannosylated peptides, of which roughly half changed greater than 2-fold, when comparing the control and treated samples. Approximately 20 mannosylated peptides were down-regulated or unchanged when compared to the control sample, while about 5 mannosylated peptides were up-regulated in the MCLR-treated sample. These findings indicate that changes in mannosylated plasma proteins occur with MCLR-induced hepatotoxicity. Further refinement of this technique and its use in comparison of control to treated plasma will identify glycoproteins altered by toxicity and disease for use in mechanistic studies and diagnostics.

FORMATION OF UVA LIGHT INDUCED OXYPEUCEDANIN DNA ADDUCTS AND DETECTION USING HPLC <sup>32</sup>P-POSTLABELING.

L. H. Couch<sup>1,2</sup>, N. V. Gopee<sup>1,2</sup>, M. I. Churchwell<sup>1</sup>, D. R. Doerge<sup>1</sup>, W. G. Wamer<sup>1</sup> and P. C. Howard<sup>1,2</sup>. <sup>1</sup>Division of Biochemical Toxicology, NCTR, USFDA, Jefferson, AR, <sup>2</sup>NTP Center for Phototoxicology, NCTR, USFDA, Jefferson, AR and <sup>3</sup>Office of Cosmetics and Colors, CFSAN, USFDA, College Park, MD.

Coumarins and furocoumarins occur in the leaves and fruits of many plants species. Several of the furocoumarins, including psoralen, 5-methoxysoralen (5MOP), and 8-methoxysoralen (8MOP), have well documented phototoxicological properties. Although most research has focused on 8MOP due to its high phototoxic potential and use in some therapy modalities (e.g. PUVA), several other naturally occurring furocoumarins are phototoxic. Oxypeucedanin is a furocoumarin that occurs at significant concentrations in lime oil. We sought to determine if oxypeucedanin formed DNA adducts following irradiation in the presence of DNA, and whether the DNA adduct formed from oxypeucedanin could be distinguished from those formed from other furocoumarins. Oxypeucedanin was isolated from commercially available lime oil using published methods. Oxypeucedanin and other furocoumarins were dissolved in ethanol, and mixed overnight with 1 mg/mL DNA. The solutions were irradiated with a fluorescent-lamp UVA source at doses of 0 to 50 J/cm<sup>2</sup>. The DNA was isolated and DNA adducts <sup>32</sup>P-postlabeled using a standard protocol, and separated using HPLC or TLC. Oxypeucedanin formed a single DNA adduct in a dose-dependent manner when illuminated with UVA light. This adduct was chromatographically resolved from the photo-induced DNA adducts of coumarin, psoralen, 5MOP, and 8MOP using TLC or HPLC. The HPLC and TLC <sup>32</sup>P-postlabeling procedure has been used to determine the contribution of the various naturally occurring furocoumarins to DNA adduct formation when lemon and lime oil were incubated with DNA and exposed to UVA. This method will allow us to distinguish the contribution of each furocoumarin to DNA adduct formation from naturally occurring furocoumarin complex mixtures.

ACTIVATION OF HUMAN AH RECEPTOR SIGNALING BY POLYCYCLIC AROMATIC HYDROCARBONS AND EXTRACTS OF SOILS FROM THE NEW ORLEANS AREA.

C. A. Miller<sup>1</sup>, G. Wang<sup>2</sup>, J. Hughes<sup>3</sup> and A. Alnafisi<sup>1</sup>. <sup>1</sup>Environmental Health Sciences, Tulane University, New Orleans, LA, <sup>2</sup>Chemistry, Xavier University, New Orleans, LA and <sup>3</sup>Biostatistics, Tulane University, New Orleans, LA.

Polycyclic aromatic hydrocarbons (PAHs) are environmental pollutants that come from natural and human sources. Exposure to PAHs at sufficient levels causes numerous effects that include immunotoxicity, reproductive and birth defects, and

cancers. These toxic effects are mediated by the Ah (aryl hydrocarbon) receptor. Thus, monitoring the environment for pollutants that activate this signaling pathway is of toxicological importance. Sixteen environmentally relevant PAHs were tested individually and as mixtures in a yeast-based Ah receptor signaling assay. We classified these PAHs into four groups (inactive, weakly active, moderately active, and strongly active) based on their activation of human Ah receptor signaling. Indeno(1, 2, 3-cd)pyrene, chrysene, benz(a)anthracene, benzo(a)pyrene, benzo(j)fluoranthene, and benzo(k)fluoranthene were strongly active PAHs in our assay. PAH mixtures showed composition-dependent additive and synergistic effects in the Ah receptor assay. Receptor independent effects may explain the synergism of some PAH mixtures. Environmental samples from the New Orleans area were analyzed for PAH composition and quantity by gas chromatography/mass spectroscopy and then tested in this bioassay. Levels of total PAHs, active PAHs, and benzo(a)pyrene were correlated with the dilutions of the environmental samples needed to give EC25 signaling levels in the Ah receptor assay. Some environmental samples gave anomalous results in the Ah receptor assay. Samples with unexpectedly high signaling could contain additional Ah receptor ligands (PCBs, dioxins, etc.) that we did not measure. The Ah receptor signaling assay is a simple, rapid, and inexpensive tool for preliminary screening of samples that contain PAHs and other chemicals with affinity for the Ah receptor.

### INDUCTION OF CYCLOOXYGENASE-2 IN THE LUNGS OF RATS EXPOSED TO TOBACCO SMOKE.

K. R. Smith<sup>1</sup>, S. T. Owens<sup>1</sup>, A. W. Goodyear<sup>1</sup>, U. P. Kodavanti<sup>2</sup> and K. E. Pinkerton<sup>1</sup>. <sup>1</sup>Center for Health and the Environment, University of California, Davis, CA and <sup>2</sup>NHEERL, USEPA, Research Triangle Park, NC.

Cigarette smoking is associated with lung inflammation, epithelial damage, and remodeling of the airways leading to chronic obstructive pulmonary disease (COPD). Chronic airway inflammation is likely to play a key role in the development and progression of tobacco smoke (TS)-induced pulmonary disease. However, the mechanism by which smoking contributes to COPD is unknown. Inflammatory mediators, including products of cyclooxygenase-2 (COX-2), play a critical role in the initiation and progression of inflammation. We wished to evaluate expression of COX-2 protein in a model of TS-induced inflammation and disease. Spontaneously hypertensive (SH) rats were exposed to TS at approximately 30, 60, or 80 mg TSP/m<sup>3</sup> for 6 hours/day, 3 days/week, for 7 or 14 weeks. COX-2 protein expression in lung tissue was determined using Western blots and found to be significantly increased at the high dose of smoke following 7 and 14 weeks as well as at the medium dose after 14 weeks. Immunohistochemistry demonstrated COX-2 positive cells in the cuboidal epithelium of the conducting airways. Numbers of COX-2 positive cells followed a dose-dependent pattern, especially in central and mid-level airways of the lungs. An increase in exposure length from 7 to 14 weeks resulted in fewer COX-2 positive cells in the central airway of rats exposed to the highest TS level, due in part to replacement of cuboidal epithelium by stratified squamous epithelium. Lung lavage demonstrated a significant increase in macrophages and neutrophils at both 7 and 14 weeks at the highest concentration of smoke. We conclude repeated exposure to TS is associated with increased expression of COX-2, persistent airway inflammation, and epithelial metaplasia. COX-2 expression in epithelial cells of the airways may play an important role in the inflammatory response leading to remodeling of the epithelium and progression of tobacco smoke-induced airway disease.

## 505

### DNA AND HEMOGLOBIN ADDUCTS FROM ORAL ADMINISTRATION OF ACRYLAMIDE TO MALE FISCHER 344 RATS.

T. Fennell<sup>1</sup>, R. W. Snyder<sup>1</sup> and M. A. Friedman<sup>2</sup>. <sup>1</sup>RTI International, Research Triangle Park, NC and <sup>2</sup>UMDNJ, Newark, NJ.

Acrylamide (AM) is carcinogenic in rats, producing tumors in the thyroid, tunica vaginalis, mammary tissue on administration in the drinking water. Glycidamide (GA), the epoxide metabolite of acrylamide reacts with DNA to form a number of adducts, the major adduct being N-7-(2-carbamoyl-2-hydroxyethyl)guanine (N7-GA-Gua). AM and GA both react with hemoglobin to form adducts at the N-terminal valine residue. The objectives of this study were to quantitate the major DNA adduct derived from the reaction of glycidamide in tissues from rats administered AM, and to quantitate the AM- and GA-derived hemoglobin adducts. Male Fischer rats were administered either vehicle alone or 1, 2, 3-<sup>13</sup>C<sub>3</sub> acrylamide by gavage at a dose of 50 mg/kg. At 24 hours following administration, DNA was isolated from liver, lung, spleen, testis, brain, white blood cells, and thyroid. Natural abundance and <sup>13</sup>C<sub>3</sub>-N7-GA-Gua were analyzed by LC-MS/MS. The unlabeled adduct was below the limit of quantitation of the method. Similar levels of <sup>13</sup>C<sub>3</sub>-N7-GA-Gua were observed in most tissues: 13.5 ± 1.7 (white blood cells), 17.3 ± 0.7 (liver), 18.0 ± 2.4 (kidney), 17.0 ± 1.5 (brain), 15.5 ± 1.7 (spleen), 14.7 ± 2.3 (lung), 14.0 (thyroid) and 13.5 ± 1.7 (white blood cells) pmol/mg DNA. N7-GA-

Gua in testis was significantly lower than the other tissues investigated (10.1 ± 0.8 pmol/mg DNA). Hemoglobin adducts derived from AM (N-(2-carbamoyl-ethyl)valine, AAVal) and GA (N-(2-carbamoyl-2-hydroxyethyl)valine, GAVal) were measured by the modified Edman method, with quantitative analysis by LC-MS/MS. In the vehicle-treated rats, unlabeled AAVal and GAVal were 0.05 pmol/mg, and were similar in the <sup>13</sup>C<sub>3</sub>-AM-treated rats. <sup>13</sup>C<sub>3</sub> AAVal and <sup>13</sup>C<sub>3</sub> GAVal were 17.3 ± 0.5 and 7.7 ± 1.0 pmol/mg globin, respectively, in the <sup>13</sup>C<sub>3</sub>-AM- treated rats. These data indicate that GA is distributed widely in the body, with the exception of testis, in which the levels of <sup>13</sup>C<sub>3</sub>-N7-GA-Gua were lower than the other tissues.

## 506

### CHARACTERIZATION OF MAINSTREAM CIGARETTE SMOKE-INDUCED CHRONIC INFLAMMATION IN ICR AND C57BL/6 MICE.

K. C. Hodge-Bell<sup>1</sup>, K. M. Lee<sup>2</sup>, A. F. Fuciarelli<sup>2</sup>, R. A. Renne<sup>2</sup>, S. J. Harbo<sup>2</sup> and W. J. McKinney<sup>1</sup>. <sup>1</sup>Research & Technology, Phillip Morris USA, Richmond, VA and <sup>2</sup>Battelle Toxicology Northwest, Richland, WA.

To understand the pathogenesis of smoke-induced emphysema, male C57BL/6 (C57) and ICR mice were exposed nose-only to mainstream cigarette smoke (MS) for 6 months at 75, 250 and 600 µg total particulate matter (TPM)/L from 2R4F standard reference cigarettes. Blood and bronchoalveolar lavage (BAL) fluid samples were collected 24 hours post-exposure at selected times (6, 13, 22, 28 weeks and 13 week recovery period). Blood was analyzed for biomarkers of exposure (carboxyhemoglobin, nicotine, and cotinine). BAL fluid was analyzed for biomarkers of effect: oxidative stress (GSH, GSSG, and 8-isoprostanate), tissue injury (elastase and collagenase), inflammation (cells, LDH, NAG, and proteins), and apoptosis. Overall, minimal strain differences were observed. Biomarkers of exposure increased in a dose-dependent manner. Changes in biomarkers of effect were primarily observed at 600 µg TPM/L. There were no significant changes in most oxidative stress and tissue injury biomarkers; however 8-isoprostanate increased following 13 week recovery period. BAL macrophage and neutrophil counts were rapidly (6 weeks) and consistently (13, 22, 28 weeks) elevated while lymphocyte counts gradually increased over time. Apoptotic activity declined with repeated exposures. Following 28 weeks of exposure, minimal emphysema of the alveolar ducts was observed in ICR (20%) and C57 (10%) mice. Additionally, inflammatory infiltrates were observed around alveolar ducts and adjacent vasculature. Morphometric analysis of the lung was inconclusive (i.e. Lm increase < 20%). In summary, changes in macrophages, neutrophils, and lymphocytes reported in smokers with emphysema were comparable to MS-induced changes observed in this mouse model. Therefore, ICR and C57 mice chronically exposed to MS may be utilized to investigate the role of inflammation in the pathogenesis of emphysema.

## 507

### NANBIOTECHNOLOGY: AUTOMATED REAL-TIME MEASURES OF TOXICANT INFLUENCE ON CELL SPEED IN CHEMOTACTIC ENVIRONMENTS.

X. Yin, N. Hadjout, D. Knecht and M. A. Lynes. Molecular and Cell Biology, University of Connecticut, Storrs, CT.

Cellular movement is a critical aspect of many physiological processes, including inflammation, immune responsiveness, and metastasis. This movement can be directed by soluble signals called chemokines and is potentially sensitive to toxicant influence both by changes to the molecular machinery of cell movement and by changes to the external signals that influence this movement. We have developed an automated real-time assessment of cell movement, and have used this ECIS/taxis system to evaluate the influence of various metal toxins and oxidative conditions on chemotactic cell movement. This system employs a target electrode as the detector. When cells cross this electrode as they respond to a chemotactic gradient, they impart an increased resistance to current that is passed through the electrode. The time of cell arrival at the target electrode can be precisely defined by the characteristic change in resistance that results, and the magnitude of the cell response is proportional to the total increase in resistance that occurs. Employing this technology, we have defined the influence of various extracellular matrix proteins on the chemotactic response of Jurkat T cells to SDF-1a. Collagen, fibronectin and laminin each significantly diminish the speed of cell movement in response to SDF-1a under certain conditions. In addition, we have found that metallothionein (MT) has chemotactic activity, suggesting that cells exposed to toxins will alter cell trafficking by releasing metallothionein to the extracellular environment. Finally, we have used ECIS/taxis to define the capacity of neutrophils to move in an oxidative environment, and the different effects oxidant has on cells with different MT levels. Toxicant-mediated changes that increase or decrease cell movement will have important implications for the progression of inflammatory disease, for the development of protective immune responses, and for the establishment of secondary tumor foci. NIEHS ES07408, NIBIB EB00208.

MODULATION OF EXTRACELLULAR MATRIX MARKS  
EARLY DEGENERATION OF KIDNEY PAPILLAE  
INTERSTITIAL CELLS (IC) OF RATS DOSED WITH  
INDOMETHACIN (IND).

P. Ciacco<sup>1</sup>, S. Emene Hart<sup>1</sup>, J. Bartock<sup>1</sup>, V. Orefeo<sup>2</sup>, C. Kind<sup>2</sup>, K. Kenne<sup>3</sup>, S. Matis<sup>1</sup>, F. Pognan<sup>4</sup> and B. Graham<sup>4</sup>. <sup>1</sup>*Safety Assessment, AstraZeneca Pharmacology, Wilmington, DE*, <sup>2</sup>*AstraZeneca Pharmacology, Leicestershire, United Kingdom*, <sup>3</sup>*AstraZeneca Pharmacology, Södertälje, Sweden* and <sup>4</sup>*AstraZeneca Pharmacology, Macclesfield, United Kingdom*.

Regionspecific renal damage such as renal papillary necrosis (RPN) is difficult to monitor and predict. Using both gene expression profiling (GEP) of papillae total RNA and 2-D gel electrophoresis of urine (protein id by Maldi-ToF), we sought to identify early markers for RPN. Rats were dosed with 0, 8.4, 14 or 16.8 umol/kg/day IND sc for 3 or 7 days. Urine was collected on days 7-8. On days 4 or 8, animals were sacrificed and the papilla removed from one kidney for RNA isolation; the 2nd kidney was used for histologic evaluation. Early, time- and dose-dependent interstitial matrix increases and IC degeneration were noted for IND-dosed animals. No significant changes in a battery of urine chemistry parameters, including urinary electrolytes, NAG and creatinine, were observed. By contrast, the pathologic changes were accompanied on days 4 or 8 by altered expression of a number of genes involved in extracellular matrix remodeling, including 12/15 lipoxygenase, syndecan, MMP inhibitor, haptoglobin, T-kininogen, latexin, MMPs, plasminogen activator, proteoglycoprotein, alpha-1 protease inhibitor and others. Uromodulin, clusterin and contrapsin-like protease inhibitor mRNA expression were also altered. Expression changes of 12/15 lipoxygenase, clusterin and Timp-1 mRNAs were confirmed by real-time PCR. The pathology and gene expression changes are consistent with the hypothesis that IND may interfere with compensation mechanisms for osmotic stress in the papilla, since alteration in interstitial glycosaminoglycan (GAG) content is seen in RPN and other hyperosmolar states and since the targeted ICs are known to be responsible for maintenance of matrix & matrix GAGs. Finally, urine levels of haptoglobin, T-kininogen, and contrapsin-like protease inhibitor protein were altered, illustrating a good correlate to the GEP signature in a relevant, noninvasive biological matrix.

A METABONOMICS INVESTIGATION OF THE  
HEPTOTOXICITY OF VALPROIC ACID.

L. K. Schnackenberg<sup>1</sup>, D. Hansen<sup>2</sup> and R. D. Beger<sup>1</sup>. <sup>1</sup>*Division of Systems Toxicology, National Center for Toxicological Research, Jefferson, AR* and <sup>2</sup>*Division of Genetic and Reproductive Toxicology, National Center for Toxicological Research, Jefferson, AR*.

Mice were injected subcutaneously with 60 mg/mL valproic acid in 0.9% sodium chloride and urine serum or liver tissue collected at 6, 12 and 24 hour timepoints. Valproic acid (VPA) has been employed for the treatment of epilepsy but has been shown to act as a hepatotoxin in some cases. Studies have proposed that the hepatotoxicity resulting from VPA treatment may result from alterations in branched-chain amino acid and fatty acid metabolism. NMR-based metabolomics was applied to investigate the changes in endogenous metabolites following dosing with VPA. Control samples were also collected at each timepoint for comparison. Principal component analysis of the urine samples showed a tight clustering of the control groups with looser clustering of the three timepoints from the dosed group. Bins associated with amino acids and glucose were responsible for the clustering noted. Discriminant analysis of the aqueous liver tissue samples was able to correctly classify the samples as control or dosed as well as by timepoint. Bins associated with amino acids and glucose were shown to be important in the development of a model for discriminant analysis.

POTENTIAL ROLE OF METHYLGUANIDINE FOUND  
IN METABONOMICS INVESTIGATION OF  
NEPHROTOXICITY.

A. Amberg<sup>1</sup>, I. Stammberger<sup>1</sup>, M. Kurz<sup>2</sup>, M. Will<sup>2</sup>, H. Juretschke<sup>3</sup> and M. Gerl<sup>1</sup>. <sup>1</sup>*Drug Safety Evaluation, Sanofi Aventis, Hattersheim, Germany*, <sup>2</sup>*Chemistry, Sanofi Aventis, Frankfurt, Germany* and <sup>3</sup>*Gobal Experimental Medicine, Sanofi Aventis, Frankfurt, Germany*. Sponsor: M. Bonnefoi.

Metabonomics is a new technology for the investigation of drug toxicity performed in biofluids (e.g. urine) with analytical methods (e.g. NMR spectroscopy). Therefore metabonomics was applied for the investigation of nephrotoxicity. For this a metabonomics study was performed with PRP-X, a drug candidate that was terminated due to renal tubular dilatation/degeneration and hepatocellular hypertrophy in rats. In this study male sprague dawley rats were treated with 0, 10 and 200 mg/kg of RPR X for 5 days and urine was collected on day 1 and 5 postdose. Urines were analyzed by 1H-NMR spectroscopy and principal component analysis (PCA). In the PCA plot the urine NMR spectra from all rats were separated into 3 different groups, the first group dosed with 0 and 10 mg/kg, the second dosed with 200 mg on day 1 and the third group dosed with 200 mg/kg on day 5. Clear sepa-

ration along the x-axis was observed for all urine spectra from rats treated with 200 mg/kg compared to the 0 and 10 mg group. Responsible for this separation was a signal in the NMR spectra at 2.83 ppm elucidated as methylguanidine. Additional to this the urine spectra from rats treated with 200 mg/kg collected on day 1 were separated along the y-axis compared to the urine spectra collected on day 5. Responsible for this separation was a signal at 2.45 ppm and 3.01 ppm in the NMR spectra elucidated as 2-oxoglutarate. In the literature methylguanidine is described to be increased in renal and liver diseases and after proximal tubular injuries. It is reported that methylguanidine is formed from creatinine by reactive oxygen species. Therefore enhanced methylguanidine production is a result of oxidative stress in combination with creatinine accumulation. The results from this study indicate the potential of metabolomics as a powerful tool in toxicological studies.

PATTERN RECOGNITION OF NMR SPECTRA OF  
URINE FROM WISTAR RATS DOSED WITH LIVER AND  
RENAL TOXICANTS.

R. D. Beger<sup>1</sup>, L. K. Schnackenberg<sup>1</sup>, Y. P. Dragan<sup>1</sup>, M. D. Reily<sup>2</sup> and D. G. Robertson<sup>3</sup>. <sup>1</sup>*Division of Systems Toxicology, National Center for Toxicological Research, Jefferson, AR*, <sup>2</sup>*Discovery Technologies, Pfizer, Ann Arbor, MI* and <sup>3</sup>*World Wide Safety Sciences, Pfizer, Ann Arbor, MI*.

A collaboration between Pfizer and the Center of Metabolomics Research at NCTR was initiated to study the ability of NMR in combination with pattern recognition techniques to rapidly detect toxicity in urine samples. Single doses of 4-aminophenol (150 mg/kg), puromycin aminonucleoside (150 mg/kg), Sodium Chromate (25 mg/kg), hexachlorobutadiene (200 mg/kg), Galactosamine (600 mg/kg), Allyl Alcohol (120 mg/kg), and thioacetamide (200 mg/kg) were administered to 4 adult male Wistar rats. Urine samples were collected daily in metabolism cages at Pfizer and monitored by 1D 1H NMR at NCTR. The NMR spectra of urine were binned using ACD's "intelligent binning" for statistical analysis. Two-dimensional principal component analysis (PCA) of the binned NMR spectra from urine on the second day after dosing was able to clearly differentiate rats dosed with renal toxins from rats dosed with hepatotoxins. Partial least squares-discriminant function (PLS-DF) models built from NMR spectra from day 2 urine samples were able to differentiate between renal toxicity, hepatotoxicity, and control samples.

DIBUTYLTIN EXPOSURE ALTERS CIRCULATING  
BLOOD GROWTH FACTOR LEVELS.

T. Lyons-Darden<sup>1</sup>, S. Jenkins<sup>2</sup>, R. Luebke<sup>4</sup> and S. Barone<sup>3</sup>. <sup>1</sup>*Neurotoxicology, USEPA, Research Triangle Park, NC*, <sup>2</sup>*Office of Air Quality Planning and Standards, USEPA, Research Triangle Park, NC*, <sup>3</sup>*National Center for Environmental Assessment, USEPA, Washington, DC* and <sup>4</sup>*Environmental Toxicology, USEPA, Research Triangle Park, NC*.

Organotin compounds are commonly used as heat stabilizers in the manufacture of PVC plastics, in pesticides, and as preservatives for a wide variety of materials. Dibutyltin (DBT) is of particular interest due to its immunotoxic effects. In this study, we used ELISA assays to determine the effects of developmental dibutyltin dichloride exposure in Wistar rats on blood concentrations of several proteins including Nerve Growth Factor (NGF), Brain-Derived Neurotrophic Factor (BDNF), Neurotrophin-3 (NT-3), Neurotrophin-4 (NT-4), Tumor Necrosis Factor Alpha (TNF $\alpha$ ), and Neuropeptide Y (NPY). These proteins are either growth factors or cytokines involved in development and inflammation, and may be useful biomarkers of effect. DBT effects were studied in pups of exposed dams (from GD6-20; gestational group) and in pups exposed directly (from PND3-21). DBT doses were given by gavage and included 0, 2.5 and 5.0 mg/kg three times per week. All pups were sacrificed at either PND21 or PND38. At PND21, gestationally exposed pups had an 11% decrease in body weight at the high-dose but no significant changes in body or brain weight at PND38. The directly dosed pups exhibited an 8% decrease in body weight at PND21 for both treatment groups, while at PND38 there was a 14% decrease in body weight and significant decreases in brain weight (7% in the low-dose and 13% in the high-dose groups). Blood from gestationally exposed high-dose pups showed increased protein concentrations of BDNF (at PND21) and decreased concentrations of NGF (at PND38). Blood from the directly dosed high-dose pups showed increased concentrations of NGF, NT-3, and NT-4 only at PND38. This study indicates DBT affects circulating levels of growth factors in blood following developmental exposure to DBT. This abstract does not necessarily reflect EPA policy.

EVALUATION OF CYTOCHROME P450 1A1 AND 1B1 IN  
HUMAN BLOOD LYMPHOCYTES AS BIOMARKERS OF  
EXPOSURE TO DIOXIN-LIKE COMPOUNDS.

M. van Duursen, T. Sanderson and M. van den Berg. *Institute for Risk Assessment Sciences, Utrecht, Netherlands*.

Cytochrome P450 1A1 (CYP1A1) and 1B1 (CYP1B1) are phase I enzymes the expression of which can be affected by many environmental compounds, including dioxins and dioxin-like compounds. Because CYP1A1 and CYP1B1 expression can

easily be determined in peripheral blood lymphocytes, it is often suggested as biomarker of exposure to these compounds. We investigated the variation in constitutive and induced ethoxresorufin-O-deethylase (EROD) activity and CYP1A1 and CYP1B1 gene expression in blood lymphocytes in a group of ten non-smoking females. Freshly isolated lymphocytes were exposed to 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) or the dioxin-like polychlorinated biphenyl 126 (PCB126). All individuals showed a concentration-dependent increase of EROD activity by TCDD, which was significantly correlated with an increase in CYP1A1, but not CYP1B1 expression. The maximum induced EROD activity by 10 nM TCDD was very different among the individuals, but the EC50 values were about the same (0.8 ± 0.07 nM TCDD). PCB126 also caused a concentration-dependent increase of EROD activity, but was a 100-1000 times less potent than TCDD among the individuals. The allele frequencies for CYP1A1 MspI and CYP1B1 Val432Leu were also determined and reflected a normal Caucasian population, but the polymorphisms had no apparent effect on the expression and activity of these enzymes in this study. To further investigate the use of CYP1B1 as biomarker, it was applied to a large human population, exposed to PCBs in Slovakia. In this population, we found a large variation in CYP1B1 expression. And despite the high blood levels of PCBs and TEQs in the study population and the separation of the population into the CYP1B1 Val432Leu genotype groups, no significant correlation was observed between PCB levels and CYP1B1 mRNA levels in human lymphocytes. These studies indicate that it is unlikely that potential effects on CYP1A1 or CYP1B1 expression due to exposure to dioxins or dioxin-like compounds can be detected which makes its suitability as biomarkers of exposure questionable.

MULTI-TISSUE CHARACTERIZATION OF RHYABDOMYOLYSIS FOR THE HIGH PROFILE FAILURE CERIVASTATIN.

B. Ganter and K. L. Kolaja. *Chemogenomics and Toxicology, Iconix Pharmaceuticals, Mountain View, CA.*

Gene-expression-based chemogenomic analysis of cerivastatin discriminated it from other HMG-CoA reductase inhibitors (i.e. statins). The ability to identify cerivastatin as distinct from other statins is critical since this compound was withdrawn from the market due to rhabdomyolysis and lethality. We have profiled 7 statins (lovastatin, simvastatin, cerivastatin, mevastatin, fluvastatin, atorvastatin and pravastatin) and close to 600 other compounds (3, 700 different dose-time treatments) in short, repeat dose studies in rats. In liver, kidney, and muscle, cerivastatin was differentiated based on its ability to perturb genes associated with hepatotoxicity, inflammatory response, and cytoskeleton. An in-depth analysis of genes perturbed, shows cerivastatin is the most potent inducer of inflammation in kidney and muscle among all compounds studied. Hierarchical clustering of liver expression data using genes correlated to ALT and AST revealed that cerivastatin clustered with a number of classic liver toxicants including methapyrilene, chloroform and 1-naphthylisothiocyanate. Perturbations in hepatic gene expression predict ammonia-induced toxicity due to repression of the urea cycle, possibly leading to secondary muscle fatigue or muscle damage, and a dysregulation of cytoskeleton genes. The dysregulation of cytoskeleton genes observed in liver is further exacerbated in muscle by the fact that key ECM and connective tissue proteins, including tenascin C, fibronectin, laminin, and collagen, are downregulated. The cytoskeleton dysregulation observed in muscle, combined with a gene expression pattern suggesting an altered excitation-contraction coupling due to an altered Ca(2+) buffering capacity, may explain the mechanism of myocyte necrosis that precedes rhabdomyolysis. To conclude, liver gene expression data in short-term rat studies discriminated cerivastatin from its peers and shed light on its risk of toxicity, while the muscle expression data confirmed the mechanistic information relevant to target organ toxicity.

EVALUATION OF KIDNEY TOXICITY DETECTION METHODS: URINARY GSTS AND PROTEIN PROFILING BY SELDI-TOF-MS.

K. Okamoto<sup>1,2</sup>, W. W. Collette<sup>2</sup>, M. Mondal<sup>2</sup>, A. de Peyster<sup>1</sup> and G. J. Stevens<sup>2</sup>.  
<sup>1</sup>*Graduate School of Public Health, San Diego State University, San Diego, CA* and  
<sup>2</sup>*Worldwide Safety Sciences, Pfizer Global Research and Development, San Diego, CA.*

Routine measures of serum and urinary biomarkers of renal injury are insensitive and nonspecific. In humans, clinical signs of renal damage usually appear only after severe renal injury has occurred. Thus, better predictive biomarkers for the early detection of kidney damage are clearly needed. The objective of this study was to compare the sensitivity and specificity of various detection methods to assess kidney injury in rats. Four known kidney toxicants (cisplatin, p-aminophenol, bromoethyamine and mercuric chloride), with varying mechanisms of toxicity, were studied. Eight male Sprague-Dawley rats were assigned to each of three treatment groups (control, low and high dose). After a single IP dose, urine samples were collected for eight days. Four animals per group were euthanized and necropsied at 48 and 168

hours. Histopathology examinations were conducted to provide pathological evidence of localized renal injury. Urinary volume, serum and urine chemistry,  $\alpha$  and  $\mu$  GST excretions, and protein expressions were measured at selected time points. Abundant proteins in urine samples were removed by affinity purification prior to running the samples through SELDI-TOF-MS. Data from the four toxicants suggest that GSTs are sensitive markers of tubular toxicity, but lack the ability to detect medullary toxicity (bromoethyamine). Serum markers often provided insensitive measurements relative to the extent of renal injury, whereas a simple measurement, such as urine volume, yielded a better indication of renal insult. SELDI-TOF-MS analysis demonstrated single or multiple protein patterns in treated groups' samples to indicate acute kidney injury. Resulting data suggest that multiple endpoint analyses of urinary markers are necessary to reliably assess acute renal injury in rats.

CHARACTERIZATION OF EPOXIDE ADDUCTS OF POLYCYCLIC AROMATIC HYDROCARBONS (PAH) WITH HEMOGLOBIN (HB).

M. Y. Ali, H. E. Hurst and S. R. Myers. *Pharmacology and Toxicology, Center for Environmental and Occupational Health Sciences, University of Louisville, Louisville, KY.*

We investigated the binding of selected PAH epoxides (benzo(a)pyrene, benzo(b)fluoranthene, dibenz(a, hanthracene, fluoranthene, benzo(ghi)perylene, and benz(a)anthracene) to Hb in order to determine the overall extent of binding kinetics of the PAH to Hb. The following experiments were carried out using mouse (C57BL/6 male) and human Hb *in vitro*. Packed red cells were resuspended in isotonic saline (2 mls) and 100  $\mu$ l aliquots were used in reactions. PAH epoxide stock solutions were dissolved in tetrahydrofuran (1 mg/ml) and 10  $\mu$ l PAH stock was added to reactions which were carried out at 37° for various times. Reactions were stopped by addition of ice cold water and globin precipitated by addition of Hb to acidified acetone. PAH epoxides were released by incubation with pronase and PAH tetrols extracted using of liquid and solid phase extraction and analyzed spectrophotometrically by HPLC. Similar kinetics were found in both mouse and human suggesting that similar nucleophilic sites of attack of the epoxide are present in both species. In addition, these results point out that the mouse model is appropriate for carrying out investigational studies using carcinogens which potentially can be applied to human biomarker studies. The results demonstrated that that those carcinogens that are weakly active had only a slight degree of binding to hemoglobin, while those that are stronger, such as BPDE, had a larger degree of protein binding. All of the epoxide metabolites yielded detectable levels of Hb adducts that were in proportion to the known carcinogenicity of the parent PAH. These results suggest that the formation of hemoglobin adducts to PAH carcinogens may serve as reliable biomarkers of exposure as well as carcinogenicity.

EXHALATION OF CYTOKINES BY LABORATORY RODENTS.

E. Bermudez and O. R. Moss. *CHI Centers for Health Research, Research Triangle Park, NC.*

The pulmonary system is a major portal for the introduction of numerous agents. Identification and treatment of exposed individuals can be greatly aided by detailed information on the elicited pulmonary response. Exhaled breath has been used to assess the physiological state of humans by examining the levels of volatile compounds. More recent work has demonstrated the presence of cytokines in human exhaled breath. The present work focuses on the capture of proteins carried in the exhaled breath of laboratory rodents, as a means of determining the inflammatory status of the lung. Mice were exposed twice to endotoxin (E. coli) by intratracheal instillation and the exhaled breath was collected from a group of 50 animals 4 d following the first endotoxin treatment. Rats were exposed to bleomycin by intratracheal instillation and the exhaled breath was collected from a group of 50 animals at various times postexposure. To collect the breath the animals were placed in a modified nose-only Canon exposure tower and the breath was condensed, in cooled collection vessels, with an efficiency of 91 to 97%. Bronchoalveolar lavage (BAL) was performed on subgroups of animals to provide a portrait of the inflammatory status of the lung. The presence of cytokines was assessed using a bead-based immunoassay (Bio-Plex, Bio-Rad) specific for mouse (18 cytokine panel) or rat (9 cytokine panel). Pulmonary inflammation elicited by endotoxin or bleomycin treatment was readily detectable in BAL fluid as increased concentrations of total protein and numbers of inflammatory cells. Multiple cytokines were detected in the BAL fluid from both control and treated mice and rats. Similarly, the presence of cytokines was detectable in concentrated exhaled breath condensate (cEBC) of both rats and mice. In general the number of detectable cytokines were fewer in cEBC than in BAL fluid, although direct comparisons between the two methods cannot be made at this time. This work demonstrates that it is feasible to monitor the pulmonary inflammatory status of the most commonly used laboratory rodent models by non-invasively capturing exhaled cytokines.

THE INFLUENCE OF DIET ON ENDPOINTS  
TYPICALLY USED IN 13-WEEK TOXICITY STUDIES FOR  
RODENTS.

E. Harvey<sup>2</sup>, L. J. Betz<sup>2</sup> and G. Travlos<sup>1</sup>. <sup>1</sup>*NIEHS, Durham, NC* and <sup>2</sup>*Constella Health Sciences, Durham, NC*. Sponsor: C. Portier.

One of the most important factors influencing the biological processes of animals is diet. For example, dietary factors can influence immune response, longevity, and responses to environmental insults. Because diet can have a profound effect, baseline values for various endpoints used in toxicity studies and creation of historical databases may be altered when diet is changed. This poster discusses changes in various endpoints between two diets fed to F344 rats and B6C3F1 mice in 13-week toxicity studies conducted by the National Toxicology Program. Until the mid 1990's the primary diet used in the NTP studies was NIH07. Because of health concerns associated with this diet, the NIH07 diet was replaced with the NTP2000 diet. Data from control animals for NTP 13-week toxicity studies were used to make comparisons between the NIH07 and NTP2000 diets. The endpoints evaluated include body and organ weights, hematology, and clinical chemistry variables. Standard parametric or nonparametric two group tests were applied to compare the endpoints. The comparison groups were stratified by animal sex, species, and diet. Diet differences were observed for several endpoints. For example, heart, kidney, liver and terminal body weights were lower and white blood cell counts were higher for the NTP 2000 diet in male rats compared to the NIH07 diet. These findings indicate that the diet is an important source of variation for several endpoints typically used in rodent toxicity studies and, therefore, should be considered when evaluating historical databases and determining reference values.

USE OF *IN VITRO* TECHNOLOGIES AND  
METABONOMICS IN THE STUDY OF  
PHOSPHOLIPIDOSIS.

C. E. Thomas<sup>1</sup>, J. M. Colet<sup>2</sup>, A. Meissner<sup>2</sup>, B. Halstead<sup>1</sup>, R. Morgan<sup>1</sup>, K. Kramer<sup>2</sup>, W. Dewe<sup>2</sup> and D. Monteith<sup>1</sup>. <sup>1</sup>*Inv. Toxicology, Lilly Research Labs, Greenfield, IN*, <sup>2</sup>*Inv. Toxicology, Lilly Development Centre, Mont-Saint-Guibert, Belgium* and <sup>3</sup>*Statistics, Lilly Development Centre, Mont-Saint-Guibert, Belgium*.

Phospholipidosis (PL) refers to the accumulation of phospholipids within cellular organelles. The presence of such lipid inclusions can present an issue for pharmaceutical drug development dependent upon the target organ(s) and the margin of safety. Thus, while not necessarily a 'show-stopper' event, ligands against certain drug targets have shown propensity to induce PL and it is advantageous to identify drug candidates least likely to induce this effect. Accordingly, we have developed a series of *in silico* and *in vitro* tools that allow ranking of molecules for physico-chemical properties that drive PL, and that guide *in vivo* testing in rodents. Animal studies conducted with a number of compounds encompassing several chemical classes indicated that pharmacokinetic parameters appeared to significantly influence PL induction; therefore, a facile *in vivo* screen was needed to further drive the SAR. Others have reported that phenylacetylglucine (PAG) can be used as a biomarker for PL. We have used <sup>1</sup>H-NMR to profile urine of rats treated with both known inducers of PL and compounds for which our *in silico* and *in vitro* data suggested a range of potential PL induction. We determined that PAG was closely associated with histologic evidence of PL. Although fasting was determined to also influence PAG excretion, statistical modeling (PLS-DA) allowed a clear distinction between non-compound and compound related effects. Logistic regression analysis of spectra obtained from an experiment in which rats were dosed with closely related analogs that induced a range of severity for PL allowed determination of a threshold ratio that could be used to predict the histologic findings. Current efforts are focused on developing chemometric models which encompass a greater number of metabolites and which improve the specificity of the prediction as compared to using only the PAG:creatinine ratio.

EVALUATION OF VITAMIN K AND VITAMIN K  
EPOXIDE AS BIOMARKERS OF COAGULOPATHY IN  
RAT SERUM UTILIZING HPLC.

K. A. Navetta, P. E. Quintas, M. D. Aleo and J. L. Colangelo. *Safety Sciences, Pfizer, Groton, CT*.

The assessment of circulating vitamin K and vitamin K epoxide status provides researchers with an earlier biomarker for coagulopathy compared to other standard measurements, such as prothrombin time in humans (*Am. J. Clin. Nut.* 1996, 64, 894-902). Vitamin K (phylloquinone) is a required co-factor for many of the proteins in the coagulation cascade and is critical for normal blood clotting. Some drug therapies can disrupt the vitamin K cycle resulting in accumulation of vitamin K epoxide with a concurrent drop in vitamin K. Use of these earlier biomarkers for coagulopathy in rats has not been investigated, but would be beneficial since rats are

commonly used for safety evaluation studies. The information presented includes a description of the liquid chromatography assay used to quantitate vitamin K and vitamin K epoxide in rat serum, an assessment of optimal study conditions necessary when collecting samples for vitamin K analysis, and the results of a preliminary study conducted to examine the anticoagulant effects of warfarin. The choice of commercial rat feed, the time of day for sample collection, and anticoagulant used were all found to affect vitamin K levels. The most critical factor is the time at which the sample is collected. Samples must be collected as close to the end of the 12-hour dark cycle as possible in non-fasted rats to ensure that vitamin K levels are measurable. Studies were also conducted to examine the levels of vitamin K and vitamin K epoxide in rats for which normal blood coagulation has been disrupted. Rats treated with warfarin for three days (0.1mg/kg, IP) were found to have significantly higher ratios of vitamin K epoxide to vitamin K (1.588) in comparison to control rats (0.293) that preceded changes in standard clinical coagulation biomarkers. Further research is warranted to determine the feasibility of using this ratio as an early biomarker of coagulopathy in rat serum for safety evaluation studies.

A MOLECULAR BASIS FOR THE PREDICTION OF  
RENAL TUBULAR INJURY BY DRUG SIGNATURES  
FOLLOWING SHORT-TERM COMPOUND  
TREATMENT.

M. Fielden, G. Natsoulis and K. Kolaja. *Chemogenomics and Toxicology, Iconix Pharmaceuticals Inc., Mountain View, CA*.

Using long-term drug-induced tubular nephrosis in the rat kidney as a model system, we used a robust and sparse support vector machine (SVM) algorithm to derive a valid signature containing only 35 genes for the prediction of late-onset kidney pathology after short-term compound administration. To better understand the biological basis of the classifier, an iterative approach of gene removal and signature re-derivation was used in order to identify all the genes that are necessary and sufficient to derive a signature. The iterative process was repeated until performance of the split sample cross validation dropped below a predetermined metric. An additional 151 genes, for a total of 186, were identified that are necessary to produce a valid classifier with an accuracy of at least 76%. The remaining 7292 genes on the microarray were tested using the SVM algorithm but were unable to produce a valid classifier. Examination of the 186 genes and their molecular and biological functions reveals many interconnected processes consistent with early nephropathy, including hypercholesterolemia, proteinuria, cellular stress, altered immune cell involvement and tubular regeneration. Many of these genes have previously been associated with nephrotoxicity or some form of renal injury. By comparison, other genes known to be responsive to nephrotoxicants in other more acute models of nephritic injury, were inaccurate for classification. Furthermore, putative biomarkers of kidney injury, such as Kim-1 or clusterin, did not accurately predict the future occurrence of toxicity, but rather reflected the actual occurrence of tissue injury. Considering the cellular heterogeneity of the kidney, it is likely that the observed changes in signature genes represent concurrent events in a complex, multi-cellular mechanism of toxicity. The multiple compound approach coupled with an iterative SVM data-mining illustrates the value of *in vivo* whole tissue mechanistic studies versus other methods which may not readily identify complex intercellular interactions.

BIOMARKERS THAT CHARACTERIZE FIBROSIS AND  
BILE DUCT HYPERPLASIA.

A. Vladimirova, R. Brennan, M. Fielden, K. Kolaja and C. Pearson. *Iconix Pharmaceuticals, Inc., Mountain View, CA*.

We have developed a large library of Drug Signatures<sup>TM</sup>, biomarkers for toxicologic, pathologic and pharmacologic mechanisms of action, to improve compound selection during drug discovery. These biomarkers are derived from a database integrating ~15,000 gene expression microarray results from rats treated with >600 compounds with traditional measurements of toxicity, pathology, and pharmacology. In particular, signatures predictive of hepatic fibrosis or bile duct hyperplasia (BDH) were derived using gene expression data from experiments in which histologically-confirmed fibrosis and/or BDH occurred and from early time-point experiments which did not induce fibrosis or BDH but used doses that caused one or both after longer exposure. Both fibrosis and BDH signatures had >70% true positive rate and >98% true negative rate. While fibrosis-inducing treatments consistently caused BDH, the converse was not necessarily true. Preliminary evidence from a more sensitive histological method, however, suggested that some BDH-inducing treatments did induce incipient fibrosis. In addition, treatments which caused BDH but not fibrosis induced genes associated with fibrogenesis. These genes, which were also induced by treatments causing fibrosis, include Mmp9 and

Plod2. The fibrosis and BDH signatures share one high-impact gene, Osf-2, a cell adhesion molecule that acts as a tumor suppressor and which has not been previously associated with either fibrosis or BDH. Except for Mmp9, genes in the predictive fibrosis signature did not contain known fibrogenic genes, suggesting that the signature genes are differentially regulated very early in the fibrotic process. Our findings indicate that fibrosis is tightly correlated with BDH, suggesting a mechanistic connection between the two. Moreover, both the fibrosis and BDH signatures identify new roles for genes not previously associated with either toxicity. These mechanistic and predictive findings can hasten and improve decision making during drug discovery, saving time and effort.

#### MULTI-ADDUCT ANALYSIS OF GLOBIN FROM MICE AND RATS AFTER INHALATION EXPOSURE TO 1, 3-BUTADIENE.

N. I. Georgieva<sup>1</sup>, G. Boysen<sup>1</sup>, P. B. Upton<sup>1</sup>, Y. Li<sup>1</sup>, V. Walker<sup>2</sup> and J. A. Swenberg<sup>1</sup>, <sup>1</sup>*ESE, UNC, Chapel Hill, NC* and <sup>2</sup>*Lovelace Respiratory Research Institute, Albuquerque, NM*.

Butadiene (BD) is an industrial chemical used in the production of synthetic rubber and is also found in gasoline and combustion products. BD is a multi-site carcinogen in rodents, with mice being the most sensitive species. BD is metabolized to several epoxides among which 1, 2, 3, 4-diepoxybutane (DEB) is the most mutagenic. Previous analysis of 1, 2, 3-trihydroxybutyl-valine (THB-Val) globin adducts suggested that most of them result from 3-buten-1, 2-diol (BD-diol) metabolism to epoxy-1, 2-butanediol (EBD), rather than from DEB. For specific examination of this metabolic step (BD to DEB), an immunoaffinity-capillary LC-MS/MS assay was developed for the analysis of the cyclic adduct N, N-(2, 3-dihydroxy-1, 4-butadiyl)valine (pyr-Val) and applied to globin samples from mice and rats exposed to BD through inhalation. Mice were exposed to 3, 6.25 or 1250 ppm BD for 10 days and rats were exposed to 3 or 62.5 ppm BD for 10 days, or to 1000 ppm for 90 days. The amounts of pyr-Val adducts were compared to 2-hydroxy-3-butenyl-valine (HB-Val), a biomarker for 1, 2-epoxy-3-butene (EB) and THB-Val, a biomarker for EBD, both measured by GC-MS/MS. This multi-adduct analysis provided new insight into species- and exposure-dependent differences in BD metabolism. In general, mice formed much higher amounts of pyr-Val than rats. The formation of HB-Val and pyr-Val was similar in mice exposed to 3 or 62.5 ppm BD, while HB-Val was 3-fold higher at 1250 ppm. In both species THB-Val adducts were much higher than HB-Val and pyr-Val. These data show that BD is primarily metabolized via the BD-diol pathway. In addition, mice are much more efficient at forming DEB adducts than rats, particularly at low exposures. The newly developed method should be readily adaptable to measurements of human globin samples from control and exposed humans. In general, the pyr-Val assay is a promising tool for understanding the formation of DEB associated with BD exposure.

524

#### INTERACTIONS OF COMPLEX CHEMICAL MIXTURES FROM CONTAMINATED SEDIMENTS AT A SUPERFUND SITE.

A. Gillespie<sup>1</sup>, T. D. Phillips<sup>1</sup>, T. J. McDonald<sup>2</sup>, L. He<sup>1</sup>, G. Zhou<sup>2, 1</sup> and K. Donnelly<sup>2, 1</sup>, <sup>1</sup>*VIBS, Texas A&M University, College Station, TX* and <sup>2</sup>*EOH, Texas A&M University H.S.C., S.R.P.H., College Station, TX*.

Because of multiple pathways of exposure and potential interactions of chemical mixtures, it is difficult to develop an accurate risk assessment for chemically contaminated sites. These include the Superfund sites. Risk characterization is the initial step towards ranking sites and evaluating appropriate remedial procedures. Chemical mixtures may alter toxicity through several different methods. Mixture interactions may alter transport across a membrane, induction of metabolizing enzymes or binding with critical macromolecules. The current study investigated potential interactions of mixtures of polychlorinated biphenyls (PCBs) and polycyclic aromatic hydrocarbons (PAHs) extracted from sediments at a Superfund site. Sediment samples were collected from a reference station and five locations along a contaminated river in the Pacific Northwest. Dried sediments were extracted and analyzed for PAHs, semi-volatile organics and PCBs. Sediment extracts were analyzed *in vitro* using microbial genotoxicity bioassays and *in vivo* using female ICR mice. The extracts were either negative or (for one sample) weakly positive in the microbial bioassays. Animal studies indicated that the genotoxicity of sediment extracts was more strongly correlated with PAH content than with PCB concentration. When the sediment extracts were co-administered with benzo[a]pyrene (BAP) to mice, the complex mixtures appeared to inhibit the formation of BAP-DNA adducts. Application of increasing concentrations of sediment extract reduced the levels of DNA adducts attributed to the BAP-diol epoxide (Spot #4). Chemical analysis identified high molecular weight PCBs as the major contaminant. Total

PCB concentrations were generally at least 4-5 times greater than total PAH concentrations. These data suggest that chemical interactions reduced the potential genotoxicity of the complex mixtures extracted from the sediments.

525

#### CORRELATION OF HEXENAL-DERIVED DNA BINDING WITH DETOXIFICATION AND DNA REPAIR STATUS IN CULTURED CELLS.

M. D. Stout<sup>1</sup>, J. Nakamura<sup>2</sup>, G. Boysen<sup>2</sup>, M. W. Powley<sup>2</sup> and J. A. Swenberg<sup>1</sup>, <sup>2</sup>*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC* and <sup>2</sup>*Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC*.

Trans-2-hexenal (hexenal) is an  $\alpha$ ,  $\beta$ -unsaturated aldehyde that is used as a flavoring agent, and is naturally present in food. Hexenal, like other  $\alpha$ ,  $\beta$ -unsaturated aldehydes, exerts genotoxic effects *in vitro* without metabolic activation. Upon reaction with DNA, these aldehydes form 1,  $N^2$ -propanodeoxyguanosine adducts (PdG). Hexenal has not been evaluated for carcinogenic potential, although treatment of rodents with some other  $\alpha$ ,  $\beta$ -unsaturated aldehydes is associated with tumor formation. There is evidence to suggest that  $\alpha$ ,  $\beta$ -unsaturated aldehydes are detoxified via conjugation to glutathione (GSH), and that PdG are repaired by nucleotide excision repair (NER). We have recently developed an LC-ESI<sup>+</sup>-MS/MS method to measure the hexenal-derived PdG (Hex-PdG) in DNA. We hypothesize that Hex-PdG measurement in cultured cells could elucidate the roles of GSH conjugation and NER in the detoxification of hexenal and the repair of Hex-PdG, respectively. HeLa cells ( $\pm$  the glutathione depleting agent buthionine sulfoximine, BSO) have been selected to study the correlation between GSH depletion and Hex-PdG formation. The role of NER in the repair of Hex-PdG will be studied by comparison of Hex-PdG formation between isogenic NER proficient and NER deficient XPA-/- and XPC-/- cell lines. To date, HeLa cells have been exposed to increasing hexenal concentrations for 6 hours. The Hex-PdG dose-response was highly sub-linear, with Hex-PdG detectable at 30  $\mu$ M, an inflection point between 100-300  $\mu$ M, and continued increases of Hex-PdG to 1000  $\mu$ M hexenal. GSH concentrations were decreased by 45, 80 or 84% at 100, 300 or 600  $\mu$ M hexenal, respectively. Acute cytotoxicity did not occur at concentrations of up to 600  $\mu$ M hexenal. Thus, preliminary data suggests that the inflection point of the Hex-PdG dose-response occurs as GSH is being depleted. Upon their completion, these studies will provide further evidence on the roles of GSH and NER in the amelioration of the cytotoxic and genotoxic effects of hexenal.

#### COMPARISON OF PLASMA AND URINE SAMPLES FROM ANIT-EXPOSED F344 RATS USING NMR SPECTROSCOPY.

D. Mahle<sup>1</sup>, N. J. DelRaso<sup>1</sup>, S. C. Gustafson<sup>2</sup>, C. L. Leakeas<sup>2</sup>, M. P. Westrick<sup>1</sup>, A. E. Neuforth<sup>3</sup> and N. V. Reo<sup>3</sup>, <sup>1</sup>*AFRL/HEPB, US Air Force, Wright-Patterson AFB, OH*, <sup>2</sup>*AFIT/ENG, US Air Force, Wright-Patterson AFB, OH* and <sup>3</sup>*Wright State University, Fairborn, OH*.

NMR metabonomic analysis was used to evaluate and compare the metabolic changes in urine and plasma caused by  $\beta$ -naphthylisothiocyanate (ANIT), a model cholestatic hepatotoxin. Male Fischer 344 rats were orally gavaged with 0, 0.01, 1.0, 20.0, 50.0 or 100 mg/kg of ANIT in corn oil. Urine was collected prior to dosing and daily for 4d post dose. Plasma was collected prior to dosing and at 24 h and 4d post dose, and clinical chemistry analyses were performed. Liver and kidney were removed at 4d post dose for histopathology. Urine and 4d plasma samples were analyzed by high resolution 600 MHz <sup>1</sup>H-NMR spectroscopy. The resulting spectra were processed and divided into 256 integral regions, and changes in the metabolic profile were assessed using principal component analysis to determine the dose-dependent biochemical variations caused by ANIT. After performing Fisher linear discriminant analysis, Receiver Operator Characteristic (ROC) curves were obtained for each dose group. Clinical chemistry analysis showed no changes at 20 mg/kg, recoverable changes at 50 mg/kg and persistently elevated liver enzyme levels at 100 mg/kg. Significant but mild liver pathological changes were detectable at 50 and 100 mg/kg. Urine NMR analyses for rats dosed with > 20 mg/kg ANIT showed a significant decrease in the tricarboxylic acid cycle metabolites, indicating a disruption in mitochondrial metabolism. ROC curves constructed from these data demonstrate the high predictive power of NMR-based metabonomics for ANIT-induced toxicity. Metabolic analyses of plasma and urine yielded complementary information. Some metabolites were detectable in both samples (lactate); however, plasma also revealed additional information not seen in urine NMR spectra, such as a significant decrease in plasma phenylalanine post-treatment. These data can be used to differentiate a recognizable pattern of metabolic profiles for injury caused by this cholestatic hepatotoxin.

## USE OF METABOLOMICS TO IDENTIFY BIOMARKERS OF BREVETOXIN EXPOSURE.

A. J. Bourdelais<sup>1</sup>, J. Benson<sup>2</sup>, A. Higgins<sup>3</sup>, H. Mei<sup>3</sup>, K. Powell<sup>3</sup>, K. Wang<sup>3</sup>, B. Tibbets<sup>2</sup> and D. G. Baden<sup>1</sup>. <sup>1</sup>*CMS, UNCW, Wilmington, NC*, <sup>2</sup>*Lovelace Respiratory Research Institute, Albuquerque, NM* and <sup>3</sup>*Icoria, Research Triangle Park, NC*.

Brevetoxins (PbTx) are toxins produced by the marine dinoflagellate *Karenia brevis*. Blooms of *K. brevis* occur along the Gulf Coast of the USA causing fish kills, marine mammal death and human health effects. Humans are exposed to PbTx by inhalation or by consumption of contaminated shellfish. Respiratory irritation seen in both normal and susceptible humans occurs at pM concentrations making quantification of exposure difficult. The goal of this work is to investigate use of metabolic profiles as indicators of PbTx exposure. Metabolomics was used to monitor urinary metabolites in mice after treatment with PbTx-3. Female mice were anesthetized and 0.1 ml PbTx-3 (5 ug/kg) was instilled into the lung. Mice were placed into metabolism cages and urine was collected at 24, 48 and 72 h. Control urine was obtained from a separate group of mice. Samples were collected on ice and stored at -80°C. Biochemical profiles were determined, in triplicate, on urine samples by LC/MS. Peaks in the LC/MS spectra were analyzed using proprietary algorithms. 4306 components were detected. Of these, 1019 were detected in all treatment groups. Cluster analysis was performed to see if replicates clustered together. Cluster analysis was performed using a pair-wise Pearson correlation for every pair of observations. Regression analysis was also performed on the log relative responses to find components that exhibit a linear or quadratic trend across time. 24 components were found with significant ( $p < 0.01$ ) quadratic trend across the 4 time points. In addition, 5 components were found with significant ( $p < 0.01$ ) linear trend. Compounds that did not show a trend were tested for a systematic difference between treated and pre-treated sample times and yielded 54 compounds with significant ( $p < 0.01$ ) differences. Of these, 23 are negative differences and 31 are positive. These data suggest that PbTx-3 produces unique metabolic changes in mice that can be identified using metabolomics.

## CAN LEVELS OF PLASMA TESTOSTERONE BE USED TO PREDICT MALE SEXUAL MATURITY IN RHESUS MONKEYS (MACACA MULATTA)?

M. D. Saunders, R. Davis, S. Fox and L. Earl. *Toxicology Operations, Huntingdon Life Sciences, Huntingdon, United Kingdom*. Sponsor: C. Hardy.

The Rhesus monkey is a species commonly used in non-clinical drug development. Much of non-clinical testing occurs in young animals. In order to assess the effects of drugs on the reproductive tract, sexually mature animals are required. Plasma testosterone concentration is sometimes used as a biomarker for the assessment of sexual development or sexual health in males from a variety of mammalian species. However, relating testosterone levels to sexual status in males is not simple in most species. The release of testosterone is pulsatile and therefore highly variable and often levels of the steroid are low in the plasma. An added complication with the Rhesus monkey is temporal variations in dominance, which may impact on testosterone secretion. This investigation was carried out to determine if plasma testosterone concentration, could determine sexual maturity *in vivo*. Plasma testosterone, testicular volume, testicular weight and bodyweight were recorded from 16 age matched Rhesus macaques. The testosterone values were recorded one week prior to termination. Terminal testicular volume and weight and terminal bodyweight were recorded at post mortem and were used as indicators of sexual status. Testosterone was compared with the terminal testicular volumes, the terminal testicular weights and the terminal bodyweight using principal components analysis. Sexual maturity was confirmed in these animals by histological examination of the testes. A strong correlation was found between testosterone values and all three indicators of sexual maturity. These data suggest that plasma testosterone has value as a biomarker of sexual maturity in the Rhesus monkey and that it may be used to monitor changes in sexual status *in vivo* as a result of sexual development or reaction to treatment.

## ADMINISTRATION OF A MEK INHIBITOR RESULTS IN TISSUE MINERALIZATION IN THE RAT DUE TO DYSREGULATION OF PHOSPHORUS AND CALCIUM HOMEOSTASIS.

A. P. Brown, C. Courtney, T. Carlson and M. Graziano. *Safety Sciences, Pfizer Global Research and Development, Ann Arbor, MI*.

Upregulation of the Ras-Raf-MEK-MAPK cell pathway is present in neoplasia. PD325901 is a selective inhibitor of MEK, and currently in cancer clinical trials. In 2-week oral studies in rats, PD325901 produced ectopic mineralization of various soft tissues and vasculature, consistent with calcium-phosphorus deposition. However, similar lesions did not occur in dogs or monkeys, despite administration

of lethal doses, significantly higher plasma drug levels, and inhibition of MEK. Studies were conducted to investigate the time-course for lesion development and identify biomarkers of toxicity. Male rats received PD325901 by gavage at 1, 3, or 10 mg/kg; controls received vehicle. Five animals/group were necropsied on Days 2, 3, or 4 after 1, 2, or 3 doses, respectively, and histology, clinical laboratory tests, and measurement of phosphorylated MAPK (pMAPK) were conducted. Lung pMAPK was inhibited ≥81% at ≥1 mg/kg on all days, indicating pharmacologic activity of PD325901. On Day 2, serum phosphorus (P) and 1, 25-dihydroxyvitamin D (Vit D) were increased 33%-43% and 2- to 7-fold, respectively, at ≥1 mg/kg. Elevations in P and Vit D were also seen on Days 3 and 4. Despite decreases in albumin, serum total calcium (Ca) remained unchanged on Days 2 and 3, indicating increases in protein-free Ca. Tissue mineralization (stomach, heart, aorta, arteries) was first observed on Days 2, 3, and 4 at 10, 3, and 1 mg/kg, respectively, and was preceded by increases in P and Vit D. Necrosis of physis/metaphysis, and thickening of hypertrophic chondrocytes occurred at ≥1 mg/kg. In a second study, male rats received a single oral dose of PD325901 at 1, 3, or 10 mg/kg and serum chemistries evaluated for 1 week. Serum P and Ca were increased on Days 2 and 3, with recovery thereafter. In conclusion, PD325901 produces tissue mineralization in rats due to dysregulation of P and Ca homeostasis, likely due to elevated Vit D levels. Frequent monitoring of serum Ca and P in the Phase I cancer trial have not indicated risk for this toxicity.

## USE OF METABONOMIC ANALYSIS FOR BIOMARKERS OF MUSCULOSKELETAL SYNDROME IN RATS.

F. Grzemski<sup>1</sup>, L. C. Robosky<sup>2</sup>, M. D. Reily<sup>2</sup>, D. Baker<sup>2</sup>, C. A. Lesch<sup>3</sup>, M. G. Evans<sup>1</sup>, D. F. Wells<sup>1</sup> and D. G. Robertson<sup>3</sup>. <sup>1</sup>*Safety Sciences, Pfizer, Ann Arbor, MI*, <sup>2</sup>*Discovery Technology, Pfizer, Ann Arbor, MI* and <sup>3</sup>*Inflammation Pharmacology, Pfizer, Ann Arbor, MI*.

Musculoskeletal syndrome (MSS) is characterized by joint pain and stiffness and microscopically by growth plate enlargement and soft tissue fibroplasia. MSS associated with matrix-metalloproteinase inhibitors (MMPI) has limited their use as therapeutic agents. Early non-invasive recognition of the potential to develop MSS, would provide insight into candidate identification for pharmaceutical development. The aim of this study was to explore the utility of metabolomic evaluation of rat urine to detect MSS during treatment with PD 200126, a broad spectrum MMPI. Male Sprague-Dawley rats were dosed with vehicle or 750mg/kg/day PD 200126 for 14 days. Urine was collected daily. Histopathological evidence indicative of MSS changes of mild to moderate severity in the femorotibial and tibiotarsal joints was seen in 75% of treated animals, which did not correlate to relevant clinical signs. NMR spectra from rats treated with PD200126 showed decreased levels of citrate, succinate, oxoglutarate, and hippurate, and increased levels of creatine. These spectral changes reverted to pretest values after dosing with PD200126 ceased and may prove useful for assessing the non-joint related toxicity of PD 200126. Supervised statistical methods were then used to determine if subtle NMR pattern changes could be related to the presence of MSS established by histopathology. Results show promise for using metabonomics as a non-invasive assessment tool for identifying MSS.

## INVESTIGATION OF A HEPATOTOXICITY SCREENING SYSTEM IN PRIMARY CELL CULTURE.

R. Kikkawa, T. Yamamoto, T. Fukushima, Y. Hamada, H. Yamada and I. Horii. *PGRD Nagoya Lab., Pfizer Japan Inc., Taketoyo, Aichi, Japan*. Sponsor: K. Masaaki.

Establishment of the *in vitro* hepatic toxicity screening system is demanded for earlier safety assessment. We investigated LDH release and mitochondrial respiration (WST-1) to detect cytotoxicity, morphological evaluation, and proteomics for estimating the proper biomarkers by using rat primary hepatocytes exposed to positive compounds known to induce hepatotoxicity. In LDH release, a dose-dependent increase was observed after exposure for 24 hours. Regarding WST-1, a dose-dependent reduction was observed after exposure for 6, and 24 hours to any of compounds. In the proteomics analysis, 31 candidate proteins were identified among the 103 showing altered expression spots. It is concluded that cytotoxicity was detected earlier by measuring WST-1 than by measuring LDH release because reduction of mitochondrial respiration is to be one of expressions of earlier toxicity in cellular function while the increase of LDH release can be shown only after failure of the cell membrane. Mitochondrial respiration ability may be a useful parameter of cytotoxicity for *in vitro* hepatotoxicity screening, as cytotoxicity can be detected in the early stage of exposure. To find out the toxicologically responsible biomarkers which correlate with the estimation of *in vivo*, precise correlation between *in vitro* and *in vivo* system is to estimate, and more comprehensive analysis of the 31 proteins identified are under investigation.

THE IDENTIFICATION OF POTENTIAL VASCULITIS BIOMARKERS TARGETED THROUGH SELDI SCREENING.

C. Drupa<sup>1</sup>, J. L. Colangelo<sup>1</sup>, R. A. Goldstein<sup>1</sup>, M. L. Mirsky<sup>1</sup>, R. M. Leimgruber<sup>2</sup>, M. Cabonce<sup>2</sup>, P. W. Brown<sup>2</sup> and E. Dalmasso<sup>3</sup>. <sup>1</sup>*World Wide Safety Sciences, Pfizer, Groton, CT*, <sup>2</sup>*World Wide Safety Sciences, Pfizer, St. Louis, MO* and <sup>3</sup>*Ciphergen Biosystems, Inc., Fremont, CA*. Sponsor: M. Lawton.

Surfaced enhanced laser desorption ionization (SELDI) is a technique being utilized to screen *in vitro* and *in vivo* samples for changes in the protein profile as a way of discovering biomarkers of disease states. Proteins that show changes between control and disease states may then be targeted for identification by mass spectrometry. Plasma samples from animals challenged with compounds known to cause vasculitis and the media from an endothelial cell line challenged with hydrogen peroxide were profiled by SELDI. Differentially expressed proteins that correlated across *in vivo* and *in vitro* samples were targeted as priorities for protein identification by mass spectrometry. A protein of interest (molecular mass of 4952) in cell media and serum was purified and concentrated by molecular weight filtration and HPLC fractionation. Identification was accomplished by digesting the purified protein with trypsin and analyzing the data by mass spectrometry (MS and MS/MS) experiments and submitting the resulting peptide mass fingerprint and *de novo* sequences to a protein database search. Proteins were also digested by carboxypeptidase Y and analyzed by matrix assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF MS) for C-terminal sequence information. The targeted protein in serum was identified by Ciphergen as inter- $\alpha$ -inhibitor H4 heavy chain. This identification was confirmed through peptide mass mapping, *de novo* sequencing and C-terminal sequencing. The protein in the *in vitro* sample with the same nominal molecular mass as the identified protein in serum has not yet been identified. However the carboxypeptidase Y derived C-terminal sequence information suggests that although the protein isolated from cell media has the same nominal molecular weight as the protein isolated from serum, the proteins are not the same.

ALANINE AMINOTRANSFERASE ACTIVITY IN THE FA2N-4 HEPATOCYTE CLONE.

E. R. Jackson and D. E. Amacher. *Safety Sciences, Pfizer, Inc., Groton, CT*.

The aim of this study was to examine the effects of xenobiotics on common cytotoxicity endpoints vs. alanine aminotransferase (ALT) leakage from the Fa2N-4 human immortalized hepatocyte clone. Previous characterization of the Fa2N-4 cell line has included gene expression and drug metabolism endpoints. Yet, there has been no information in the literature regarding the leakage of the necrosis marker, ALT in response to toxicants in the Fa2N-4 cells. Elevated serum transaminases, especially ALT, are the single most important laboratory indicator of hepatic effects from early preclinical testing to the post market monitoring. Fa2N4 cells were dosed in multiwell plates with sodium phenobarbital, acetaminophen, tamoxifen, valproic acid, or staurosporine in the presence of vehicle. After 24 hours, the spent media was removed for lactate dehydrogenase (LDH), aspartate aminotransferase (AST) and ALT analysis. Subsets of the samples reserved for ALT determination were analyzed in the absence/presence of cofactor supplement, pyridoxal 5'-phosphate (P-5'-P). The ALT reaction mixture in commercially available reagents lacks the cofactor P-5'-P and the possible effect of a deficiency encountered with a cell line was investigated within this study. In addition, the cells were evaluated for neutral red dye uptake, ATP depletion, and protein content. Results indicate that the addition of the cofactor to the reaction mixture produced no reproducible effect on ALT activities. Using ALT as a cytotoxicity marker, the rank order is as follows staurosporine>tamoxifen>acetaminophen>valproic acid>sodium phenobarbital. ALT leakage values corresponded to neutral red and/or ATP depletion results. In summary, addition of the P-5'-P cofactor at the tested concentrations did not increase the ALT responsiveness of the Fa2N-4 cells. The Fa2N-4 cell line was useful for ranking compounds for cytotoxicity, but the low levels of basal ALT leakage for the cell population on multiwell plates are lower than values seen with primary hepatocytes and not due to P-5'-P cofactor deficiencies.

TOXICOLOGIC AND PATHOLOGIC SURVEILLANCE OF SEARCH & RESCUE DOGS DEPLOYED TO THE WORLD TRADE CENTER, THE PENTAGON, AND THE STATEN ISLAND FRESH KILLS LANDFILL SITES.

W. K. Rumbeha<sup>1</sup>, S. D. Fitzgerald<sup>1</sup>, E. W. Braselton<sup>1</sup>, C. M. Otto<sup>2</sup> and A. B. Downend<sup>2</sup>. <sup>1</sup>*Pathobiology and Diagnostic Investigation, Michigan State University, Lansing, MI* and <sup>2</sup>*Clinical Sciences, School of Veterinary Medicine, University of Pennsylvania, Philadelphia, PA*.

This was a prospective surveillance study to evaluate toxicant exposure, long-term mortality, and pathology in dogs utilized in search and rescue (SAR) efforts at the Sept. 11, 2001 terrorist attack sites. A total of 152 dogs were enrolled in the study.

Of these, 70 dogs deployed to the sites were used in the toxicology study and 51 non-deployed SAR dogs were enrolled as controls. Of the 70 deployed dogs, 13 were deployed at the Pentagon, 11 at Staten Island Fresh Kill, and 46 at the World Trade Center sites. Whole blood or blood plasma samples were collected between October 2001 and June 2002 for toxicological analyses. End-points included blood lead and mercury, plasma polychlorinated biphenyls (PCBs), and gas chromatography/mass spectrometric (GC/MS) analysis of blood plasma for presence of toxic organic compounds. A standardized protocol was used in all necropsies. Results indicated that two dogs deployed at the WTC tested positive for lead at 0.06 and 0.07 ppm. All plasma samples tested negative for PCBs at a 0.05 ppm detection limit. All plasma samples tested negative for toxic organic compounds by GC/MS. No statistically significant differences were found in blood mercury concentration between control dogs and deployed dogs for any of the three study sites. To date, 11 deployed dogs have died compared to 2 non-deployed control dogs. Causes of death included cardiomyopathy, neoplasia, enterotoxaemia, and unspecified respiratory disease. Some deployed dogs had mild to moderate anthracosis. These results indicate a higher mortality rate for deployed vs non-deployed dogs. However, the mortality rate in SAR dogs was not as high as had been anecdotal reported after the Oklahoma City Federal Building bombing. The study also showed that there was no significant exposure to monitored toxicants in dogs deployed for SAR at the sites.

SEQUENCE AND EXPRESSION ANALYSIS OF CANINE ALT1 AND ALT2.

L. Nelms, B. Lu and M. Lawton. *Pfizer, Groton, CT*.

Alanine aminotransferase (ALT), also known as glutamate pyruvate transaminase (GPT), is a pyridoxal enzyme that reversibly catalyzes transamination between alanine and 2-oxoglutarate to form pyruvate and glutamate. Because of its relatively high and specific expression in liver, detection of ALT activity in the serum is considered a biomarker (or an indication) of potential damage to hepatocytes. In the rat, human, and mouse, it has recently been shown that there are two isoforms of ALT known as ALT1 and ALT2 each encoded by a different gene. The expression of these isoforms appears to vary with tissue type, and may also be species different. For example, in the human ALT2 is highly expressed in the brain, whereas in the mouse, it is less abundant. In preclinical rodent and clinical safety studies, some compounds are found to increase the level of serum ALT activity in the absence of corresponding hepatic necrosis. One possible explanation for this apparent anomaly is increased transcription of ALT1 and/or ALT2 in the liver; another is leakage or mobilization of ALT1 and/or ALT2 from extra hepatic tissues. To determine baseline expression of ALT1 and ALT2 in the dog, we have developed RNA-based assays that can specifically detect each isoform. cDNA sequences were determined based on *in silico* cloning from in-house, commercially available, and public domain databases. A putative full-length cDNA clone encoding ALT1 was assembled from EST and genomic fragments and its translated amino acid sequence found to be 90% identical to human ALT1. A partial clone for ALT2 was 94% identical to human ALT2. TaqMan (quantitative RT-PCR) assays were developed and used to measure expression in a variety of canine tissues. Results show that the level of ALT 1 expression is: liver > heart > kidney > fat > gastrocnemius. ALT 2 shows expression in the following order: gastrocnemius > fat > kidney > liver > heart. Relative expression of the isoforms is also tissue specific. For example, in liver, ALT1 mRNA expression is greater than ALT2 expression, whereas in fat and gastrocnemius, ALT2 is greater than ALT1.

AUTOMATED BIOCHEMICAL MEASUREMENTS OF ACYL-COA OXIDASE AND CARNITINE PALMITOYLTRANSFERASE FOR ASSESSMENT OF PPAR-INDUCED PEROXISOME PROLIFERATION IN CYNOMOLGUS MONKEYS.

D. F. Adams, M. A. Tirmenstein, K. M. Lynch, C. X. Hu, B. E. Maleeff, T. L. Gales, T. S. Sellers, D. Ennulat and L. W. Schwartz. *Safety Assessment, GlaxoSmithKline, King of Prussia, PA*.

Peroxisome proliferator activated receptor (PPAR) agonists are currently being developed for a wide range of therapeutic indications including diabetes, dyslipidemia and obesity. PPAR preclinical safety assessment studies in rats and monkeys have been associated with increases in liver weight and proliferation of peroxisomes and mitochondria. PPAR associated enzyme activities are established markers of peroxisomal proliferation in rats but have not been extensively evaluated in monkeys. To help characterize PPAR-induced hepatic effects in cynomolgus monkeys, we automated and evaluated spectrophotometric biochemical assays for measuring two fatty acid  $\beta$ -oxidation enzymes in liver tissue homogenates from control and PPAR-treated monkeys. Peroxisomal enzyme acyl-CoA oxidase (ACOX) activity was assessed by measuring the cyanide-insensitive reduction of NAD in the presence of palmitoyl-CoA. Mitochondrial enzyme carnitine palmitoyltransferase (CPT) activity was assessed by measuring the carnitine-dependent release of CoA-SH from

palmitoyl-CoA. Assays were performed at 37°C on the Bayer ADVIA 1650 and normalized per mg protein. Intra-assay CV's were 1.7-6.5% for ACOX and 1.2-1.6% for CPT. Inter-assay CV's were 1.2-9.9% for ACOX and 1.6-6.2% for CPT. Linearity was demonstrated across the ranges of values encountered in each assay (ACOX:  $y = 0.9977x + 0.0022$ ,  $R^2 = 0.9998$ , CPT:  $y = 0.9970x + 0.0033$ ,  $R^2 = 0.9999$ ). Recoveries ranged from 100-102%. Enzyme activities were elevated 1.2 to 4.2-fold (ACOX) and 1.3 to 2.9-fold (CPT) in monkeys dosed for 14 days with a PPAR alpha/gamma agonist. Increases in liver weights (relative to body weight) were observed in mid and high dose monkeys. Peroxisomal proliferation was confirmed by transmission electron microscopy and morphometric analysis. Results suggest that increases in ACOX and CPT activities correlate with peroxisomal proliferation in monkeys.

#### EVALUATING TOXICOLOGY AT A SYSTEMS LEVEL USING COHERENT ANALYSIS OF LARGE-SCALE DATA STREAMS.

I. Shah, Z. Cai, B. Bullard, T. Colatsky, A. Berger, M. Fedor, P. Hurban, G. Yuan and A. Higgins. *Ichora, INC, Research Triangle Park, NC.* Sponsor: N. Sponsor.

We have developed a novel systems biology approach for the study of liver injury based on the coherent analysis of genomic, metabolomic and histomorphometric data streams. We used this approach to study the effects of single oral doses (150-2000 mg/kg) of acetaminophen (APAP) on rat livers over a 48 hour period. At each sampling time (0, 6, 18, 24 and 48h), livers were snap frozen and processed for transcriptional analysis using Affymetrix RAE230 microarrays and metabolomic profiling using LC/MS. These experiments produced two large-scale data streams of 15, 923 transcripts and 549 endogenous small molecular weight biochemicals, which were combined with clinical chemistry data and histopathological classifications (normal, mild necrosis, medium necrosis and severe necrosis). Pattern recognition methods based on supervised machine learning algorithms were used to mine the data streams to discover sets of biochemical and transcriptional biomarkers that classified the samples by pathology end-point. Pathway analysis was then used to explore the possible range of biochemical mechanisms underlying the hepatotoxic effect. Classifiers identified using pattern recognition methods predicted liver histopathology with an accuracy of 94% measured objectively by 10-fold cross-validation testing. The classification accuracy for either transcriptional data and metabolomic data alone was lower than the performance of the data streams in combination. Automated pathway analysis using these data highlighted mechanisms that included phase I and II detoxification, oxidative stress, glutathione (GSH) metabolism, and amino acid metabolism. The biochemical changes associated with liver injury appeared more sensitive than traditional markers of liver injury, e.g. serum ALT and AST. This approach allows for detection of biochemical changes associated with liver injury at earlier times and lower doses than with conventional diagnostic endpoints.

#### A COMPARISON OF THE SPECIFICITY AND SENSITIVITY OF TRADITIONAL BIOMARKERS OF NEPHROTOXICITY IN THE RAT WITH METABONOMIC AND PROTEOMIC METHODOLOGIES.

A. C. Gibbs. *Scientific and Regulatory Consulting, Covance Laboratories Ltd., Harrogate, United Kingdom.* Sponsor: D. Everett.

There is currently great scientific interest concerning the possible advantages that proteomic and metabolomic technologies might have over traditional biomarkers of toxicity. Numerous papers promise great things from these technologies, however, there appears to be little hard evidence of their superiority over traditional techniques for assessing toxicity. This work evaluated the relative sensitivity and specificity of proteomic and metabolomic techniques compared to traditional methods for assessing xenobiotic-induced nephrotoxicity. A range of published studies with nephrotoxicants, where both old and new techniques were used for nephrotoxicity assessment, were evaluated. The data from each study were assessed and a comparison made of the relative sensitivity and specificity of the old and new methodologies. The data showed no consistent evidence that the novel methodologies were any more sensitive than traditional methods for assessing nephrotoxicity. However, this could be due to the relatively small number of published studies in which both old and new methodologies for nephrotoxicity assessment were used, and may not be the case with other forms of toxicity. In contrast, the novel methodologies were able to discriminate between the effects caused by different toxicants, both on the basis of different mechanisms of toxicity as well as on the basis of the specific location of the nephrotoxic lesion. In conclusion, despite high expectations for these new technologies, their benefit over traditional methodologies in terms of sensitivity remains to be demonstrated within the context of nephrotoxicity, although they can unlock mechanistic information. A great deal of validation work is

necessary before these techniques gain full acceptance by the regulatory authorities, however if they do achieve this hurdle then widespread use within regulatory toxicology studies is likely to become the norm.

#### THE RELATIONSHIP OF TREATMENT-RELATED DECREASES IN SERUM ALKALINE PHOSPHATASE ACTIVITY WITH ALTERATIONS IN BODY WEIGHT FOR RATS IN 13-WEEK TOXICITY STUDIES.

L. Betz<sup>2</sup>, E. Harvey<sup>2</sup> and G. Travlos<sup>1</sup>. <sup>1</sup>*NIEHS, Durham, NC* and <sup>2</sup>*Constella Health Sciences, Durham, NC.* Sponsor: C. Portier.

It is not uncommon for significant decreases in serum enzyme activities to occur in toxicity studies. Often these enzyme decreases are an enigma and not considered clinically or toxicologically relevant. There may be, however, underlying biological processes that can explain some of these changes. For example, in a series of studies conducted by the National Toxicology Program (NTP), alkaline phosphatase (ALP) activity demonstrated treatment-related decreases at a rate of about 39 to 56%, depending on the sex and study day. It has been suggested that decreases in ALP activity may be related to decreased food intake (anorexia or food avoidance) associated with chemical exposure. Since body weight can also be an indicator of nutritional status or food intake, assessing the relationship between ALP activity and body weight may be potentially useful in explaining the decreases in ALP activity. This poster will discuss the relationship of body weight and ALP as a function of treatment. Data from 13-week toxicity studies conducted by the National Toxicology Program are used to assess this relationship. Treatment-related decreases in body weight and serum ALP activity were evaluated using nonparametric trend tests and pairwise comparisons. Incidences of treatment-related body weight and ALP effects, individual and combined, are also reported. Results suggest a relationship between ALP and body weight and, thus, altered food intake may help to explain the decrease in ALP activity observed in toxicity studies.

Vitamin D analogs such as calcitriol are used for the treatment of osteoporosis. The major side effect of this therapy is dose-limiting hypercalcemia and hypercalciuria with or without resultant nephrotoxicity. The particular type of nephrotoxicity that is commonly seen with vitamin D analogs is renal mineralization. The development of biomarkers for early detection of nephrotoxicity is necessary to help monitor patients on these drugs. To identify candidate biomarkers of vitamin D analog-induced renal mineralization, animals were dosed with a low dose and high dose (20 and 4000 ng/kg/day, respectively) of calcitriol to induce renal toxicity. Overall the high dose, 14 day male rats were hypercalcemic, having a serum calcium level that differed by greater than 2 mg percent from the control. They also had hypercalciuria, which was evident by the markedly increased urine calcium excretion levels from the controls. Other findings include: Decreased food consumption with concomitant decreased body weight gain; clinical observations of rough fur and hunched stance; acidic urine and an increase in n-acetyl- $\beta$ -D-glucosaminidase (NAG) concentration, a tubular enzyme. Tissues and body fluids from this study are also being characterized by a variety of other techniques, including genomics, proteomics, metabolomics, and image analysis. Results from these broad profiling techniques should help to identify specific genes, proteins, and metabolic intermediates and other biomolecules that can be further investigated and characterized as potential biomarkers for renal mineralization.

#### EFFECT OF TESTICULAR EDEMA ON SPERMATOGENESIS IN TOXICANT-TREATED RAT TESTES.

K. Porter, C. C. Weng and M. L. Meistrich. *Experimental Radiation Oncology, U.T. M.D. Anderson Cancer Center, Houston, TX.*

Radiation or toxicant exposure induces azoospermia in LBNF1 rats by blocking spermatogonial differentiation, even though stem spermatogonia persist. Intratesticular testosterone levels increase at week 4, followed by development of testicular edema, and a block in spermatogonial differentiation at week 6, indicating that elevated testosterone (T) may be responsible for testicular edema. Treatment of irradiated rats with GnRH antagonist (GnRH-ant) rapidly decreases

T levels and stimulates spermatogenic recovery after a 3-week delay. In this study, we test whether GnRH-ant treatment can reduce testicular edema and the relationship between T suppression, edema reduction, and spermatogenic recovery. Rat testes were irradiated with 6 Gy and at week 15, some rats were treated with GnRH-ant, exogenous T, or 17 $\beta$ -estradiol (E2) for 8 weeks. Rats were killed weekly, testicular interstitial fluid volume determined, T analyzed, and spermatogonial differentiation assessed by histology. In irradiated rats, the GnRH-ant treatment caused T to fall at week 1 of treatment, followed by interstitial fluid volume decrease at week 3, leading to recovery of spermatogenesis starting at week 4. Treatment with both GnRH-ant and T largely maintained T levels and interstitial fluid volume, and blocked GnRH-ant stimulated spermatogonial recovery, indicating that testicular edema is associated with increased T. Treatment with both GnRH-ant and E2 partially blocked the effect of GnRH-ant on T, but accelerated fluid volume decrease to 2 weeks, and spermatogenic recovery to 3 weeks, indicating that E2 may act directly, apart from T suppression, to promote fluid reabsorption. Since the time course and extent of testicular edema reversal by GnRH-ant and steroid treatment parallels the recovery of spermatogenesis, we suggest that steroid-mediated increases in testicular interstitial fluid can block spermatogenesis and decreasing fluid levels can induce recovery. Experiments are in progress to determine whether dibromochloropropane-induced spermatogonial arrest is similarly modulated.

EFFECT OF ETHYLENE GLYCOL MONOETHYL ETHER ON SPERM MOTION IN RAT.

R. WANG<sup>1</sup>, K. Ohtani<sup>1</sup>, N. Jia<sup>2</sup>, M. Suda<sup>1</sup>, X. Gao<sup>2</sup> and T. Honma<sup>1</sup>. <sup>1</sup>*National Institute Ind. Health, Kawasaki, Kanagawa, Japan* and <sup>2</sup>*Beijing Diseases Control and Prevention Center, Beijing, China*. Sponsor: X. YU.

Ethylene glycol monoethyl ether (EGEE) can cause testicular damage in experimental animals and man, resulting in decreased sperm count. In this study, we analyzed how EGEE affect sperm motion in rats after acute and subchronic treatment. EGEE was administered by oral gavage to adult male Sprague-Dawley rats at 100, 300 or 600 mg/kg/day, 6 times per week for 5 weeks. In another experiment, one dose at 300 or 1000 mg/kg was used. Twenty-four hours after the last treatment, sperm from cauda epididymis and spermatid was analyzed for changes in motion with a Hamilton-Thorne Sperm analyzer (HTM-IVOS). Subchronic treatment of EGEE resulted in decrease in motile sperm percentage and progressive motility in both epididymal and spermatid sperm dose-dependently. The values for the two parameters in highest dose group were less than 25% of that in controls. The velocity parameters (curvilinear velocity, average path velocity and straight line velocity) were also affected by EGEE. Unlike the subchronic treatment regimen, a single-dose of EGEE did not induce change in weight of the testes and epididymis. However, the percentages of motile sperm and progressively motile sperm were significantly decreased in the high-dose group. The proportion of sperm with rapid velocity was also 33% less than that of controls, whereas the percentage of static sperm was doubled. Interestingly, these changes occurring in the acute experiment were only observed in spermatid, while those in the epididymis were not evident. These results demonstrated that EGEE may not only induce testicular toxicity but also directly affect sperm motion.

CHANGES OF GENE EXPRESSION IN THE EPIDIDYMIDES AND SPERM ACROSOME REACTION IN RATS TREATED WITH SULFASALAZINE FOR SEVERAL DAYS.

Y. Hamada<sup>1</sup>, T. Fukushima<sup>1,2</sup>, M. Komiyama<sup>2</sup>, C. Mori<sup>2</sup> and I. Horii<sup>1</sup>. <sup>1</sup>*Worldwide Safety Sciences, Pfizer Global and Research Nagoya Laboratories, Taketoyo, Aichi, Japan* and <sup>2</sup>*Bioenvironmental Medicine, Chiba University, Chiba, Chiba, Japan*. Sponsor: M. Kurata.

Sulfasalazine (SASP) is known to affect fertility in mammals. We have reported that a decreased expression of CD59, membrane cofactor protein (MCP) and decay accelerating factor (DAF) genes may affect acrosome reaction and sperm motility in rats treated with SASP at 600 mg/kg for 28 days. In the present study, we investigated sperm motility with HTM-IVOS, acrosome reaction using FITC-concanavalin A lectin assay and the expression of the above mentioned genes by real-time RT-PCR. The assays were carried out after 1, 7 and 14 days of treatment. The acrosome reaction ratio decreased in a time-dependent manner (93.8, 82.6 and 59.1% of control on Days 1, 7- and 14 of treatment, respectively). The acrosome reaction ratio on Day 14 was the same as that of Day 28 of treatment. On the other hand, the expression of CD59, MCP and DAF genes decreased in the epididymides on Day 1 continued to decrease thereafter. It is known that many molecules such as CD59, MCP and DAF proteins, that are secreted from the epididymides participate in spermatozoa maturation. In rats, sperm maturation needs for about 14 days and it correlated with the date of the lowest acrosome reaction ratio. From these findings, we hypothesized that SASP reduces the expression of CD59, MCP and DAF as primary effects and continued treatment affects the maturation of sperm due to insufficient secretion of CD59, MCP and DAF proteins, which in the end reduces sperm motility and/or acrosome reaction.

**544**

DEVELOPMENTAL TOXICOLOGY OF CJC-1131, A LONG-ACTING GLP-1 ANALOGUE.

B. Lawrence<sup>1</sup>, S. Wen<sup>1</sup>, Y. Fukushima<sup>1</sup>, E. M. Lewis<sup>2</sup>, S. Morseth<sup>3</sup> and J. Castaigne<sup>1</sup>. <sup>1</sup>*ConjuChem, Inc., Montreal, QC, Canada*, <sup>2</sup>*Argus Research, Horsham, PA* and <sup>3</sup>*Morseth Consulting LLC, Jefferson, MD*.

CJC-1131 is an anti-diabetic compound being developed for the control of type 2 diabetes and is currently in Phase II clinical trials. By applying the Drug Affinity Complex (DAC) technology to glucagon-like peptide-1 (GLP-1), the peptide selectively and covalently binds to circulating albumin after subcutaneous (SC) administration. The developmental toxicity of CJC-1131 was evaluated in pregnant Sprague-Dawley rats dosed SC with CJC-1131 from gestation day (DG) 7 to 17 either every other day (q2d) at 0, 0.1, 0.3, 1 and 3 mg/kg (pilot study) or daily at 0, 0.025, 0.2 and 1.5 mg/kg (main study). All CJC-1131 dosages with both dosing regimens caused dose-dependent reductions in maternal body weight gain and/or body weight losses and food consumption. Non dose-dependent decreases in fetal body weights occurred at all doses administered q2d whereas dose-dependent reductions in fetal body weights were observed with daily dosing of  $\geq$ 0.2 mg/kg/day. There were no changes observed during fetal gross external examination at doses as high as 3 mg/kg q2d in the pilot study. In the main study, postimplantation loss (i.e., early and late resorptions) was slightly increased, although within historical range, following daily dosing at 1.5 mg/kg/day. Reflecting the dose-dependent reductions in fetal body weight, reversible delays in skeletal development were noted at  $\geq$ 0.2 mg/kg/day and included reductions in average numbers of ossified caudal vertebrae, forelimb and hindlimb phalanges, and ossified hindlimb tarsals. Although within historical range and a common finding in rats of this strain, variations in vessel formation (absent innominate artery) were noted at 1.5 mg/kg/day. Despite some maternal toxicity of reduced food consumption and decreased body weight gain at 0.025 mg/kg/day, there was no effect on the fetal development and organogenesis at this dose level. Therefore, the developmental no-observable-effect-level (NOEL) for CJC-1131 in rats is considered to be 0.025 mg/kg/day.

**545**

EFFECT OF IMPLANTED DEPLETED URANIUM (DU) ON MALE RAT REPRODUCTIVE SUCCESS, SPERM CONCENTRATION AND MOTION.

D. P. Arfsten<sup>1</sup>, E. R. Wilfong<sup>1</sup>, E. W. Johnson<sup>1</sup>, D. J. Schaeffer<sup>2</sup> and K. R. Still<sup>1</sup>. <sup>1</sup>*NHRC EHE Lab., Wright-Patterson AFB, OH* and <sup>2</sup>*Department of Veterinary Biosciences, University of Illinois at Urbana Champaign, Urbana, IL*.

DU projectiles are currently in use with the US military and possibly the armed forces of other countries. Therefore, battle injury from DU projectiles and shrapnel is a possibility. Removal of DU projectiles from the body may not always be possible because of their location in the body or their small size. It has been demonstrated that DU mobilizes and translocates to the gonads and several other tissues in rats implanted with DU alloy. In this study the effects of implanted DU pellets on sperm concentration, motility, and male reproductive success were evaluated in adult Sprague-Dawley rats implanted with 0, 12, or 20, 1 x 2 mm DU pellets. Twenty, 1 x 2 mm DU pellets (760 mg) of DU in a 500 gram rat is equal to approximately 0.2 pounds of DU in a 154 lbs (70 kg) person. The 0.2 pounds of DU in a 154 lbs person is equivalent to one-third of a 300 g, 30 mm APFSDS-T DU projectile. Urinary analysis at post-implantation day 30 indicated that the DU-implanted animals were excreting uranium in urine with urinary levels directly correlated with the implanted DU pellet dose. There was no effect of DU implantation on mating success when evaluated at 30-45 days and 120-145 days post-implantation. Velocity and motion of sperm isolated from rats treated with the positive control compound alpha-chlorhydrin were significantly reduced as compared with those for sperm isolated from sham surgery controls. When assessed at post-implantation day 150, the concentration and motion of sperm isolated from DU-implanted animals were not significantly different from sham surgery controls. Overall, the results of this study suggest that implantation of up to 20, 1 x 2 mm DU pellets in rats for approximately 21% of their adult lifespan does not have an adverse impact on male reproductive success or sperm motility or velocity.

**546**

THE EFFECTS OF SUBACUTE ORAL EXPOSURE TO VINCLOZOLIN ON REPRODUCTIVE PARAMETERS IN PERIPUBERTAL AND POST-PUBERTAL BOARS.

T. J. Evans<sup>1</sup>, E. M. Walters<sup>1</sup>, Y. Agca<sup>1</sup>, T. J. Fangman<sup>2</sup>, F. Williams III<sup>1</sup>, J. K. Critser<sup>1</sup> and R. A. Hess<sup>3</sup>. <sup>1</sup>*Veterinary Pathobiology, University of Missouri, Columbia, MO*, <sup>2</sup>*Veterinary Extension and Continuing Education, University of Missouri, Columbia, MO* and <sup>3</sup>*Veterinary Biosciences, University of Illinois, Urbana, IL*.

Although the antiandrogenic properties of vinclozolin (VCZ) and its metabolites are well-documented in rodents, little is known about the effects of VCZ on other mammals. Similarities in size and physiology, as well as genomic complexity, between humans and swine, make the boar a novel animal model for studying the potential effects of putative endocrine-disrupting compounds (EDCs). It was hypothesized that subacute oral exposure to VCZ would adversely affect reproductive

parameters, such as serum hormone concentrations, testicular and epididymal histology and sperm morphology and motility, in peripubertal and post-pubertal boars. Nine, 7-month-old and eight, 12 to 14-month-old boars were each divided into two groups which were orally exposed to either 0 or 100 mg VCZ/kg body weight for 14 days. Serum samples collected prior to and during the study were analyzed for concentrations of testosterone and estradiol. Following euthanasia, semen was collected from the cauda epididymis for computer-assisted analysis, and tissues were selected and prepared for histologic examination. Statistical analyses were performed using ANOVA and the general linear model (GLM) procedure. Testosterone concentrations increased initially and then decreased in VCZ-treated post-pubertal boars. Estradiol levels were higher in boars of both age groups dosed with VCZ. Histologic changes in the testes and epididymides, as well as abnormal sperm morphology and decreased sperm motility, were observed with administration of VCZ. Exposure to VCZ adversely affected various reproductive parameters in peripubertal and, in particular, post-pubertal boars. VCZ-associated histologic changes were more severe in swine than those reported in rodents administered the same dosage of VCZ. The boar shows promise as a sensitive comparative model for studying the effects of EDCs on male reproductive morphology and function.

DELAYED PREPUTIAL SEPARATION (PPS) AND SP22 MEASUREMENT IN RATS ADMINISTERED BROMOCHLOROACETIC ACID (BCA) IN DRINKING WATER.

C. S. Sloan<sup>1</sup>, G. R. Klinefelter<sup>2</sup>, J. M. Goldman<sup>2</sup>, K. D. Vick<sup>1</sup>, P. A. Fail<sup>1</sup> and R. W. Tyl<sup>1</sup>. <sup>1</sup>*Life Sciences and Toxicology, RTI International, Research Triangle Park, NC* and <sup>2</sup>*Reproductive Toxicology Division, NHEERL, USEPA, Research Triangle Park, NC*.

Reproductive effects of BCA were determined in a dose range finding study (DRFS) and definitive two-generational study. Adult male and female CD<sup>®</sup>(SD) rats were administered BCA in drinking water for two weeks in the DRFS (10/sex/group) and ten weeks in the definitive study (25/sex/group) before mating. Females were dosed until the weaning of their litters. The F1 post-weanlings received BCA until acquiring puberty [PPS in males, vaginal patency (VP) in females] in the DRFS, and through mating to generate F2 offspring in the definitive study. The concentrations were 0, 50, 200, 400, 600, 800, and 1000 ppm BCA *ad libitum* in the DRFS and 0, 30, 300, and 600 ppm BCA in the definitive study. Age of male PPS was used to assess reproductive development. The males at  $\geq$  600 ppm in both studies, showed significant delay of PPS vs. the control males; At 600 ppm mean PPS delays were 2.2 days in the definitive study and 2.7 days in the DRFS; At 800 ppm, males had mean delays of 4.7 days and those males at 1000 ppm had delays of 5.2 days. Ages at acquisition were adjusted using body weight (BW) at acquisition as a covariant. In the DRFS, F1 females at  $\geq$  600 ppm had VP delays of 6.2 days; comparable delays were not seen in the definitive study. In the DRFS, the F0 females, males and F1 offspring at both weaning and puberty had dose-related decreases in BW. In the definitive study, BW was unaltered in F0 males, but was decreased in 600 ppm F0 females. The F1 males and females had decreased BW at 600 ppm at pnd 21 and as adults; the males also had decreased BW at 300 ppm. The sperm membrane protein SP 22 was determined in the caudal sperm of adult F0 and F1 males as a measure of adult reproductive competence and an important biomarker of fertility. Significant decreases in SP22 were seen with increasing BCA concentrations in both F0 and F1 males in the definitive study. This work was funded by a cooperative agreement from USEPA, RTP.

548

USE OF 5 $\alpha$ -DIHYDROTESTOSTERONE (DHT)-EXPOSED UROGENITAL SINUSES (UGS) FROM FEMALE MICE TO INVESTIGATE INHIBITION OF PROSTATIC BUDDING CAUSED BY 2, 3, 7, 8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD).

T. Lin and R. E. Peterson. *School of Pharmacy, University of Wisconsin, Madison, WI*.

Mouse prostate development starts as projections (buds) of UGS basal epithelial cells into the surrounding mesenchyme on Gestation Day (GD) 16. *In utero* TCDD exposure blocks ventral bud formation and reduces dorsolateral bud number in male UGS. Prostatic budding is an androgen-dependent process, and only rudimentary UGS buds are evident in normal female UGS. TCDD appears to inhibit budding without affecting androgen signaling but the inhibitory mechanism remains unknown. Experiments were conducted to determine if DHT-exposed female UGSs can be a model system to investigate prostatic bud formation. This system allows androgen exposure times to be regulated. Pregnant mice were implanted with DHT-releasing pellets on GD 13, 14, 15, or 16. Each dam was then treated with single dose of 5  $\mu$ g/kg TCDD or vehicle 24, 48, 72, or 96 hours later, depending on how early pellet implantation occurred, such that treatment occurred no later than GD 17. UGSs were collected from female fetuses on GD 19 and observed by light microscopy. All DHT- and vehicle-exposed female UGSs displayed

characteristic male UGS development, including UGS enlargement, dorsal sulcus formation, and region-specific bud formation patterns. A male pattern UGS-urethral angle ( $\sim 100^\circ$ ) was also present when DHT exposure began before GD 16. These results demonstrate that exposure of female UGSs to DHT can closely replicate normal male UGS development. TCDD exposure on GD 16 or earlier blocked formation of all ventral and almost all dorsolateral buds regardless of when DHT exposure began. In males a similar time-course occurs and ventral budding is completely blocked by TCDD, but dorsal, lateral, and anterior budding is less vulnerable. The use of DHT-exposed female UGSs therefore provides a useful tool to investigate effects of TCDD on prostatic budding. The sex difference in region-specific sensitivity to budding inhibition by TCDD may facilitate elucidation of the mechanism by which TCDD inhibits prostatic budding. (Supported by NIH ES01332)

549

IN VIVO EXPOSURE OF PREPUBERTAL RATS TO METHOXYCHLOR (M) INHIBITS *EX VIVO* LEYDIG CELL (LC) BASAL AND HUMAN CHORIONIC GONADOTROPIN (HCG)-STIMULATED TESTOSTERONE (T) FORMATION.

E. P. Murono and R. C. Derk. *Pathology and Physiology Research Branch, CDC/NIOSH, Morgantown, WV*. Sponsor: V. Castranova.

M is pesticide which has been used as a replacement for DDT. Its active metabolite is reported to be 2, 2-bis(p-hydroxyphenyl)-1, 1, 1-trichloroethane (HPTE), and both M and HPTE exhibit weak estrogenic and/or antiandrogenic activities and have adverse reproductive effects on animals. In the current studies, prepubertal male rats (12 animals per treatment group) were gavaged once daily between 24-30 days of age with 0, 5, 40 or 200 mg/kg body weight of M in corn oil to evaluate whether LC from immature rats are sensitive to M. Animals were sacrificed  $\sim$ 24 h after the last exposure, and LC were isolated by density-gradient centrifugation of dispersed testes. *Ex vivo* LC T formation was measured after 4 h of incubation under basal conditions and following exposure to 10 mIU/ml hCG. In addition, because immature LC express high 5 $\alpha$ -reductase (5 $\alpha$ -R) activity, which causes the majority of synthesized T to be metabolized to dihydrotestosterone and its hydroxylated metabolites, a 5 $\alpha$ -R inhibitor was added to assess total T biosynthetic capacity. Final body weights of M-treated animals were no different than control; however, testes and seminal vesicle weights declined significantly to 81 and 69% of control, respectively, in animals exposed to 200 mg/kg M. *Ex vivo* LC T formation over 4 h under basal conditions declined significantly to 29% of control at the highest dose of M. A similar pattern of decline in T was observed when LC were incubated with a 5 $\alpha$ -R inhibitor, but T levels were  $\sim$ 30-fold higher. LC T formation following exposure to hCG for 4 h declined significantly to 34% of control in animals exposed to 200 mg/kg M, and a similar pattern of T decline was observed when LC were incubated with a 5 $\alpha$ -R inhibitor, except T levels were  $\sim$ 60-fold higher. Of interest, serum T, LH and FSH levels were unaffected by M. These results suggest that LC from immature rats are highly sensitive to the inhibitive effects of M.

550

IN UTERO EXPOSURE TO 2, 3, 7, 8-TETRACHLORODIBENZO-*P*-DIOXIN ALTERS SONIC HEDGEHOG AND BONE MORPHOGENETIC PROTEIN 4 EXPRESSION IN THE DEVELOPING MOUSE UROGENITAL SINUS.

W. A. Fritz, W. A. Bushman and R. E. Peterson. *University of Wisconsin, Madison, WI*.

2, 3, 7, 8-Tetrachlorodibenzo-*P*-dioxin (TCDD) inhibits mouse ventral prostate development through inhibition of epithelial bud formation in the fetal urogenital sinus (UGS). Prostate bud formation occurs as proliferating epithelial buds penetrate into the surrounding mesenchyme. Sonic hedgehog (Shh) in the UGS epithelium activates mesenchyme-mediated paracrine signaling to stimulate epithelial proliferation in emerging buds. Bone morphogenetic protein (Bmp4) expressed in the mesenchyme inhibits epithelial proliferation and budding is accompanied by clearing of Bmp4 expression at the sites of bud emergence. To determine if impaired ventral prostate bud formation following TCDD exposure is associated with disruption of mesenchymal-epithelial interactions involving these pathways, expression of *Shh* and *Bmp4* in male UGS of vehicle- and TCDD-exposed fetuses were compared by whole mount *in situ* hybridization. Pregnant dams were exposed to TCDD (5  $\mu$ g/kg, po) or vehicle on gestation day 13 (GD13), and male fetuses removed daily from GD14-GD19 for comparison of gene expression. *Shh* expression was uniformly distributed in UGS epithelium lining the urethra of both vehicle- and TCDD-exposed UGS up to GD17. Starting at GD18, concentrated expression in the nascent buds was evident in the dorsolateral region in both groups but was absent from the ventral region of TCDD-exposed UGS. Lack of Shh staining in this area was likely due to the absence of ventral bud formation in TCDD-ex-

posed mice. Initially, there was broad *Bmp4* expression in the vehicle-exposed UGS that progressively became restricted to areas surrounding the emerging buds from GD17 to birth. The ventral region of TCDD-exposed mice had no *Bmp4* expression, even though the canonical pattern of expression and re-distribution was present in other regions of the developing prostate. These findings suggest that inhibition of ventral prostate bud formation in the TCDD-exposed mouse fetus correlates with altered Shh and *Bmp4* signaling in the developing UGS. (Supported by NIH Grant ES 01332)

551

### CRITICAL WINDOW OF MALE REPRODUCTIVE TRACT DEVELOPMENT IN RATS FOLLOWING GESTATIONAL EXPOSURE TO DI-N-BUTYL PHTHALATE.

C. M. Carruthers<sup>1</sup> and P. Foster<sup>2</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC and <sup>2</sup>NIEHS, Research Triangle Park, NC.

Gestational exposure to di-n-butyl phthalate (DBP), a ubiquitous environmental contaminant, has been shown to interfere with the development of the male reproductive tract by acting as an antiandrogen. This study was conducted to identify the critical days for the abnormal development of the male reproductive tract, specifically the testis and epididymis. Timed-pregnant Sprague-Dawley rats were dosed with DBP at 500 mg/kg/day on gestation day (GD) 14&15, 15&16, 16&17, 17&18, 18&19, or 19&20 (GD 0 = plug day). Anogenital distance (AGD) was measured on postnatal day (PND) 1, and 13; while nipple number was recorded on PND 13 only. After weaning males were allowed to mature to PND 90 at which time they were necropsied. Nipple number, and AGD were recorded and testes, epididymides, seminal vesicles, prostate gland, kidneys and liver weighed. Blood serum was collected and assayed for total testosterone concentration. There were no observable effects on litter size, sex ratio, or mortality of pups. Serum testosterone concentrations were not biologically affected in PND 90 DBP-treated offspring. Significant permanent reductions in AGD were seen in males exposed prenatally to DBP on GD 15&16 or GD 18&19. On PND 13 areolae were present in males exposed to DBP on GD 15&16, 16&17, 17&18, and 19&20, however significant permanent nipple retention occurred only in males after DBP exposure on GD 16&17. Exposure to DBP on only GD 17&18 elicited a significant reduction in epididymal weights; while exposure on only GD 16&17 caused a significant increase in the weights of the testes due to edema. Epididymal and testicular malformations were most prevalent after exposure to DBP on any gestational day. Epididymal malformations, characterized by agenesis of various regions, and small or flaccid testes were significantly increased in DBP exposed males only on GD 17& 18. These findings suggest that two-day DBP exposure is highly detrimental to the developing reproductive tract of the male fetus and the critical window for abnormal development is GD 16-18.

### EFFECT OF DI(N-BUTYL) PHTHALATE ON MALE REPRODUCTIVE ORGAN DEVELOPMENT IN HYPOTHYROID RATS.

H. Kim, E. Lee, M. Ahn and H. Kim. College of Pharmacy, Pusan National University, PUSAN, South Korea. Sponsor: I. Yu.

Thyroid hormones play an important role in the growth and development of the male reproductive tissues, but their effects are not clearly understood. This study examined the effects of di(n-butyl) phthalate (DBP) on male reproductive organ growth and development in hypothyroid rats. Hypothyroidism was induced in pubertal male rats (4 weeks of age) by administering 0.1% propylthiouracil (PTU) in their drinking water for 30 days. DBP was administered to the hypothyroid (250, 500 or 750 mg/kg) and normal (750 mg/kg) rats by oral gavages for 30 days. The body weight of the PTU-treated hypothyroid rats was markedly lower than the control group. No significant changes in the testis, epididymides and adrenal weight were observed in the hypothyroid rats. However, DBP (750 mg/kg) significantly reduced the weights of the reproductive tracts in both the normal and hypothyroid rats. The total T3 and T4 serum level decreased, but the TSH level increased in the hypothyroid rats. Although the histomorphological examination showed a severe diffused Leydig cells hyperplasias in the DBP (750 mg/kg)-treated groups, these effect was mild in the DBP-treated hypothyroid rats. In order to investigate the metabolism of the sex steroid hormone, the steroidogenic factor-1 (SF-1) and StAR mRNA expressions levels were measured in the testis. The expression of SF-1 and StAR mRNA levels were significantly reduced in the PTU-treated hypothyroid rats. DBP (750 mg/kg) also significantly inhibited the expression of SF-1 and StAR in the testis of the normal rats, but SF-1 and StAR mRNA levels were slightly increased in the DBP-treated hypothyroid rats. In conclusion, the DBP-induced male reproductive organ alterations are weaker as a result of the induction of hypothyroidism than under normal conditions. The results suggest that an alteration in the thyroid hormone level can affect the male reproductive organ toxicity induced by DBP through a disturbance of the steroid hormone metabolism.

553

### EFFECTS OF TCDD ON STEROIDOGENESIS OF RAT LEYDIG CELLS.

K. P. Lai, H. Y. Yeung, M. H. Wong and C. K. Wong. Biology, Hong Kong Baptist University, Hong Kong, China.

Polychlorinated dibenzo-p-dioxins, such as 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) has been recognized as a highly potent developmental and reproductive toxicant. We have previously demonstrated effects of TCDD in modulating the expressions of rat Sertoli cell secretory products and markers for cell-cell interaction. In this study, we examined the direct biological effect of TCDD in primary culture of rat Leydig cells. Leydig cells were purified by percoll gradient centrifugation and the cell purity was determined by 3beta-hydroxysteroid dehydrogenase staining and testosterone induction assay. To examine TCDD induced biological consequences, we measured the changes in the secretion of progesterone and testosterone as well as transcripts levels of some selected steroidogenic enzymes (i.e. StAR, P450ssc, 3beta-HSD & CYP17alpha) in TCDD/hCG co-treated cells. Our results indicated that TCDD (0.2 or 2 ng/ml) treatments significantly suppressed hCG (5 or 10 ng/ml) induced testosterone secretion. The suppressive effect aligned with a reduction of progesterone secretion ( $P<0.05$ ) as well as a decrease in P450ssc mRNA expression ( $P<0.05$ ). Expressions of other steroidogenic enzymes (i.e. StAR, CYP17alpha and 3beta-HSD) were not significantly reduced. Interestingly, our data demonstrated that the TCDD-mediated suppressive effect cannot be overturned by a co-treatment with an AhR antagonist (PD98059). This observation indicated that the TCDD-elicited inhibitory effect was not directly mediated by AhR pathway. Moreover the inhibitory effect can be reversed by dbcAMP (2 mM) or high dose of hCG (50ng/ml) cotreatments. Taken together, our results implicated that direct TCDD exposure can interfere with the normal Leydig cell functions.

554

### ESTROGEN RECEPTOR ALPHA IS NOT REQUIRED FOR NORMAL PROSTATIC BUD FORMATION OR FOR INHIBITION OF PROSTATIC BUD FORMATION BY 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) IN MICE.

S. M. Hicks<sup>2</sup>, T. Lin<sup>1</sup>, M. Mukai<sup>3</sup>, P. S. Cooke<sup>3</sup> and R. E. Peterson<sup>1,2</sup>. <sup>1</sup>School of Pharmacy, University of Wisconsin, Madison, WI, <sup>2</sup>Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI and <sup>3</sup>Department of Veterinary Biosciences, University of Illinois, Urbana, IL.

A single maternal dose of TCDD on gestation day (GD) 13 impairs prostate development in C57BL/6J mice. Complete inhibition of prostatic bud formation in the ventral region of the prostatic anlage, the urogenital sinus (UGS), results in ventral prostate agenesis in adults. TCDD affects budding less severely in dorsolateral and anterior regions and causes smaller adult lobes with aberrant ductal structures. These effects of TCDD are mediated by the aryl hydrocarbon receptor (AhR) in the UGS mesenchyme (UGM), into which buds from the UGS epithelium (UGE) grow. The UGM is also the target tissue for prenatal androgens that drive prostate formation. Crosstalk between the UGM and UGE is therefore required for normal bud formation and for budding inhibition by TCDD. The AhR has been reported to interact with estrogen receptors alpha (ER $\alpha$ ) and beta (ER $\beta$ ), leading to transcription of estrogen-responsive genes in the absence of estrogen. ER $\alpha$  is predominantly expressed in UGM, the site of action of TCDD, whereas ER $\beta$  is predominantly expressed in UGE. In the current study, we utilized ER $\alpha$  knockout mice (KO) to assess the potential roles of ER $\alpha$  in mediating effects of TCDD on the UGS and in normal bud formation. ER $\alpha$  heterozygous (HT) males and females were mated overnight, and timed-pregnant dams were exposed to a single oral dose of 5  $\mu$ g/kg TCDD on GD 13. UGSs from male fetuses were collected on GD 18, UGM removed, and bud formation was visualized by scanning electron microscopy. No differences in position or appearance of buds in any region of the UGS were observed when vehicle-exposed ER $\alpha$  KO, HT, and wild-type (WT) male UGSs were compared. Likewise, effects of TCDD on bud formation appeared equivalent regardless of ER $\alpha$  genotype. Thus, ER $\alpha$  does not mediate inhibition of UGS budding by TCDD and is not required for normal prostatic bud formation. (NIH grant ES01332)

### CHARACTERIZATION OF 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) RESPONSIVENESS IN MOUSE UROGENITAL SINUS (UGS) USING ARYL HYDROCARBON RECEPTOR (AHR)-DEPENDENT LACZ MICE.

D. R. Kelman<sup>1</sup>, J. C. Bemis<sup>3</sup>, T. Lin<sup>2</sup>, T. A. Gasiewicz<sup>3</sup> and R. E. Peterson<sup>1,2</sup>.

<sup>1</sup>Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI, <sup>2</sup>Pharmacy, University of Wisconsin, Madison, WI and <sup>3</sup>Environmental Medicine, University of Rochester, Rochester, NY.

Exposing C57BL/6J mice on gestation day (GD)13 to TCDD causes abnormal prostate development. The ventral region of the UGS is affected most severely; TCDD prevents formation of epithelial buds, leading to ventral prostate agenesis.

The critical window to inhibit budding in the ventral UGS is GD15-16. TCDD also alters bud formation in the dorsolateral region and has minimal effects on the anterior region of the UGS. These effects are mediated via AhR located in the UGS mesenchyme. RT-PCR shows that AhR mRNA is present ubiquitously in the UGS and is about twice as high in the ventral as in the dorsolateral region. It is unknown whether the AhR is activated by TCDD in a region-specific manner in the UGS. To determine whether region specificity of AhR activation can account for region-specific bud inhibition in the UGS, transgenic mice with an AhR-dependent *lacZ* reporter gene construct were examined. Male mice exposed *in utero* to a maternal dose of 5 µg TCDD/kg on GD13, 15 or 17 were sacrificed on GD14, 16 or 18. Two regions in all exposed UGS samples showed LacZ staining which increased in intensity as time of exposure increased. Staining was most evident in the ventral region, extended into the urethra in all samples and was weakly expressed in the dorsolateral region. Staining in the UGS and urethra was located specifically in the immediate periurethral region. A higher number of LacZ stained cells was found by flow cytometry in the ventral mesenchyme than in the dorsolateral mesenchyme. LacZ staining was not found in the UGS epithelium in any region. Control UGSs showed no staining, indicating little to no intrinsic AhR activity. These findings suggest that the loss of ventral buds is related to the presence of selectively activated AhR in the periurethral mesenchyme in the ventral UGS. (NIH grants ES01332, ES07026, ES01247 and ES09430).

ANALYSIS OF CORTACTIN EXPRESSION IN THE ECTOPLASMIC SPECIALIZATION OF TESTES IN FLUTAMIDE TREATMENT MOUSE.

R. Anahara<sup>1</sup>, Y. Toyama<sup>2</sup>, M. Maekawa<sup>2</sup>, M. Kai<sup>3,4</sup>, F. Ishino<sup>5</sup>, K. Toshimori<sup>2</sup> and C. Mori<sup>1,6</sup>. <sup>1</sup>*Bioenvironmental Medicine, Chiba University, Chiba, Japan*, <sup>2</sup>*Anatomy and Developmental Biology, Chiba University, Chiba, Japan*, <sup>3</sup>*Pharmaceutical Research Laboratories, Kirin Brewery Co. Ltd., Gunma, Japan*, <sup>4</sup>*Division for Gene Research, Center for Biological Resources and Informatics, Tokyo, Japan*, <sup>5</sup>*Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan* and <sup>6</sup>*CREST, Japan Science and Technology Agency, Kawaguchi, Japan*.

The apical and basal ectoplasmic specialization (ES) is an actin-based (cell-cell) junctional structure in the Sertoli cell of the seminiferous epithelium, playing an important role in spermatogenesis. Recent reports showed that the apical ES was sensitive to exogenous chemicals, such as flutamide (FLUT), β-estradiol 3-benzoate and bisphenol A, inducing the deformation. Besides, cortactin is an actin-binding protein in the both ESs regulating the testicular dynamics associating with mediator proteins. The purpose of the present study is to evaluate whether the expression of cortactin becomes one of biomarkers of the adverse effect of the exogenous chemicals on spermatogenesis. ICR mice were subcutaneously injected with FLUT (0.012 µg/g body weight/day for 5 days, dissolved in corn oil), and were sacrificed on 6th day. Whole testis was processed for Western blot analysis. Localization of cortactin in the testis was detected by both immunohistochemistry and immunoelectron microscopy. Results obtained were: 1) the relative amount of cortactin in the treated testis were significantly decreased by 62%, 2) decreased cortactin expression in the apical ES of treated testis was confirmed by immunostaining, and 3) immunostaining of cortactin in the basal ES was obviously not affected by FLUT. Interestingly, the apical and basal ES responded differently to FLUT. These results suggest that cortactin may be one of biomarkers in the apical ES disruption caused by exogenous chemicals. Also, investigation of cortactin mediated dynamics in spermatogenesis may help studies in the field of testicular infertility and be a key to elucidate the mechanisms of the ES.

CHARACTERIZATION OF THE GENE EXPRESSION PROFILE INDUCED BY ETHYLENE GLYCOL MONOMETHYL ETHER IN THE RAT TESTIS WITH DNA MICROARRAYS.

E. Blomme<sup>1</sup>, R. Ciurlionis<sup>1</sup>, K. Whitney<sup>1</sup>, I. Milicic<sup>1</sup>, M. Strakhova<sup>1</sup> and J. Waring<sup>1</sup>. <sup>1</sup>*Abbott Labs, Abbott Park, IL* and <sup>2</sup>*Abbott Labs, Abbott Park, IL*.

Ethylene glycol monomethyl ether (EGME) is an organic solvent in paints, printing inks, thinners and photoresists. Its adverse effects on the male reproductive tract are well described and are characterized by testicular atrophy and impaired fertility. The most sensitive target cell is the primary spermatocyte in the dividing late pachytene stages. While the early lesion has been well characterized, the mechanism of toxicity is still poorly understood. In this study, we analyzed transcription profiling data generated with microarrays (Affymetrix RAE230A) to generate a mechanistic understanding of EGME-induced testicular toxicity. Testes were collected from male CD rats (n = 4), treated orally for 1 (Day 1) and 4 (Day 4) days with EGME at 200 mg/kg/day, and for 4 days with methoxyacetic acid (MAA), the major metabolite of EGME, at 200 mg/kg/day. Testes were collected for transcription profiling and histology. At Day 1, EGME induced apoptosis of spermatocytes in Stage XIV tubules, while at Day 4, changes were more extensive and extended to

Stages XII, II and V. MAA induced changes similar to those induced by EGME. Both compounds regulated the expression of a relatively low number of genes at both timepoints, and overall induced relatively similar gene expression profiles at Day 4, supporting MAA as being the major metabolite involved in EGME-induced testicular toxicity. Analysis of these gene expression changes provided some potential mechanisms for the toxicity, especially within the DNA damage and apoptotic pathways. Moreover, we identified several genes with a consistently altered expression pattern, providing a basis for the formulation of hypotheses. Collectively, these results indicate that transcription profiling can be used to gain a molecular understanding of testicular toxicity in the rat.

THE USE OF CD-1 MICE FOR FERTILITY AND EARLY EMBRYONIC DEVELOPMENT (ICH-1 STUDIES).

L. Pinsonneault, A. St-Pierre, C. Tremblay, M. Adamo, L. Pouliot and K. Robinson. *Reproductive Toxicology, CTBR Bio-Research Inc., Senneville, QC, Canada*. Sponsor: M. Vezina.

In circumstances where the rat may not be a suitable model, the mouse (*Mus musculus*) may be a substitute for fertility and early embryonic development studies (ICH-1). Standard dose routes (oral, inhalation, injection [subcutaneous, intermuscular and intravenous]) can be utilized with these mice. Male mice (Crl:CD®-1(ICR)BR) 7 weeks of age are dosed for 28 days prior to the placement for mating, during mating and following mating until terminal euthanasia. Female mice 8 weeks of age are treated in a similar manner for 14 days prior to mating, during mating and until Day 7 of gestation, inclusive. Estrous cycles of the females are monitored prior to mating by vaginal lavage. Mating is performed by pairing overnight and observation for the presence of vaginal plugs. The following standard parameters are typically measured: mortality, clinical observations, bodyweights, food consumption, estrous cycles, mating, gross pathological examination and organ weights. Male reproductive assessments, including epididymal sperm measures (motility, count and morphology) and testicular histopathology can be evaluated. Terminal examinations of the females include ovarian and uterine examinations on gestation Day 13. The reproductive parameters assessed show that this strain of mice has suitable fertility (fertility index 88-95%) and male and female reproductive characteristics for the use of group sizes of 20 to 25 mice per sex in an ICH-1 study.

UNDERSTANDING HEPATIC VACUOLATION: GENE EXPRESSION ANALYSIS OF PHOSPHOLIPIDOSIS AND STEATOSIS IN RAT LIVER.

D. Pelletier, B. Lu and M. Lawton. *Molecular and Investigative Toxicology, Pfizer Inc, Groton, CT*.

Hepatocellular vacuolation, commonly observed in preclinical drug development, is a morphological indicator of possible phospholipidosis or steatosis. A more accurate classification of hepatic vacuolation relies on electron microscopy (EM) or special stains, such as Oil Red-O. In an effort to understand the molecular mechanism behind liver vacuolation, we used oligonucleotide microarray analysis to examine changes in gene expression profiles associated with these phenotypes. Amiodarone, which is known to cause phospholipidosis, and hydrazine, known to cause steatosis, were used as model compounds in this study. Sprague-Dawley rats were treated with these compounds and their liver samples harvested for gene expression profiling with RG\_U34A GeneChips (data from Gene Logic's Toxicology Express database). In addition to the gene expression data, clinical chemistry, hematology and histopathology data were collected and analyzed. We found that the expression profiles of amiodarone and hydrazine at early time points are similar, potentially indicating a common mechanism governing transcriptional responses leading to phospholipidosis or steatosis. A gene ontology (GO) and pathway analysis showed that stress, oxidative reaction, and fatty acid metabolism are the major theme among the changed genes. We were able to isolate a small subset of genes that differentiate expression profiles of phospholipidosis from steatosis and conducted the GO and pathway analysis on this subset of genes. The similarity between amiodarone and hydrazine may help to explain a previous report on steatosis induced by amiodarone, a drug more known for its ability to cause phospholipidosis. Mechanistic implications of relevant genes and pathways will be discussed, as will further characterization with other compounds that cause hepatic vacuolation.

TOXICOGENOMIC STUDY OF HYCANTHONE, AN ANTITUMOR AGENT: MOLECULAR MECHANISMS OF HEPATOTOXICITY.

A. E. Roberts, Y. Wang, X. Luo, R. Khan-Malek, V. Shultz, J. Morsman, N. Bowen, N. Bichet, O. Gillardeaux and V. Baker. *Toxicology, Sanofi-aventis, Malvern, PA*.

Toxicogenomic studies have been conducted using thioxanthone antitumor agents with well-characterized target organ toxicity. Three have been tested in clinical trials; two have failed and one is in Phase I. Hycanthone (Etrenol®), caused dose-lim-

iting hepatotoxicity (increased ALT and AST) in mice and in humans in Phase I clinical trials for leukemia. The purpose of this study was to evaluate hycanthone-related gene expression in the context of conventional clinical and anatomic pathology endpoints. Hycanthone was administered i.p. to female CD-1BR mice for five days, at dosages of 50, 70, or 90 mg/kg. On Day 5, blood was collected for clinical pathology and livers were removed for histology and evaluation of gene expression using the Atlas<sup>TM</sup>Mouse Toxicology 1.2 arrays (Clontech). Statistically significant changes in gene expression were identified by analysis of variance (ANOVA). Hycanthone resulted in increased ALT and AST levels on Day 5 at 70 and 90 but not at 50 mg/kg. Histological effects were limited to capsular inflammation (due to i.p. administration) at all dosages. Changes in gene expression increased with dose. At 50 mg/kg, only genes involved in the acute phase response and genes with protease inhibitor activity were altered. At 70 or 90 mg/kg, gene changes occurred in pathways regulating: DNA damage and repair, the oxidative stress response, hydroxylase and isomerase, apoptosis, and the stress and inflammatory responses. The gene expression data suggest that the major pathways affected by hycanthone are consistent with the well-characterized cytotoxic action of thioxanthones and that DNA damage and oxidative stress are involved in thioxanthone-mediated liver cell injury and antitumor activity. The inflammatory/immune response is attributed to the effects of the drug on the liver surface after i.p. administration.

### GENE EXPRESSION PROFILING IN RAT LIVER AND HEPATOCYTES TREATED WITH FIBRIC ACIDS: ANALYSIS OF THE DATA IN THE TOXICOGENOMICS PROJECT IN JAPAN.

K. Tamura, T. Miyagishima, T. Urushidani and T. Nagao. *Toxicogenomics Project, National Institute of Health Sciences, Tokyo, Japan.* Sponsor: T. Inoue.

National Institute of Health Sciences and 17 pharmaceutical companies have started a five-year project, the Toxicogenomics Project in Japan (TGPJ) in 2002. The objective of TGPJ is to construct a large-scale database of over 150 drugs on rats and develop a system which will forecast the toxicity of new chemical in the early stage of drug development. In the present study, we examined gene expression profiles in rat liver and rat primary cultured hepatocytes treated with PPAR $\alpha$ -specific ligands, clofibrate, gemfibrozil and WY-14643, using Affymetrix GeneChip. Rats were treated orally with 3 dose levels of each compound and gene expression profiling was performed 3, 6, 9 and 24 hours after single dose, and 24 hours after 3, 7, 14 and 28-day repeated dose. Rat primary cultured hepatocytes were treated with 3 concentrations of the compounds and GeneChip analysis was performed 2, 8 and 24 hours after the exposure. In the liver of rats received repeated administration, we extracted genes which showed dose-dependent expression changes in common with the 3 compounds. These genes were categorized into lipid metabolism, transcription, signal transduction and stress response. A hierarchical clustering analysis of the expression data of 40 compounds in our database was performed by using the extracted gene set. It was found that the cluster containing clofibrate, gemfibrozil, WY-14643 also contained benzboromarone. The latter compound is for gout and structurally different from the peroxisome proliferators, but it was reported to be a PPAR $\alpha$  ligand. In TGPJ, this compound was found to cause hepatic hypertrophy as well as decrease in serum triglycerides, as observed in the fibrin acids. The expression profile of genes related to PPAR $\alpha$ -specific ligands showed a high similarity between *in vivo* and *in vitro* experiments. It was concluded that the extracted gene set could be a marker for PPAR $\alpha$ -specific ligands.

### GENE EXPRESSION PROFILING IN RAT LIVER AND HEPATOCYTES TREATED WITH ETHIONINE - ANALYSIS OF THE DATA IN THE TOXICOGENOMICS PROJECT IN JAPAN -.

T. Matsushita, T. Miyagishima, T. Urushidani and T. Nagao. *Toxicogenomics Project, National Institute of Health Sciences, Tokyo, Japan.* Sponsor: T. Inoue.

National Institute of Health Sciences and 17 pharmaceutical companies have started a five-year project, the Toxicogenomics Project in Japan (TGPJ) in 2002. The objective of TGPJ is to construct a large-scale database of over 150 drugs on rats and develop a system which will forecast the toxicity of new chemical in the early stage of drug development. In the present study, we analyzed the effects of ethionine, a typical hepatotoxicant. Male SD rats were treated with ethionine (0, 25, 50 or 250 mg/kg, p.o., suspended in 0.5% methylcellulose) and sacrificed 3, 6, 9 and 24 hr after single administration, and 4, 8, 15 and 29 days after daily administration. Gene expression was evaluated in 3 out of 5 animals for each group by Affymetrix 230A GeneChip. Rat primary cultured hepatocytes were exposed to 0, 0.4, 2 and 10 mM of ethionine dissolved in 0.1% DMSO. Gene expression profile of the cell was examined 2, 8 and 24 hr after exposure using Affymetrix 230 2.0 GeneChip (n=2). Changes in gene expression (ratio to the control value) were sta-

tistically filtered. Repeated administration of ethionine decreased plasma cholesterol, triglycerides, and phospholipids. In histopathological examination, microvesicular steatosis was observed in the liver. The number of genes detected as modulated by the drug was dose-dependently increased and varied over time. Many of these changes were confirmed in rat primary hepatocytes. Therefore, our multi-dosage and multi-sampling point protocol was significant for data analysis. Among the modulated genes, the expression of sterol regulatory element binding factor-1 was decreased. This gene was suggested to be one of the early responsible genes for the effect of ethionine, since its down regulation was followed by the changes in other lipogenesis-related genes, such as apoprotein A-IV and lecithin-cholesterol acyltransferase. These results provide critical information regarding the mechanism of ethionine-induced hepatotoxicity.

## 563

### GENE EXPRESSION ARRAY ANALYSIS OF MALE C3H AND C57BL/6 LIVER.

J. C. Fuscoe<sup>2, 1</sup>, A. Naito<sup>1</sup>, T. Han<sup>2, 1</sup> and Y. Dragan<sup>1</sup>. <sup>1</sup>*Systems Toxicology, National Center for Toxicological Research, Jefferson, AR* and <sup>2</sup>*Center for Functional Genomics, NCTR, Jefferson, AR*.

C3H and C57Bl/6 mice are examples of strains of mice that are sensitive and resistant, respectively, to the spontaneous and chemical induction of liver tumors. In addition, these mice differ in their bone density and provide models for this endpoint. In order to understand the bases for the biological differences between C3H and C57Bl/6 mice, gene expression analysis was performed on livers from 4-week-old male mice. In this study, livers were harvested into RNALater and stored at -80° until further analysis. Long-oligonucleotide microarrays of 20, 000 mouse genes were used in 2-color hybridizations using a reference design. Correlation (R value) within the 2 groups ranged from 0.94-0.97. The background-subtracted raw data was normalized using locally weighted linear regression (LOWESS) in ArrayTrack, a database with software tools developed at the NCTR. Cluster analysis of the gene expression profiles showed a clear distinction between the C3H and C57Bl/6 mice. The Significance Analysis of Microarray (SAM) program was then used for analysis of significant gene expression changes between the two groups (1.4-fold and false discovery rate <0.05). The expression of more than 500 genes was found to be significantly altered and included genes involved in inter- and intra-cell signaling pathways, cholesterol metabolism, and lipid metabolism. In addition, there were differences in the expression of many of the cytochrome P450s and transcription factors. These results provide many candidate genes to explain the liver cancer susceptibility differences between these two strains.

## 564

### REGULATION OF MOUSE HEPATIC TRANSPORTERS BY PERFLUORODECANOIC ACID (PFDA).

X. Cheng, J. M. Maher, M. Z. Dieter and C. D. Klaassen. *Pharmacology & Toxicology, KUMC, Kansas City, KS.*

Perfluorodecanoic acid (PFDA), also referred to as nonadecafluorodecanoic acid, is used as a corrosion inhibitor, lubricant, surfactant and wetting agent. In rodents, PFDA causes peroxisome proliferation, but is not a liver carcinogen like other peroxisome proliferators. The liver is thought to be the primary target organ of PFDA-induced toxicity due to efficient hepatic uptake and persistence in liver. Major hepatic transporters include uptake transporters, such as Na<sup>+</sup>/taurocholate cotransporting polypeptide (Ntcp) and organic anion transporting polypeptides (Oatps), as well as efflux transporters, including bile salt export pump (Bsep) and multidrug resistance-associated proteins (Mrps). Modulation of transporter gene expression may have profound effects on the toxicity of certain chemicals by altering their liver uptake and export. In the present study, we determined whether PFDA alters the mRNA expression of mouse hepatic transporters by using the branched DNA signal amplification (bDNA) assay. PFDA treatment markedly reduced the steady state mRNA expression of liver-predominant Oatp1a1, 1a4, 1b2, 2b1, and Ntcp by 99, 69, 93, 92, and 99%, respectively. Thus, there was a marked decrease in the expression of the transporters that are responsible for uptake of chemicals into liver. In contrast, PFDA increased mRNA expression of the Mrp transporter family that transports chemicals out of liver. PFDA increased the hepatic expression of Mrp2, 3, and 4 mRNA by 100, 200, and 3500%, respectively. However, PFDA decreased hepatic mRNA expression of Bsep, which exports bile acids into bile, by 80%. These data show that PFDA decreases the mRNA expression of the hepatic uptake transporters, Ntcp and Oatps, but increases the mRNA expression of the Mrp family of efflux transporters. In conclusion, there appears to be a coordinated down-regulation of uptake transporters, and up-regulation of efflux transporters. This response may decrease the liver burden of chemicals, and thus serves to protect the liver from toxicity. (Supported by NIH grant ES-09649, ES-09716, and ES-07079)

ANALYSIS OF BENZO(A)PYRENE-INDUCED GENE EXPRESSION CHANGES IN FISHER 344 RAT LIVER BY QUANTITATIVE REAL-TIME PCR.

A. U. N and J. C. Means. *Chemistry/Environmental Institute, Western Michigan University, Kalamazoo, MI.*

Benzo(a)pyrene (BaP), an environmental contaminant produced from diesel exhaust and organic matter combustion, is associated with a variety of adverse health effects, including cancer. In this study, we used Real-Time quantitative (Taqman) PCR (RT-PCR) to validate the expression of 6 target genes of interest cytochrome p450 1a1 and 1a2 (Cyp1a1, Cyp1a2), Glutathione-s-transferase (GST-yc2), Tumor Suppressor protein (p53), B-cell lymphoma (Bcl-2), Interleukin-1 beta (IL-1 beta) previously identified from our Affymetrix microarrays global transcript profiling experiment of BaP induced gene expression changes in Fisher 344 rat liver. These genes were selected because they showed 3-fold level of change in our Affymetrix experiments and also for their involvement in pathways regulated by BaP. Adult male F344 rats were exposed to BaP through the diet for either 2 weeks (0.1 or 0.01mg/g-diet) or 12-weeks (0.01, 0.1 or 1.0 mg BaP/g of diet). Real-Time PCR quantitative analysis of the target genes of interests revealed significant differences ( $p < 0.05$ ) between the control and treated groups. We also observed a temporal separation in the dose response of the genes selected. For instance, p53 was induced significantly over the control after 2-weeks of exposure, whereas Cyp1a1 and Cyp1a2 were strongly induced only after 12-weeks of exposure. On the other hand, both Gst-yc2 and IL-1 beta was induced after 2-weeks and higher dose-dependent inductions observed after 12-weeks of exposure. Furthermore, significant differences in average weight gain and feed consumption was observed between the high dose (1mg BaP/g of diet) and control groups after 12-weeks of exposure. Also, percent differences in tissue weights between the control and treated groups were observed.

ALTERATIONS OF GENE EXPRESSION IN FEMALE LUNG ADENOCARCINOMA CL5 CELLS BY MOTORCYCLE EXHAUST PARTICULATES AND BENZO(A)PYRENE.

T. Ueng and C. Hung. *Institute of Toxicology, National Taiwan University, Taipei, Taiwan.*

Motorcycle exhaust (ME) consists of a wide spectrum of toxicants including carcinogenic polycyclic aromatic hydrocarbons and volatile organic compounds. The major objective of the present studies was to investigate the ability of ME particulates (MEP) and benzo(a)pyrene to alter the expression profiles of genes important in metabolic activation and tumorigenesis, which may increase the risk of acquiring lung cancer. cDNA array studies were carried out using female lung adenocarcinoma CL5 cells treated with 100 mg/ml organic extracts of MEP for 6 hr. Gene expression changes were confirmed by real-time RT-PCR. The results showed that in metabolic genes, treatment with MEP extracts increased the mRNA levels of carcinogen-activation enzymes cytochrome P450 (CYP) 1A1 and CYP1B1. In oncogenes and tumor suppressor genes, MEP increased the expression of oncogene fra and tumor suppressor p21 and in contrast decreased the expression of tumor suppressor Rb. In cytokines and growth factors, MEP increased the expression of interleukin (IL)-1 $\alpha$ , IL-6, IL-11, fibroblast growth factor (FGF)-6, FGF-9, and vascular endothelial growth factor (VEGF)-D. Treatment of CL5 cells with 10 mM benzo(a)pyrene, a carcinogenic MEP constituent, for 6 hr increased the mRNA levels of CYP1A1, CYP1B1, fra, p21, IL-1 $\alpha$ , IL-6, IL-11, IL-15, FGF-6, FGF-9, and VEGF-D; but decreased Rb gene expression. These results show that MEP and benzo(a)pyrene have the ability to induce multiple genes in carcinogen-activation, inflammatory cytokine, and growth factor families of female lung adenocarcinoma cells and suggest that ME and gene interaction may present an environmental risk contributing to lung cancer.

EXPRESSION OF GENES INVOLVED IN POLYCYCLIC AROMATIC HYDROCARBONS (PAH) TOXICITY IN HEPG2 CULTURE CELLS.

F. Castorena-Torres<sup>1</sup>, M. Bermudez de Leon<sup>2</sup>, B. Cisneros<sup>2</sup>, J. E. Salinas-Moreno<sup>3</sup> and A. Albores<sup>1</sup>. <sup>1</sup>*Toxicology Section, Cinvestav-IPN, Mexico City, Mexico*, <sup>2</sup>*Genetics and Biology Molecular Department, Cinvestav-IPN, Mexico City, Mexico* and <sup>3</sup>*Hospital General de Zona 24, IMSS, Nueva Rosita, Coah., Mexico.*

PAHs are complex mixtures produced by industrial processes. PAHs are carcinogenic to humans and display pleiotropic effects on gene expression. PAHs serve as substrates and inducers of phase I and II xenobiotic metabolism enzymes (e.g. CYP1A1, -1A2, -1B1, and GST). PAHs affect the metabolic rate and homeostasis and generate reactive intermediates that may act as final toxicants damaging human health. Therefore, due to the wide PAHs exposure and to their deleterious health effects, it is necessary to develop earlier, more specific and sensitive biomarkers to de-

tect their earliest alterations. Thus, the aim of this study is to evaluate the PAHs effects on gene expression in HepG2 cells, a human hepatic cell line, using a micro array approach. PAHs were extracted from soil samples collected in the neighborhood of coke ovens which contained benz[a]pyrene (BAP), benz[a]anthracene, and chrysene. The PAHs extracts were added to HepG2 cell cultures and the responsive genes detected. Cell viability was assessed by a MTT method. Gene expression was evaluated using cDNA microarray analysis using a 10K human genes library. About 1500 genes were shown to be regulated by the PAHs soil extract treatments, and the results were compared to those of BAP (positive control). The PAHs soil extract and BAP treatments up regulated 65 and 58% and down regulated 35 and 42% of the genes evaluated, respectively. These genes are involved in metabolic process such as cell cycle regulation, transcription, DNA replication and signal transduction. The PAHs effects on gene expression could be relevant tools as biomarkers of exposure. This approach is being investigated in our laboratory.

EFFECTS OF DIETS CONTAINING HIGH SOY PROTEIN AND ISOFLAVONES ON GENE EXPRESSION IN FEMALE RAT LIVERS.

A. Hierlihy, G. Cooke and I. Curran. *Toxicology Research Division, Health Canada, Ottawa, ON, Canada.*

Phytoestrogens have been implicated both as agonists and antagonists of estrogen-dependent cancers. These naturally occurring compounds have been shown to have estrogenic properties. The major human dietary source of isoflavones is obtained from soy foods. In addition to the purported health benefits of phytoestrogens, possible concerns exist in their actions as endocrine disrupters. Particularly in populations where exposure is high, such as in infants consuming soy-based milk formulas. In this study, the effect of dietary soy and isoflavones on gene expression and protein levels in female rat liver was examined at days 28 and 70. Method: Rats were fed a controlled diet of isoflavone-free casein or one of two treatment diets replacing casein with either alcohol-washed soy protein or alcohol-washed soy protein plus Novasoy (isoflavone supplement) at a dose of 1250 mg/kg of diet. Results: Isoflavones are known estrogen mimics; as a result the effects isoflavones on known estrogen targets were assessed. Increases in estrogen receptor alpha/beta and progesterone receptor A (PR-A) (2-fold) were detected at day 28, while decreases in ER alpha and PR-A were observed by day 70. In order to investigate multiple gene targets, microarrays (containing 22K genes) were used. Data comparing the effects of control vs high isoflavone diets on female liver from day 28 show greater than 2-fold increases in gene expression in several metallothionein genes. Decreased gene expression (> 2-fold) was observed in genes involved in fatty acid metabolism. The list of genes includes fatty acid synthase, and fatty acid binding protein 5. Conclusion: Temporal expression of estrogen-responsive receptors was observed. In addition, metallothionein-related genes, which are known to respond to oxidative stress, were upregulated, suggesting a possible protective mechanism. Furthermore, downregulation of several genes involved in fatty acid metabolism may have serious consequences. Investigation into the changes in gene expression at day 70 and day 240 are on going.

A GENE SIGNATURE FOR BILE DUCT TOXINS.

M. K. McMillian<sup>1</sup>, J. B. Parker<sup>1</sup>, A. M. Leone<sup>1</sup>, M. Kemmerer<sup>1</sup>, A. Y. Nie<sup>1</sup>, S. Bryant<sup>1</sup>, J. Herlich<sup>1</sup>, L. Yieh<sup>2</sup>, A. Bittner<sup>2</sup>, X. Liu<sup>2</sup>, J. Wan<sup>2</sup>, M. D. Johnson<sup>1</sup> and P. G. Lord<sup>1</sup>. <sup>1</sup>*Mechanistic Toxicology, Johnson & Johnson PRD, LLC, Raritan, NJ* and <sup>2</sup>*Bioinformatics & Microarrays, Johnson & Johnson PRD, LLC, La Jolla, CA.*

Hepatic bile duct cells (cholangiocytes) make up such a small percentage of the liver that their gene expression signatures are generally obscured by mRNA changes in the parenchymal cells, however bile duct damage is a common and sometimes serious side effect of novel compounds. Early prediction of bile duct damage is useful, and a gene expression signature should increase our understanding of this toxicity. Since bile duct networks are difficult to separate from other liver cells, we focused on the more easily dissected common duct as a surrogate for cholangiocytes. In addition to vehicle controls, rats were gavaged with the paradigm bile duct toxins (anaphthalisothiocyanate, ANIT, and dimethylaniline, DMA) or intrahepatic cholestasis inducers (ethinyl estradiol, EE, and erythromycin estolate, ERY), and common ducts and livers were removed 24 hours later for RNA preparation. Microarray analysis showed very different gene signature responses for common duct and liver to test compounds. ANIT and DMA had mild effects on gene expression in liver samples, and were best characterized as mild macrophage activators. EE produced a robust gene signature in liver characteristic of oxidative stress/reactive metabolites, as did ERY to a lesser extent. In contrast, gene expression responses were much stronger in the common duct than in the liver for ANIT and DMA with pronounced effects on mRNAs for cholesterol/ bile salt synthetic enzymes; EE and ERY had milder effects on common duct gene expression responses. We speculate that the gene changes observed in the common duct are adaptive and protective to the cells. Further study is required to investigate whether similar gene expression changes are occurring in the hepatic cholangiocytes.

CENTRAL ROLE OF LIVER RECEPTOR HOMOLOG-1 IN INDUCING LIVER-SPECIFIC GENES AND REGULATING LIPID METABOLISM IN KIDNEY OF 5/6 NEPHRECTOMIZED RATS.

H. Lu and C. D. Klaassen. *Pharmacology and Toxicology, KU Medical Center, Kansas City, KS.*

Liver differs from kidney in its high expression of enzymes and transporters controlling cholesterol, bile acid, and lipid metabolism (CBLM). In parallel, liver receptor homolog-1 (Lrh-1), an orphan nuclear receptor, is highly expressed in liver, but minimally expressed in kidney. Lrh-1 is critical in liver development, and can activate genes involved in CBLM, such as cytochrome P450 (Cyp) 7a1 and ATP-binding cassette (ABC) g5 and g8. Patients and experimental animals with chronic renal failure (CRF) have defects in CBLM. In CRF patients, blood and urine profiles of bile acids markedly change. The present study was aimed to investigate changes in renal expression of genes involved in CBLM during CRF and its molecular mechanism. Data show that in a CRF model of 5/6 nephrectomized rats, mRNA transcripts of Lrh-1 and 14 other liver-predominant genes (determined with the branched DNA signal amplification assay) were markedly induced in 4 of 7 female, and 1 of 7 male remnant kidneys with moderate injury. Renal induction of Lrh-1 correlated highly with renal induction of these 14 genes: Cyp2e1, 3a1, and 7a1, UDP-glucuronosyltransferase 2B2, sulfotransferase 20, Na<sup>+</sup>/taurocholate co-transporting polypeptide, bile salt export pump, organic anion transporting polypeptide 1, 2, and 4, Mdr2, Mrp2, as well as ABCG5 and g8. This is the first report of a correlation of Lrh-1 with ectopic expression of liver-specific genes. Moreover, induction of Lrh-1 in the four female remnant kidneys was associated with a complete prevention of renal triglyceride accumulation that occurred in the three female remnant kidneys lacking Lrh-1 induction. In summary, induction of Lrh-1 appears to confer to kidney the ability to express a large variety of liver-specific enzymes and transporters involved in CBLM. During CRF, renal induction of liver-specific enzymes and transporters may have profound effects on drug metabolism and disposition, thus affecting drug efficacy and toxicity. (Supported by NIH grants ES-09649 and ES-09716)

GENE EXPRESSION PROCESS IS A MAJOR INTRACELLULAR TARGET ASSOCIATED WITH A-NAPHTHYLISOTHIOCYANATE HEPATOTOXICITY.

V. Chan<sup>1</sup>, A. R. Stapleton<sup>1</sup> and N. DelRaso<sup>2</sup>. <sup>1</sup>*ManTech Environmental Technology, Inc., Wright-Patterson AFB, Dayton, OH* and <sup>2</sup>*Applied Biotechnology Branch, Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson AFB, Dayton, OH.* Sponsor: J. Gearhart.

*a*-Naphthylisothiocyanate (ANIT) is a widely used model hepatotoxin for intrahepatic cholestasis. To elucidate the molecular basis for ANIT hepatotoxicity, DNA microarray analysis of liver tissues from rats 4 days after ANIT treatment (0.1 – 100 mg/kg) was performed. Statistical analysis showed that the expression levels of 195 genes were significantly changed after ANIT treatment. Hierarchical clustering analysis demonstrated that using the expression profiles of these genes as input data, animals could be grouped into clusters grossly corresponding to the dose of ANIT they received. Of the genes showing altered expression, 54 genes are related to the gene expression processes including transcriptional regulation, mRNA processing, translation, post-translational modification, protein folding, sorting and trafficking. Other biological processes affected by ANIT treatment include mitochondrial electron transport, transporter/carrier, cell adhesion and communication, signal transduction and metabolism. Self Organization Map Clustering analysis revealed co-regulation of genes in certain functional classes. For instance, genes related to mitochondrial electron transport were clustered in a group with a maximum response of down-regulation at low level exposure (0.5 mg/kg), while genes involved in transcriptional regulation/mRNA processing were clustered in a group showing a progressive decrease. In contrast, genes involved in translation, post-translational modification and protein sorting/trafficking were up-regulated. However, these genes almost evenly distributed into two clusters with a progressively increasing pattern and a biphasic pattern respectively. We are currently pursuing additional analysis addressing the biological pathways involved. These results should provide a better understanding of the molecular basis for ANIT hepatotoxicity and perhaps intrahepatic cholestasis in general.

GESTATIONAL EXPOSURE TO THE PHYTOESTROGEN GENISTEIN INFLUENCES EPIGENETIC GENE REGULATION IN MICE.

D. C. Dolinoy<sup>1</sup>, R. L. Jirtle<sup>1</sup> and R. A. Waterland<sup>2</sup>. <sup>1</sup>*Department of Radiation Oncology, Duke University Medical Center, Durham, NC* and <sup>2</sup>*Departments of Pediatrics and Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.*

Exposure to the phytoestrogen genistein has been linked to a variety of beneficial effects, including cancer chemoprevention (1) and decreased adipose deposition (2), as well as a number of negative outcomes including reduced reproductive

health (3). Since the epigenome is particularly susceptible to dysregulation during embryogenesis, we investigated the effect of gestational exposure to moderate levels of dietary genistein in viable yellow Agouti (Avy) mice. Female a/a dams were randomly assigned to receive soy-free diet or soy-free diet supplemented with 250 mg/kg diet of genistein two weeks prior to mating with Avy/a males and throughout gestation and lactation. Coat color phenotype and CpG methylation of the Avy intracisternal A particle (IAP) retrotransposon were assessed in day 21 Avy/a offspring. Bisulfite sequencing was used to quantify site-specific CpG methylation (4). Maternal supplementation with genistein shifted the coat color distribution of Avy/a offspring toward the brown (pseudoagouti) phenotype. Methylation analysis at nine Avy IAP CpG sites showed increased percentage of cells methylated in genistein exposed litters in comparison to controls. IAP methylation profiles in day 120 tissue derived from the endoderm (liver), mesoderm (kidney), and ectoderm (brain) were correlated to day 21 tail tissue suggesting that genistein acts early in embryonic development and that methylation effects are not transitory but persist into adulthood. These results suggest that early exposure to genistein affects adult phenotype via permanent alterations in the epigenome and may influence cancer chemoprevention and disease susceptibility. 1. USING RNA INTERFERENCE TO VALIDATE MECHANISMS OF TOXICITY.

J. Milano and D. Tran. *Safety Assessment, AstraZeneca, Wilmington, DE.* Sponsor: P. Ciacco.

Small molecule inhibitors of the  $\gamma$ -secretase ( $\gamma$ -sec) complex have been shown to prevent the cleavage of amyloid precursor protein thus preventing the release and deposition of neurotoxic forms of  $\beta$ -amyloid in Alzheimer's disease. The reported *in vivo* toxic effects of  $\gamma$ -sec inhibitors in the gastrointestinal tract are associated with the dysregulation of Hes1 and Rath1 in the Notch1 differentiation pathway (Milano et al, 2004). Seeking further experimental support for Notch1 cleavage inhibition as the mechanism for toxicity mediated by  $\gamma$ -sec inhibitors, we employed RNA interference (RNAi) using a siRNA against Notch1. RNAi is a relatively new technology for negative genetic analysis that allows for sequence specific post-translational degradation of mRNA. A duodenal adenocarcinoma cell line, Htu80, expresses Notch1 and Hes1 and was chosen for our model system. Transfection conditions were optimized for 3 siRNAs targeted against Notch1. In two independent experiments, one of three siRNAs (Notch1\_C), showed  $\approx$ 65% gene knock down 48 hours post transfection. Notch1\_C was then used in two 3-day time course experiments that examined Notch1 expression 24, 48 and 72 hours post-transfection. Cells treated with medium containing transfection reagent for 72 hours in Experiment A were crenated and senescent by visual observation, indicating cytotoxicity. When transfection reagent was removed after 24 hours in Experiment B treated cultures were indistinguishable when compared to untreated controls. Data from these 2 experiments showed a similar expression pattern relative to the controls with 60% knockdown occurring at 48 and 72 hours. However, the data show no change in the expression of the Notch1 regulated transcriptional repressor, Hes1 in the 3-day time course experiment. This may be due to the duration of the time course or the degree of the silencing effect. While RNAi is a powerful method for negative genetic analysis, great consideration must be taken for the value of target analysis weighed against the investment of time. With experience, workflows may be streamlined for a less time intensive commitment.

CIGARETTE SMOKE CONDENSATE INHIBITS PROMOTER ACTIVITY OF LYSYL OXIDASE IN CULTURED LUNG FIBROBLASTS.

S. Gao<sup>1</sup>, Y. Zhao<sup>1</sup>, L. Chen<sup>1</sup>, D. K. Chou<sup>1</sup>, P. Toselli<sup>1</sup>, L. Chou<sup>2</sup>, P. Stone<sup>1</sup> and W. Li<sup>1</sup>. <sup>1</sup>*Biochemistry, Boston University School of Medicine, Boston, MA* and <sup>2</sup>*Microbiology, Boston University School of Medicine, Boston, MA.*

Lysyl oxidase (LO) catalyzes the crosslinking of collagen and elastin stabilizing the lung extracellular matrix. LO deficiency is implicated in the pathogenesis of emphysema. Cigarette smoke is a major cause of emphysema development. Our previous studies have shown downregulation of LO mRNA in rat fetal lung fibroblasts (RFL6) exposed to cigarette smoking condensate (CSC). To further study CSC effects on LO gene expression, we isolated the 5'-flanking region of the LO gene from rat genomic DNA by PCR. DNA sequence inspection revealed a number of potential cis-elements such as CTF1, MTF1, HIF1 $\alpha$ , ARE, SP1, Oct-1, CdxA and AP2 existing in this LO promoter region, but the lack of a typical TATA box. The LO promoter region was restricted into the plasmid pGL3-basic upstream of the luciferase gene. Deletion analysis of the LO promoter showed that the proximal 1.6 kb upstream of the putative transcription start site (+1) was required for maximal expression of the reporter gene in transfected RFL6 cells. Two positive regulatory

segments, i.e., -124/-231 and -312/-518, and one negative regulatory segment, i.e., -232/-312, were identified. Transient transfection analysis demonstrated that although CSC-resistant cells derived from RFL6 cells exposed to graded doses of CSC displayed higher transfection efficiency these cells exhibited 60% lower luciferase activity in comparison to the parental control without CSC treatment. The 24-h pulse assay showed that CSC induced a biphasic response in the luciferase gene expression such that 20 $\mu$ g/ml of CSC enhanced LO promoter activity to 3.6-fold of the control, while 120 $\mu$ g/ml of CSC totally inhibited the luciferase gene expression. These results suggest that suppression of LO promoter activity by CSC at high doses is a key mechanism for downregulation of LO at the mRNA level while enhanced effects of CSC at low doses on LO promoter activity are under study (Supported by Philip Morris ERP & NIH grant R01-ES11340).

#### REGULATION OF THE STEROIDOGENIC ACUTE REGULATORY PROTEIN (STAR) BY TRANSFORMING GROWTH FACTOR BETA (TGF-BETA).

J. Kocerha<sup>1</sup>, N. Denslow<sup>1</sup> and M. Prucha<sup>2</sup>. <sup>1</sup>Department of Physiological Sciences, University of Florida, Gainesville, FL and <sup>2</sup>Department of Pharmacology and Therapeutics, University of Florida, Gainesville, FL.

Exposure to environmental contaminants, including Roundup, Lindane, phthalates, and paper mill discharge, can significantly repress steroid production in mammals and in lower vertebrates such as fish. StAR is involved in the rate-limiting step in steroid production and is transcriptionally down regulated by toxin exposure. StAR transports cholesterol across the mitochondrial membrane for metabolism into steroids. We cloned the entire coding region of largemouth bass (LMB) StAR and used this sequence to develop a real-time PCR assay to quantify StAR mRNA levels in LMB ovarian follicle cultures. Exposure to dbcAMP and TGF-beta, two potent signaling molecules known to regulate mammalian steroidogenesis, also regulated StAR in bass. Dose response experiments at 0.25, 0.5, 0.75, and 1 mM dbcAMP show increased mRNA expression that saturates between 0.75 mM and 1 mM dbcAMP. TGF-beta, on the other hand, down regulates StAR mRNA by 2.3 fold after 14 hours. A polyclonal antibody specific to LMB StAR was developed to measure protein levels by western blot. To further analyze the regulation of LMB StAR, a 3 kb portion of the promoter was cloned. In silico analysis of this segment with other StAR promoters available in the database showed potential conserved regulatory sites that imply control by a wide range of transcription factors. The 3 kb promoter segment was transfected into Y-1 cells, a mouse adrenocortical cell line and tested with dbcAMP and TGF beta. The 3 kb and the 1.8 deletion constructs responded positively to dbcAMP but only the 1.8 kb construct was repressed by around 2-fold after 40 hr incubation with 10 ng/ml TGF-beta. Mutation of potential regulatory sites in the promoter, including estrogen response elements and COUP-TF sites are being tested for their role in TGF-beta signaling. Together, this data suggest that one way toxins may repress steroid synthesis, and more specifically StAR, is through TGF-beta signaling.

#### COMPENSATORY CHANGES IN PHASE I, II, AND III ENZYMES IN MICE LACKING THE MULTIDRUG RESISTANCE-ASSOCIATED PROTEIN 1 (MRP1/ABCC1).

J. Sivils, L. Bain, R. A. Feldman, A. J. Zimmerman and I. Gonzalez. Biology, University of Texas El Paso, El Paso, TX.

The multidrug resistance-associated protein-1 (MRP1/ABCC1) is a 190kDa membrane-bound glycoprotein that mediates cellular efflux of a variety of xenobiotics, typically as glucuronide, sulfate, or glutathione conjugates. We examined alterations in phase I, II, and III (transporter) activity or gene expression in the liver, kidney, colon, lungs, stomach, heart, and testes between FVB mice and mice that lacked the multidrug resistance associated protein 1 (mrp1) termed FVB/mrp1-/- mice. In the testes, 16a hydroxylation and 2a-hydroxylation activities were significantly upregulated in the FVB/mrp1-/- mice, which correspond to CYP2C11. In the lung, 15a hydroxylation and 16a hydroxylation were significantly reduced in the knockout animals, which correspond to CYP2A4 and CYP2C11, respectively. In the kidney, two unidentified hydroxylation activities and 2a hydroxylation were significantly upregulated. There were no differences in the liver, heart, or the stomach. Significant changes in phase II metabolizing enzymes included a 2.6-fold increase in hepatic sulfotransferase activity and 1.5-fold reduction in hepatic glucuronosyltransferase activity in the FVB/mrp1-/- mice. The expression of mrp2 and mrp5 was significantly increased in the liver, while mrp5 expression was reduced by 2-fold in the lungs in the FVB/mrp1-/- mice. There were no differences in transporter expression in the kidneys, testes, or stomach. Thus, mice lacking mrp1 have tissue-specific changes in levels of phase I, phase II, and phase III enzymes, presumably to compensate for the lack of mrp1.

#### TIME COURSE OF HEPG2 GENE EXPRESSION FOLLOWING TREATMENT WITH THIOXANTHONE ANTITUMOR COMPOUNDS.

A. E. Roberts, X. Luo, Y. Wang, R. Khan-Malek, V. Shultz, J. Morsman, N. Bowen, N. Bichet, O. Gillardeaux and V. Baker. Sanofi-aventis, Malvern, PA.

Toxicogenomic studies have been conducted using thioxanthone compounds with well-characterized target organ toxicity. Three thioxanthones have been tested in clinical trials; two have failed and one is in Phase I. The present *in vitro* study compares the time course of gene expression in HepG2 cells for two thioxanthones, Hycanthone (Etrenol®) and SR33377. Hycanthone is hepatotoxic in humans and rodents, while SR33377 is not. HepG2 cells were exposed for 4 hrs (mimicking *in vivo* half-life) at concentrations resulting in 70-80% cell viability. After 4 hrs, compounds were removed and fresh media was added. Total RNA was extracted mid-incubation, at the end of the incubation, and 2, 8, 20 and 44 hours post-incubation. Atlas™ Human Toxicology II arrays (Clontech) were used to evaluate gene expression. Statistically significant changes in gene expression were identified by analysis of variance (ANOVA). Selected changes were confirmed by real-time RT-PCR. The fewest changes in gene expression occurred during the drug incubation period: 42 with Hycanthone and 26 with SR33377. The greatest number occurred at 2 hours with SR33377 (337) and 8 hours with Hycanthone (251). By 44 hours, gene expression had returned to control levels. Maximal gene expression preceded the peak in cytotoxicity (MTT). The major pathways affected by SR33377 and Hycanthone included genes regulating: DNA damage/repair, cell cycle progression, the oxidative stress response, immune response and induction of apoptosis. The primary difference in the expression profiles of the two compounds was prolonged gene expression changes observed with SR33377, most notable for genes involved in metabolism, the immune response and DNA damage/repair. Hycanthone and SR33377 are cytotoxic antitumor agents that both intercalate and bind DNA. The pathways affected by Hycanthone and SR33377 in HepG2 cells are consistent with this and suggest that DNA damage and oxidative stress are involved in thioxanthone-mediated cell injury and antitumor activity.

#### ISOLATING (NEURO)TOXIC GENE EXPRESSION SIGNATURES.

P. S. Spencer and N. and. Center for Research on Occupational and Environmental Toxicology, Oregon Health & Science University, Portland, OR.

Toxicogenomic experiments present challenges in isolating phenotype-specific transcriptional changes. We use active and inactive isomers and other controls to address this issue. 1, 2-Diacetylbenzene (DAB), but not 1, 3-DAB, is (a) instantaneously protein-reactive, (b) chromogenic after a single systemic dose and, with repeated treatment, (c) able to induce axonopathy. Transcriptional changes were examined in brains of 12-wk-old male C57Bl/6 mice 1 hr-7 days after single intraperitoneal (i.p.) puncture (Mock) or i.p. treatment with Vehicle (2% acetone in saline), 50 mg/kg body weight 1, 3-DAB or 50 mg/kg 1, 2-DAB (a neuropathic dose if repeated). Gene expression studies employed fluorescently-tagged cRNAs hybridized to an Agilent mouse 60-mer oligonucleotide microarray with >22, 000 features. Data were subjected to Significant Analysis of Microarrays for  $q = 0.1$  and fold changes = or >1.5. At 1 hr post-treatment, gene expression with 1, 3-DAB vs. Vehicle (mostly down-regulation) differed from that of 1, 2-DAB vs. Vehicle (mostly up-regulation). Changes specific to the neurotoxic property (NP) of 1, 2-DAB were assessed by excluding genes co-modulated by Mock (few), Vehicle (some) and 1, 3-DAB (n=290 down- and 8 up-regulated features). The NP was associated with increased expression of only 28 genes encoding certain transcription factors/regulators and proteins linked to cell-cycle progression, synaptic function, and microtubule integrity, among others. The NP associated with a different set of genes at 6 hr, and overall modulation was markedly reduced by 24-48 hr post-treatment. These studies indicate the critical need for adequate controls (Mock, Vehicle, 1, 3-DAB) to isolate evolving gene expression signatures peculiar to the pathological mechanism initiated by 1, 2-DAB. Genes modulated by confounding factors (e.g. injection, vehicle, chemical class) must be excluded to identify toxic mechanisms. #### PREDICTION OF TRANSCRIPTION FACTORS COMMONLY AFFECTED BY GLUTAMATE-CYSTEINE LIGASE EXPRESSION IN MICE EXPOSED TO ACETAMINOPHEN, CARBON TETRACHLORIDE OR TUMOR NECROSIS FACTOR.

S. Shi, D. Botta, T. Bammler, R. P. Beyer and T. J. Kavanagh. Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.

Glutathione is a major cellular antioxidant and free radical scavenger and its synthesis is rate limited by the activity of glutamate-cysteine ligase (GCL). We have created transgenic mice in which GCL can be induced using the progesterone an-

agonist mifepristone. Using DNA microarrays, we compared global gene expression in the livers of these mice after exposure to the hepatotoxins acetaminophen (APAP), carbon tetrachloride and tumor necrosis factor-alpha (TNF-a), all of which exert oxidative stress. Gene expression profiles were processed using GenMapp to retrieve gene ontology (GO) information, and gene expression patterns were analyzed for common up-stream promoter transcription response elements (TREs) using the program PAINT. The hepatotoxins induced stress response genes, inflammatory response genes and phase I and II metabolism genes. Induction of GCL transgenes modified gene expression profiles, especially in APAP and TNF-a treated mice. Analysis of the GO and TREs present in the promoters of up- or down-regulated genes revealed common themes of oxidative stress, inflammatory response and lipid metabolism. However, relatively few TREs were over represented ( $p<0.1$ ) in common among all three hepatotoxins. These included CAAT, Elk1, Ap4, CREBP, NGFI-C, c-ETS1, v-Maf, SREBP-1 and Brn-2. Genes whose expression after treatment was attenuated by GCL over expression had several TREs in common: v-Maf, Pax-3, NF-Y, SREBP-1, MYOGNF1, NGFI-C, Oct-1, Nkx2-5. This possibly indicates GCL status was an important factor associated with the genes expressed or repressed in common by these factors. We conclude that GCL status may be an important determinant for a number of gene expression responses common to all three hepatotoxins. Supported by NIH Grants 1P42ES04696, 1R01ES10849, 5U19ES011387, and 1P30ES07033.

### MOLECULAR MECHANISMS OF PPARA-MEDIATED GENE EXPRESSION OF PXR.

S. aouabdi, G. Gibson and N. Plant. *school of biological and molecular sciences, university of surrey, guildford, surrey, United Kingdom.*

The Pregnan-X-Receptor (PXR) plays a central role in the transcriptional regulation of genes associated with compound metabolism, including CYP3A4, CYP2B6, GST-A2 and MDR1. Ligand promiscuity for activating PXR, combined with its large target gene set, allows PXR to act as a central regulator to changes in the fluxome, relating to both xenobiotics (many therapeutic agents are ligands for PXR), or endogenous chemicals (PXR target genes are involved in bile acid homeostasis, haem and cholesterol synthesis). PXR expression has been shown to be increased by several chemicals, and of particular interest are chemicals not traditionally associated with PXR target genes, such as the peroxisome proliferators. The aim of this study was to examine possible molecular mechanisms underlying this phenomenon. Bioinformatic analysis of 2.2kp of DNA immediately upstream of the PXR transcription start site, using MatInspector Professional to interrogate the Transfac 4.0 database identified putative binding sites for numerous factors. Next, this region was cloned into a SEAP reporter plasmid and a deletion series created (1.8kp, 1.5kp, 1.3kp, 1kp, 900bp, 600bp and 400bp anchored at the 3 end). Human hepatoma cells were transiently transfected and expression levels measured, to produce a map of positive and negative regulatory regions: Comparing this to the in silico assignments allows evidence-based predictions for the transcription factors involved in basal expression. A putative binding site for Peroxisome Proliferator Activated Receptor alpha (PPAR $\alpha$ ) was identified 1.3kb from the transcription start site, and shown to respond in a positive fashion to co-transfected PPAR $\alpha$  protein. In addition, electromobility shift analysis demonstrated binding of nuclear protein to this site and disruption of the site via mutagenesis resulted in both reduced binding of protein, and reduced activation in the reporter gene assay. In summary, we have used both in silico and *in vitro* approaches to characterise potential molecular mechanisms underlying PPAR $\alpha$ -mediated transcriptional activation of PXR expression.

### DECREASED LONGEVITY AND ENHANCEMENT OF AGE-DEPENDENT LESIONS IN MICE LACKING THE NUCLEAR RECEPTOR PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA.

P. Howroyd<sup>1,2</sup>, C. Swanson<sup>1</sup>, C. Dunn<sup>1</sup>, R. C. Cattley<sup>1,3</sup> and J. C. Corton<sup>4,1</sup>.  
<sup>1</sup>*CITI, Research Triangle Park, NC*, <sup>2</sup>*EPL, Research Triangle Park, NC*, <sup>3</sup>*Amgen, Thousand Oaks, CA* and <sup>4</sup>*ToxicoGenomics, Chapel Hill, NC*.

The nuclear receptor peroxisome proliferator-activated receptor alpha (PPAR $\alpha$ ) is activated by peroxisome proliferators (PP), a large class of structurally diverse xenobiotic chemicals, hypolipidemic drugs and endogenous lipids. PPAR $\alpha$  alters the transcriptional programs of genes whose functions include lipid metabolism, inflammation, cell fate, and stress responses in liver, heart, kidney and skin. Many of these genes are also under control of PPAR $\alpha$  in the absence of exogenous peroxisome proliferator exposure. Mice which lack PPAR $\alpha$  (PPAR $\alpha$ -null mice) exhibit a number of defects in lipid metabolism and accumulate lipids in the liver. Here, we compared the age-dependent lesions in the liver, kidney and heart in PPAR $\alpha$ -null mice with those observed in wild-type SV129 mice, in the absence of exogenous chemical exposure. Groups of mice were sacrificed, at 6, 12, 18, 21, or 24 months of age, or allowed to age until moribund or found dead.

PPAR $\alpha$ -null mice had decreased longevity, due to a variety of causes. Statistically significant differences in the occurrence of a number of lesions between strains was observed. Hepatocellular carcinomas and multiple hepatocellular adenomas occurred in the livers of PPAR $\alpha$ -null mice but not wild type mice. Various non-neoplastic spontaneous aging lesions occurred at higher incidence, shorter latency, or increased severity in PPAR $\alpha$ -null mice compared with wild-type mice. In the liver, these included vacuolated hepatocytes and sinusoidal cells and mixed cell inflammation. The kidneys of PPAR $\alpha$ -null mice exhibited higher incidences and severities of cortical mineralization. Minimal myocardial mineralization occurred at a higher incidence in PPAR $\alpha$ -null mice. Our results imply that PPAR $\alpha$  delays the development of some spontaneous lesions associated with aging in the liver, kidney and heart of SV129 mice.

### CONSTITUTIVE EXPRESSION OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA-REGULATED GENES IN DWARF MICE.

A. J. Stauber<sup>2</sup>, J. Liu<sup>4</sup>, M. P. Waalkes<sup>4</sup>, H. Brown-Borg<sup>3</sup>, K. A. Voss<sup>5</sup>, J. J. Kopchick<sup>6</sup> and J. C. Corton<sup>1,2,7</sup>. *ToxicoGenomics, Chapel Hill, NC*, <sup>2</sup>*CIT Centers for Health Research, Research Triangle Park, NC*, <sup>3</sup>*University of North Dakota, Grand Forks, ND*, <sup>4</sup>*NCI at NIEHS, Research Triangle Park, NC*, <sup>5</sup>*USDA, Athens, GA* and <sup>6</sup>*Ohio University, Athens, OH*.

Defects in growth hormone (GH) secretion or signaling in mice are associated with decreased body weights (dwarfism), increased longevity, increased resistance to stress and decreases in factors which contribute to cardiovascular disease and cancer. Peroxisome proliferators (PP) alter a subset of these changes in wild-type mice through activation of the nuclear receptor family member, PP-activated receptor alpha (PPAR $\alpha$ ). We tested the hypothesis that an overlap in the transcriptional programs between untreated dwarf mice and PP-treated wild-type mice underlies these similarities. Using transcript profiling, we observed a statistically significant overlap in the expression of genes differentially regulated in control Snell dwarf mice (Pit-1dw) compared to phenotypically normal heterozygote (+/dw) controls and those altered by the PP WY-14, 643 (WY) in +/dw mice. The genes included those involved in beta- and omega-oxidation of fatty acids (Acox1, Cyp4a10, Cyp4a14) and those involved in stress responses (the chaperonin, TCP1 epsilon) and cardiovascular disease (fibrinogen). The levels of some of these gene products were also altered in other dwarf mouse models including Ames, Little and GH receptor-null mice. The constitutive increases in PPAR $\alpha$ -regulated genes may be partly due to increased expression of PPAR $\alpha$  mRNA and protein as observed in the livers of control Snell dwarf mice. These results indicate that some of the beneficial effects associated with the dwarf phenotype may be due to constitutive activation of PPAR $\alpha$  and regulated genes.

## 583

### PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR $\beta$ (PPAR $\beta$ ) REGULATES EXPRESSION OF CANCER-RELATED GENES IN LIVER.

W. Shan<sup>1,2</sup> and J. M. Peters<sup>1</sup>. <sup>1</sup>*Department of Veterinary Science and Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA* and <sup>2</sup>*The Intercollege Graduate Degree Program in Genetics, The Pennsylvania State University, University Park, PA*.

Previous studies in our laboratory using two chemically-induced liver toxicity models suggested that peroxisome proliferator activated receptor  $\beta$  (PPAR $\beta$ ) attenuates hepatotoxicity, and may function to prevent hepatocarcinogenesis. In this study, gene expression profiles of liver samples from wild-type and PPAR $\beta$ -null mice were examined, to identify potential PPAR $\beta$  target genes that are involved in liver toxicity, cell proliferation, and carcinogenesis. A cDNA-microarray analysis of 1706 genes was performed, and 47 genes were shown to be up-regulated while 43 genes were down-regulated in PPAR $\beta$ -null samples as compared to wild-type ( $p<0.05$ ). Subsequent northern blot analysis and/or real-time PCR was performed to confirm the expression changes detected by microarray analysis for some of the genes related to liver toxicity and carcinogenesis. E-cadherin, a tumor suppressor gene, is down-regulated by 2 fold in PPAR $\beta$ -null mice as compared to wild-type. Additionally, cathepsin E, which is highly expressed in multiple human cancers and is implicated in the promotion of metastasis, is up-regulated by 11.5 fold in PPAR $\beta$ -null livers as compared to the wild-type counterparts. Combined, these results indicate that PPAR $\beta$  modulates expression of critical cancer-related genes in the liver that could participate in the prevention of liver toxicity and carcinogenesis.

### GENE EXPRESSION PATTERNS ASSOCIATED WITH FENOFIBRATE INDUCED MYOPATHY.

N. R. Bordelon, B. H. Romach, R. Brown and R. T. Miller. *SA, GSK, Research Triangle Park, NC*.

Fenofibrate (FB) is a PPAR-alpha agonist that is used to treat dyslipidemia. Skeletal muscle myopathy is a rare, but serious adverse event reported in people taking FB. Myofiber damage may be a result of increased beta-oxidation leading to oxidative

stress. Generally, in the rat, the soleus depends on oxidative lipid metabolism and is composed of Type 1 fibers while the gastrocnemius depends on glycolytic metabolism and is composed of Type 2 fibers. The purpose of this study was to investigate gene expression changes in the soleus and gastrocnemius of rats given a myopathic dose of FB and to correlate these changes with clinical and anatomic endpoints. Following 10 days of treatment with 200 mg/kg/day FB, blood was collected for clinical chemistry and the soleus and gastrocnemius were collected for microscopic evaluation and gene expression analysis using Clontech Toxicology II arrays. Treatment-related myopathy was observed in the soleus but was not noted in the gastrocnemius. Increases in AST (3-fold) and ALT (2 fold) were observed; however there was no change in CK. In general, genes associated with oxidative stress, lipid synthesis and transport, and myofiber and collagen formation were more strongly upregulated in the soleus compared to the gastrocnemius. For example, metallothionein (MT)-1 and hemeoxygenase (HO)-1 were upregulated by 19.2- and 4.4-fold, respectively, in the soleus while in the gastrocnemius MT-1 was upregulated by 1.4-fold and there was no change observed in HO-1. Upregulation of genes associated with oxidative stress appear to be related to the myopathic response in the soleus. Genes associated with beta-oxidation were more strongly upregulated in the gastrocnemius and may suggest a shift from glucose utilization to lipids and beta-oxidation. The myopathic response observed in the soleus may be consistent with some clinical chemistry endpoints and with upregulation of genes associated with oxidative stress. However, the relationship of fiber-type sensitivity to damage remains unclear as a shift towards beta-oxidation was noted in the gastrocnemius without evidence of myopathy.

### EVALUATION OF THE ACTIVITY OF THE PESTICIDE CYHALOFOP-BUTYL IN A PEROXISOME-PROLIFERATOR RECEPTOR- $\alpha$ REPORTER ASSAY.

G. D. Charles<sup>1</sup>, L. Kan<sup>1</sup>, T. R. Hanley<sup>2</sup> and B. B. Gollapudi<sup>1</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI and <sup>2</sup>Dow AgroSciences LLC, Indianapolis, IN.

The potential of cyhalofop-butyl, a registered rice herbicide, to bind to and activate the peroxisome proliferator activated receptor-alpha (PPAR- $\alpha$ ) was evaluated *in vitro*, in a gene transactivation assay. The plasmids pSI-PPAR- $\alpha$  (containing the rat PPAR- $\alpha$  gene), pGL3-3XPPRE (containing 3 tandem repeats of the recognition sequence for the PPAR- $\alpha$ ), and pCMV- $\beta$ gal-SPORT, were transiently transfected into the rat hepatoma cell line H4IIE. The assay was validated by assessing the activity of a series of activating and non-activating PPAR- $\alpha$  ligands. WY14643 (EC50 ~250 nM) produced the maximal response and was the most potent of the test materials evaluated. Fenoprofen (EC50 ~7 uM), LY171883 (~5 uM) and arachidonic acid (~80 uM) exhibited similar maximal responses to WY14643, but at much higher concentrations. The plant-derived terpenoid geranylgeraniol (EC50 ~250 nM) and indomethacin (above 600  $\mu$ M) exhibited less-than-maximal responses in the assay. The negative control PPAR- $\gamma$  agonist ciglitazone and the phorbol ester, TPA, exhibited no significant activity in the assay. For the assessment of cyhalofop-butyl, two separate assays were conducted at eight concentrations ranging from 10 pM-1 mM. Cyhalofop-butyl exhibited a concentration-related increase in response, with maximal 2.8 and 3-fold increases >100  $\mu$ M, relative to vehicle control (DMSO). The concurrently run positive control, WY14643 (100 pM-1 mM) exhibited a maximal 8-fold induction in both assays relative to vehicle. The reproducible, concentration-related responses indicate that under the conditions of the study, cyhalofop-butyl binds to and activates the PPAR- $\alpha$ . This demonstrates a plausible mechanism whereby cyhalofop-butyl, though negative in both rat and mouse cancer studies, could produce peroxisome proliferator-associated tumors in rodent liver at excessive doses. However, hepatic PP induction is a physiological response associated primarily with rodents and generally not considered relevant to humans.

### PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR $\beta$ (PPAR $\beta$ ) SELECTIVELY REGULATES KERATINOCTYE DIFFERENTIATION AND PROLIFERATION.

D. J. Kim<sup>1,2</sup>, A. N. Billin<sup>3</sup>, T. M. Willson<sup>3</sup> and J. M. Peters<sup>1,2</sup>. <sup>1</sup>Department of Veterinary Science and The Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA, <sup>2</sup>Graduate Program in Molecular Toxicology, The Huck Institute for Life Sciences, The Pennsylvania State University, University Park, PA and <sup>3</sup>Discovery Research, GlaxoSmithKline, Research Triangle Park, NC.

Previous work has shown that peroxisome proliferator-activated receptor  $\beta$  (PPAR $\beta$ ) attenuates chemically-induced skin carcinogenesis, suggesting a critical role of PPAR $\beta$  in regulating keratinocyte cell proliferation and/or differentiation. In these studies, the functional role of PPAR $\beta$  in keratinocyte proliferation, differentiation, and inflammation was investigated using a highly specific PPAR $\beta$  ligand (GW0742) and a null mouse model. Differentiation induced by two classical methods of increasing culture medium Ca<sup>++</sup> level or TPA was not markedly different be-

tween wild-type and PPAR $\beta$ -null keratinocytes. However, GW0742 selectively induced mRNA markers of differentiation in primary keratinocytes and mouse skin, and this effect did not occur in the absence of PPAR $\beta$  expression. Treatment of cells with GW0742 inhibited cell proliferation in wild-type keratinocytes in a dose-dependent manner, whereas no influence on cell proliferation was observed in PPAR $\beta$ -null keratinocytes. In addition, myeloperoxidase (MPO), an enzyme marker of inflammation in skin, was significantly increased in TPA-treated mouse skin, and co-administration of GW0742 resulted in reduced activity in both wild-type and PPAR $\beta$ -null mice. Further analysis showed that GW0742 uncompetitively inhibits MPO activity. Combined, these results show that the antiproliferative role of PPAR $\beta$  in skin is due to its selective induction of differentiation and inhibition of cell proliferation, and that inhibition of inflammation induced by GW0742 is independent of PPAR $\beta$ . Supported by the National Cancer Institute (CA89607), J.M.P.

### THE PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR $\beta$ (PPAR $\beta$ ) AGONIST GW0742 INHIBITS SKIN CARCINOGENESIS.

M. K. Devlin<sup>1,2</sup>, D. J. Kim<sup>1</sup>, A. N. Billin<sup>3</sup>, T. M. Willson<sup>3</sup> and J. M. Peters<sup>1,2</sup>.

<sup>1</sup>Department of Veterinary Sciences and The Center for Molecular Toxicology and Carcinogenesis, Penn State University, University Park, PA, <sup>2</sup>Graduate Program in Molecular Medicine, Huck Institute for Life Sciences, Pennsylvania State University, University Park, PA and <sup>3</sup>Discovery Research, GlaxoSmithKline, Research Triangle Park, NC.

The peroxisome proliferator-activated receptor  $\beta$  is ubiquitously expressed, and high expression levels are found in the skin. The biological roles of PPAR $\beta$  remain uncertain. Previous studies have shown that PPAR $\beta$ -null mice subjected to a two-stage chemical carcinogenesis bioassay exhibit greatly accelerated formation of papillomas in addition to a greater average number and size of papillomas, as compared to wild-type mice. These results suggest that PPAR $\beta$  attenuates cell proliferation and that activation of this receptor may inhibit skin cancer. In this study, PPAR $\beta$ -null and wild-type mice were subjected to a two-stage chemical carcinogenesis bioassay and topical treatment with a selective PPAR $\beta$  agonist (GW0742). The onset of papilloma formation was delayed in ligand treated wild-type mice, and this effect did not occur in PPAR $\beta$ -null mice. After 24 weeks of TPA and ligand treatment the average number of papillomas was decreased in ligand treated wild-type and PPAR $\beta$ -null mice as compared to controls. However, the average size of papillomas was smaller in ligand treated wild-type mice, and this effect was not observed in PPAR $\beta$ -null mice. These results support the hypothesis that PPAR $\beta$  attenuates proliferation and shows promising support that activation of this receptor may be used to inhibit skin cancer. Dose response studies with higher concentrations of ligand are currently underway. Supported by National Cancer Institute (CA89607), J.M.P.

### TRANSCRIPTIONAL REGULATION OF TISSUE-SPECIFIC INHIBITOR OF MATRIX METALLOPROTEINASE 1 (TIMP1) BY PEROXISOME PROLIFERATOR-ACTIVATOR RECEPTOR $\beta$ (PPAR $\beta$ ).

M. T. Bility<sup>1,2</sup>, D. J. Kim<sup>1,2</sup>, A. N. Billin<sup>3</sup>, T. M. Willson<sup>3</sup> and J. M. Peters<sup>1,2</sup>.

<sup>1</sup>Department of Veterinary Science and The Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA, <sup>2</sup>Graduate Program in Molecular Toxicology, The Huck Institutes for Life Sciences, The Pennsylvania State University, University Park, PA and <sup>3</sup>Discovery Research, GlaxoSmithKline, Research Triangle Park, NC.

PPAR $\beta$ -null mice exhibit an early onset of skin tumor formation, increased skin tumor size and increased skin tumor multiplicity in response to a two-stage carcinogen bioassay (DMBA/TPA). Matrix metalloproteinases (MMPs) are overexpressed in many tumors and promote tumor progression, angiogenesis and metastasis through the degradation of extracellular matrix proteins. Tissue-specific inhibitor of matrix metalloproteinases (TIMPs) are the physiological inhibitors of MMPs, and overexpression of TIMPs have been associated with reduced metastasis and chemical carcinogenesis in skin. In these studies, the role of PPAR $\beta$  in the regulation of MMP9 and TIMP1 was examined. Zymogram analysis showed increased MMP9 activity for PPAR $\beta$ -null keratinocytes as compared to wild-type keratinocytes in response to TPA. Northern blot analysis showed increased TIMP1 mRNA expression in wild-type mice as compared to PPAR $\beta$ -null mice in response to TPA. A putative peroxisome proliferator response element (PPRE) was identified in the promoter region of TIMP1 and was subsequently cloned into a luciferase reporter vector. Co-transfection of the reporter vector into keratinocytes showed a dose-dependent increase in luciferase activity compared to controls following treatment with GW0742 in wild-type keratinocytes but not in PPAR $\beta$ -null keratinocytes. Results from these studies showed that PPAR $\beta$  can significantly regulate MMP9 activity, and that this may occur through direct regulation of an MMP9 in-

hibitor, TIMP1. Further, these results suggest that tumor progression and angiogenesis may be inhibited by ligand activation of PPAR $\beta$ . Supported by the National Cancer Institute (CA89607), J.M.P.

TRANSCRIPTION PROFILING REVEALS HEPATIC HYPERTROPHY TO BE INDISTINGUISHABLE FROM THE PHARMACOLOGY OF PPAR $\alpha$  AGONISM IN THE RAT.

A. T. De Souza<sup>1</sup>, P. D. Cornwell<sup>1</sup>, X. Dai<sup>2</sup>, M. J. Caguyong<sup>3</sup> and R. G. Ulrich<sup>1</sup>.

<sup>1</sup>Preclinical Molecular Profiling, Rosetta Inpharmatics, a wholly owned subsidiary of Merck & Co. Inc., Seattle, WA, <sup>2</sup>Informatics, Rosetta Inpharmatics, a wholly owned subsidiary of Merck & Co. Inc., Seattle, WA and <sup>3</sup>Project Management, Rosetta Inpharmatics, a wholly owned subsidiary of Merck & Co. Inc., Seattle, WA.

Peroxisome proliferator activated receptor alpha (PPAR $\alpha$ ) agonism by xenobiotics in rodent models can result in hepatomegaly (a combination of hepatic peroxisome proliferation and hypertrophy) and tumor formation via poorly understood non-genotoxic mechanisms. Hepatomegaly is widely believed to be an on-target effect of PPAR $\alpha$  treatment but a systematic approach to characterizing this relationship has not been reported. Sprague-Dawley rats were treated p.o. for 2, 3, 4, 5, 6, 9 and 16 days with five nuclear hormone receptor agonists. Using compounds that target PPAR $\alpha$  (fenofibrate and Wy-14, 643), PPAR $\gamma$  (rosiglitazone), PPAR $\delta$  (bezafibrate, a pan agonist with PPAR $\alpha$ ,  $\gamma$  and  $\delta$  activities) and retinoic acid receptor (RAR) followed by transcription profiling of liver tissue, we designed a strategy of selection and deselection of ANOVA signature gene sets to characterize and rank the specificity of the transcriptional response for agonism of individual receptor classes. The modulation of 196 genes that correlated highly ( $p \leq 3.5 \times 10^{-6}$ ) with hepatic hypertrophy using a Monte Carlo simulation were found to be almost exclusively regulated by fenofibrate and Wy-14, 643 treatments but not by rosiglitazone or RAR treatments. Many of the 196 hypertrophy regulated genes are intimately involved at various stages of glucose and lipid metabolism, five of which have putative peroxisome proliferator response elements identified through sequencing. These data suggest that hepatic hypertrophy is indistinguishable from the pharmacological effects of PPAR $\alpha$  agonism in the rat.

DISTRIBUTION OF COPPER (CU) AND ZINC (ZN) TRANSPORTER IN RAT CHOROID PLEXUS, BRAIN REGIONAL CAPILLARIES, AND CHOROIDAL Z310 CELLS BY REAL TIME RT-PCR.

M. Chigurupati, G. Li, B. Choi, S. X. Wang and W. Zheng. School of Health Sciences, Purdue University, West Lafayette, IN.

Cu and Zn are essential elements in living organisms. Evidence suggests that an altered brain homeostasis of Cu and Zn may contribute to the etiology of Alzheimer's disease. Both Cu and Zn in brain are regulated by transport mechanisms located at blood-brain barrier (BBB) and blood-cerebrospinal fluid (CSF) barrier (BCB). However, the distribution and abundance of related transporters in BCB and regional BBB were unknown. This study investigated the normal distribution of Cu and Zn transporters in choroid plexus (CP), capillaries of striatum, hippocampus, frontal cortex, and cerebellum in normal rats, and their expression in Z310 choroidal epithelial cells, by using quantitative real-time RT-PCR. Results showed that among five Cu transporters tested in brain capillaries, Ctrl1 and MTP1 mRNAs were most abundant in striatum, while DMT1 and ATP7B were highest in frontal cortex, and ATP7A in hippocampus capillaries. The CP contained Ctrl1 and ATP7B about 1.6-5.2 fold and 13-54 fold, respectively, higher than those of brain capillaries. Of seven Zn transporters, the DMT1 and ZnT1-4 mRNAs were greatest in frontal cortex capillary, whereas ZIP and PHT1 were highest in striatum. In comparison, the CP tissues had far more abundant ZnT1-4 mRNA levels, about 1.6-8.1 fold higher than those in frontal cortex capillaries. Moreover, the levels of ZIP and PHT1 were 1.3 and 17.2 fold, respectively, higher than those in striatum capillary. Z310 cells showed a generally decreased level of most Cu and Zn transporters compared to CP, except for ZnT2, which is higher in Z310 cells than in CP. Our data indicate that the transporters responsible for Cu and Zn movement in brain barriers appear to be unevenly distributed in brain regional BBB, with most active transport in brain cortex. The higher expression of Cu/Zn transporters in BCB than BBB suggests a critical role of BCB in maintaining Cu and Zn homeostasis in normal brain. (Supported by NIH/NIEHS ES08146)

591

COPPER (CU) TRANSPORT AND TRANSPORTERS IN THE BLOOD-BRAIN BARRIER (BBB) AND BLOOD-CSF BARRIER (BCB).

B. Choi, J. S. Crossgrove, M. Chigurupati and W. Zheng. School of Health Sciences, Purdue University, West Lafayette, IN.

Cu is an essential metal involving in important enzymatic reactions. Deficient or excessive Cu in brain is reportedly associated with neurodegenerative diseases such as Menkes disease, Parkinson's disease, and Wilson disease. However, the mecha-

nisms whereby Cu is transported by brain barriers and the relative regional transport of Cu were unknown. This study tested the hypothesis that brain barriers play a major role in maintaining brain homeostasis of Cu. Uptake rates of Cu into brain capillary, parenchyma, cerebrospinal fluid (CSF), and choroid plexus (CP) were determined by *in situ* brain perfusion technique followed by capillary depletion. Levels of mRNAs encoding Ctrl1, DMT1 and ATP7B were assessed by real time RT-PCR. The perfusate contained 64Cu and a space marker, [<sup>14</sup>C]sucrose. Cu uptakes into brain were linear up to 120s. The unidirectional transport rate constants (Kin) for Cu into the CP and brain capillary were 1034 $\pm$ 369 and 319 $\pm$ 90  $\mu$ l/s/g, respectively, while Kin in CSF and parenchyma were much reduced, 0.8 $\pm$ 0.5 and 112 $\pm$ 29  $\mu$ l/s/g, respectively. A higher uptake by CP vs. much lower uptake by CSF indicates that cumulated Cu in CP is likely derived from blood rather than CSF. The uptake rate of Cu was about 3 fold more rapidly to capillaries than to parenchyma, supporting a significant role of BBB in transport of Cu into brain. Patterns of brain Cu uptake showed a regional difference. The Kin in regional brain exhibited in a descending order, hippocampus, midbrain, frontal cortex, striatum, and cerebellum, with cerebellum statistically significantly slower than other brain regions. The mRNA levels of Ctrl1 and DMT1 were about 3-5 fold higher in brain capillaries than those in parenchyma ( $p < 0.05$ ). The mRNA levels of Ctrl1 and ATP7B in the choroid plexus were 1.6-5.2 and 13-54 fold, respectively, higher than those in brain capillaries. Our data suggest that the choroids plexus has a high capacity in accumulating Cu from blood and Cu uptake into brain may be coordinated by Ctrl1/DMT1 at BBB and Ctrl1/ATP7B at BCB. (Supported by NIH/NIEHS ES08146)

592

THE EFFECTS OF COPPER DIMETHYLDITHIOCARBAMATE (CDDC) ON RAT HIPPOCAMPAL ASTROCYTES.

L. Passaint and L. D. Trombetta. Pharmaceutical Sciences, St. Johns University, Jamaica, NY.

Health concerns over chromated copper arsenate (CCA) treated lumber has lead to the use of alternative chemicals for wood preservation. One such compound is copper dimethyldithiocarbamate (CDDC). Few toxicity studies have been performed on the effects of CDDC on neural cells. Copper has been known to accumulate in astrocytes resulting in oxidative stress, peroxidative damage and alterations in cytoskeletal structure. To determine the effects of CDDC, rat hippocampal astrocytes were exposed to various concentrations of CDDC (1.75 to 35  $\mu$ g/ml) for 1h washed in buffer and re-fed with complete media (Dulbecco's modified Eagle's media with 10% FBS) and allowed to recover for 24h. Cell viability was determined at the end of this time by trypan blue exclusion to be 77.2%, 66%, 55.3%, 27.5%, and 22.5% for 1.75, 3.5, 7.0, 14.0, and 35  $\mu$ g/ml, respectively. These results showed a significant decrease in viability relative to controls even at the lowest doses. Light and scanning electron microscopy confirmed the viability studies. Light microscopy showed cellular distortion including shorten processes and cell rounding. Granulation of the cytosol was observed and increased with increasing dose of toxicant. Scanning electron microscopy revealed alterations in the cell surface, including blebbing and fragmentation of processes. The higher doses of 14, and 35  $\mu$ g/ml resulted in severe morphological distortion. Nuclei often appeared raised, irregular and sometimes fragmented. Further investigations will study the effects of CDDC on the cytoskeleton particularly with reference to microtubular structure and copper concentration.

593

MANGANESE EXPOSURE ALTERS IRON REGULATORY MECHANISMS AT BLOOD-CEREBROSPINAL FLUID BARRIER (BCB) AND SELECTED REGIONS OF BLOOD-BRAIN BARRIER (BBB) IN RATS.

G. Li<sup>1</sup>, J. Liu<sup>2</sup>, M. P. Waalkes<sup>2</sup> and W. Zheng<sup>1</sup>. <sup>1</sup>School of Health Sciences, Purdue University, West Lafayette, IN and <sup>2</sup>Inorganic Carcinogenesis Section, NCI at NIEHS, Research Triangle Park, NC.

Previous *in vitro* data suggest that manganese (Mn) exposure increases the expression of mRNAs encoding transferrin receptor (TfR), which possess an iron (Fe) response element (IRE), by altering binding of iron regulatory protein-1 (IRP1) to TfR mRNA. The current study tested the hypothesis that *in vivo* exposure to Mn alters TfR expression at both BBB and BCB, leading to altered Fe transport at brain barriers. Male SD rats received daily oral gavages at doses of 5 or 15 mg Mn/kg as MnCl<sub>2</sub> for 30 days. Blood, cerebrospinal fluid (CSF) and choroids plexus were collected. Brain capillaries from striatum, hippocampus, frontal cortex, and cerebellum, were separated from parenchyma. Atomic absorption spectrophotometry revealed that the Fe concentration in controls was about 17-22 fold higher in choroid plexus than in other brain regions. Mn exposure resulted in a 67% decrease of serum Fe and an increased Fe in CSF (25%) and choroid plexus (67%) compared to control, while the concentrations of Mn and Fe in most brain regions tested did not change significantly. Capillary depletion followed by gel shift assay using S100

cytosolic extracts showed that binding of IRP1 to [32P] IRE-RNA probes was significantly enhanced in choroid plexus and capillaries of striatum, hippocampus, and frontal cortex ( $p < 0.01$ ). Quantitative real-time RT-PCR demonstrated increased levels of TfR mRNA in choroid plexus and capillaries of striatum and hippocampus ( $p < 0.05$ ), but not in frontal cortex and cerebellum capillaries, suggesting an up-regulation of TfR in BCB and selected regional BBB. The mRNA levels of ferritin, an Fe storage protein, were reduced by 87% in the choroid plexus and 34% in striatum capillary. Taken together, these data indicate that Mn, on the way to brain, alters Fe regulatory mechanisms at BCB and selected regions of BBB. This may underlie the distorted Fe homeostasis in the CSF. (Supported by NIH/NIEHS ES08146)

## 594 OVEREXPRESSION OF DMT1 IN THE CHOROID PLEXUS FOLLOWING MANGANESE (Mn) EXPOSURE.

X. Wang, J. G. Li and W. Zheng. *Health Sciences, Purdue University, West Lafayette, IN.* Sponsor: W. Zheng.

Divalent Metal Transporter 1 (DMT1), whose mRNA possesses a 3'-UTR stem-loop structure, has been identified in most organs and responsible for transport of various divalent metal ions. Previous work from this laboratory has shown that Mn exposure alters the function of iron regulatory protein (IRP) and increases iron (Fe) concentrations in blood-cerebrospinal fluid (CSF). This study aimed to test the hypothesis that Mn treatment, by acting on protein-mRNA binding between IRP and DMT1 mRNA, altered the expression of DMT1 in the choroid plexus (CP), where the blood-CSF barrier resides, leading to a compartmental shift of Fe from the blood to CSF. Western blot and real time PCR confirmed the presence of DMT1 in an immortalized choroidal epithelial Z310 cell line. Following *in vitro* exposure to Mn at 100  $\mu$ M for 24 and 48 hrs, the expression of DMT1 mRNA in Z310 cells was significantly increased by 45.4% ( $p < 0.05$ ) and 78.1% ( $p < 0.01$ ), respectively, as compared to controls. Accordingly, Western blot analysis revealed a significant increase of DMT1 protein concentrations at 48 hr after Mn exposure (100  $\mu$ M). When rats received, by oral gavage, 5 and 15 mg Mn/kg as MnCl<sub>2</sub> per day for 30 consecutive days, the levels of DMT1 mRNA in choroids plexus tissues were significantly increased by 258% and 305% ( $p < 0.05$ ), respectively. An electrophoretic mobility shift assay (EMSA), by using S100 cytosolic extracts from both *in vitro* cells and *in vivo* brain tissues, was conducted to investigate the effect of Mn exposure on the interaction between IRP and DMT1 mRNA. Results showed that Mn exposure increased binding of IRP to DMT1 mRNA in cultured choroidal Z310 cells, in animal CP, as well as in selected brain tissues. These data suggest that Mn appears to stabilize the binding of IRP to DMT1 mRNA, thereby increasing the expression of DMT1. The facilitated transport of Fe by DMT1 at the blood-CSF barrier may partly contribute to Mn-induced neurodegenerative Parkinsonism. (Supported by NIH/NIEHS ES08146)

## 595 IRON DEFICIENT AND MANGANESE ENHANCED DIETS ALTER METALS AND TRANSPORTERS IN THE DEVELOPING RAT BRAIN.

S. J. Garcia<sup>1</sup>, T. Syversen<sup>2</sup>, K. Gellein<sup>3</sup> and M. Aschner<sup>4</sup>. <sup>1</sup>*Physiology/ Pharmacology, Wake Forest University Health Sciences, Winston Salem, NC*, <sup>2</sup>*Neuroscience, Norwegian University of Science & Technology, Trondheim, Norway*, <sup>3</sup>*Chemistry, Norwegian University of Science & Technology, Trondheim, Norway* and <sup>4</sup>*Pediatrics, Vanderbilt University Medical Center, Nashville, NC*.

Fe-deficiency is a prevalent nutritional disorder, affecting ~2 billion people, mostly pregnant and lactating women and children. Fe and Mn share similar transport mechanisms, competing for transport. In adults Mn toxicity leads to neurological disturbances, but little is known about developmental Mn toxicity. To study the interactions of Fe and Mn during brain development, pregnant Sprague-Dawley rats were fed one of four semi-purified diets from gestational day 7 until postnatal day (PN)21: control (35 Fe:10 Mn mg/kg diet), low Fe (ID; 3 Fe:10 Mn), high Mn (Mn; 35 Fe:100 Mn), or low Fe with high Mn (IDMn; 3 Fe:100 Mn). Control neonates were cross-fostered to experimental or control dams on PN4 and exposed to the diets via lactation until PN21. Hematological measurements confirmed Fe-deficiency (decreased Fe, hemoglobin; increased transferrin (Tf), total Fe binding capacity) in dams and pups fed "ID" or "IDMn" diets, while those fed "Mn" had some trends toward similar hematological changes. Western blot analysis revealed that both "ID" and "IDMn" increased expression of the metal transporters, Tf receptor and divalent metal transporter 1 (DMT1). Inductively coupled plasma mass spectrometry (ICP-MS) showed that all three experimental diets decreased brain Fe levels, while both Mn enhanced diets increased brain Mn levels. In addition, "ID" increased copper (Cu); "Mn" increased chromium (Cr); and "IDMn" increased Cr, Cu, cobalt (Co), zinc (Zn), and vanadium (V). Upregulated DMT1, a non-specific transporter, may be a route for increased metals in the brain following dietary manipulations. Because each of the metals affected by low Fe and/or high Mn are es-

sential metals for normal development and function, homeostatic disturbances may contribute to later consequences. Supported by NIEHS 10563 (MA) and 12768 (SJG)

## 596 INFLUENCE OF SUBACUTE MANGANESE SULFATE ON DOPAMINE AND N-METHYL-D-ASPARTATE RECEPTORS.

H. Komiske. *Xavier University of Louisiana, New Orleans, LA*.

The potential of manganese sulfate (MnSO<sub>4</sub>) to alter the dopamine (D<sub>2</sub> + D<sub>3</sub>) and N-methyl-D-aspartate (NMDA) receptor after fourteen days of daily gavage was studied in rats. Sprague-Dawley male rats were randomly given, by gavage, one of six liquid mixtures (suspended in 40 % corn starch; 10 % sucrose, and 12 % dextrinized corn starch) of manganese sulfate (MnSO<sub>4</sub>), negative control (40 % corn starch, 10 % sucrose, and 12 % dextrinized corn starch), or the positive control (6 mg/kg midazolam). The doses of the MnSO<sub>4</sub> were given to provide: 1.0, 10, 30, or 100 milligrams manganese/kg. Binding studies of the (D<sub>2</sub> + D<sub>3</sub>) receptor with raclopride were preformed in the basal ganglia. Binding studies of the NMDA receptor with CGP-39653 were preformed in the cerebellum, cerebral cortex, globus pallidus, and hippocampus. The receptor binding studies indicate that fourteen of daily gavage with 1 to 100 mg/kg MnSO<sub>4</sub> did not alter the affinity of the NMDA receptor or the maximum number of binding sites in the three of the brain areas examined (cerebellum, cerebral cortex, and globus pallidus). Only the affinity of the NMDA receptor in the hippocampus was altered by the 14-day oral exposure to 10 mg/kg MnSO<sub>4</sub>. In contrast, the affinity of (D<sub>2</sub> + D<sub>3</sub>) binding sites was not altered by any of the liquid mixtures containing manganese relative to the negative control given for fourteen days. The liquid mixtures containing the highest concentrations of manganese altered the maximum number of (D<sub>2</sub> + D<sub>3</sub>) binding sites. The receptor binding studies indicate that two weeks of daily gavage with 10 mg/kg MnSO<sub>4</sub> altered the affinity of the NMDA receptor in only one of the four brain regions examined, while higher oral concentrations of MnSO<sub>4</sub> altered the maximum number of (D<sub>2</sub> + D<sub>3</sub>) binding sites in the basal ganglia. (Supported by ATSDR 398948).

## 597 BIOLOGICAL MARKERS OF MN EXPOSURE: RELATIONSHIPS BETWEEN MN DOSE, PARTITIONING IN BLOOD, AND ACCUMULATION IN BRAIN.

C. Kern<sup>1</sup>, L. Cadena<sup>1</sup>, R. Gwiazda<sup>1</sup>, R. Lucchini<sup>2</sup> and D. R. Smith<sup>1</sup>.

<sup>1</sup>*Environmental Toxicology, University of California, Santa Cruz, CA* and <sup>2</sup>*Institute of Occupational Health, University of Brescia, Brescia, Italy*.

Elevated manganese (Mn) exposures are known to elicit a range of neurotoxic effects, including the well characterized manganism syndrome at very high exposures. However, the relationship between Mn exposure, the accumulation of a Mn body burden, and the emergence of neurotoxic effects is not very well defined, partly because of the absence of good biomarkers of exposure suitable for use in human studies. Here we investigated whether the nominal Mn dose metric (Mn dose per exposure event), as compared to the cumulative Mn dose metric (total Mn administered over the duration of exposure) was more predictive of resultant Mn levels in plasma, whole blood, and brain of Sprague-Dawley rats treated with Mn ip 3 times/wk at nominal doses of 0, 1.2, 4.8 and 9.6 mg/Kg over 5 wks, or 0, 1.2, and 4.8 mg/Kg over 15 wks. Also, to specifically investigate the partitioning of Mn in erythrocytes versus plasma in humans, we spiked fresh human whole blood with MnCl<sub>2</sub> to achieve [Mn] of 12, 25, and 50 ng Mn/mL (control ~7ng/mL), and separated plasma from the erythrocytes for analysis. In the animal study, the relative fraction (%) of Mn in plasma decreased in an exponential fashion from ~50% in controls (blood Mn 8ng/mL) to <10% in animals with blood Mn levels >50ng/mL. In contrast, in human blood, <10% of Mn in control samples was partitioned in plasma, whereas >70% of added Mn partitioned in plasma in blood spiked with Mn. In the animal study, blood and brain Mn levels showed the same dose dependent increase from 8 to 650ng/mL whole blood, and 1.5 to 8.3  $\mu$ g Mn/g brain (dw), regardless of the duration of treatment (5 or 15 wk). Blood vs brain Mn levels followed an asymptotic relationship with brain Mn leveling off at ~8  $\mu$ g Mn/g for blood Mn >400 ng/mL. The relationship between plasma Mn and brain Mn was less defined. These data substantiate the need for additional study into predictive biomarkers of Mn exposure and brain uptake that may be suitable for use in humans.

## 598 PROGRESSION OF NEUROCHEMICAL EFFECTS IN DIFFERENT BRAIN REGIONS AS A FUNCTION OF THE MAGNITUDE AND DURATION OF MANGANESE EXPOSURE.

R. Gwiazda, C. Kern and D. Smith. *Environmental Toxicology, University of California, Santa Cruz, Santa Cruz, CA*.

Manganese (Mn) is known to elicit symptoms resembling those of Parkinson's disease (PD) at high exposure levels, but its effects at low levels of exposure are uncertain. Because of the similarity of behavioral deficits at elevated Mn exposure to PD

symptoms, earlier Mn toxicity studies have proposed that striatal dopamine (DA) depletion, a hallmark of PD, is also produced by Mn, despite the observation in humans that Mn accumulates in the globus pallidus. To reconcile this, we have proposed the hypothesis that there is a progression of effects from the globus pallidus to striatum as a function of increasing magnitude of Mn dose and treatment duration (Gwiazda et al., *Neuro Toxicology*, 95:1-8, 2002). To test this, we administered Mn ip 3 times/wk to Sprague-Dawley rats at nominal doses of 0, 1.2, 4.8 and 9.6 mg/Kg over 5 wks, and 0, 1.2, 4.8 mg/Kg over 15 wks. We conducted a battery of motor tests, spontaneous motor activity (SMA) and rotarod measurements, evaluated brain, blood, and plasma Mn levels, and neurochemical levels in the striatum, globus pallidus, substantia nigra and motor regions of the thalamus. Mn treatment increased DA levels in the globus pallidus in animals receiving the highest Mn doses over both 5 and 15 wks, but had no effect on striatal or substantia nigra DA levels. Motor deficits measured as impairment in the balance beam and in hind limb hopping, and shorter latency to fall from the rotarod were observed at the highest dose at 5 weeks. No Mn effects were detected on SMA. Blood and brain Mn showed similar relative increases as a function of nominal dose at 5 and 15 wks, even though the cumulative Mn doses of 15 wks animals were three times higher than in animals exposed for 5 wks. These results suggest that 1) Across a wide range of Mn doses the globus pallidus is a more sensitive locus of Mn toxicity compared to the striatum, and 2) The magnitude of the Mn nominal dose is more important than exposure duration in bringing about an increase in Mn body burden and eliciting Mn toxicity

### DETERMINATION OF DEPLETED URANIUM (DU) IN RATS FOLLOWING 6-MONTH EXPOSURE TO SURGICALLY IMPLANTED DU PELLETS.

V. A. Fitsanakis<sup>1</sup>, K. M. Erikson<sup>2</sup>, S. J. Garcia<sup>3</sup>, T. L. Syversen<sup>4</sup> and M. Aschner<sup>1</sup>. <sup>1</sup>Pediatrics, Vanderbilt University Medical Center, Nashville, TN, <sup>2</sup>Nutrition, UNC-G, Greensboro, NC, <sup>3</sup>Physiology & Pharmacology, Wake Forest University Medical School, Winston-Salem, NC and <sup>4</sup>Neuroscience, Norwegian University of Science & Technology, Trondheim, Norway.

Depleted uranium (DU) is used to reinforce armor shielding and increase penetrability of military munitions. Although there is conflicting data, concern exists regarding the role of the metal in the etiology of Gulf War syndrome. We examined the potential of DU to accumulate in various brain regions following surgical implantation of metal pellets in rats. Male Sprague-Dawley rats were divided into five groups: non-surgical controls (NS), sham (SH, 0/20 DU pellets), low (LW, 4/20 DU pellets), medium (MD, 10/20 DU pellets) and high (HI, 20/20 DU pellets). Rats were weighed weekly as a measure of general health. No statistically significant changes in weight were observed among any of the groups for the duration of the experiment. At the conclusion of the study, animals were perfused with buffer to prevent contamination of brain samples with DU from blood. Brains were removed and dissected into six regions: cerebellum, brain stem, midbrain, hippocampus, striatum and cortex. Although there is dose-dependent trend toward greater DU accumulation among the various treatment groups, one-way ANOVA of preliminary data indicates that DU does not significantly accumulate in cortex (NS 1.849, SH 0.337, LW 0.658, MD 1.595, HI 2.542 ng DU/g wet tissue, n=3 for each group, p > 0.05) or hippocampus (NS 3.577, SH 2.829, LW 0.759, MD 1.346, HI 1.910 ng DU/g wet tissue, n=3 for each group, p > 0.05) compared to controls. Our data suggest that elevated brain-DU levels in non-perfused animals may not be due to tissue accumulation, but to DU present in the blood. ### NEUROLOGICAL EFFECTS OF ACUTE URANIUM EXPOSURE.

D. Barber<sup>1</sup>, S. Hancock<sup>2</sup>, A. McNally<sup>1</sup>, J. Hinckley<sup>2</sup>, E. Binder<sup>2</sup>, M. Ehrlich<sup>2</sup> and B. Jortner<sup>2</sup>. <sup>1</sup>Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL and <sup>2</sup>Laboratory for Neurotoxicity Studies, VPI&SU, Blacksburg, VA.

We have previously shown that a single intraperitoneal exposure to depleted uranium increased regional brain uranium content. In the current study, we examined the neurological effects of a single intramuscular injection of 0, 0.1, 0.3, or 1 mg uranium/kg (as uranyl acetate, UA) in the presence and absence of stress. Stress treatments were applied for five days prior to injection and ceased just prior to injection. Animals that were stressed had four-fold higher plasma corticosterone levels at the time of uranium exposure ( $763 \pm 131$  vs.  $189 \pm 91$  ng/ml). Treatment with UA produced time and dose-dependent increases in serum and brain uranium levels, with the highest levels observed on day 3. Exposure to UA decreased ambulatory activity, forelimb grip strength, and weight gain, regardless of stress treatment. Rats treated with 1 mg/kg UA exhibited a 30% decrease in striatal dopamine content 3 days after dosing ( $59 \pm 6$  vs.  $41 \pm 5$  ng/mg tissue). The effect on dopamine was ameliorated by prior application of stress. No effect of DU or stress was ob-

served on levels of GABA, serotonin, norepinephrine, or GSH in the striatum, hippocampus, cerebellum, or cortex. These results indicate that single exposures to soluble uranium at doses as low as 0.1 mg/kg can have adverse neurological effects. However, uranium also produces renal toxicity (see Tobias et al., this meeting), so it is unclear if the neurological effects are a direct result of uranium or are secondary to renal injury. This work was supported by the US Army Medical Research and Materiel Command DAMD17-1-01-0775.

### DIFFERENTIAL EFFECT OF LEAD (Pb) EXPOSURE ON THE N-METHYL-D-ASPARTATE (NMDA) INDUCED INWARD CURRENT IN DOPAMINE (DA)-CONTAINING NEURONS AND HIPPOCAMPAL CA1 NEURONS.

D. K. Pitts and M. W. Lewis. *Pharmaceutical Sciences, Wayne State University, Detroit, MI*.

Inorganic lead (Pb) exposure occurred either chronically *in vivo* or acutely *in vitro*, and then all electrophysiological experiments were conducted on rat midbrain or forebrain slices *in vitro* using the whole-cell patch-clamp recording technique. Newborn rat pups were exposed to inorganic lead (Pb) via the dam's milk during the first 10-17 days of postnatal life. The Pb-treated dams received 250 ppm lead acetate through their drinking water and controls received deionized water. Brain slices were also obtained from unexposed 2-week-old rat pups to examine the acute effects of Pb exposure *in vitro* for a short, 5-10 minute period, or a long, 2-6 hour period, before N-methyl-D-aspartate (NMDA) challenge. A population study design was used to compare the concentration-dependent effects of the NMDA-induced inward current in both the chronic and acute Pb-exposure models. In both the chronic *in vivo* and the acute *in vitro* Pb exposure models, the Pb concentrations were 0.01-10  $\mu$ M and the concentrations of the glutamatergic agonist, NMDA were 1-60  $\mu$ M. Neither the chronic *in vivo* nor the acute *in vitro* Pb exposure decreased the NMDA-induced currents elicited in nigral DA neurons. Under one specific condition, a 30  $\mu$ M challenge of NMDA in the presence of a long-acute Pb exposure to 3  $\mu$ M Pb resulted in a significantly augmented receptor current. Experiments were also conducted on nigral DA and hippocampal CA1 neurons, where each individual neuron acted as its own control. In these latter experiments, each neuron was first challenged with NMDA alone, then following short-acute perfusion with 3  $\mu$ M Pb, was re-challenged with NMDA in the continuing presence of Pb. The short-acute Pb exposure did not alter the magnitude of the NMDA-induced inward current in nigral DA neurons, but did significantly decrease the amplitude of the NMDA-induced inward current in hippocampal CA1 neurons. These results strongly suggest that Pb exposure has a differential impact on NMDA receptors that occur on different neuronal types.

## 602

### ORAL EXPOSURE TO INORGANIC LEAD (Pb) IN RATS: BLOOD CONCENTRATIONS, BRAIN CONCENTRATIONS AND EFFECTS ON ACOUSTIC STARTLE.

R. Commissaris, A. Davis and D. K. Pitts. *Pharmaceutical Sciences, Wayne State University, Detroit, MI*.

The present studies investigated the effects of chronic oral exposure to inorganic lead (Pb) in rats on Pb blood and brain concentrations and on the acoustic startle response and its modulation by pre-pulse inhibition (PPI) stimuli. Male SD rats were exposed to oral Pb exposure in drinking water for six weeks (Pb concentrations of 0, 25, 50, 100, 250 and 500 ppm Pb) or 12 weeks (0, 50, 250 ppm Pb). Subjects were tested for acoustic startle and the startle PPI before Pb treatments and at 3-week intervals. Startle test sessions were characterized by four different acoustic trials: (1) no stimulus (background activity), (2) Noise Alone (40 msec, 118 dB; 48 dB over background), (3) Prepulse Stimulus Alone (100 msec, 80 dB), (4) Pre-Pulse Stimulus + Noise (Pre-pulse Stimulus presented 100 msec prior to the 118 dB Noise). The startle trials were presented randomly using an average 30-second inter-stimulus interval. At the end of the Pb exposure period (6 weeks or 12 weeks), subjects were sacrificed and blood and brain Pb concentrations were determined. Pb concentrations in both blood (5-30  $\mu$ g Pb/deciliter) and brain tissue (50-400 ng Pb/gram brain) were linearly-related to the Pb exposure level. Pb concentrations in brain and blood were highly correlated within subjects. Two of the Pb treatments, 50 ppm and 500 ppm, reduced body weight gain when compared to controls. Exposure to 50 ppm Pb significantly reduced acoustic startle amplitude when compared to vehicle controls; this 50 ppm Pb exposure in drinking water resulted in blood Pb concentrations slightly below 10  $\mu$ g Pb/deciliter (the CDC threshold for toxicity). Presentation of the weak acoustic stimulus immediately prior to presentation of the full acoustic startle stimulus reduced the response to the full acoustic stimulus compared to control levels (the PPI effect); Pb exposure in drinking water for 6 or 12 weeks did not significantly affect this PPI effect. The present studies demonstrate that the acoustic startle response is a sensitive measure of Pb behavioral toxicity.

### LIPID PEROXIDATION AND DISTRIBUTION OF INORGANIC ARSENIC AND ITS METABOLITES IN RAT NERVOUS SYSTEM.

E. Garcia-Chavez<sup>1</sup>, I. Jimenez<sup>2</sup>, B. Segura<sup>3</sup>, L. C. Sanchez-Pena<sup>1</sup>, J. C. Guadarrama<sup>2</sup> and L. M. Del Razo<sup>1</sup>. <sup>1</sup>Toxicology, Cinvestav-IPN, Mexico D.F., Mexico, <sup>2</sup>Physiol. Biophys. & Neurosci., Cinvestav-IPN, Mexico D.F., Mexico and <sup>3</sup>FES-Iztacala, UNAM, Mexico D.F., Mexico.

In environmentally exposed humans to inorganic arsenic (iAs) it has been observed a deficit in attention, memory and learning abilities as well as peripheral neuropathies. Rodents exposed to iAs have been showed changes in several brain neurotransmitter systems and alterations in the locomotor activity. These effects have been associated to the presence of arsenic in cerebral tissue. In the present study we analyze the possible relationship between lipid peroxidation (LPO) and distribution of iAs and its metabolites (monomethyl arsenic, MMA and dimethyl arsenic, DMA) in several structures of the rat nervous system (brain, spinal cord, sciatic and sural nerves). Sodium arsenite diluted in water (10 mg/kg/day) was dosed to male Wistar rats (200-300 gr bw) during 30 days, by gavage. iAs and its metabolites concentrations were determined. Results indicated that DMA was the major iAs metabolite in nervous tissues (~95%) and it was higher in peripheral than in central nervous structures (sural nerve>sciatic nerve>spinal cord ≥brain). LPO, expressed by means of malondialdehyde content (MDA), was also observed in rat nervous tissues and it significantly differs from control group ( $p<0.0001$ ). In addition, MDA content show a close relationship with the arsenic concentration observed in all nervous tissues. Our results may indicated that the presence of DMA induce the formation of MDA and in consequence, the occurrence of oxidative stress in peripheral and central nervous tissues. In addition, our observations also illustrate the existance of a differential distribution of arsenic in peripheral nerves and spinal cord of the exposed rat.

### EFFECT OF INORGANIC ARSENIC EXPOSURE INITIATING FROM *IN UTERO* THROUGH AFTER BIRTH ON THE NEUROBEHAVIOR AND NEUROTRANSMITTERS IN THE BRAIN OF MOUSE OFFSPRING.

T. Itoh<sup>1</sup>, Y. Nakagi<sup>1</sup>, K. Nakai<sup>2</sup>, H. Sato<sup>2</sup>, C. Watanabe<sup>3</sup>, H. Yamauchi<sup>4</sup> and T. Yoshida<sup>1</sup>. <sup>1</sup>Asahikawa Medical College, Asahikawa, Japan, <sup>2</sup>Tohoku University, Sendai, Japan, <sup>3</sup>Tokyo University, Tokyo, Japan and <sup>4</sup>St. Marianna Medical College, Kawasaki, Japan.

It is known that chronic arsenic (As) exposure causes a wide variety of adverse health effects. Although there is a possibility of occurring damage on the central nervous system (CNS) of infant by As exposure during their premature period, a few was known. In this study, we investigated the effect of CNS function of the offspring from the dam exposed to As via drinking water after their growing period. Sodium arsenite solution at 50 ppm As was given as drinking water to couple mice (C57BL/6J, C3H and B6C3F1) for a week and then they were crossed. As was exposed to offspring through whole experimental period; via placenta, via breast-feeding, and via drinking water directly after weaning. We observed body weight, surface righting reflex, cliff avoidance, pivoting, walking, negative geotaxis, grasping reflex and grip strength to estimate growth as indicators of growth on offspring. Neurobehavioral tests; open-field test and Morris water maze test were operated on offspring at optimal age. We found no difference in growth indexes between As exposed offspring and control. Similar tendencies were also observed in neurobehavioral test. However high concentration of As were detected in the brain and liver of the offspring. Although biological exposure monitoring on As showed significant difference, we did not find the appreciable influences in the offspring. But we could not deny the possibility of faint appearing minor effects on CNS of offspring. So we analyzed neurotransmitter and their metabolisms in the brain from offspring by using HPLC and bio-technological ways. The results are helpful to understand the functional influences of CNS by chronic As exposure in the development period.

### NEUROBEHAVIORAL CHANGES IN METALLOTHIONEIN-NULL MICE PRENATALLY EXPOSED TO MERCURY VAPOR.

M. Yoshida<sup>1</sup>, C. Watanabe<sup>2</sup>, K. Horie<sup>1</sup>, M. Satoh<sup>3</sup>, M. Sawada<sup>4</sup> and A. Shimada<sup>4</sup>. <sup>1</sup>Department of Biochemistry, St. Marianna University School of Medicine, Kawasaki, Japan, <sup>2</sup>Department of Human Ecology, Graduate School of Medicine, University of Tokyo, Tokyo, Japan, <sup>3</sup>Department of Hygienics, Gifu Pharmaceutical University, Gifu, Japan and <sup>4</sup>Department of Veterinary Pathology, Tottori University, Tottori, Japan.

We studied the neurobehavioral effects of prenatal exposure of MT-null and wild-type mice to elemental mercury vapor (Hg0). Pregnant mice of both strains were repeatedly exposed to Hg0 vapor at 0.50 and 0.56 mg/m<sup>3</sup> for 6 h per day until the 18th day of gestation. The behavioral effects were evaluated with locomotor activi-

ty in the open field, learning ability in the passive avoidance response and spatial learning ability in the Morris water maze at 12 weeks of age. Hg0-exposed MT-null mice showed a significant decrease in total locomotor activity in males, and a learning disability in the passive avoidance response and a retarded acquisition in the Morris water maze in females as compared with the control. In contrast, Hg0-exposed wild-type mice did not differ from controls in three behavioral measurements. The results indicate that MT-null mice would be more susceptible than wild-type mice to the behavioral neurotoxicity of prenatal Hg0 exposure. Mercury concentrations in the brain of both strains were slightly higher in the exposed group than in the control group, indicating the retention of residual mercury even 12 weeks after the cessation of the exposure. Brain concentrations of mercury were also significantly higher in the exposed-females than exposed-males in either strain. From these results, we suggest that the increased susceptibility of MT-null females to behavioral changes caused by prenatal Hg0 exposure is due to a greater retention of mercury and lack of MT-I, -II in the brain.

### MERCURY EXPOSURE OF MOTHERS AND NEWBORNS IN SURINAM: A PILOT STUDY.

S. Mohan<sup>1</sup>, M. Tiller<sup>2</sup>, G. B. Vandervoet<sup>2</sup>, H. Kanhai<sup>2</sup> and F. A. de Wolff<sup>2</sup>.

<sup>1</sup>Department of Obstetrics and Gynecology, <sup>2</sup>Lands Hospital, Gravenstratt, Netherlands and <sup>2</sup>Toxicology Laboratory, Leiden University Medical Center, Leiden, Netherlands.

Aim: To study mercury levels in hair from mothers and newborns in Surinam. Methods: Hair and urine was collected from thirty-nine mothers of different ethnicity and hair from their newborns. The women delivered in a large hospital in the capital. Mercury analysis was performed. Results: Fourteen (36%) of the mothers had elevated Hg concentrations in the hair as compared with a reference US population. Thirty-one newborns (80%) presented with a higher mercury level in hair than their mothers. A positive correlation existed between the hair levels of the mothers and their newborns. Urine Hg concentrations were not elevated. Conclusion: Mercury accumulates during pregnancy in the unborn. Further study is needed to elucidate the background and consequences of this finding.

### THE EFFECTS OF TRIBUTYLTIN (TBT) CHLORIDE ON DOPAMINE METABOLISM IN BRAIN TISSUES OF FEMALE MICE AFTER SUBACUTE ORAL EXPOSURE.

M. Tsunoda<sup>1</sup>, Y. Kudo<sup>1</sup>, K. Nakano<sup>2</sup>, N. Konno<sup>3</sup>, Y. Sugita-Konishi<sup>4</sup> and Y. Aizawa<sup>1</sup>. <sup>1</sup>Preventive Medicine and Public Health, Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan, <sup>2</sup>Fukushima Prefecture Ken-poku Public Health and Welfare Office, Fukushima, Fukushima, Japan, <sup>3</sup>Home Economics, Koriyama Women's University, Koriyama, Fukushima, Japan and <sup>4</sup>Division of Microbiology, National Institute of Health Sciences, Setagaya-ku, Tokyo, Japan.

Tributyltin (TBT) compounds have been used as antifouling agents, and they are known as environmental pollutants and endocrine disruptors. One of target organs of TBT compounds is the central nervous system. We evaluated the neurotoxicity of TBT chloride in female mice following subacute oral exposure by determining the levels of neurotransmitters (norepinephrine, dopamine (DA), serotonin) and their metabolites (dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA), 5-hydroxyindoleacetic acid) in discrete brain regions using HPLC. Female BALB/c mice were exposed to 0, 25, 50, 125 or 250 ppm TBT chloride in their feed for one month. Following the treatment period, liver, kidney and spleen of each mouse were removed, and brain was dissected into six brain regions. The mean body weight of mice treated with 250 ppm TBT was significantly lower than those of the other groups. For relative organ weight, the mean relative liver or kidney weight of the high dose groups were significantly higher than the control or low dose groups. While, the mean relative spleen weight increased dose-dependently, and that of the 250 ppm group was significantly higher than those of other groups. HVA in the cerebrum of the 250 ppm group was significantly higher than other groups. DA in the medulla of the high dose-treated groups was significantly lower than that of the control. HVA/DA ratio in the medulla or midbrain of the 250 ppm group was significantly higher than that of control. Although there were differences of the effects of TBT on DA and DA metabolites among brain regions, TBT at the higher doses may increase DA turnover in brain of female mice.

### BLOOD BRAIN BARRIER (BBB) DISRUPTION AFTER VANADIUM INHALATION.

M. AVILA-COSTA<sup>1,2</sup>, A. Zepeda-Rodriguez<sup>2</sup>, L. Colin-Barenque<sup>1</sup>, F. Pasos<sup>2</sup>, P. Aley<sup>1</sup>, A. Gonzalez-Villalva<sup>2</sup>, P. Mussali-Galante<sup>2</sup>, J. Ordóñez-Librado<sup>1</sup>, A. Gutierrez-Valdez<sup>1</sup>, V. Rodriguez-Lara<sup>2</sup>, A. Reyes-Olivera<sup>1</sup>, G. Pinon-Zarate<sup>2</sup>, M. Rojas-Lemus<sup>2</sup>, V. Delgado<sup>2</sup>, B. Chavez<sup>2</sup> and T. I. Fortoul<sup>2</sup>. <sup>1</sup>Neuroscencias, UNAM, Mexico, D.F., Mexico and <sup>2</sup>Biología Celular Y Tisular, UNAM, Mexico, D.F., Mexico.

Regulation of blood brain exchange is accomplished by ependymal cells which possess intercellular tight junctions. Loss of BBB function is an etiologic component of many neurological disorders. Vanadium (V) is an element widely distributed in the

environment and exerts potent toxic effects on a wide variety of biological systems. We reported previously that V produced dopaminergic cell death in substantia nigra and alterations in striatal neurons. Our aim was to investigate if V enters the SNC through the ventricles analysing the structure of the ependimal cells. CD-1 male mice 35g inhaled 0.02  $\mu\text{M}$  V2O5, one hour twice a week for 8 weeks. Mice were sacrificed after the 2nd, 4th, 6th, and 8th inhalation. The ventricle fragments were processed for scanning and transmission electron microscopy. The difference between the control and the exposed ependyma was the loss of cilia and the disruption between ependymal cells junctions. This damage might allow toxicants to easily access to underlying neuronal tissue releasing inflammatory mediators causing injury and neuronal death. The recognition of the mechanisms of BBB disruption would allow planning strategies to protect the brain from toxicants such as metals, which are related with neurotoxicity. Supported in part by DGAPA IN\_204304 and P.O.S Institute.

CYTOTOXIC EFFECTS OF TELLURIUM TETRACHLORIDE AND (4-METHOXYPHENYL) TRICHLOROTELLURIUM ON RAT HIPPOCAMPAL ASTROCYTES.

M. Aravantinou<sup>2</sup> and D. Hardej<sup>1</sup>. <sup>1</sup>*Pharmaceutical Sciences, St. John's University, Jamaica, NY* and <sup>2</sup>*Biological Sciences, St. John's University, Jamaica, NY*.

Tellurium is a rare metalloid that is used in the manufacturing of rubber, in photography, as a component of pesticides, and as a byproduct of copper processing. High concentrations of naturally occurring tellurium may be found in dairy products, nuts, fish and garlic, which accumulates tellurium from the soil. Tellurium has a similar electronic configuration to selenium, but does not have any known biological functions. Inorganic and organic tellurium compounds have been shown to be highly neurotoxic in rodents, causing peripheral demyelination. Chronic exposure to tellurium dioxide in rats, has been shown to cause tissue necrosis and decreased growth. Increased industrial use of this compound resulting in increased exposure may prove cause for concern. The purpose of this study was to investigate the cytotoxicity of two tellurium containing compounds on rat hippocampal astrocytes. Tellurium tetrachloride, and the organometalloid compound, 4-methoxyphenyl trichlorotellurium, were used to evaluate their cytotoxic effects. Rat hippocampal astrocytes were treated for 24h with the following concentrations of each compound: 500, 250, 125, 62.5, 31.25, 15.68, 7.81, 3.91, 1.95, 0.98 0.49 $\mu\text{M}$ . Viability was measured by 3-[4, 5-dimethylthiazol-2-yl]-2, 5-diphenyl tetrazolium (MTT) reduction based assay. Cells treated with tellurium tetrachloride showed a significant decrease in cell viability at all concentrations compared to control. Significant increases in cell viability were seen at the 62.5 $\mu\text{M}$  and lower concentrations when compared to the higher treatment groups. 4-methoxyphenyl trichlorotellurium showed markedly greater toxicity, with a significant reduction in cell viability seen at all concentrations except the 0.98 and 0.49 $\mu\text{M}$  doses. Light and scanning electron microscopy showed severe alterations in cell architecture. Loss of processes, cytoplasmic blebbing and fragmentation were observed.

610

TMT-INDUCED NEUROGENESIS IN THE ADULT MOUSE HIPPOCAMPUS.

B. C. Weig, K. R. Reuhl and H. E. Lowndes. *Department of Pharmacology and Toxicology, Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ*.

Neurogenesis in the hippocampus of the mammalian brain continues from birth through adulthood and serves to maintain CNS function by compensating for cell loss due to aging or injury. The ability of a neurotoxic lesion to promote neurogenesis was examined in the hippocampus of adult mice given trimethyltin (TMT). C3H mice were dosed with bromodeoxyuridine (BrdU), a marker of cell proliferation, and 2.7 mg/kg TMT. Brains were removed for immunohistology on days 1-28 post-treatment. Onset of neurogenesis was observed within 48 hours after TMT exposure and continued at an accelerated rate for at least 4 days after TMT injury. Twenty-eight days after TMT exposure a significant number of BrdU+ cells remained visible in the hippocampal region, including the dentate gyrus and molecular layers. These cells also stained positive for the neuronal marker NeuN. TMT exposure did not appear to effect BrdU incorporation into cells in the ventricular zone (VZ), known to harbor stem cells and rapidly dividing neuronal precursors. To determine if the hippocampal BrdU+ cells were derived from the VZ, mice were injected i.c.v. with the carbocyanine dye DiI prior to TMT exposure. Twenty-eight days after TMT injection, DiI+ cells were detected in the hilus and granule cell layers of the dentate, and the molecular layer adjacent to the ventral arm of the dentate. Approximately 15% of the BrdU+ cells in the dentate gyrus co-labeled with DiI indicating a peri-ventricular origin. The DiI/BrdU co-labeled cells appeared to be GFAP— and may represent new neurons. These studies indicate that the regenerated cells in the chemically damaged hippocampus are likely daughter cells produced from nascent precursors within the hippocampus, as well as cells migrating from the VZ to the site of injury. (ES 11256, ES 10153, ES 05022)

NEURONAL MICROTUBULE DAMAGE CAUSED BY *IN VITRO* EXPOSURE TO LEAD AND METHYLMERCURY.

J. L. Bisson<sup>1</sup> and K. R. Reuhl<sup>1,2</sup>. <sup>1</sup>*Joint Graduate Program in Toxicology, Rutgers/UMDNJ, Piscataway, NJ* and <sup>2</sup>*Neurotoxicology Labs, Department of Pharmacology and Toxicology, Rutgers University, Piscataway, NJ*.

The heavy metal contaminants lead and methylmercury (MeHg) continue to pose human health risks, particularly to children. Numerous studies have described the cytotoxicity of either lead or methylmercury, but their interactive effects are poorly understood. This study examined the effect of joint exposures to lead and MeHg on the microtubule (MT) network, previously shown to be affected by the metals. Undifferentiated P19 embryonal carcinoma (EC) cells and their neuronal derivatives were treated with lead citrate (1.5, 3, 10, 50, and 100  $\mu\text{M}$ ) alone or in combination with methylmercury (1.5 and 3  $\mu\text{M}$ ). The microtubule network was stained for  $\alpha$ -tubulin or neuron specific  $\beta$ -III tubulin and examined by immunofluorescence. At 3  $\mu\text{M}$ , MeHg induced nearly complete MT disassembly in undifferentiated cells and loss of neurites and perikaryal MTs in EC derived neurons. At 1.5  $\mu\text{M}$  MeHg, partial MT disassembly was noted in undifferentiated cells, while neurites were retracted and perikaryal MTs were reduced in the neuronal derivatives. In contrast, MT injury was seen only at the 50 and 100  $\mu\text{M}$  lead concentrations. Joint exposures to lead and MeHg did not result in enhanced MT toxicity except at 1.5  $\mu\text{M}$  MeHg/100  $\mu\text{M}$  lead. Undifferentiated P19 cells were significantly more sensitive to MeHg and high concentrations of lead, presumably because of the high content of tyrosinated tubulin. Neuronal differentiation confers greater resistance to the metals as indicated by the increased stability of the MT network in D5 and 7 neurons. These observations suggest that lead does not significantly contribute to cytotoxicity caused by a joint exposure with methylmercury until high concentrations are reached. THE EFFECTS OF MANCOZEB ON THE MICROTUBULAR ARCHITECTURE OF RAT HIPPOCAMPAL ASTROCYTES.

M. M. Tsang and L. D. Trombetta. *Pharmaceutical Sciences, St. John's University, Jamaica, NY*.

Mancozeb [Manganese-zinc ethylenebis(dithiocarbamate)] is a polymeric dithiocarbamate fungicide that has been used commercially for decades. It has recently been reported to severely alter olfactory neurophysiology. It has also been shown that manganese inhibits motor proteins that link membrane organelles along the secretory pathway to the cytoskeleton. Astrocytes play a central role in manganese (Mn) regulation in the CNS. Nevertheless, no adequate experimental studies on the effects of this divalent cation particularly in the form of a potential environmental toxicant on the cytoskeleton of astrocytes, has been reported. Rat hippocampal astrocytes maintained in Dulbecco's Modified Eagle's Medium with 10% Fetal Bovine Serum (FBS) were exposed to a range of concentrations of Mn-Zn dithiocarbamate for an hour at 37°C. Trypan blue exclusion was carried out to determine cell viability. After 1 hour of treatment a dose related effect with treatment was observed. Viabilities of 94.1%, 68.5%, 41.5%, 13.7% and 10.4% were seen with 5 $\mu\text{M}$ , 10 $\mu\text{M}$ , 12.5 $\mu\text{M}$ , 15 $\mu\text{M}$  and 20 $\mu\text{M}$  doses, respectively. The long term effect on astrocyte cytotoxicity/recovery was also investigated. Astrocytes were treated with low doses of Mancozeb for one hour (5 $\mu\text{M}$ , 7.5 $\mu\text{M}$ , 8.75 $\mu\text{M}$  and 10 $\mu\text{M}$ ) and then refed with complete medium and left to recover for 24 hours. Viabilities of 86.7%, 61.1%, 45.6% and 22.9% were seen. The 7.5 $\mu\text{M}$  dose of Mancozeb was chosen to study its effect on microtubular architecture in the astrocytes during this recovery period. Quantum dot biotin/streptavidin confocal microscopy directed against alpha-tubulin revealed severe alterations in microtubular architecture resulting from Mancozeb. These changes included condensation of tubulin with a loss of fibrillar structure, and a perinuclear loss of microtubular architecture. No effect on the marginal band was noted.

613

NEUROPROTECTIVE EFFECTS OF MELATONIN ON NEUROBLASTOMA CELLS EXPOSED TO LEAD.

C. S. Chetty<sup>1</sup>, A. O. Dennis<sup>1</sup>, J. Heinz<sup>1</sup>, M. C. Vemuri<sup>2</sup> and C. Suresh<sup>1</sup>.

<sup>1</sup>*Natural Sciences and Mathematics, Savannah State University, Savannah, GA* and <sup>2</sup>*Surgery, Children's Hospital of Philadelphia, Philadelphia, PA*.

The nervous system is the primary target for the low-levels of lead (Pb)-exposure and the developing brain appears to be especially vulnerable to Pb-neurotoxicity. Chronic low-levels of Pb-exposure cause growth retardation and intellectual impairment. In the present study the impact of low-levels of Pb on human SH-SY5Y neuroblastoma cells were assessed. The neuroblastoma cells were cultured in RPMI 1640 medium with 10% fetal-calf serum in a humidified air/5% CO<sub>2</sub> chamber at 37°C. The cells were exposed to Pb acetate (0.01-10  $\mu\text{M}$ ) for 48 hrs and proliferation was determined. The cell viability was determined using MTT reduction assay. Pb inhibited the proliferation of neuroblastoma cells in a concentration-dependent

manner. A 50% inhibition ( $IC_{50}$ ) in the proliferation of cells was observed typically at 5  $\mu$ M Pb. At 0-100  $\mu$ M melatonin, a metal chelating agent did not elicit any significant effect on growth and proliferation of these cells are exposed for 48 hrs. However, melatonin significantly reduced the inhibitory effect of Pb (at 5  $\mu$ M) on proliferation of these cells suggesting a protective effect against Pb-toxicity. The data also suggest that even low-concentrations of Pb can influence growth and development of brain leading to cognitive dysfunction in Pb-exposed children. These results further support our recent findings of detrimental effects of low-level Pb-exposure on neuronal dysfunction (This research work supported by NIGMS/NIH grant # GM 60853).

#### BLOCKAGE OF INTERLEUKIN-6 SECRETION FROM ASTROGLIA BY LEAD: INVOLVEMENT OF GRP78.

**Y. Qian<sup>1</sup>, F. Valencia<sup>1</sup>, Y. Zheng<sup>1</sup>, K. S. Ramos<sup>2</sup> and E. Tiffany-Castiglioni<sup>1</sup>.**

<sup>1</sup>Texas A&M University, College Station, TX and <sup>2</sup>University of Louisville Health Sciences Center, Louisville, KY.

The involvement of lead (Pb), a developmental neurotoxicant, in neurologic disorders is consistent with both an astroglial role in neurologic disorders and Pb deposition in astroglia. However, the mechanism of Pb neurotoxicity is still not clear. Interleukin-6 (IL-6) is a cytokine, which is produced mainly by microglia and astroglia and plays a pleiotropic role including neuroprotection in the central nervous system (CNS). IL-6 secretion by astroglia is chaperoned by a 78 kD glucose-regulated protein (GRP78). Pb strongly binds to GRP78 and alters GRP78 compartmentalized redistribution. Thus, in this report we hypothesize that Pb can block IL-6 secretion from astroglia via binding to GRP78. In rat primary astroglial cultures, IL-6 secreted into the medium was stimulated by neuron-conditioned medium as detected by dot-blot assay. Pb at 1 to 10  $\mu$ M but not 50  $\mu$ M reduced IL-6 levels in the medium. This phenomenon was explained by the observation that the higher concentration of Pb induced IL-6 gene expression as assayed by RT-PCR. The reduction of IL-6 in the medium was in part contributed to by the impairment of IL-6 secretion, because IL-6 retention significantly increased in Pb-treated astroglia as detected by the fusion fluorescence protein image analysis. GRP78 depletion by approximately 35% with vector-based dsRNAi also significantly increased IL-6 retention in astroglia, supporting the involvement of GRP78 in IL-6 secretion. Co-localization of IL-6 with GRP78 in live astroglia, as determined by the image analysis of two differently colored fusion fluorescence proteins, further supports a chaperone role of GRP78 in IL-6 secretion. Therefore, these data indicate that Pb blocks IL-6 secretion and GRP78 probably mediates this process in astroglia.

#### MANGANESE INDUCED APOPTOSIS IN SH-SY5Y HUMAN NEUROBLASTOMA CELLS.

**A. P. Stephenson and R. Reams.** College of Pharmacy, Florida A&M University, Tallahassee, FL.

Excessive exposure to Manganese (Mn) has been shown to cause Manganism, a neurodegenerative disorder similar to Parkinson's disease. Although Mn toxicity has been studied for years, the mechanism by which Mn causes neurons to degenerate is still poorly understood. In recent years, the use of the manganese compound, MMT, as a gasoline additive has gained approval for use in the US. This could result in increased exposure to airborne manganese. Differentiated SH-SY5Y Human Neuroblastoma cells have been demonstrated to represent a valuable neuronal model to study the effects of neurotoxic drugs on cells in culture. Experiments conducted with this model, investigate the mode of cell death induced by Mn<sup>2+</sup>. To determine the effect of Mn<sup>2+</sup> on cell viability, SH-SY5Y cells were incubated with drug concentrations up to 500  $\mu$ M at 24, 48, and 72 hours, followed by morphological and biochemical analyses. The present study demonstrated that exposure to Mn<sup>2+</sup> caused loss of viability in differentiated SH-SY5Y cells at concentrations of the metal as low as 100  $\mu$ M. Morphological evaluation of Mn<sup>2+</sup> treated differentiated SH-SY5Y cells showed nuclear condensation and fragmentation as visualized by DAPI and *in situ* TUNEL staining at the following concentrations (1.953 and 62.5  $\mu$ M). These findings suggest that Mn-induced cell death occurs by apoptosis. The results of this study will help to elucidate the mechanism of Mn-induced cell death and allow for the design of neurotoxicity preventative strategies.

#### THE MODULATION OF METALLOTHIONEIN-3 (MT-3) EXPRESSION IN MOUSE ASTROCYTES IN RESPONSE TO PROINFLAMMATORY MEDIATORS, SECOND MESSENGER ACTIVATORS, AND CELL STRESS.

**S. H. Garrett.** Pathology, University of North Dakota, Grand Forks, ND.

A common feature of many neurodegenerative diseases is the decreased expression of MT-3, a protein first identified as the growth inhibitory factor missing in Alzheimer's disease (AD). Due to this protein's neuroprotective properties (protec-

tion against  $\beta$ -amyloid toxicity and oxidative stress), the ability to increase the level of this protein during neurodegeneration could potentially slow the progression of the disease. Paradoxically, acute brain trauma such as stab wounds causes an increase in MT-3 expression several days after the insult. In an effort to identify factors that may be responsible for the modulation of MT-3 expression in the brain under the above pathological conditions, cultures of isolated mouse astrocytes were exposed to a series of candidate agents consisting of proinflammatory mediators [lipopolysaccharide and interleukin-1 $\beta$  (IL-1 $\beta$ ), cellular stress (sodium azide), general activators of second messenger pathways [tetradecanoyl phorbol acetate, dibutyryl-cyclic adenosine monophosphate (Bt<sub>2</sub>-cAMP), and calcium ionophore, (A23187)], a growth factor [epidermal growth factor (EGF)], and a known inducer of other metallothionein isoforms (zinc). The expression of MT-3 was monitored by real time PCR and normalized to the expression of glyceraldehyde phosphate dehydrogenase in exposures extending out to 8 days. Acute exposure to EGF and Bt<sub>2</sub>-cAMP (24 hrs) and sodium azide (4 hr exposure followed by 18 hr recovery) induced MT-3, 20-30%. During 8 day exposure to Bt<sub>2</sub>-cAMP, MT-3 was decreased 40%, whereas cells recovering from 4 hr of azide treatment still exhibited induced levels. Long-term exposure to zinc caused a 90% increase whereas at 24 hr no increase was noted. Exposure to proinflammatory mediators both acutely and chronically caused nearly a 50% decrease in MT-3 expression. Since chronic IL-1 $\beta$  exposure can down regulate MT-3, and sustained elevated levels of this cytokine have been found in AD lesions, this mediator may play a role in the modulation of MT-3 expression in neurodegenerative disease

#### MANGANESE-INDUCED ALTERATIONS IN NF- $\kappa$ B-RELATED GENE EXPRESSION BY ACTIVATED MICROGLIA.

**P. L. Crittenden and N. M. Filipov.** Center for Environmental Health Sciences, Basic Sciences, Coll. Vet. Med., Mississippi State University, Mississippi State, MS.

The central nervous system is uniquely sensitive to inflammation and the brain microglia are a primary source of proinflammatory cytokines. In previous work we demonstrated that manganese and lipopolysaccharide in combination (Mn+LPS) potentiate microglial production of proinflammatory cytokines such as IL-1 $\beta$ , IL-6, and TNF- $\alpha$ . Microglial cells (N9) were exposed to up to 500  $\mu$ M MnCl<sub>2</sub> either by itself or combined with LPS (100 ng/ml). The Mn+LPS combination elicited dose-dependent cytokine production that was substantially greater than that induced by Mn or LPS alone. To determine the mechanism of Mn-induced potentiation of cytokine production, the early NF- $\kappa$ B-signaling pathway genes were examined by utilizing a pathway-specific gene array. N9 cells were exposed to Mn, LPS, or Mn+LPS for various time periods. At the end of exposure, RNA was isolated and cDNA synthesized to probe the gene array. In comparison to control cells, 1 hour exposure to Mn (250  $\mu$ M) and LPS (100 ng/ml) increased the mRNA expression for the TNF-receptor associated factor-1 (TRAF1) and GM-CSF. Both GM-CSF and TRAF-1 are known to promote cell growth while TRAF-1 may also induce proinflammatory cytokine synthesis by a NF- $\kappa$ B-dependent mechanism. Expression of the proinflammatory molecule complement component 3 (C3) was also increased following Mn+LPS exposure. By examining the time-dependent expression of these (and other) growth and inflammatory factors, we hope to elucidate the possible mechanism(s) for the Mn-induced proinflammatory cytokine production. (Supported by NIEHS ES11654).

#### DIFFERENTIAL GENE EXPRESSION AT TWO DOSES OF METHYLMERCURY IN MOUSE CEREBELLA AS ANALYZED BY APOPTOSIS-SPECIFIC MICROARRAY.

**K. A. Thuett, S. Bellum and L. C. Abbott.** Veterinary Integrative Biosciences, Texas A&M University / College of Veterinary Medicine & Biomedical Sciences, College Station, TX.

The neurotoxicant methylmercury (MeHg) is known to cause death of granule cells within the cerebellum. Although apoptosis has been implicated in this death, the specific apoptotic pathway is unknown. In this study, C57BL/6J mice at postnatal day (P) 34 were administered a total dose of 5.0 mg/kg or 1.0 mg/kg body weight methylmercury chloride via their food over 5 days. Cerebella from control mice and those exposed to MeHg were extracted on P50 following a 12 day latent period after final dosing. Genetic expression was analyzed in triplicate (12 mice total per treatment, 4 cerebella were pooled for each comparison) using apoptosis-gene-specific microarray analysis. Up-regulated genes (2+ fold compared to control) in the 5.0 mg/kg treated mice include: caspase-6, DR-6, Fasl, IL-15, IL-1ra, LIGHT, TRANCE and iNOS. Down-regulated genes include GAS2 and TNF R1. Gene alteration in the 1.0 mg/kg treated mice differed dramatically from those in the high dose group both in specificity and direction. The bulk of these genes was down-regulated (2+ fold) and include: A1, Apaf 1, Bax-a, Cyclin G1, NF- $\kappa$ B DNA binding subunit, RBBP4 and p53. While a total dose of 5.0 mg/kg MeHg results in primarily an up-regulation of genes involved in apoptosis, a total dose of 1.0 mg/kg

MeHg appears to have the opposite effect. In addition, the up-regulated genes observed in the 5.0 mg/kg treated mice are mainly cell surface receptor and immune associated, whereas the low-dose down-regulated genes are primarily mitochondrial and cell cycle related. It may be that significant cell death has already occurred in the 5.0 mg/kg treated cerebella and the analyzed cells are survivors of the high level MeHg insult. The cells analyzed at 1.0 mg MeHg may represent a different population that has not undergone cell death and is attempting to survive a lower MeHg insult.

619

#### FORMATION OF REACTIVE OXYGEN SPECIES IN CEREBELLAR GRANULE CELLS OF MICE EXPOSED TO METHYLMERCURY.

S. Bellum, K. A. Thuet and L. C. Abbott. *Veterinary Integrative Biosciences, Texas A&M University College Station, TX.*

Methylmercury (MeHg) is a potent neurotoxicant that causes neuronal degeneration; neocortical and cerebellar granule neurons are particularly sensitive to MeHg toxicity. Studies using cultured granule cells exposed to MeHg demonstrate altered intracellular calcium ion homeostasis leading to increased intracellular calcium concentrations and cell death. Key gaps still exist concerning the specific mechanisms that cause granule cell death following *in vivo* MeHg exposure. Previously we found that mitochondrial membrane potential (MMP) was decreased in MeHg treated mouse cerebellar granule cells. Therefore, we postulate that *in vivo* MeHg exposure decreases MMP, alters mitochondrial function and potentiates reactive oxygen species (ROS) generation and that ROS species promote apoptosis. Male and female C57BL/6J mice at postnatal day (P) 29 were divided into control, 1.0 mg/kg and 5.0 mg/kg MeHg treatment groups and trained to eat moistened rodent chow for 5 days. At P34 mice were exposed to MeHg orally via moistened rodent chow. Cerebellar granule cells were acutely isolated at P50 and plated into chamber slides. Cells were loaded with 5-(and 6-) chloromethyl-2', 7'-dichlorodihydro fluorescein diacetate, acetyl ester (CM-H2DCFDA), a cell-permeant indicator for ROS that remains nonfluorescent until modified by intracellular esterases followed by oxidation occurring within the cell. Sequential time course analysis was performed; fluorescent images of granule cells from all three groups were acquired at 90-second intervals for 24 minutes. ROS species generated in granule cells from 1.0 mg/kg and 5.0 mg/kg MeHg treated mice were significantly higher than from controls at 24 minutes. Performance on footprint and vertical pole test is being analyzed to assess motor coordination. These observations suggest that *in vivo* MeHg exposure results in accumulation of ROS in cerebellar granule cells, which ultimately could promote apoptotic cell death and/or dysfunction of these cells. This work was supported in part by NIEHS (CERH) support to LCA (P30EF09106).

#### METHYLMERCURY (MEHG)-INDUCED REACTIVE OXYGEN SPECIES (ROS) LEVELS ARE MODULATED BY INTRACELLULAR REDOX.

M. Aschner<sup>2</sup>, G. Shanker<sup>1</sup>, T. Syversen<sup>3</sup>, J. Aschner<sup>2</sup> and U. Sonnewald<sup>3</sup>. <sup>1</sup>*Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC.* <sup>2</sup>*Pediatrics, Vanderbilt University Medical Center, Nashville, TN* and <sup>3</sup>*Neuroscience, University of Trondheim, Trondheim, Norway.*

Excessive free radical formation has been implicated in neurotoxic damage associated with MeHg exposure. The present study addresses the relationship between MeHg and cellular redox levels in neonatal rat cerebral astrocytes by employing laser scanning confocal microscopy (LSCM). We utilized three redox-sensitive fluorescent probes, CM-H2DCFDA (chloromethyl derivative of dichlorodihydrofluorescein diacetate), a probe for intracellular hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) detection; hydroethidine (HETH), a probe for superoxide anion (O<sub>2</sub><sup>-</sup>) detection; and CM-H2XRos (chloromethyl derivative of dihydro X-rosamine), a probe selective for mitochondrial ROS. Exposure of astrocytes to MeHg (10 uM; 30 min.) led to a significant (p<0.05) increase in mitochondrial as well as cytoplasmic ROS formation, and this effect was potentiated by pretreatment (24 hrs) with buthionine sulfoxane (BSO), a glutathione (GSH) depleter. Notably, mitochondria were the cellular organelles to exhibit the earliest increase in ROS production, preceding any other cellular site. Accordingly, mitochondria appear to play a prominent role in MeHg-induced injury. Treatment of astrocytes with MeHg (10 uM; 30 minutes) following pretreatment (24 hrs) with L-2-oxothiazolidine-4-carboxylic acid (OTC; an agent known to increase intracellular GSH levels) attenuated MeHg-induced ROS formation to levels statistically indistinguishable from controls. The free radical scavenger n-propyl gallate (n-PG) was equally effective in attenuating MeHg-induced ROS formation. In contrast catalase (H<sub>2</sub>O<sub>2</sub> scavenger) was ineffective in reducing MeHg-ROS formation in the astrocytes. Taken together, these studies suggest that (1) MeHg increases ROS formation; (2) GSH levels can modulate MeHg-induced ROS formation; (3) there is specificity for the effectiveness of antioxidants in protecting against MeHg-triggered oxidative stress. Supported by PHS grant NIEHS 07331.

#### EFFECTS OF METHYLMERCURY ON MITOCHONDRIAL FUNCTION AND REACTIVE OXYGEN SPECIES FORMATION IN STRIATAL SYNAPTOSONES FROM RAT.

A. Dreiem<sup>1</sup> and R. F. Seegal<sup>1, 2</sup>. <sup>1</sup>*New York State Department of Health, Wadsworth Center, Albany, NY* and <sup>2</sup>*School of Public Health, University at Albany, Albany, NY.*

Methylmercury (MeHg) is an environmental neurotoxicant. Several mechanisms have been suggested for its toxicity, including effects on calcium homeostasis, the cytoskeleton, mitochondrial function, formation of reactive oxygen species (ROS), and apoptosis and necrosis. The object of this study was to examine the relationship between ROS formation and mitochondrial function in isolated nerve terminals (synaptosomes) from the striatum of rats. We found that MeHg at concentrations of 0.5  $\mu$ M or higher decreased mitochondrial membrane potential ( $\Delta\Psi_m$ ), measured by the fluorescent dye JC-1 (Molecular Probes Inc.). Concentrations of MeHg of 1  $\mu$ M or greater lead to a total loss of  $\Delta\Psi_m$ , comparable to that seen after exposure to the mitochondrial uncoupler carbonyl cyanide m-chlorophenylhydrazone (CCCP). Because MeHg can increase ROS formation in synaptosomes, and ROS can lead to mitochondrial dysfunction, we also measured ROS formation after MeHg exposure. MeHg increased ROS formation, measured by 2', 7'-dichlorofluorescein oxidation, in rat striatal synaptosomes. The effects were both time- and concentration dependent, but statistically significant effects were not evident unless MeHg concentrations were 10 times higher than those that reduced  $\Delta\Psi_m$ . ROS formation was almost completely abolished by treatment with the antioxidant Trolox. In contrast, Trolox had no effect in protecting against loss of  $\Delta\Psi_m$ . From these data we conclude that loss of  $\Delta\Psi_m$  is an initial event in MeHg toxicity in striatal synaptosomes. The loss of  $\Delta\Psi_m$  may, in turn, lead to other events involving opening of the mitochondrial permeability pore, release of mitochondrial calcium, and formation of ROS. Supported by NIEHS grant 1P01ES11263 and EPA grant R829390 to RFS.

622

#### POTENTIATION OF MITOCHONDRIAL SUSCEPTIBILITY, OXIDATIVE STRESS AND NF-KB SIGNALING FOLLOWING CHEMICAL MIXTURE (LEAD AND ARSENIC)-INDUCED NEUROTOXICITY.

R. Yasmeen, G. Hashim, O. Ogunmosin, D. Ghosh and P. G. Gunasekar. *Biology, Texas Southern University, Houston, TX.*

Lead (Pb) and arsenic (As) as neurotoxic metals, can produce a cognitive deficits, central and peripheral neuropathy in human. The mechanism responsible for these effects on the central nervous system is not clear. Previous studies in animals and cell culture models show that both arsenic and lead can produce neuronal cell death that may be related to oxidative stress. In the present study, the vulnerability of the cultured dopaminergic neurons to Pb and As mixture by characterizing the cytotoxic interaction between Pb and As and then examined the underlying mechanism. In mesencephalic cells (dopaminergic cell lines), lead (0, 10, 20, 50 and 100 uM) and arsenic (0, 10, 20, 50, and 100 uM) produced minimal reactive oxygen species (ROS) dose dependently over 24 hr period. When cells were exposed concurrently to these metals, a burst of ROS was noted. To test the role of mitochondrial viability in response to Pb and As mixture, MTT up-take assay were done as a mitochondrial marker in cultured neurons. Cells that were exposed concurrently to Pb and As showed reduced MTT-up-take in dose dependent manner over the control and Pb and As alone exposed cells. Further, incubation of cells with Pb and As induced alteration in redox sensitive transcription factor, NF- $\kappa$ B activity and its significant change over the Pb and As alone have been analyzed and results will be discussed with cell death mechanism. This explains the neurochemical basis of the cells vulnerability to chemical mixture induced toxicity and determine if any antioxidants prevent cytotoxicity.

623

#### EFFECTS OF GABA<sub>B</sub> RECEPTOR ACTIVATION & INHIBITION ON METHYLMERCURY-INDUCED ALTERATIONS OF INTRACELLULAR CA IN RAT CEREBELLAR GRANULE NEURONS.

D. K. Atchison and W. D. Atchison. *Department Pharmacology/Toxicology, Michigan State University, East Lansing, MI.*

Acute exposure of cerebellar granule cells to methylmercury (MeHg) causes a biphasic increase in intracellular Ca<sup>2+</sup> ([Ca<sup>2+</sup>]<sub>i</sub>) which contributes to delayed cell death. The pathways responsible for these effects are not yet known. The goal of this study was to determine whether G-protein-coupled GABA<sub>B</sub> receptors contribute to the MeHg induced increase in [Ca<sup>2+</sup>]<sub>i</sub> in rat cerebellar granule cells in culture. Baclofen and phaclofen were used to either inhibit or stimulate GABA<sub>B</sub> receptor function respectively. Single cell microfluorimetry using the Ca<sup>2+</sup> sensitive fluorophore fura-2 was used to examine the effects of MeHg on [Ca<sup>2+</sup>]<sub>i</sub>. Two specific measurements were taken: time-to-onset for increases in [Ca<sup>2+</sup>]<sub>i</sub> after exposure

to MeHg, and the ratio of the increase in fura-2 fluorescence induced by MeHg divided by the maximum increase in fluorescence following depolarization with 40mM KCl. Cells received one of three treatments: 30 min pre-treatment with 200 $\mu$ M baclofen followed by 0.5 $\mu$ M MeHg and 200 $\mu$ M baclofen, 30 min pre-treatment with 200  $\mu$ M phaclofen followed by 0.5 $\mu$ M MeHg and 200 $\mu$ M phaclofen, or 0.5  $\mu$ M MeHg. To assess cell viability and  $Ca^{2+}$  buffering ability, each cell dish received a 2 min depolarization with 40mM KCl 12 min before MeHg and/or GABA<sub>B</sub> receptor modulation treatment was administered. Both baclofen and phaclofen altered the fluorescence response to KCl-induced depolarization in the absence of MeHg. However, neither baclofen nor phaclofen altered the time-to-onset for MeHg-induced increases in fura-2 fluorescence for either the first or second phase compared to cells treated with MeHg alone. Baclofen and phaclofen, when compared to MeHg alone, also didn't alter the change in ratio fluorescence during either the first or second phase. Therefore, modulation of the GABA<sub>B</sub> receptor did not affect the time-to-onset for increases in  $[Ca^{2+}]_i$  induced by MeHg. The pathways affected by GABA<sub>B</sub> receptor modulation may not play a role in  $[Ca^{2+}]_i$  increases caused by MeHg in cerebellar granule cells. Supported by NIH grant R01-ES03299.

**624**

**COMPARATIVE EFFECTS OF METHYLMERCURY (MEHG) ON INTRACELLULAR CA IN RAT CEREBELLAR GRANULE & CORTICAL NEURONS IN CULTURE.**

A. Segarra and W. D. Atchison. *Department Pharmacology/Toxicology, Mich State University, East Lansing, MI*.

Cerebellar granule cells are very sensitive to the neurotoxic actions of MeHg after both *in vivo* and *in vitro* exposure. Reasons for this selective vulnerability are unclear. Acute exposure of granule cells to MeHg increases  $[Ca^{2+}]_i$ , an effect which leads to delayed cell death. The goal of this study was to compare the sensitivity of granule cells and cortical neurons to MeHg-induced alterations in  $[Ca^{2+}]_i$ . Cortical neurons are not sensitive to MeHg exposure *in vivo*; we hypothesized that they would also be less sensitive to MeHg-induced increases in  $[Ca^{2+}]_i$ . Single cell micro-fluorimetry using the  $Ca^{2+}$  sensitive fluorophore fura-2 and neonatal rat cerebellar granule and cortical cells in culture were used to compare the effects of MeHg on  $[Ca^{2+}]_i$ . The time-to-onset for increases in  $[Ca^{2+}]_i$  after exposure to MeHg were measured. We tested the hypothesis that if cerebellar granule cells are more sensitive to MeHg than other less-sensitive neurons, then there will be a more prominent or earlier fura-2 response than with cortical cells. In both cell types, MeHg caused a biphasic increase in fura-2 fluorescence. Increasing the concentration of MeHg reduced the time to onset of this effect. At 0.5 $\mu$ M MeHg the 1st phase increase occurred in cortical cells at  $13.78 \pm 1.81$  min while in granule cells it occurred at  $6.22 \pm 1.01$  min. The 2nd phase increase in cortical cells at 0.5 $\mu$ M MeHg was seen at  $18.05 \pm 1.53$  min; in granule cells it was seen at  $8.08 \pm 1.0$  min. At 1.0 $\mu$ M MeHg, 1st and 2nd phases occurred at  $4.14 \pm 1.24$  and  $6.21 \pm 1.27$  min, respectively, in cortical cells. Corresponding values for granule cells were  $1.81 \pm 1.13$  and  $3.41 \pm 1.18$  min respectively. Thus there is a trend toward more rapidly occurring increases of fura-2 fluorescence with MeHg in granule cells than in cortical cells. Whether this will reflect fundamental differences in sensitivity of  $Ca^{2+}$  buffering or  $Ca^{2+}$  entry pathways between the two cell types is not yet clear. Supported by NIH grant R01ES03299, and a summer undergraduate research fellowship from the McNair SROP Program.

**EFFECTS OF SEMI-CHRONIC METHYLMERCURY EXPOSURE ON INTRACELLULAR CALCIUM LEVELS IN RAT UNDIFFERENTIATED PC12 CELLS.**

S. Baker<sup>2,1</sup> and W. D. Atchison<sup>1,2</sup>. <sup>1</sup>*Department Pharmacology/Toxicology, Mich State University, East Lansing, MI* and <sup>2</sup>*Coll Vet. Med., Mich State University, East Lansing, MI*.

Methylmercury (MeHg) is an environmental neurotoxicant which disrupts intracellular Ca levels ( $[Ca^{2+}]_i$ ) when applied acutely to neurons. This effect occurs in two kinetically distinct phases: the first phase consists of release of  $Ca^{2+}$  from intracellular stores. The second phase is due to entry of  $Ca^{2+}$  into the cytoplasm from the extracellular fluid, perhaps via voltage-gated  $Ca^{2+}$  channels. The objective of the current study was to determine if semi-chronic exposure to MeHg of a neuron-like cell would alter  $[Ca^{2+}]_i$ . Single cell microfluorimetry using the  $Ca^{2+}$  indicator fura-2AM was used to examine effects of MeHg on  $[Ca^{2+}]_i$ . Undifferentiated, neuron-like rat pheochromocytoma (PC12) cells were treated for up to 72 hrs with 50 or 100 nM MeHg. Two specific measurements were made: baseline fluorescence representing resting levels of  $[Ca^{2+}]_i$ , and the response to membrane depolarization using KCl (40 mM). Resting levels of fura-2 fluorescence were not significantly altered by exposure to MeHg. PC12 cells typically respond to KCl depolarization with a distinct increase in  $[Ca^{2+}]_i$ . However, when PC12 cells exposed to MeHg were depolarized with KCl, the corresponding fluorescence response increased in

amplitude in a time-dependent manner at 24, 48 and 72 hrs when compared to control responses. The amplitude of this response was greater at all time points after 100 nM MeHg exposure than 50 nM exposure. Thus, semi-chronic exposure to low concentrations of MeHg causes a time- and concentration-dependent disruption of  $[Ca^{2+}]_i$  homeostasis during activity in PC12 cells, but doesn't appear to affect resting  $[Ca^{2+}]_i$ . (Supported by NIH grants 5T35RR017491-02 and R01ES03299).

**EFFECTS OF THIMEROSAL ON NGF SIGNAL TRANSDUCTION AND CELL DEATH IN NEUROBLASTOMA CELLS.**

D. K. Parran, A. M. Barker and M. F. Ehrlich. *Biomedical Sciences, Virginia Tech, Blacksburg, VA*.

Signaling through neurotrophic receptors is necessary for differentiation and survival of the developing nervous system. The present study examined the effects of thimerosal on nerve growth factor (NGF) signal transduction and cell death in a human neuroblastoma cell line (SH-SY5Y cells). Following exposure to 100 ng/ml NGF and increasing concentrations of thimerosal, we measured the activation of TrkA, MAPK and specific isoforms of PKC (delta and epsilon). In controls, the activation of TrkA MAPK and both isoforms of PKC peaked after 5 minutes of exposure to NGF and then decreased but was still detectable at 60 minutes. Concurrent exposure to increasing concentrations of thimerosal and NGF resulted in a concentration-dependent decrease in TrkA, MAPK and PKC activation, with an EC50 of approximately 50 nM. Cell viability was assessed by the LDH assay. Following 24 hr exposure to increasing concentrations of thimerosal, the EC50 for cell death in the presence or absence of NGF was 596.3 nM and 38.7 nM, respectively. Following 48 hr exposure to increasing concentrations of thimerosal, the EC50 for cell death in the presence and absence of NGF was 104.7 nM and 4.35 nM, respectively. This suggests NGF provides protection against thimerosal cytotoxicity. To determine if apoptotic versus necrotic cell death was occurring, oligonucleosomal fragmented DNA was quantified by ELISA. Control levels of fragmented DNA were similar in both the presence and absence of NGF. In both, thimerosal caused increased levels of fragmented DNA (apoptosis) at 100 nM, which decreased at higher concentrations of thimerosal (necrosis). These data demonstrates that thimerosal could alter NGF-induced signaling in neurotrophin-treated cells at concentrations lower than those responsible for cell death.

**METHYL MERCURY (MEHG) ALTERS IL-6 SIGNAL TRANSDUCTION IN MOUSE CEREBELLAR CELLS IN CULTURE.**

E. S. Calderon-Aranda<sup>1,2</sup>, L. C. Acosta-Saavedra<sup>2</sup> and E. K. Silbergeld<sup>1</sup>. <sup>1</sup>*EHS, BSPH, Johns Hopkins University, Baltimore, MD* and <sup>2</sup>*Toxicologia, Cinvestav, Mexico, DF, Mexico*.

MeHg is highly toxic to the developing CNS in humans, rodents, and primates, and its effects on neurocognitive and neuromotor function are persistent, ranging from subtle developmental delays to severe motor dysfunction and death. These effects have been associated with disruption of neuronal migration early in development, producing irreversible structural changes in specific brain regions including the cerebellum. We and others have shown that cytokines, of microglial origin, play a critical role in stimulating and supporting the movement of neurons during critical periods of development. We showed that *in vitro* exposure of murine cerebellar cultures to a non-cytotoxic dose (100nM) of MeHg inhibits neuronal migration and increases production of IL-6 and TNF-alpha and increases expression of IL1-beta mRNA. We also showed that administering anti IL-6 antibodies blocks the effects of MeHg on neuronal migration. Using the same *in vitro* cell system we utilized the Affymetrix ToxChip system to evaluate a broad range of molecular targets of MeHg in LPS-activated or non-activated organotypic cultures prepared from cerebella of 5 day old CD1 mice. For those transcripts altered by at least two-fold, the effect was confirmed by ELISA and Western blot analysis. MeHg exposure induced expression of several genes, including cytokines, chemokines, and cytokine receptors, including IL1-beta, IL6-alpha receptor, chemokine (CXC motif) ligand 2, and chemokine (CXC motif) as well as other genes involved in cytokine-dependent signaling and cell adhesion molecules N-CAM2 and V-CAM. IL6 protein was not modified; however MeHg increased levels of gp130, and IL-6Ralpha proteins. MeHg decreased phosphorylated STAT3, and CXCR4, and increased NCAM protein. These results are consistent with the hypothesis that MeHg may act on the IL-6 pathway, with effects on NCAM and CXCR4 as part of the molecular mechanisms of neuronal disruption induced by MeHg in early CNS development. This work was supported by Cure Autism Now and Heinz Family Foundations.

ACUTE EXPOSURE TO URANYL ION (UO<sub>2</sub>) *IN VITRO* DIMINISHES K<sub>+</sub>-STIMULATED GLUTAMATE/GABA RELEASE INDEPENDENT OF EXTRACELLULAR CALCIUM.

S. M. Lasley and K. R. Vietti. *Biomedical & Therapeutic Sciences, University of Illinois College of Medicine, Peoria, IL.*

Gulf War veterans retaining fragments of depleted uranium (DU) shrapnel have exhibited lowered performance on neurocognitive tests, and rats chronically exposed to DU have displayed apparent decreases in neuronal excitability. The goal of this study was to determine if acute exposure to divalent UO<sub>2</sub> *in vitro* alters calcium-independent glutamate/GABA release in a manner similar to that of other heavy metals (e.g., lead). A crude hippocampal P2 fraction was prepared from 2 month old Sprague-Dawley rats, and 0.8 mg synaptosomal protein loaded onto glass fiber filters. Synaptosomes were superfused with phosphate-free 25 mM HEPES (pH 7.4) saturated with O<sub>2</sub> and containing 200  $\mu$ M methoxyverapamil with Mg<sup>2+</sup> replacing Ca<sup>2+</sup>. Release was stimulated with brief perfusion of high K<sub>+</sub>-HEPES containing a glutamate reuptake blocker. Concentrations of UO<sub>2</sub> nitrate (0.01 - 316  $\mu$ M) were added to perfusion solutions, and 2-min fractions were collected beginning 45 min after exposure was initiated. Aliquots were derivatized and quantified by binary gradient liquid chromatography with fluorescence detection. In the absence of UO<sub>2</sub> and Ca<sup>2+</sup>, K<sub>+</sub> stimulation resulted in ~2-fold elevation of glutamate and GABA concentrations over baseline values. Perfusion of UO<sub>2</sub> in the absence of Ca<sup>2+</sup> diminished endogenous evoked transmitter release compared to responses in control tissue, resulting in an approximate IC<sub>50</sub> of 5  $\mu$ M. Thus, its inhibitory potency was similar to that observed in the presence of Ca<sup>2+</sup> (~2.6  $\mu$ M). Other heavy metals are well known to exhibit Ca<sup>2+</sup>-mimetic properties that are best observed under Ca<sup>2+</sup>-free conditions, but the actions of forms of uranium on exocytosis have not been identified. It is possible that acute exposure is insufficient to permit accumulation of intrasynaptosomal UO<sub>2</sub> concentrations. The use of permeabilized synaptosomes would be an approach to address this issue. (Supported by USAMRMC grant DAMD17-02-1-0212)

EFFECTS OF LOW-LEVEL MN EXPOSURE ON THE METABOLISM OF AMINO ACIDS, GABA, AND CELLULAR RESPIRATION IN GABAERGIC AF5 NEURAL CELLS.

D. R. Crooks<sup>1</sup>, N. Welch<sup>1</sup>, A. F. Rosenthal<sup>1</sup>, J. Sanchez<sup>2</sup>, W. J. Freed<sup>2</sup> and D. R. Smith<sup>1</sup>. <sup>1</sup>*Environmental Toxicology, University of Calif. Santa Cruz, Santa Cruz, CA* and <sup>2</sup>*Cellular Neurobiology Branch, National Institute on Drug Abuse, Baltimore, MD.*

Chronic elevated manganese (Mn) exposure has been associated with neurological disorders, while the effects and mechanistic basis of lower exposures remains controversial. Human occupational and recent animal model studies suggest that elevated Mn may first affect GABAergic function in the basal ganglia of the brain, with comparatively little or no effect in the nigro-striatal dopaminergic system until higher exposures are reached. To investigate the mechanistic basis for low-level Mn effects on GABAergic cells, a rat striatal cell line (AF5) was treated with Mn, and compared to treatments with other agents of known mechanisms of toxicity (rotenone, paraquat, fluorocitrate, and gabaculine). Outcome measures included intracellular amino acid content, activity of selected enzymes, and mitochondrial function. Results thus far have shown that Mn affected cellular metabolism differently than the other compounds. Mn treatment caused 15 - 20% increases in cellular GABA and glutamate (GLU), and a 40% increase in cellular GLU released into the medium. Culture medium glutamine (GLN) consumption was increased to 180% of control, while alanine release into the medium was decreased to 75% of control with Mn treatment. In contrast, rotenone caused a 30% decrease in cellular GLU levels while cellular GABA levels were increased by 15%. Activity assays of the enzymes responsible for the synthesis and degradation of GABA, glutamate decarboxylase (GAD) and GABA-transaminase (GABA-T), revealed no direct effect of Mn. Assay of mitochondrial Complex II activity similarly revealed no direct effect of Mn. These data indicate that significant alterations in amino acid metabolism, presumably due to altered mitochondrial function, occur in AF5 neural cells during sub-lethal Mn exposure, and that these effects may account for increases in tissue GABA observed in animal models treated with Mn.

MN ALTERS CELLULAR COMT-1, SECRETORANIN II, AND UCH-LI LEVELS IN PC12 CELLS: IMPLICATIONS FOR MN NEUROTOXICITY.

D. R. Smith, S. Reaney, S. Whitman, R. Gwiazda and T. Holman. *Environmental Toxicology, University of California, Santa Cruz, CA.*

Elevated manganese (Mn) exposures have been shown to cause neurotoxicity in cell and animal models, and humans. Cell and animal model studies have reported dopaminergic systems as targets of Mn, though results have differed widely with

Mn dose. Human studies have identified elevated Mn (and iron) exposures as risk factors for Parkinsonism, and occupational studies have indicated that elevated Mn exposures produce a Manganism syndrome. In spite of these parallels, the mechanistic basis underlying Mn exposures as a risk factor for Parkinsonism remains unclear. To better understand this, we utilized a 2-D differential in-gel electrophoresis (DIGE) method to evaluate changes in protein expression patterns in a dopamine (DA) producing PC12 cell model. Cells were exposed to 100  $\mu$ M Mn for 24 hours, followed by assessment of cellular Mn levels, cytotoxicity (trypan blue, LDH, ATP, 8-isoprostanes), DA and metabolites, and changes in protein expression identified through the 2-D DIGE analyses. Cellular Mn accumulation increased ~100-fold with Mn exposure, with no measurable change in cell viability, LDH, ATP, or 8-isoprostanes. Cellular DA levels were reduced by a significant 20%, while DA metabolites were increased 45 to 145 % over controls. Cellular serotonin levels did not change. A total of 46 proteins (out of ~600) were shown to change with Mn exposure (25 increased, 21 decreased expression), and 30 of these were identified. Several proteins related to DA metabolism (COMT-1), packaging (secretorgranin-II), and protein degradation (UCH-LI) measurably changed in a pattern consistent with the observed changes in DA and metabolites: COMT-1 was increased 47%, secretorgranin-II (all seven detected isoforms) was decreased 40%, while an isoform of UCH-LI increased 90% in expression in Mn exposed cells. These results were confirmed by Western blot analyses. These data suggest that elevated Mn exposure may contribute to reduced packaging and elevated turnover of cellular DA, and thereby alter DAergic function without causing overt cytotoxicity.

MANGANESE INHIBITS THE BINDING OF THE COCAINE ANALOG [<sup>3</sup>H]-WIN 35, 428 TO THE DOPAMINE TRANSPORTER (DAT) FROM RAT STRIATUM.

M. Chen, E. Furukawa and T. R. Guilarte. *Environmental Health Sciences, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Exposure to high levels of manganese (Mn) causes a Parkinsonian-like syndrome in humans and non-human primates. The striatum and globus pallidus are basal ganglia structures that exhibit the highest Mn concentrations following exposure. We have previously shown a transient increase in [<sup>1</sup>C]-WIN 35, 428 binding to DAT in the primate striatum *in vivo* after acute Mn administration using positron emission tomography (Chen et al., *Toxicology Sciences* 78 supp: 75, 2004). We suggested that DAT in dopaminergic terminals is a target for Mn in the brain. To investigate the molecular mechanisms of acute Mn-induced dopaminergic dysfunction, we used an *in vitro* assay to measure the effect of Mn on the binding of [<sup>3</sup>H]-WIN 35, 428 to DAT from rat striatal membranes. We found that Mn inhibits [<sup>3</sup>H]-WIN 35, 428 binding to DAT with an inhibitory constant ( $K_i$ ) of  $2.0 \pm 0.3$   $\mu$ M (n=4). To determine the nature of the inhibition we performed saturation isotherms and Scatchard analysis of [<sup>3</sup>H]-WIN 35, 428 binding to DAT with or without 2 mM MnSO<sub>4</sub>. We found a significant decrease (30%, p<0.001) in the maximal number of binding sites ( $B_{max}$ ) in the presence of Mn ( $1270 \pm 127$  fmol/mg protein; n=4) relative to control ( $1819 \pm 161$  fmol/mg protein; n=4). No significant effect of Mn was measured on binding affinity ( $K_d$ ) (Mn =  $24.0 \pm 2.4$  nM, n=4; control =  $20.0 \pm 1.6$  nM, n=4; p>0.05). These *in vitro* findings suggest that the increase in DAT levels *in vivo* following acute Mn administration may be a compensatory response to its inhibitory action on the transporter. Further, Mn-induced DAT inhibition *in vivo* may increase extracellular dopamine levels leading to DA autoxidation, generation of reactive oxygen species and neuronal injury. [Supported by NIEHS ES10975 to TRG]

DIFFERENTIAL EFFECTS OF MANGANESE (MN) AND MPP<sup>+</sup> IN DIFFERENTIATED AND NON-DIFFERENTIATED PC12 CELLS.

L. T. Russel, K. S. Squibb and A. M. Elnabawi. *Program in Toxicology, University of Maryland School of Medicine, Baltimore, MD.*

Mn and 1-methyl-4-phenylpyridinium (MPP<sup>+</sup>) are well-known neurotoxins which can cause Parkinson-like symptoms in humans and non-human primates by affecting dopaminergic neurons. Several studies have also suggested that the dopamine transporter (DAT) may play a role in the neurotoxicity of these compounds. Therefore, we addressed the characterization of DAT and the differential cytotoxicity of MnCl<sub>2</sub> and MPP<sup>+</sup> in two types of PC12 cells, differentiated and non-differentiated. PC12 (rat pheochromocytoma) cells have been used as an *in vitro* model cell line of dopamine-containing neurons. Cell death was measured using Alamar Blue assay and DAT-mediated cellular uptake was measured by a radiolabeled-based uptake assay in non-differentiated and differentiated PC-12 cells. The two types of PC12 cells exhibited different responses and sensitivity to MnCl<sub>2</sub> and MPP<sup>+</sup>. The dose-time response curves revealed that MnCl<sub>2</sub> was more effective in producing cytotoxic effects in non-differentiated PC12 cells with EC<sub>50</sub> values of

>10, 2 and 1.2 mM at 24, 48 and 72 hr, respectively. But, in contrast to  $MnCl_2$ ,  $MPP^+$  failed to cause cytotoxicity in non-differentiated PC12 cells over a concentration range from 0.001 to 1 mM for exposures up to 72 hr. On the other hand, the pattern of cytotoxicity was reverse in differentiated PC12 cells.  $MPP^+$  significantly decreased cell viability in differentiated cells with  $EC_{50}$  values of 0.25 and 0.20 mM at 48 hr and 72 hr, respectively, while the  $EC_{50}$  value of  $MnCl_2$  was > 8 mM at 72 hr. In uptake experiments, specific [ $^3H$ ]GBR12935 uptake in non-differentiated and differentiated PC12 cells was temperature sensitive and time dependent; however, rates of activity were different in the two cell types. These results provide support for the hypothesis that DAT-mediated uptake of Mn and  $MPP^+$  plays a role in the selective dopaminergic neurodegeneration characteristic of Parkinson's Disease that occurs following exposure to these compounds.

### NEUROTOXIC EFFECT OF MANGANESE AND NEUROPROTECTIVE EFFECT OF COPPER IN A CELL CULTURE MODEL OF PRION DISEASES.

C. J. Choi, V. Anantharam, A. Kanthasamy and A. Kanthasamy. *Biomedical Sciences, Iowa State University, Ames, IA.*

Prion diseases are fatal neurodegenerative disorders increasingly recognized in both humans and animals. Normal prion proteins (PrPc) are abundantly expressed in the CNS, but the effect of environmental agents on the physiological function of prion proteins remains to be characterized. Because PrPc have high affinity for certain divalent cations, we characterized in the present study the effect of copper (Cu) and manganese (Mn) on prion-expressing neural cells and prion-knockout (KO) cells. Mn and Cu induced dramatically different effects; Mn was much more toxic than Cu. In general, PrPc-expressing cells were less susceptible to metal toxicity than prion-KO cells, suggesting that endogenous prion protein may protect against metal toxicity. Interestingly, Mn treatment depleted cellular glutathione (GSH) levels more significantly and in a dose-dependent manner in both cells, whereas Cu significantly increased GSH in prion cells. Mn treatment also activated the apoptotic cascade; including caspase-9 and 3, in a time-dependent manner in both cells. However, caspase activation was not observed after Cu treatment. Likewise, Mn-treated cells showed a dose-dependent increase in DNA fragmentation, which was blocked by the caspase inhibitor ZVAD and ZDEVD, while DNA fragmentation was not significantly increased in Cu-treated cells. Trace element analysis through Induction Coupled Plasma Mass Spectrometry (IC-PMS) revealed that prion cells have higher basal Mn levels and lower basal Cu levels consistent with Cu deficiency observed in certain prion diseases. Mn and Cu accumulation was proportional to the respective treatments, but with different rates of accumulation. Collectively, these results demonstrate that the essential metals Mn and Cu produce opposing effects - neurotoxicity vs. neuroprotection in neuronal cells - possibly by altering the ion handling mechanism and antioxidant capacity. This novel observation may have some functional implications in the pathogenesis and/or progression of prion diseases. [support : Iowa Healthy Livestock Initiative grant]

### MECHANISM OF ARSENIC PERIPHERAL NEUROTOXICITY.

A. Vahidnia, G. B. Vandervoet and F. A. de Wolff. *Toxicology Laboratory, Leiden University Medical Center, Leiden, Netherlands.*

**Introduction:** Peripheral arsenic neurotoxicity has been demonstrated clinically and in electrophysiological studies. The aim of this study is to investigate the mechanism of the peripheral neurotoxicity of As in rats, with special focus on interactions with axonal cytoskeletal proteins. **Methods:** Male Wistar rats (225-250g) were exposed to arsenite ( $NaAsO_3$ ) given as a single dose iv (0; 15 or 20 mg/kg) for 3, 6 or 9 hrs. Urine samples were collected for the duration of exposure namely 3, 6 or 9 hrs, whereafter the rats were sacrificed. Sciatic nerves (N. ischiadicus) were excised and cytoskeletal proteins were analysed with SDS-PAGE and Western blot. Arsenic in urine, blood and sciatic nerve was measured with AAS. **Results:** The amount of arsenic in urine of 15-mg/kg groups decreased in the 9-hour time course from 0.5 to 0.25 (mM As/mM creatinine). Blood arsenic content diminished from 2.3 to 1.58 mg/l in rats group receiving 15 mg/kg doses and reduction of 2.9 to 2.34 mg/l in rats group receiving 20 mg/kg doses. Arsenic was present in sciatic nerve but did not correlate with doses and/or duration of exposure. Biochemical analysis of N. ischiadicus revealed disappearance of neurofilament protein bands and fibroblasts in rats treated with the arsenite doses of 15 and 20 mg/kg. Few fibroblast protein bands disappeared in 20-mg/kg doses analyzed by SDS-PAGE. Some neurofilament proteins diminished in dose/effect manner measured in time and analyzed with western blot. **Discussion:** Arsenic affects the composition of cytoskeletal proteins in the rat sciatic nerve, especially the neurofilaments. The loss of these neurofilaments could explain the neurotoxicological effects.

### TOXIC TORTS: TOXICOLOGISTS IN THE COURTROOM.

W. J. McKinney<sup>1</sup>, R. Parent<sup>2</sup>, R. G. Smith<sup>3</sup> and A. R. Brody<sup>4</sup>. <sup>1</sup>*Philip Morris USA, Richmond, VA*, <sup>2</sup>*Consultox, Damariscotta, ME*, <sup>3</sup>*Venable LLP, Baltimore, MD* and <sup>4</sup>*Pathology and Laboratory Medicine, Tulane University Health Sciences Center, New Orleans, LA.*

Litigation involving exposure to chemicals is on the rise in the United States. This has created a new role for toxicologists. Toxicologists are often called upon to provide testimony (e.g. expert, fact) in a variety of legal situations (e.g. court, deposition, hearings, state, federal, defense, and plaintiff). However, explaining extremely complex and sometimes controversial scientific concepts and data to a non-scientist (e.g. judges, juries) can be challenging. Therefore, knowledge of skills necessary for effective clear testimony, attorney/client expectations, and potential ethical conflicts are critical prior to entering the court room. In addition, a toxicologist called upon to provide litigation support should be aware of the potential positive and negative career impacts. This sunrise session will provide a forum to discuss issues a scientist functioning as an expert witness may encounter as well as give information that will be valuable for scientist called upon for expert testimony.

### ALTERED IRON HOMEOSTASIS (AIH) AS A BASIS FOR PULMONARY IMMUNOTOXICOLOGIC EFFECTS OF PARTICULATE MATTER.

M. Cohen. *Environmental Medicine, New York University, Tuxedo, NY.*

The scientific literature is replete with reports on the pulmonary toxicologic and immuno-toxicologic effects of particulate matter (PM). Although it has become increasingly accepted that the composition of PM is a major factor influencing biological effects, mechanisms to describe how composition might induce observed toxicities are mostly lacking. The altered iron homeostasis (AIH) theory postulates that specific components in PM induce alterations in the levels of free catalytically-active iron within the lungs as well as in iron availability to both lung epithelial and immune cells. These changes, in turn, impact upon local responses to infectious agents and allergens, as well as upon the release of cell products that might contribute to cardiopulmonary changes. The AIH theory not only provides a basis to explain how select PM constituents might induce these effects, but also how day-to-day or regional differences in the amounts of these components (relative to that of iron) may underlie the variability in reported health effects induced with equivalent doses of differing PM samples. Following introductory talks about the role of iron homeostasis in maintenance of immune cell functions and how components of PM may be selectively mobilized, this symposium will highlight specifically how AIH could be the basis for the observed alterations in allergic, immunologic, and cardiopulmonary responses after host exposures to PM.

**637**

### THE ROLE OF IRON (FE) HOMEOSTASIS IN IMMUNE CELL FUNCTIONALITY.

C. L. Bowlus. *Department of Internal Medicine, University of California Davis Medical Center, Sacramento, CA.* Sponsor: M. Cohen.

This introductory talk will review the ways in which the maintenance of iron homeostasis is critical to both the normal and induced functionalities of lymphocytes and macrophages. The reciprocal regulation of iron metabolism and immune function occurs at many levels and macrophages are central to both processes. Within endosomal vesicles of macrophages, iron transport and antigen presentation pathways converge. Reactive oxygen species generated from iron may uniquely fragment autoantigens or expose cryptic epitopes. The iron transporter NRAMP1 is primarily expressed in macrophages and is critical for macrophage activation and differentiation as well as expression of tumor necrosis factor- $\alpha$ , interleukin-1 $\beta$  and MHC class II. In turn NRAMP 1 is regulated by interferon- $\gamma$ . In addition, alleles of NRAMP1 are associated with susceptibility to pulmonary infections and autoimmune disorders. Recently, a signaling role for iron has been recognized in the NF-kappa B activation of macrophages. Abnormalities in iron homeostasis can also affect lymphocytes. Iron deficiency is associated with impaired cell-mediated immunity, T cell proliferation and decreased numbers of circulating T cells, likely secondary to thymic atrophy. Conversely, the effects of transfusion iron overload on lymphocytes include decreases in CD4 T cells and T cell proliferation. Mutations in the MHC class I-like gene HFE results in hemochromatosis, which is associated with many T cell abnormalities including decreased CD8 T cells and p56lck activity. However, these differences have not been replicated in animal models. Future studies are needed to elucidate the precise pathways by which iron alters macrophage and lymphocyte functions and how alleles of genes central to iron metabolism influence immune function, particularly as they relate to the immunotoxicity of particulate matter.

## 638 MOBILIZATION OF METALS FROM PARTICLES: IMMUNOTOXICOLOGIC IMPLICATIONS.

*A. E. Aust. Department of Chemistry and Biochemistry, Utah State University, Logan, UT.*

Particulate air pollution contains iron that may be involved in pathological effects after inhalation. Ambient particulate samples and a specific combustion source, coal fly ash (CFA), contain iron that can be mobilized from the particle *in vitro* and inside cultured human lung epithelial cells. The mobilized iron can then catalyze the formation of reactive oxygen species. The amount of iron mobilized from the combustion particulate CFA was dependent on the source of coal used to generate the fly ash and was greatest in the smallest size fraction collected from three different coal sources. In addition, the amount of iron mobilized from the CFA in solution by citrate correlated closely with the amount mobilized in human lung epithelial (A549) cells, as indicated by induction of the iron storage protein ferritin. The amount of the proinflammatory cytokine, interleukin (IL)-8, secreted in response to CFA treatment varied with the amount of iron mobilized intracellularly from the particles, with the greatest response to the smaller size fractions which released the largest amounts of iron. There was a direct relationship, above a threshold level of bioavailable iron, between the level of IL-8 and bioavailable iron in cells treated with CFA. Radical scavengers, e.g. tetramethyl thiourea and dimethyl sulfoxide, prevented the increased production of IL-8 by A549 cells treated with CFA, suggesting the role of a radical species in the induction of this inflammatory mediator. The mobilization of iron from CFA by citrate or within human lung epithelial cells, as well as the induction of IL-8, did not correlate with the total amount of iron in the particles. Instead, these measured values correlated directly with the amount of iron contained specifically in the aluminosilicate fraction of CFA. This work emphasizes the importance of determining the specific iron species responsible for the bioavailable iron in particles, since this could aid in identifying sources and/or combustion factors responsible for generation of bioavailable iron. (This work supported by the Health Effects Institute)

## 639 METALS, PARTICLES AND IMPACT UPON PULMONARY ALLERGIC RESPONSES.

*M. Gilmour. National Health and Environmental Effects Research Laboratory, USEPA, Research Triangle Park, Durham, NC.*

The increase in allergic asthma over the past few decades has prompted investigations into whether air pollution may affect either the incidence or severity of allergic lung disease. Population studies have demonstrated that as air pollution rises, symptoms, medication use and hospital admissions for asthma attacks increase, and this has been confirmed in a variety of animal models. There is less epidemiological evidence for air pollution exposure directly contributing to increased incidence of asthma, although recent studies are showing that proximity to highways is a risk factor for development of disease. Clinical experiments have demonstrated that diesel particles can potentiate *de novo* allergic immune responses in human volunteers, and these effects are amply supported by a large body of animal experiments. These effects have recently been associated with increased oxidative stress in the mitochondria of pulmonary epithelial cells. While the ability of metals themselves to act as immunological adjuvants has received less attention, a study comparing two towns in Germany found that the town of Hettstedt, with more metal-related industries and metals in the ambient air, had increased incidence of allergic disease than a nearby town Zerbst, which was largely agricultural and office-based with less metals in the air. Mice treated with filter extracts from Hettstedt had increased allergic immune responses after sensitization with ovalbumin allergen compared to Zerbst treated animals and there was also increased lung disease following antigen challenge. This presentation will describe the how metals potentiate allergic lung disease and discuss connections with altered iron homeostasis and oxidative stress. This abstract does not reflect EPA policy.

## 640 EFFECTS OF PARTICLES ON FE TRANSPORT AND THE IMMUNOTOXICOLOGIC OUTCOMES.

*A. J. Ghio. National Health and Environmental Effects Research Laboratory, USEPA, Research Triangle Park, NC.*

While Fe is essential for many aspects of cellular function, it can also generate oxygen-based free radicals that can result in significant injury to biological molecules. For this reason, Fe acquisition and distribution must be tightly regulated. Constant exposure to the atmosphere, however, results in significant exposure of the lungs to catalytically active Fe associated with particles. The same proteins that participate in the highly regulated Fe uptake in the gut are also employed in the lung. Iron transported intracellularly in the lungs can be sequestered within ferritin to prevent generation of oxidative stress. These proteins also expedite a release of ferritin from lung tissue to the lining fluid for clearance by the mucociliary pathway or to the

reticuloendothelial system for longterm storage. This is likely a major method for control of oxidative stress in the respiratory tract. We hypothesized that the protein responsible for Fe uptake in airway epithelial cells, divalent metal transporter 1 (DMT1), participates in detoxification of metals associated with particulate matter. Exposure of human airway epithelial cells to oil fly ash unexpectedly resulted in decrements in both DMT1 mRNA and protein expression. Similar decreases expressions were demonstrated after exposure of cells to vanadyl sulfate, a metal in high concentration in this specific ash. Pre-exposures of the cells to Fe and V were associated with an increased and a decreased uptake of metal, respectively. Pre-exposure of an animal model to Fe was associated with an elevated expression of DMT1, a more rapid transport of metal out of the lung, and diminished injury after particle exposure; in contrast, V pre-exposure decreased metal transport and increased injury from the particle. Exposure of Belgrade rats (deficient in functional DMT1) to the same particle resulted in a decreased transport of metal out of the lung and a greater injury relative to control rats. We conclude that DMT1 expression is associated with both metal transport in the lower respiratory tract and injury following exposure to a particle.

## 641 DO ALTERED FE STATUS-INDUCED EFFECTS ON TRANSCRIPTION FACTORS HAVE A ROLE IN PM-INDUCED PULMONARY/CARDIOVASCULAR DISEASES?

*K. Salnikow. Laboratory of Comparative Carcinogenesis, National Cancer Institute, Frederick, MD.*

At-risk populations, i.e., individuals with pre-existing hypertensive disease and/or atherosclerosis, as well as inflammatory and allergic responses, appear to have overtly negative responses to exposure to particulate matter (PM). However, both the mechanisms underlying these effects and the constituents in PM that might be causing these outcomes remain unclear. We hypothesized that the metals in PM - by targeting intracellular ascorbate - are altering the iron status (i.e., increasing the ratio of Fe[III]/Fe[II]) in lung cells. This leads to the inhibition of all iron-containing cellular hydroxylases followed by the loss of HIF-1α hydroxylation and hypoxia-like stress. The loss of ascorbate is deleterious for collagen proline hydroxylation and extracellular matrix assembly. Additionally, the inhibition of cellular hydroxylases causes impairment of assembly of all protein molecules that have collagen-like domains, including surfactants A and C and complement C1q. Thus, the depletion of cellular ascorbate by metals provides a link between metal exposure and a variety of respiratory and cardiovascular diseases and, maybe, to a carcinogenic process. Experimental data will be provided to show that metals like nickel, cobalt and a few select others indeed deplete intracellular ascorbate in human lung cells and activate HIF-1 transcription factor and the battery of hypoxia-inducible genes. In the absence of ascorbate, the iron in cellular hydroxylases is oxidized to iron[III] and can be reduced back to iron[II] only by ascorbate.

## 642 BEYOND LIVER TOXICOGENOMICS: GENE EXPRESSION BASED BIOMARKERS IN NON-HEPATIC TISSUES.

*K. L. Kolaja. Toxicology, Iconix Pharmaceuticals, Mountain View, CA.*

Toxicogenomics, the genome scale analysis of chemically induced changes in complex populations of mRNA to understand toxicity, has already dramatically impacted predictive and mechanistic toxicology. Gene expression based biomarkers can provide a precise and rapid assessment of toxicity or exposure, but most toxicogenomics efforts to date have been conducted in liver due to toxicological interest, technical ease of data creation, relative homogeneity of tissue sample, and historical inertia. Recently analysis of gene expression data in non-hepatic organs and tissues has started to gain momentum, and this session will include presentations of significant and promising examples ranging from toxicogenomic analyses of vascular, cardiac, kidney, neural and reproductive tissues treated with various drugs, chemicals, and toxicants. From these burgeoning studies, researchers are identifying biomarkers predictive of toxicity and indicative of various mechanisms and pharmacology in non-hepatic tissues.

## 643 MEASURING GENE EXPRESSION IN BLOOD VESSELS: THE CHALLENGES OF APPLYING TOXICOGENOMICS TO VASCULITIS.

*M. P. Lawton. Molecular and Investigative Toxicology, Pfizer, Inc., Groton, CT.*

Vasculitis is defined as an inflammation of blood vessels. In preclinical toxicology testing, drug-induced vasculitis has been observed with a number of structurally and pharmacologically diverse compounds. Although several mechanisms of vascular toxicity have been proposed, the exact mechanism(s) by these drugs damage

blood vessels is not known. In addition, there are no specific biomarkers that can be used preclinically or clinically to either predict or diagnose vasculitis; histopathology is currently the only method to detect vasculitis. To help address the need for mechanistic understanding and specific biomarkers we have been using gene expression profiling as a tool to characterize this lesion. Like most tissues, blood vessels are comprised of multiple cell types and can be found in close association with surrounding connective tissues such as fat, pancreas or lymph nodes. This complexity, along with the small size of most vessels, present unique challenges when generating and interpreting gene expression data from this tissue. Some of these challenges, along with the use of newer technologies to overcome them, such as laser capture microdissection, will be discussed in this presentation.

#### **644** GENE EXPRESSION PROFILING TO IDENTIFY BIOMARKERS OF REPRODUCTIVE TOXICITY.

**D. J. Dix.** *Office of Research and Development, USEPA, Research Triangle Park, NC.*

Testicular gene expression has been analyzed in rodents exposed to a variety of chemicals to identify biomarkers predictive or indicative of toxicity and impaired reproductive health. Using DNA microarrays we identified numerous biomarkers of reproductive toxicity in mouse and rat testes. In some cases these biomarkers were unique to the chemical or class of chemical exposures, while other biomarkers were associated with impaired reproductive function irrespective of exposure specifics. In order to extrapolate this animal research to considerations of human reproductive health, profiles of gene expression in human testis, sperm and steroidogenic cells were compared to profiles of rodent gene expression. Similarities between testis, sperm and cellular profiles; and rodent and human profiles, indicate the potential for using this type of toxicogenomic data for understanding chemical risks to human reproductive health. This abstract does not necessarily reflect EPA policy.

#### **645** EXPOSURE-INDUCED NEURODEGENERATION: A TOXICOGENOMICS CASE STUDY OF NEURONAL FUNCTION AND NEURODEGENERATIVE DISEASE.

**A. Brooks<sup>1,2</sup>, D. Cory-Slechta<sup>3</sup>, E. Richfeild<sup>3</sup> and M. Thiruchelvam<sup>3</sup>.**

<sup>1</sup>*Environmental Medicine, University of Rochester Medical Center, Rochester, NY,*

<sup>2</sup>*Functional Genomics Center, University of Rochester Medical Center, Rochester, NY*

*and<sup>3</sup>Environmental and Occupational Medicine, UMDNJ, Piscataway, NJ.*

The way in which chemical exposure affects molecular networks is critical for a complete biological understanding of behavioral, physiological, biochemical and clinical outcomes. To this end a variety of biomarkers technologies are being employed to help answer these questions. In addition, it is clear that the discovery of biomarkers at the level of gene, protein and the metabolite will be of paramount importance in assessing neural toxicity as a function of any environmental or chemical exposure. To this end, biomarker discovery from both neuronal tissue and peripheral blood will be essential in developing tools that can be used to accurately and efficiently predict the effects of a variety of exposures. Data from a model of idiopathic Parkinsons disease in addition to several models of exposure induced cognitive decline will be presented in this session. Correlations between behavior and gene expression profiles utilizing novel analysis approaches will be defined and illustrated. Lastly, a molecular model for data integration which ties together disparate data forms (i.e gene expression, protein expression and metabolite profiling) in the biomarker process will be presented.

#### **646** GENE EXPRESSION-BASED BIOMARKERS OF CARDIAC AND RENAL PHARMACO- AND TOXICOGENOMICS.

**K. L. Kolaja.** *Chemogenomics and Toxicology, Iconix Pharmaceuticals, Mountain View, CA.*

Chemogenomics is the study of pharmacology and toxicology using a combination of traditional drug development practices and new genomic tools. As a result of higher content genomic analyses, chemogenomics can be used to uncover previously unappreciated activities, good or bad, of a development candidate. We've created a database consisting of over 600 drugs, chemicals, and toxicants in short term rat studies to apply the strength of chemogenomics to drug development. Our approach has been to examine multiple end points across many tissues including liver, kidney and heart to create a broadly applicable drug development tool. This talk will describe the results of systematic mining of the database to create a library of gene expression based biomarkers (drug signatures), in the kidney and heart. In kidney, we've identified a biomarker that can predict compound-induced histopathology before it is detected using traditional approaches. In this example, we used *in vivo* kidney gene expression profiles from 64 nephrotoxic and non-

nephrotoxic compound treatments to derive a 35 gene signature to predict the future development of tubular nephrosis weeks before it appears histologically following short-term test compound administration. This kidney signature represents a validated genomic biomarker for the early prediction of compound-induced pathology. In heart, we've created over 70 drug signatures, which were used to better understand the off-target cardiotoxic mechanism of action of the anthracyclines. In addition, Signature Analysis, and Pathway and Gene Ontology Analysis indicated that the mechanism of action of the anthracycline drugs were consistent with oxidative stress, DNA damage, cell cycle arrest, inflammation and effects on cardiac electrophysiology. The above findings in heart and kidney confirm the utility of non-hepatic gene expression analysis as a means to create biomarkers for determining pharmacology, toxicology and mechanisms of action, which can be used at a very early stage in development and optimize selection of drug candidates.

#### **647** APPLICATION OF TOXICOGENOMICS BEYOND LIVER.

**Y. Yang, R. Ciurlionis, S. J. Abel, E. A. Blomme and J. F. Waring.** *R463, Abbott Laboratories, Abbott Park, IL.*

The application of gene expression analysis towards toxicology, also referred to as toxicogenomics, is rapidly being embraced by the pharmaceutical industry as a useful tool to identify safer drugs in a faster, more cost-effective manner. Almost all major pharmaceutical companies have devoted significant resources to develop and apply gene expression analysis towards toxicology. Toxicogenomics studies have so far mostly focused on the liver because of the homogeneous nature of this tissue and its importance in toxicology. At our laboratories, we have expanded our gene expression analysis studies to several other tissues, such as testis, bone marrow, spleen, kidney, and pancreas. The objectives of these studies include rank-ordering discovery compounds, guiding in dose selection for repeated-dose *in vivo* preclinical studies and generating a mechanistic understanding of toxicologic changes occurring in preclinical studies. This talk will highlight some applications as well as challenges when conducting toxicogenomics study using non-liver tissues.

#### **648** EMERGING ISSUES IN RISK ASSESSMENT AND RISK PERCEPTION OF NANOMATERIALS.

**J. S. Tsuji.** *Health Risk, Exponent, Bellevue, WA.*

Nanotechnology has been hailed as the new industrial revolution akin to silicon chip development in the last century. Nanomaterials are generally <100nm in size that potentially involve a variety of chemicals, shapes, and physicochemical properties that confer unique electrical, thermal, and imaging characteristics. Such variable characteristics have complex exposure and toxicological implications. Research supporting assessments of the health risks of nanomaterials, however, has greatly lagged technological development and nanomaterials are currently being used and proposed for various applications in technology, medicine, and consumer products with great potential for exposure, but relatively limited understanding of health risks. Little health risk information plays into public fears of nanotechnology. Like genetically modified organisms, the future of nanotechnology will depend on public acceptance of the risks versus benefits. Toxicity and exposure studies supporting health risk assessments of different nanomaterials are crucial to fill the current void in the knowledge of the potential effects of these products. This symposium presents recent findings for the components of characterizing health risks of nanomaterials. In addition to applications of available data for risk assessments of nanomaterials, risk perceptions by the public and by toxicology dogma, along with possible reasons for different interpretations of the recently published pulmonary toxicity studies will be presented. Methodologies and recent findings for characterizing aerosol exposures and the potential for dermal penetration are essential for assessing exposures to nanomaterials. Recent and ongoing research on various types of carbon nanotubes in mice indicates a potential for pulmonary toxicity. However, recent studies refute the common belief that inhalation toxicity always increases with smaller particle size. These recent toxicity and exposure data are beginning to shape risk assessments and safety evaluations that will be used to regulate nanomaterials in consumer products and provide assurance of health and environmental protection.

#### **649** CHARACTERIZING EXPOSURES TO NANOMATERIALS.

**A. D. Maynard.** *NIOSH, Cincinnati, OH. Sponsor: J. Tsuji.*

Characterizing exposures to particulate matter has always carried with it a unique set of challenges. Unlike bulk materials or gases and vapors, pertinent properties of particles extend beyond the chemistry of the material and encompass physical attributes such as shape and size. As available information on the toxicity of nanometer-scale particles and structures increases, it is apparent that we are being faced with a new set of challenges: Particle number, size, structure, surface area and sur-

face activity are indicated as potentially more relevant than mass concentration and bulk chemistry. As nanotechnology moves closer to widespread commercialization, new methods of characterizing relevant material attributes in toxicity studies and appropriately measuring exposure and dose, are required. Examples are given from two studies: On-line aerosol surface area measurements are becoming increasingly necessary when studying the toxicity of insoluble airborne nanoparticles. Diffusion charging, transmission electron microscopy and scanning mobility particle analysis have been compared for measuring aerosol surface area using particles of various sizes and morphologies. All three techniques give comparable results for particles smaller than 100 nm in diameter. For larger particles, some divergence between the three techniques is observable. Aerosol surface area alone is insufficient to characterize exposures where the bulk nanomaterial is heterogeneous. Research has shown that powders of unprocessed single walled carbon nanotubes (SWCNT) can release nanoscale particles into the air when agitated. The raw material in this case is a matrix of single walled carbon nanotubes, metal catalyst particles and compact carbonaceous material. To further explore the nature of nanoparticles generated while handling unprocessed SWCNT, the mass of single mobility diameter aerosol particles has been measured and effective particle density derived. Current results indicate that compact carbonaceous particles are primarily released into the air during agitation, suggesting that the nanotubes preferentially remain in the bulk material.

## 650 PULMONARY TOXICITY OF CARBON NANOTUBES IN MICE AND IMPLICATIONS FOR HUMAN RISK ASSESSMENT.

J. T. James and C. Lam. *SF23, Johnson Space Center, Houston, TX.*

The lungs of male B6C3F1 mice, held 7 or 90 days after intratracheal instillation of single-walled, carbon nanotubes, suspended in heat-inactivated serum and administered at doses of 0.1 and 0.5 mg/mouse, exhibited dose-dependent pulmonary granulomas and interstitial inflammation. Three carbon nanotube products, differing in their method of manufacture and the content of residual catalytic metals, were evaluated in this bioassay. In addition, serum (blank), carbon black (negative control), and quartz (positive control) were similarly administered to other groups of mice. We found that after 90 days quartz had induced a dose-dependent inflammation; however, no granulomas were found. In contrast, all 3 types of nanotubes induced pulmonary granulomas. One type of nanotube caused granulomas only at the highest dose, but the others caused granulomas at the lowest dose. If we assume that the pulmonary deposition of nanotubes is about 40%, that the 8-hour/day airborne concentration of respirable dust is 5 mg/m<sup>3</sup> (this is also the PEL for synthetic graphite), and that no significant clearance from the lung occurs, then we estimate that the lung burdens we delivered to the mice would be achieved in about 4 or 20 days for the 0.1 mg/mouse group and 0.5 mg/mouse group, respectively. This clearly suggests that, for the time being and until inhalation studies show that these materials have no effect on the lung, carbon nanotubes cannot be regarded as a relatively non-hazardous carbonaceous dust. In fact it appears prudent to treat the hazard from carbon nanotube dust similarly to the hazard from quartz dust. Further work will answer the important questions for human health assessment; these are as follows: Under what conditions are the nanotubes, which are produced and purified in industrial settings, respirable? How quickly are inhaled nanotubes cleared from the lungs and where are do they go? What are the long-term tissue responses to persisting nanotubes? How do the metal impurities influence the toxicity?

## 651 IMPACT OF EXPOSURES TO NANOPARTICLES ON RESPIRATORY HEALTH: PARTICLE SIZE MAY NOT BE MORE IMPORTANT THAN SURFACE CHARACTERISTICS.

D. B. Warheit. *Pulmonary Toxicology, DuPont Haskell Lab, Newark, DE.*

Several pulmonary toxicity studies in rats have demonstrated that nanoscale particles (defined as particles in the size range <100 nm) administered to the lung cause a greater inflammatory response when compared to microscale or macroscale particles of identical composition at equivalent mass concentrations. Contributing to the effects of nanoscale particles is their very high size-specific deposition when inhaled as singlet ultrafine particles rather than as aggregated particles. Some evidence suggests that inhaled nanoparticles, after deposition in the lung, largely escape alveolar macrophage surveillance and gain access to the pulmonary interstitium. In addition, *in vitro* studies indicate that nanoparticles are more toxic to pulmonary cells. However, some recent preliminary studies indicate that pulmonary exposure to nanoscale particulates may not always be more inflammmogenic compared to macro/microscale particles. For instance, preliminary studies comparing the effects of nano vs. fine-sized particles, have indicated that pulmonary exposures in rats to uncoated TiO<sub>2</sub> nanorods (200 nm lengths x 30 nm diameters) or TiO<sub>2</sub> nanodots (particle size < 30 nm) did not produce enhanced lung inflammation in rats when compared to fine-sized TiO<sub>2</sub> particle exposures (particle size ~ 270 nm). Similar results have been observed with nano and fine ZnO particles. Additional studies have compared lung toxicity in rats of uncoated nanoscale quartz particles (50 nm) vs. fine-sized quartz particles (particle size ~ 1.6  $\mu$ m). In pulmonary instillation studies,

at equivalent mass doses, the nanoquartz particles produced less intensive and sustained pulmonary inflammatory and cytotoxic responses when compared to the effects produced by the Min-U-Sil quartz particles. This result is intriguing since crystalline quartz silica particles are classified as a Category 1 human carcinogen by the International Agency for Research on Cancer (IARC). In summary, the preliminary findings from these three studies suggest that particle size is only one factor in determining pulmonary toxicity.

## 652 EVALUATION OF THE DERMAL PENETRATION OF NANOSCALE MATERIALS.

P. C. Howard. *Jefferson Labs, US Food & Drug Administration, Jefferson, AR.*

The skin is an important organ that has great surface area, provides a physical barrier, has immunologic and metabolic functions, and interacts with materials from the environment. Exposure of skin to ultraviolet light, for example, results in enzyme induction, the alteration of structural proteins and DNA, and the induction of cancer. The range of interactions of chemicals with the skin varies from those that do not penetrate the skin to others that penetrate very rapidly and elicit significant changes. Humans will be exposed to nanoscaled materials as the consequence of several natural and anthropogenic activities, including the incorporation of nanoscale materials into consumer products. What is not clear, but needs to be determined, is the effectiveness of the skin as a barrier to nanoscaled materials. For example, nanoscaled titanium dioxide and zinc oxide have been included recently in sunscreens as physical sunblock agents. Some studies have reported that nanoscale titanium dioxide can penetrate rodent and human skin; however, other reports have indicated nano- and micron-scaled titanium dioxide did not penetrate skin. The interpretation of the toxicity of dermally applied nanoscale materials relies on a thorough knowledge of the chemical and physical characteristics of the nanoscale material in the vehicle and on the skin. Ongoing research is evaluating the potential of, and the conditions under which, nanoscale materials can penetrate the skin and mediate effects such as phototoxicity. Issues central to the interpretation of dermal penetration include physical nature of the materials, the characterization of the test material, the vehicles used to deliver the nanoscale particles, the condition of the skin, and the methods used to assess penetration.

## 653 RISK ASSESSMENT AND SAFETY EVALUATION OF NANOMATERIALS IN CONSUMER PRODUCTS.

A. B. Santamaría<sup>1</sup> and N. J. Rachman<sup>2</sup>. <sup>1</sup>*Health Risk, Exponent, Houston, TX* and <sup>2</sup>*Food and Chemicals, Exponent, Washington, DC.*

Development of nanomaterials is rapidly transforming a variety of consumer products. With the increasing diversity of product applications, risk assessment screening adapted for new nanomaterials is critical to guide research and develop products that pose minimal health and environmental concerns, and to regulate potential risks. With more data, lifecycle risk assessments of products from manufacture to disposal can be conducted. Although research to support risk assessment and regulation lags behind product development, much of the current risk assessment framework can be adapted to screen materials for potential risks and to identify data needs. Screening tools may include QSAR analyses or *in vitro* tests to evaluate cellular absorption, effects on organelles, molecular changes, and stability of nanomaterial components. Although preliminary studies indicate that nanomaterials may be transported across cell membranes, be absorbed or retained in the lung, and penetrate skin, additional *in vivo* studies are necessary to continue addressing pharmacokinetic questions, including how the various nanomaterials are absorbed and transported, and whether they can penetrate blood-brain and placental barriers. Direct uptake to the brain via olfactory or trigeminal nerves is a concern based largely on rat studies, although potential compound and species differences are possible. Toxicity of nanomaterials is more complicated than smaller is more toxic, which is not always true; other factors such as chemistry, surface properties, and shape also affect toxicity. Exposure assessment considers aerosol potential, solubility, size, concentration, and tendency to agglomerate. Because of the diversity of products and target populations, carefully designed exposure scenarios with appropriate defaults are needed. Available research on ultrafine particles, metal fume, and fibers can help guide research and exposure assessments on nanomaterials. As the fields of nanotechnology and toxicology converge, creative approaches to risk assessment will be needed to ensure the safety of consumers.

## 654 NUCLEOCYTOPLASMIC TRAFFICKING IN MECHANISMS OF TOXICITY.

W. H. Watson<sup>1</sup> and G. H. Perdew<sup>2</sup>. <sup>1</sup>*Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD* and <sup>2</sup>*Center for Molecular Toxicology, Penn State University, University Park, PA.*

Transport of proteins across the nuclear membrane is tightly regulated by the nuclear pore, a multisubunit complex consisting of at least 30 proteins. There are few known examples of toxins or toxicants that act directly at the nuclear pore to affect

transport. However, import or export of specific proteins is a key component of cellular responses to a variety of toxicants. For example, many transcription factors are maintained as inactive cytoplasmic pools that can rapidly translocate to the nucleus upon exposure to toxicants and other stimuli. Interactions that anchor proteins in either compartment or target proteins to the nuclear pore may be disrupted (or enhanced) by toxicants or by specific posttranslational modifications such as phosphorylation or SUMO modification. An understanding of the factors that control the dynamic localization of proteins across the nuclear membrane is necessary for the definition of toxicological mechanisms and physiological pathways.

## 655 NUCLEOCYTOPLASMIC TRAFFICKING IN MECHANISMS OF TOXICITY.

**W. H. Watson.** *Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Transport of proteins across the nuclear membrane is tightly regulated by the nuclear pore, a multisubunit complex consisting of at least 30 proteins. There are few known examples of toxins or toxicants that act directly at the nuclear pore to affect transport. However, import or export of specific proteins is a key component of cellular responses to a variety of toxicants. ## 656 NUCLEAR PROTEIN TRANSPORT: A ROLE IN REGULATING CELLULAR RESPONSES TO STIMULI.

**A. H. Corbett, M. T. Harreman, T. M. Kline and A. E. Hodel.** *Biochemistry, Emory University School of Medicine, Atlanta, GA.* Sponsor: W. Watson.

All transport of macromolecules between the cytoplasm and the nucleus is mediated by the nuclear pore complex (NPC), which are large macromolecular channels embedded in the nuclear envelope. Although numerous proteins are synthesized in the cytoplasm and then routinely imported into the nucleus to perform their cellular function, there are also numerous examples of proteins that undergo regulated nuclear transport. For example, many transcription factors of toxicological relevance are maintained as inactive cytoplasmic pools that can be rapidly activated and imported into the nucleus upon exposure to toxicants and other stimuli. These regulated transport processes are mediated by soluble nuclear transport receptors that recognize and bind to cargo in the cytoplasm and then transport that cargo into the nucleus through NPCs. The best understood protein transport process is the import of proteins that contain a classical nuclear localization signal (NLS), but many other nuclear targeting signals also exist. Numerous studies have led to a rather detailed understanding of the molecular mechanism of transport receptor-mediated protein trafficking into and out of the nucleus. Interactions between transport receptors and cargoes are regulated by a small GTPase, Ran, which cycles between a nuclear RanGTP state and a cytoplasmic RanGDP state. This presentation will provide a basic overview of protein transport into and out of the nucleus as well as give an overview of some regulatory mechanisms. To illustrate one regulatory mechanism, results of our recent study that examined the molecular mechanism by which nuclear localization of a yeast transcription factor is regulated in a cell cycle-dependent manner will be presented. This study demonstrated that phosphorylation proximal to a classical NLS directly modulates binding to the transport receptor and hence import into the nucleus. These results could suggest a general mechanism by which post-translational modifications of proteins regulate their nuclear localization.

## 657 SPECIES-DEPENDENT DIFFERENCES IN AH RECEPTOR NUCLEOCYTOPLASMIC SHUTTLING PROPERTIES.

**G. Perdew, P. Ramadas and B. D. Hollingshead.** *Center for Molecular Toxicology and Carcinogenesis and Department of Veterinary Science, The Pennsylvania State University, University Park, PA.*

A series of studies were initiated to determine the nucleo-cytoplasmic shuttling (NCPS) properties of the Ah receptor. The mouse Ah receptor (mAhR)-yellow fluorescent protein (YFP) undergoes dynamic NCPS in COS 1 cells and shuttling is inhibited by co-expression of XAP2. *In vitro* protein binding studies revealed that the presence of XAP2 in the mAhR complex inhibited importin beta binding to the

nuclear localization signal (NLS) of the mAhR. Differences in NCPS properties of mAhR-YFP and human Ah receptor (hAhR)-YFP in the presence or absence of XAP2 were determined in COS 1 cells. The mAhR-YFP localizes predominantly in the nucleus, whereas hAhR-YFP is cytoplasmic. Co-expression of XAP2 redistributes mAhR-YFP to the cytoplasm and inhibits NCPS, but has no effect on hAhR-YFP distribution or NCPS properties. XAP2 does not inhibit importin beta binding to the hAhR. XAP2-NLS, which contains a NLS sequence fused to the carboxy terminus, is capable of dragging a NLS mutant of hAhR-YFP into the nucleus, but not a NLS mutant of mAhR-YFP suggesting that only the human AhR moves into the nucleus with XAP2 in the receptor/hsp90 complex. Both the mouse and human AhR transcriptional activity is inhibited by XAP2. Mouse and human chimeric receptors with C-terminal half of the Ah receptor swapped between receptors were used to determine whether the divergent transactivation domains of these two receptors influences receptor properties found in the N-terminal half. Results revealed that the C-terminal half influenced NCPS properties of the AhR. Treatment with H2O2 to induce oxidant stress leads to rapid translocation of both the human and mouse Ah receptor into the nucleus, indicating that the shuttling properties of the AhR may be altered during disease processes.

## 658 SUMO MODIFICATION AND REGULATION OF NUCLEAR TRANSPORT.

**M. J. Matunis and H. Zhang.** *Biochemistry and Molecular Biology, Johns Hopkins University, Baltimore, MD.* Sponsor: W. Watson.

SUMOs are small ubiquitin-related proteins that are posttranslationally conjugated to other proteins, thereby regulating a wide range of cell functions. Several lines of evidence indicate that SUMO modification regulates the transport of proteins and/or RNAs between the nucleus and the cytoplasm. Of particular significance, enzymes that regulate SUMO modification and demodification localize to nuclear pore complexes (NPCs). We have found that the SUMO-specific protease SENP2 localizes to the nucleoplasmic filaments of the NPC. Interactions between SENP2 and the NPC, however, were found to be indirect. Using purified proteins, we found that SENP2 interacts directly with nuclear transport receptors that tether it to the NPC. Similar to transport receptors, SENP2 was also found to shuttle between the nucleus and the cytoplasm. Significantly, disruption of the SUMO modification pathway disrupted the nucleocytoplasmic shuttling of SENP2-interacting transport receptors. Our findings indicate that SUMO modification regulates the shuttling of nuclear transport receptors between the nucleus and the cytoplasm and implicate the SUMO-specific protease SENP2 as a direct player in this process.

## 659 TOXICANT-INDUCED NUCLEAR TRANSLOCATION OF THIOREDOXIN.

**W. H. Watson.** *Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Thioredoxin (Trx1) is a protein that plays a central role in protecting cells against oxidative damage. A wide variety of stimuli including peroxides, UV light and inflammatory cytokines cause Trx1 to move from the cytoplasm to the nucleus. Trx1 contains no recognizable nuclear localization or nuclear export signals, so it is unclear how the subcellular distribution of Trx1 is regulated. We have been investigating the effect of changes in the redox state of Trx1 itself on its localization within the cell. Trx1 contains five cysteines, two of which are in the active site and cycle between the reduced dithiol form and the oxidized disulfide form during catalysis. Under oxidative stress conditions a second disulfide between two of the non-active site cysteines was found, and this correlated with an increase in the amount of Trx1 in the nucleus. The amount of active Trx1 in the nucleus affected the expression of an NF- $\kappa$ B-dependent reporter gene. Because nuclear Trx1 affects the DNA-binding activity of redox-sensitive transcription factors such as NF- $\kappa$ B, the redistribution of Trx1 appears to be an important factor in regulating transcriptional responses to oxidative stress.

## 660 CURRENT STATUS AND FUTURE CONSIDERATIONS FOR THE DEVELOPMENT OF *IN VITRO* ALTERNATIVES TO THE DRAIZE RABBIT EYE TEST FOR ASSESSING OCULAR IRRITANTS.

**T. Hartung<sup>1</sup> and W. S. Stokes<sup>2</sup>.** <sup>1</sup>*ECVAM, Ispra, Italy* and <sup>2</sup>*NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC.*

The Draize rabbit eye test has been used as the standard test method for assessing ocular irritation and corrosivity potential of chemicals and products for over 60 years. Largely due to the pain and discomfort associated with this test, there have been extensive efforts to develop and validate alternative test methods that would

partially or fully replace the current regulatory version of the Draize rabbit eye test. These efforts are also being driven by the 7th Amendment to the European Union Cosmetics Directive that will ban the use of animals for ocular testing by 2009 and pressure to minimize or avoid animal use for the European Union Chemicals Policy Initiative (REACH). This workshop will address scientific and regulatory considerations for developing and validating *in vitro* test methods that will refine, reduce, and replace the Draize rabbit eye test. ICCVAM, NICEATM, and ECVAM have recently initiated collaborations to assess the usefulness of currently available *in vitro* ocular toxicity methods and to review the state-of-the-science with regard to *in vitro* test methods. These efforts include an evaluation of several *in vitro* test methods for their ability to detect severe ocular irritants, an assessment of the performance characteristics of the *in vivo* rabbit eye test, and a review of the current status of methods for identifying nonirritants and mild to moderate irritants. Current and future challenges in validating alternative methods and approaches to evaluate ocular toxicity will be presented including the need for high quality reference data to assess test method performance.

## 661 CURRENT STATUS AND FUTURE CONSIDERATIONS FOR ALTERNATIVE METHODS TO REFINE, REDUCE, AND REPLACE ANIMAL USE FOR OCULAR SAFETY TESTING.

W. S. Stokes, NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC.

The original and modified Draize rabbit eye tests have been used for over 60 years to identify potential acute ocular hazards of chemicals and products. Such testing has been highly effective in safeguarding human health by identifying and classifying potential ocular hazards. Nevertheless, public animal welfare concerns and a European law banning the use of this test for cosmetics testing no later than 2009 have led to significant efforts during the past 20 years to develop and validate *in vitro* tests to replace animals for ocular testing. While there is still no valid replacement for the Draize eye test, new testing guidelines now allow for the use of valid and accepted *in vitro* test methods in a tiered testing strategy. When animals are needed, such determinations can now be made with only 1-3 animals. The proposed tiered testing strategy provides for stepwise weight-of-evidence hazard decisions to be made based on existing data, structure activity/property relationship evaluations, *in vitro* data, and/or data from other *in vivo* testing. Topical anesthetics are also now permitted to reduce or avoid animal pain, provided that there is no interference with the outcome of the study. Future *in vitro* test methods and/or test batteries proposed to completely replace the *in vivo* test will require adequate validation and will need to accurately identify ocular irritants and corrosives, especially those that may cause permanent visual impairments. Appropriate reference chemicals with high quality *in vivo* data will be necessary to assess the performance of these new tests. Progress in refining, reducing, and replacing animal use for ocular toxicity is expected as tiered testing strategies are implemented, and existing and new mechanism-based test methods are validated and accepted.

## 662 THE PERFORMANCE CHARACTERISTICS OF THE *IN VIVO* RABBIT EYE TEST.

J. H. Haseman<sup>1</sup>, N. Y. Choksi<sup>2,3</sup>, C. Inhof<sup>2,3</sup>, J. Truax<sup>2,3</sup>, R. R. Tice<sup>2,3</sup> and W. S. Stokes<sup>3</sup>. <sup>1</sup>Consultant, NIEHS/NIH/DHHS, Research Triangle Park, NC, <sup>2</sup>ILS, Inc., Research Triangle Park, NC and <sup>3</sup>NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC.

Alternative *in vitro* test methods proposed to substitute or replace an *in vivo* assay should provide equivalent or improved protection of human or animal health to gain regulatory and general acceptance. The Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) is evaluating four *in vitro* ocular test methods as partial replacements for the detection of severe ocular irritants (i.e., those that induce or are likely to induce irreversible ocular damage). Integral to this evaluation and to the future evaluation of *in vitro* ocular toxicity test methods that are proposed as full replacements is an assessment of the performance characteristics of the current *in vivo* rabbit eye test. Ideally, this analysis would evaluate the ability of the rabbit eye test to correctly predict ocular toxicity in humans. However, due to the absence of adequate human data, estimating the likelihood of underpredicting a positive response in the *in vivo* rabbit eye test is the best approach for assessing the performance of this assay. Relevant *in vivo* rabbit eye test method data have been obtained from US Federal agencies and published literature. The underprediction rate for the *in vivo* rabbit eye test depends on the regulatory classification system used. For this analysis, the UN Globally Harmonized System of Classification and Labeling of Chemicals and the USEPA Ocular Toxicity Classification Scheme are the regulatory approaches being used to distinguish between nonirritants and various classes of ocular irritants. More than 500 chemicals were assigned to ocular irritation categories based on the observed responses in 3 to 6 animals. Based on this distribution of animal responses within each irritation clas-

sification level, the underprediction rate associated with a sequential testing strategy (maximum of three animals) was evaluated. The results and implications of these analyses will be presented and discussed. Supported by NIEHS contract N01-ES-35504.

## 663 PERFORMANCE OF BCOP, IRE, ICE, AND HET-CAM IN DETECTING SUBSTANCES THAT INDUCE SEVERE IRRITATION AND IRREVERSIBLE OCULAR DAMAGE.

N. Y. Choksi<sup>1,2</sup>, D. A. Allen<sup>1,2</sup>, C. Inhof<sup>1,2</sup>, J. Truax<sup>1,2</sup>, R. R. Tice<sup>1,2</sup> and W. S. Stokes<sup>2</sup>. <sup>1</sup>ILS, Inc., Research Triangle Park, NC and <sup>2</sup>NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC.

Exposure of rabbit eyes to a test substance is one of the most common methods for assessing the ocular hazard potential of substances that are proposed to come in contact with or be placed near the eye. Concerns about animal welfare have led researchers to develop *in vitro* test methods as alternatives to the currently used *in vivo* rabbit eye test method. Recently, the USEPA (EPA) requested that NICEATM and the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) evaluate four test methods; the Bovine Corneal Opacity and Permeability (BCOP) test; the Isolated Rabbit Eye (IRE) test; the Isolated Chicken Eye (ICE) test; and the Hens Egg Test-Chorioallantoic Membrane (HET-CAM) for their ability to detect severe ocular irritants, as defined by U. S. and international ocular irritancy classification systems. For this evaluation, substances that were classified as Category I ocular irritants according to the EPA classification system, as Category 1 ocular irritants according to the United Nations Globally Harmonized classification system, or as R41 ocular irritants according to the European Union classification system were defined as severe ocular irritants. The accuracy of each of the test methods for identifying severe ocular irritants, as defined by each of the identified regulatory classification systems, was evaluated. Based on the available data, this analysis indicated the extent that each of these *in vitro* test methods could be used to identify severe ocular irritants. Appropriate use of these *in vitro* methods to identify severe irritants prior to animal testing will reduce the likelihood of pain and suffering associated with subsequent ocular testing. Supported by NIEHS contract N01-ES-35504.

## 664 THE STATE OF THE SCIENCE ON *IN VITRO* TEST METHODS FOR DETECTING MILD TO MODERATE OCULAR IRRITANTS.

C. Eskes, T. Hartung and V. Zuang, ECVAM, IHCP, European Commission - DG JRC, Ispra, Varese, Italy. Sponsor: W. Stokes.

European chemicals and cosmetics legislation call for alternatives to animal testing, in particular in the areas of acute topical toxicity, such as eye irritation. Major validation studies in the 90's to replace the Draize test for eye irritation showed good reproducibility and reliability of some alternative methods but the range of criteria for injury and inflammation covered by the Draize rabbit eye test was found to be unlikely to be replaced by a single *in vitro* test. One of the major recommendation from experts in the field is to define test strategies for eye irritation testing, that utilizes the strengths of particular *in vitro* assay systems to address required ranges of irritation potential and/or chemical classes. In particular, the following methods appear to be promising for identifying mild to moderate ocular irritants: - Organotypic models: Chicken Enucleated Eye Test (CEET), Hen's egg test on the Chorio-Allantoic Membrane (HET-CAM), and CAM vascular assay (CAM-VA), - Human Corneal Epithelium (HCE) models: EpiOcular<sup>TM</sup> assay, and SkinEthic *in vitro* reconstituted HCE, - Cell-cytotoxicity based methods: Neutral Red Release (NRR) assay, and Red Blood Cell (RBC) haemolysis test for surfactants, - Cell-function based assays: Fluorescein Leakage (FL) and Silicon Microphysiometer (SM). Whereas the human corneal epithelium models have undergone (pre)validation, the organotypic models, cell cytotoxicity and cell function based assays, have undergone extensive evaluation studies. In parallel and in collaboration with ICCVAM's assessment of the organotypic models, ECVAM is currently evaluating the further models, based on the acquired data and on an in-depth review of the existing data. If validated, these methods might be able to identify mild to moderate irritants and could be part of test strategies allowing a reduction or replacement of animals used for eye irritation testing.

## 665 CHALLENGES IN THE VALIDATION OF ALTERNATIVE TEST METHODS TO EVALUATE OCULAR TOXICITY.

T. Hartung, C. Eskes and V. Zuang, European Centre for the Validation of Alternative Methods, European Commission DG JRC, Ispra, Varese, Italy. Sponsor: W. Stokes.

The current political environment in Europe strongly requests alternatives to animal testing, in particular in the areas of acute topical toxicity, such as eye irritation. Major validation and evaluation studies took place in the 90's to replace the Draize

test for eye irritation, but no single method was able to replace the Draize rabbit eye test. This was due to several factors including the limited quality of the existing *in vivo* data, the limitations of the animal and alternative test methods, and the fact that the range of criteria for injury and inflammation covered by the Draize rabbit eye test is unlikely to be replaced by a single *in vitro* test. Despite of the fact that no method has been validated according to the current criteria, several methods appear to be promising for replacing the animal test if used in combination with other alternative tests. In order to achieve the validation of alternatives that could fully replace the Draize rabbit eye test the following major challenges need to be addressed: - Make use of the existing data and apply a weight-of-evidence approach; - Acquire high quality *in vivo* data sets; - Define and validate test strategies; - Consider different regulatory schemes including the upcoming implementation of the Globally Harmonised System for classification; - Develop mechanistically based alternatives able to evaluate the persistence or reversibility of effects. ECVAM has established a Task Force and has organised a series of workshops involving international experts in the field in order to address those challenges; and is currently evaluating the different single promising methods in collaboration with ICCVAM-NICEATM. In addition, ECVAM is collaborating with the European Cosmetics Industry Trade Association (COLIPA), which entertains a research programme on eye irritation based on the mechanistic understanding of eye irritation and the possibility to assess irreversibility and reversibility of eye irritation effects.

## 666 MODE OF ACTION IN RELEVANCE OF RODENT LIVER TUMORS TO HUMAN CANCER RISK.

M. P. Holsapple<sup>1</sup> and Y. P. Dragan<sup>2</sup>. <sup>1</sup>HESI, Washington, DC and <sup>2</sup>NCTR, Jefferson, AR.

The recent adoption of the IPCS mode of action paradigm (Sonich-Mullin et al., 2001, *Regul Toxicol Pharmacol* 34:146-152) coupled with the recent ILSI human relevance framework (Cohen et al., 2003, *Crit Rev Toxicol* 33:581-589) have led to an approach for the systematic analysis of data on modes of carcinogenic action of chemicals in experimental animals and its application to the assessment of human cancer risk assessment. Hazard identification and risk assessment paradigms depend on the presumption of similarity of rodents to humans, yet species-specific responses and high dose to low dose extrapolation plague the development of appropriate risk assessments. The first step in a mode of action analysis is to establish the key biochemical and cellular events, temporal occurrence, and dose response concordance relationships common to each mode of action of a chemical. The next step is to assess the biological plausibility and relevance to human cancer risk of the proposed mode(s) of action taking kinetic and dynamic factors into consideration. The identification of key events can be used to bridge species and dose differences. These discussions will be used to generate a minimal dataset necessary to establish selected modes of action. This mode of action framework has been previously applied to rodent liver tumors associated with exposure to peroxisome proliferators mediated through the alpha receptor (Klaunig et al., 2003, *Crit Rev Toxicol* 33:655-780). More recently, several additional modes of action for rodent liver cancer development have been described including cytotoxicity, P450 induction, hormone mediated and porphyrogenicity / metal overload. An understanding of the mode of action underlying cancer development in the liver will place rodent liver tumors into a more appropriate perspective when human risk assessment is performed.

## 667 THE PATHOGENESIS OF RODENT HEPATOCARCINOGENESIS: POTENTIAL APPLICATIONS TO HUMAN CANCER RISK.

H. C. Pitot. *Oncology, McArdle Lab., University of Wisconsin, Madison, WI.*

A variety of model systems of hepatocarcinogenesis in the rat and the mouse have been developed. Several in the rat have allowed the delineation and characterization of the stages of initiation, promotion, and progression as sequential processes in the pathogenesis of hepatocarcinogenesis. Identification of single putatively initiated hepatocytes in both rats and mice is possible by specific gene expression. Quantitation of such single initiated hepatocytes shows a linear dose response with chemical carcinogens in the rat. Clonal growth of about 1% of putatively initiated hepatocytes form focal lesions termed altered hepatic foci (AHF). The dose response of the development of AHF to several promoting agents, including phenobarbital, exhibits a sigmoidal response with a clear no-effect level and hormetic effect. Withdrawal of the promoting agent or fasting for five days results in a rapid loss of focal cells, which is primarily due to selective apoptosis. Re-administration of the promoting agent results in a rapid regrowth of the original number of AHF. Many, possibly all, promoting agents interact with specific receptors in target cells as the rate limiting and necessary step in their effect. Administration of a genotoxic carcinogen during the action of a promoting agent can result in expression of different genes in foci within AHF during the stage of progression. During the pro-

gression stage of chemical and genetic carcinogenesis in the rat, specific cytogenetic alterations occur. Epidemiologic studies indicate that the major causes of human neoplasia, tobacco abuse, diet, and reproductive and sexual behavior, involve tumor promotion as the principal pathway in their development. Thus, reversibility and threshold as well as hormetic effects of carcinogens should be taken into account in risk determination in the human.

## 668 FRAMEWORK FOR EVALUATING THE HUMAN RELEVANCE OF CARCINOGENIC MODES OF ACTION IN ANIMALS.

S. M. Cohen. *Pathology and Microbiology, University of Nebraska Medical Center, Omaha, NE.*

Considerable effort has been made to evaluate the mode of action for specific chemicals causing cancer in rodents during the past several decades. However, the key question is the relevance of this mode of action to humans and what the implications of that mode of action (MOA) are for human risk assessment. A framework for such an analysis has recently been developed by an ILSI/RSI working group sponsored by EPA and Health Canada. The process is divided into three specific questions. The first is, Is the weight of evidence sufficient to establish the MOA in animals? This evaluation is performed based on the framework developed by the IPCS/EPA for determining animal mode of action. The measurable key events in the MOA are explicitly stated and evaluated. This is not only useful in formulating a mode of action, but clearly identifying any data gaps and uncertainties that remain. The second question is, Are key events in the animal MOA plausible in humans? This evaluation is based on a concordance analysis comparing the information known about the specific key events in both animals and humans. This evaluation is primarily a qualitative assessment. The third question is, Taking into account kinetic and dynamic factors, are key events in the animal MOA plausible in humans? This is a more quantitative analysis, and again relies on a concordance analysis between the animal model and humans. For both questions two and three, data may or may not be available for the specific chemical in humans, but broad knowledge of processes involved in humans, including anatomy, physiology, biochemistry, metabolism, etc., are critical. Based on the results of this analysis, a statement of the confidence in the analysis is made along with implications for carrying forward to the remainder of the risk assessment process. This human relevance framework is focused on hazard identification and evaluation. Several examples will be presented illustrating the process by which this framework can be applied

## 669 MODE OF ACTION AND HUMAN RELEVANCE OF PHENOBARBITAL-LIKE RODENT LIVER CARCINOGENS.

A. R. Boobis<sup>1</sup>, B. G. Lake<sup>2</sup>, E. Harpur<sup>3</sup>, J. M. Rice<sup>4</sup> and J. I. Goodman<sup>5</sup>.

<sup>1</sup>Experimental Medicine and Toxicology, Imperial College London, London, United Kingdom, <sup>2</sup>BIBRA International Ltd., Carshalton, United Kingdom, <sup>3</sup>Sanofi-Synthelabo, Malvern, PA, <sup>4</sup>Georgetown University, Washington, DC and <sup>5</sup>Michigan State University, East Lansing, MI.

Phenobarbital (PB) is the prototype of several rodent hepatocarcinogens (e.g. oxazepam, DDT) that induce tumors by a non-genotoxic mechanism. PB is negative in a wide range of genotoxicity tests and is not cytotoxic. A diagnostic effect of PB is induction of some P450 enzymes, particular of the CYP2B family. This is due to activation of nuclear receptors, particularly constitutive androstane receptor (CAR). However, whilst there is evidence that CAR plays a key role in the carcinogenicity of PB, it is uncertain if CYP induction is a surrogate for a wider pleiotropic response or if P450 itself plays a role, e.g. by generation of active oxygen species. Additional PB responses that are key in the tumorigenic effect include increased cell proliferation, inhibition of apoptosis, hypertrophy and development of altered hepatic foci. Hence, it is possible to identify a series of key events comprising a mode of action for PB. PB induces CYP enzymes in human liver, although it may act more through pregnane X receptor (PXR) than CAR. Nevertheless, human CAR is expressed and appears to be activatable by PB. Liver size is increased in humans treated with PB. Limited studies with human hepatocytes indicate that such cells are refractory to the hyperplastic and anti-apoptotic effects of PB. However, whilst the data for concordance analysis for PB are limited, there are convincing data showing that in patients receiving PB for many years, at doses producing plasma concentrations similar to those following a carcinogenic dose in rodents, there is no evidence of a carcinogenic effect. This is a situation where epidemiology data are useful in a human relevance framework. Once a robust mode of action has been established in rodents, and adequate human data show no evidence of a carcinogenic response, these data can be applied to chemicals sharing that mode of action.

## MODE OF ACTION AND HUMAN RELEVANCE OF METAL OVERLOAD AND PORPHYRINOGENIC COMPOUNDS.

J. E. Klaunig<sup>1</sup>, A. Nyska<sup>2</sup>, J. Popp<sup>3</sup>, A. Smith<sup>4</sup>, W. Stott<sup>5</sup> and G. Williams<sup>6</sup>. <sup>1</sup>Indiana University, Indianapolis, IN, <sup>2</sup>NIEHS/NTP, Research Triangle Park, NC, <sup>3</sup>Purdue Pharmacology, New York, NY, <sup>4</sup>MRC Toxicology, University of Leicester, United Kingdom, <sup>5</sup>The Dow Chemical Company, Midland, MI and <sup>6</sup>New York Medical College, Valhalla, NY.

Using the recently developed USEPA Framework for examining the mode of action of rodent carcinogens and their human relevance, the mode of action for metal overload (copper and iron) and porphyrinogenic chemical induced rodent hepatocellular cancer induction was examined. Iron and copper overload in the liver are seen in the human diseases hemochromatosis and Wilson's disease. Both iron and copper overload have been implicated as causal factors in both rodent and human hepatic cancer. Using the Framework Evaluation, our working group concluded that while copper and /or iron overload are associated with the development of rodent and human hepatic neoplasia, the scientific proof that either compound solely produces rodent or human liver cancer is lacking. It appears that additional toxicity to the liver resulting in hepatic damage are necessary for the induction of liver cancer by either copper or iron overload. We also evaluated the mode of action of porphyrinogenic compounds for hepatic rodent neoplasia. With the established porphyrinogenic agent, hexachlorobenzene, as a model, we concluded that porphyrinogenic compounds have a definable mode of action for rodent hepatic cancer that involves a chronic, dose and threshold dependent, persistent hepatocellular injury with resulting persistent compensatory hyperplasia. Using the USEPA Framework approach, our group concluded that for iron and copper metal overload, a definable mode of action for the formation of hepatic cancer in rodents by either iron or copper was not achievable based on the currently available scientific evidence. For porphyrinogenic compounds, with hexachlorobenzene used as an example, we concluded that the induction of rodent liver cancer followed a cytotoxic mode of action, and, as in the case of other cytotoxic hepatic carcinogens, the rodent mode of action was deemed possible for humans.

## HORMONAL PERTURBATION AS A MODE OF ACTION FOR RODENT LIVER TUMORS.

T. Pastoor<sup>4</sup>, Y. Dragan<sup>1</sup>, M. Cunningham<sup>3</sup>, L. White<sup>7</sup>, J. Teeguarden<sup>6</sup>, H. Pitot, III<sup>5</sup> and C. Capen<sup>2</sup>. <sup>1</sup>NCTR, Jefferson, AR, <sup>2</sup>Ohio State University, Columbus, OH, <sup>3</sup>NIH/National Center for Toxicogenomics, Research Triangle Park, NC, <sup>4</sup>Syngenta CropScience, Greenboro, NC, <sup>5</sup>University of Wisconsin, Madison, WI, <sup>6</sup>ENVIRON Corporation, Collegeville, PA and <sup>7</sup>University of Leicester, Leicester, United Kingdom.

Hormonally active agents can contribute to the development of rodent liver tumors. In determining the mode of action of a non-genotoxic carcinogens, perturbation of hormonal regulation should be considered. Although the liver is not generally considered as a target tissue for hormones, it is quite hormonally responsive. Using estrogen as an example, rat liver is responsive to its carcinogenic action, while mouse liver is protected from cancer development. With respect to humans, the mode of action observed in rat; namely, hormonal perturbation is a plausible mechanism for primary liver cancer induction in the human. The key events in rodent liver carcinogenesis following exposure to estrogenic agents is perturbation of hormone level or function, altered cell proliferation to apoptosis balance, development of altered foci of cellular alteration. Use of the mode of action approach permits initial development of quantitative risk assessment that can be applied across species by use of the human relevance framework.

## RODENT HEPATIC TUMORS: CYTOTOXICITY MODE OF ACTION.

V. L. Dellarco<sup>1</sup>, S. Cohen<sup>2</sup>, D. Wolf<sup>3</sup>, R. Maronpot<sup>4</sup> and D. Jacobson-Kram<sup>5</sup>. <sup>1</sup>Office of Pesticide Programs, USEPA, Washington, DC, <sup>2</sup>University of Nebraska Medical Center, Omaha, NE, <sup>3</sup>Health and Environmental Effects Research Laboratory, USEPA, Research Triangle Park, NC, <sup>4</sup>NIEHS, National Toxicology Program, Research Triangle Park, NC and <sup>5</sup>CDEP, USFDA, Rockville, MD.

Cytotoxicity is a generally accepted mode of action (MOA) and has been defined for a number of nongenotoxic rodent carcinogens (e.g., formaldehyde-induced nasal tumors, chloroform-induced liver and kidney tumors, melamine-induced bladder tumors). In the liver, a cytotoxicant would produce protracted hepatocyte death leading to regenerative growth (persistent), allowing mutated cells to persist and proliferate, giving rise to preneoplastic foci and ultimately to tumors via further clonal expansion. Before a cytotoxic MOA can be defined, it is critical to ensure that other MOAs do not contribute significantly to hepatocarcinogenesis. For instance, it is important to ensure that DNA reactivity is not the source of the tumor findings. Furthermore, it is important to establish that there are parallel dose re-

sponses for the key events (i.e., cytotoxicity and proliferation) and tumors (not necessarily identical), as well as a specificity of the key events and the tumor response. Hepatotoxicity can be demonstrated with histopathology (necrosis versus apoptosis) with or without enzyme changes. Cell proliferation can be measured by BrdU labeling index and/or cell number and may need to be collected based on zonal distribution. Liver tumors formed as a result of sustained cytotoxicity and regenerative proliferation are considered relevant for evaluating human cancer risk. The dose-response relationship for a cytotoxic MOA is dependent on events which are nonlinear (or threshold).

## NEUROIMAGING STRATEGIES FOR APPLICATION TO NEUROTOXICOLOGY AND RISK ASSESSMENT.

W. Slikker<sup>1</sup> and T. R. Guilarte<sup>2</sup>. <sup>1</sup>Division of Neurotoxicology, NCTR/FDA, Jefferson, AR and <sup>2</sup>Department of Environmental Health Sciences, Johns Hopkins Medical Institutions, Baltimore, MD.

Recent technological innovations now make it possible to apply many *in vivo* neuroimaging technologies such as positron emission tomography (PET) and magnetic resonance imaging (MRI) to small animals, including nonhuman primates, rats and mice. The availability of these new technologies coincides with progress in developing animal models of various developmental and neurodegenerative diseases and improvements in assessment protocols for identifying deficits in animals that correlate well with human deficits. The integration of neuroimaging techniques with traditional neurotoxicological assessments has the potential to enhance greatly the ability to relate behavioral, cognitive or motor dysfunction induced by a toxicant to structural and functional brain pathology. Changes in anatomy of soft and hard tissue, metabolism and gene expression can now be done in both a preclinical and a clinical setting using such technologies as Magnetic Resonance Imaging (MRI), Magnetic Resonance Spectroscopy (MRS), Positron Emission Tomography (PET), Computer Tomography Scanning (CT scan) and Visible and Infrared Spectral Imaging. This permits longitudinal studies of the same subject subsequently reducing the number of animals required for studies while providing definitive information as a basis of risk assessment. This workshop will be of interest to toxicologists in general and in particular to neurotoxicologists and risk assessors.

**674**

## NEUROIMAGING: NEW APPROACHES FOR NEUROTOXICOLOGY.

W. Slikker. Division of Neurotoxicology, NCTR/FDA, Jefferson, AR.

Recent technological innovations now make it possible to apply many *in vivo* neuroimaging technologies such as positron emission tomography (PET) and magnetic resonance imaging (MRI) to small animals, including nonhuman primates, rats and mice. Approaches have been delineated that promise the ability to assess apoptosis and gene expression in a longitudinal and noninvasive manner. Changes in anatomy of soft and hard tissue, metabolism, function and gene expression can now be done in both a preclinical and a clinical setting using such technologies as Magnetic Resonance Imaging (MRI), Magnetic Resonance Spectroscopy (MRSI), Positron Emission Tomography (PET), Computer Tomography Scanning (CT scan) and Visible and Infrared Spectral Imaging. This type of information is not readily accessible using conventional toxicological procedures and usually requires total destruction of the intrinsic structure of the sample of interest. Imaging provides an opportunity to provide much of this data in a nondestructive manner and presents the data in a three-dimensional format. The availability of these new technologies coincides with progress in developing animal models of various developmental and neurodegenerative diseases and improvements in assessment protocols for identifying deficits in animals that correlate well with human deficits. The integration of neuroimaging techniques with traditional neurotoxicological assessments has the potential to enhance greatly the ability to relate behavioral, cognitive or motor dysfunction induced by a toxicant to structural and functional brain pathology.

## MAGNETIC RESONANCE IMAGING OF METALS IN THE BRAIN.

D. C. Dorman. CIIT Centers for Health Research, Research Triangle Park, NC.

High intensity signals in the basal ganglia on T1-weighted images are associated with increased deposition of iron, manganese, and copper at this site. There is growing interest in whether these changes in the magnetic resonance image (MRI) signal may be a useful biomarker of metal exposure. For example, the pallidal index (PI) calculated from the ratio of globus pallidus (GP) to subcortical frontal white matter signal intensity in the T1 MRI has been proposed as a biomarker of manganese exposure. To date, the PI has been used despite the paucity of data demonstrating any relationship between PI changes and brain manganese concentrations.

To address this data gap we exposed young male rhesus monkeys to manganese sulfate ( $MnSO_4$ ) at 0, 0.06, 0.3, and 1.5 mg  $Mn/m^3$  for 6 hr/day, 5 days/week, for 13 weeks. T1-weighted brain MRI studies (1.5 T) were performed on propofol anesthetized monkeys near the end of the 13-week  $MnSO_4$  inhalation. Brain manganese concentrations were determined shortly thereafter by graphite furnace atomic absorption spectrometry. Statistically significant linear relationships were found between GP manganese concentrations and T1 relaxation times and for the relationship between GP manganese concentrations and the PI. The calculation of the PI presumes that the white matter does not accumulate manganese; however, subchronic manganese exposure resulted in increased manganese concentrations in white matter tracts adjacent to the GP. These data show that T1 relaxation times and the PI are semi-quantitative biomarkers of manganese exposure and should prove useful for other paramagnetic metals as well.

## 676 MOLECULAR IMAGING OF CENTRAL NERVOUS SYSTEM BIOLOGY IN SMALL ANIMALS.

M. G. Pomper. *Department of Radiology, Pharmacology, and Molecular Sciences and Oncology, Johns Hopkins University School of Medicine, Baltimore, MD.* Sponsor: W. Slikker.

Better mechanistic understanding of disease through mapping of the human and mouse genomes enables rethinking of human infirmity. For example, we may begin to associate disease states with their underlying genetic defects rather than with the organ system involved. That will enable more selective therapies in patients who are genetically predisposed to respond to them. Molecular imaging can briefly be defined as the remote sensing of cellular and molecular phenomena *in vivo*, i.e., in laboratory animals. Because one of the major goals of molecular imaging research is to interrogate gene expression non-invasively, it can impact greatly on the development of new therapies for a number of diseases. Most of molecular imaging research is undertaken in small animals, which provide a conduit between *in vitro* studies and human clinical imaging. We are fortunate to be able to manipulate small animals genetically, and to have increasingly better models of human disease. The ability to study those animals non-invasively and quantitatively with new, high-resolution imaging devices provides the most relevant milieu in which to find and examine new therapies or to understand the biochemical basis of disease. We will discuss molecular imaging broadly, but with an emphasis on applications within the central nervous system. We will compare and contrast the available imaging modalities and will provide specific examples including translation of molecular imaging research to the clinic and the motivation behind this emerging field in imaging science.

## 677 MRS TO ASSESS DEVELOPMENTAL NEUROTOXICITY.

C. Cloak. *Manoa School of Medicine, University of Hawai'i, Honolulu, HI.* Sponsor: W. Slikker, Jr.

Drug exposure during development can have profound effects on brain development. However many women still use drugs of abuse while pregnant and many children and young adults are exposed to the first and second hand effects of drug use. Several drugs of abuse, including nicotine, cocaine, and methamphetamine, have been well studied in adult animal models and humans. With the increasing availability of brain imaging techniques, including magnetic resonance spectroscopy (MRS), the effects of these drugs on brain development are now also being studied in humans, with corresponding animal models. MRS can measure the levels of several major brain metabolites, including neuronal and glial markers, cell membrane turnover, cellular metabolism and energy, as well as some neurotransmitters. A review of MRS studies conducted in humans and animal models, *in vivo* and *ex vivo*, will be discussed, noting differences associated with type of drug exposure, age at exposure, length and dose of exposure, sex, and possible recovery after exposure to these drugs of abuse.

## 678 EARLY BIOMARKERS OF PARKINSON'S DISEASE AS DEFINED BY POSITRON EMISSION TOMOGRAPHY.

T. R. Guilarde<sup>1</sup>, M. K. Chen<sup>1</sup>, H. Kuwabara<sup>2</sup>, J. L. McGlothan<sup>1</sup>, M. Alexander<sup>2</sup>, J. R. Brasic<sup>2</sup>, R. J. Adams<sup>3</sup> and D. F. Wong<sup>1,2</sup>. <sup>1</sup>*Department Environmental Health Sciences, Johns Hopkins Un., Baltimore, MD*, <sup>2</sup>*Department Radiology, Johns Hopkins University, Baltimore, MD* and <sup>3</sup>*Department Comparative Med., Johns Hopkins University, Baltimore, MD*.

Parkinson's disease (PD) is a neurodegenerative disorder that afflicts approximately 1% of the US population. We are using a non-human primate/MPTP model of PD to assess the progression of MPTP neurotoxicity. The goal is to measure the earliest changes in brain chemistry to identify an early biomarker of disease. Dopaminergic

phenotypic markers, including dopamine transporter (DAT) and vesicular monoamine transporter type 2 (VMAT-2) are being measured using PET with [<sup>11</sup>C]-WIN 35, 428 and [<sup>11</sup>C]-dihydrotetraabenazine, respectively. We also measure peripheral benzodiazepine receptor (PBR) levels as a marker of glial cell activation using [<sup>11</sup>C]-R-PK11195 PET. Finally, since MPTP is a potent inhibitor of complex I in mitochondria, complex I is being measured using [<sup>11</sup>C]-dihydrotetraabenazine PET. Our initial findings suggest that the loss of DAT and VMAT-2 in the striatum is present prior to behavioral manifestation of Parkinsonism. Decreased complex I level and increased glial cell activation is present early but is not selective to the striatum, the brain region affected in PD. These preliminary findings indicate that DAT and VMAT-2 may be useful markers for the early detection of PD. The finding that complex I level decreases in other brain structures besides the striatum suggests that other brain regions are also affected by MPTP administration. This is supported by the finding that the same brain regions exhibiting decreased levels of complex I also express increased PBR binding. These studies demonstrate the utility of *in vivo* imaging techniques such as PET in studying the progressive effects of neurotoxicant exposure on brain chemistry. We demonstrate the ability to measure multiple neuronal and glial markers in the same animal in a prospective fashion. This allows for each animal to serve as its own control and reduces the number of animals needed to obtain meaningful data. [Supported by MJ Fox Foundation]

## 679 EARLY EXPOSURE TO TCDD IMPAIR RAT BONE TISSUE COMPOSITION AND FUNCTION.

M. P. Lind<sup>1</sup>, H. M. Miettinen<sup>2</sup>, J. Orberg<sup>3</sup>, M. Backstrom<sup>1</sup>, I. Pettersson<sup>3,1</sup>, S. Larsson<sup>4</sup> and M. Viluksela<sup>2</sup>. <sup>1</sup>*Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden*, <sup>2</sup>*Department of Environmental Health, National Public Health Institute, Kuopio, Finland*, <sup>3</sup>*Department of Environmental Toxicology, Uppsala University, Uppsala, Sweden* and <sup>4</sup>*Department of Orthopaedics, Uppsala University Hospital, Uppsala, Sweden*. Sponsor: G. Johansson.

Previously own studies in rats have shown that the dioxin TCDD and the dioxin-like PCB congener, PCB126, impair bone tissue composition and function. The purpose of this study was to investigate effects on rat bone caused by early exposure to TCDD. Pregnant dams were exposed to a single oral dose of 1  $\mu g/kg$  b.w. at gestation day 15. Control rats received the vehicle (corn oil). After weaning the pups were given either sucrose-rich diet (15% sucrose) and tap water containing 7% sucrose or normal rat powder feed and tap water. Offspring were killed at the age of 77 days. Peripheral quantitative computed tomography (pQCT) and biomechanical testing (3-point bending test) were performed on the excised tibia. Trabecular bone mineral density (BMD) was determined by metaphyseal scans of the proximal tibiae. Cortical parameters, including total and cortical bone mineral density, total and cortical cross-sectional area (CSA), were determined by diaphyseal scans. In the female rats a significant reduction of bone growth manifested as a reduced total BMD as well as total and cortical CSA were observed. The bone strength and the stiffness of the tibia were also reduced. Adding sucrose to the diet reduced the effects of TCDD. These findings were seen also after adjustment for effects on body weight. In the limited number of male offspring no significant effects were seen. In conclusion, our results show that a single oral dose of TCDD to rat dams during gestation impair bone tissue composition and function in the female offspring.

## 680 EXPRESSION OF EGFR AND ITS LIGANDS IN RESPONSE TO TCDD OR RETINOIC ACID IN EGF AND TGF $\alpha$ KO FETAL MOUSE PALATE.

B. D. Abbott<sup>1</sup>, H. Boyd<sup>2</sup>, C. Wood<sup>1</sup> and G. Held<sup>1</sup>. <sup>1</sup>*Reproto. Toxicology, Division, USEPA/ORD/NHEERL, Research Triangle Park, NC* and <sup>2</sup>*MARC Program, NCCU, Durham, NC*.

Epidermal growth factor (EGF) and transforming growth factor-alpha (TGF) are expressed in the developing palate and changes in patterns of expression are associated with cleft palate (CP) induction by retinoic acid (RA) and 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD). The incidence of CP is reduced in EGF knockout (KO) mice after exposure to TCDD or RA on gestation day (GD)12. TGF KO affected CP incidence only at high doses of TCDD or after exposure to RA on GD10. The teratogenic responses in embryos lacking EGF or TGF may be related to compensatory expression of other ligands for the EGF receptor (EGFR) in the target tissues. In the present study, EGFR, EGF, TGF, amphiregulin (AR), epiregulin (ER), heparin binding EGF (HB-EGF), and betacellulin (BTC) mRNA expression was evaluated by real time PCR. Pregnant mice were dosed with 100  $\mu g/kg$  RA or 24  $\mu g/kg$  TCDD on GD12 and total RNA was prepared from GD14 palates of wild type (WT), EGF KO, C57BL/6J, and TGF KO fetuses. Data are reported as cycle threshold for each strain, treatment and gene. EGFR and BTC expression were significantly elevated in both EGF KO and TGF KO palates. In the TGF KO the expression of EGF and HB-EGF was induced relative to levels in C57BL/6J. In response to either RA or TCDD, the WT palates had increased expression of EGF, HB-EGF and AR, compared to WT controls. In TGF KO, ex-

pression of ER was elevated by exposure to TCDD compared to control TGF KO. In EGF KO, TCDD or RA altered expression of EGFR or the ligands was not detected. In summary, the EGF and TGF KO palates show upregulation of EGFR and some of its ligands. Exposure to TCDD or RA also altered regulation of the ligands in the WT and TGF KO palates. Increased expression of EGFR and some of its ligands may represent compensation for the lack of expression of EGF and TGF in the KO and may facilitate palatogenesis in the KO. Absence of these responses in the RA and TCDD exposed EGF KO may be implicated in the reduced sensitivity for CP induction. This abstract does not necessarily reflect EPA policy.

A ROBUST EXAMINATION OF EFFECTS OF TCDD ON THE DEVELOPING MALE REPRODUCTIVE SYSTEM.

D. R. Bell<sup>1</sup>, G. Loizou<sup>2</sup>, S. White<sup>3</sup>, A. Fernandes<sup>3</sup>, M. Rose<sup>3</sup>, B. G. Miller<sup>4</sup>, L. Tran<sup>4</sup>, S. Clode<sup>5</sup>, P. M. Foster<sup>6</sup> and A. MacNicoll<sup>3</sup>. <sup>1</sup>*Biology, Nottingham, Notts, United Kingdom*, <sup>2</sup>*HSL, Sheffield, United Kingdom*, <sup>3</sup>*CSL, York, United Kingdom*, <sup>4</sup>*IOM, Edinburgh, United Kingdom*, <sup>5</sup>*Covance, Harrogate, United Kingdom* and <sup>6</sup>*NIEHS, Raleigh, NC*.

One of the most potent reported adverse effects of 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) is on the developing male reproductive system, after exposure of the embryo/ foetus via dosing of the pregnant mother. This endpoint has been used as the basis of advisory limits for exposure to TCDD by the EU and UK [1]. We set out (1) to determine the foetal dose of TCDD associated with a toxic endpoint in a concurrent experiment; (2) to clarify inconsistency in the reported literature. Timed Wistar rats were exposed to control vehicle, 50, 200 or 1000 ng TCDD /kg bwt. on GD15. Dams were killed on GD16 and 21 for determination of TCDD concentration. ~20 dams per group were allowed to litter, and 5 males per litter retained after weaning. 25 animals per group were killed for reproductive assessment on PND 70. The remaining animals (~60) were assessed on PND120. TCDD at 1000 ng/kg caused a reduction in the number of pups born, and reduced the number of pups surviving to PND14. The male offspring in this group were lighter than control at all times although their weight gain exceeded controls, and had a delayed balano-preputial separation. The testes were slightly lighter than control in this group, and the seminology at PND70 showed a transient increase in abnormal sperm. There was no significant effect on epididymal sperm number at PND 70 or 120. There was no significant effect of TCDD at PND70 or 120 at lower dose levels. The foetal concentration of TCDD was ~ 0.02, 3, 9 and 50 ng/kg tissue in the 0, 50, 200 and 1000 ng/kg groups, respectively. This experiment has greater statistical power than previous investigations of TCDD developmental reproductive toxicity. A follow-up sub-chronic study will provide more robust data as a basis for further consideration of tolerable intake levels. This work was supported by a UK Food Standards Agency contract, T01034 1.

COMPARISON OF MATRIGEL™ AND GELATIN SUBSTRATA FOR FEEDER-FREE CULTURE OF UNDIFFERENTIATED MOUSE EMBRYONIC STEM CELLS FOR TOXICITY TESTING.

A. R. Greenlee<sup>1,2</sup>, T. A. Kronenwetter-Koepel<sup>2</sup>, S. J. Kaiser<sup>2</sup> and K. Liu<sup>3</sup>. <sup>1</sup>*School of Nursing and Center for Research on Occupational and Environmental Toxicology, OHSU, La Grande, OR*, <sup>2</sup>*Marshfield Clinic Research Foundation, Marshfield, WI* and <sup>3</sup>*Department of Biostatistics, Forest Research Institute, Jersey City, NJ*.

Murine embryonic stem (mES) cells have been used to evaluate cytotoxicity and developmental injury following exposure to embryotoxic agents. However, maintaining a homogeneous population of undifferentiated mES cells for this purpose has been complicated by the need for continuous co-culture with murine embryonic fibroblast (mEF) cells or limited passaging on plastic surfaces coated with gelatin. Here, we compare the synthetic basement membrane Matrigel™ with 0.1% gelatin substratum for feeder-free propagation of undifferentiated mES cells. Biomarkers of pluripotentiality, chromosome number, caspase-3 expression, and cardiomyocyte differentiation were monitored for mES cells cultured on Matrigel™ or 0.1% gelatin up to passage 7 (P<sub>7</sub>). Our results suggest that choice of substratum had no significant effect on population doubling time, cell viability, stage-specific embryonic antigen-1 (SSEA-1) expression, or early passage formation of beating cardiomyocytes (all  $P \geq 0.09$ ). In other comparisons, however, Matrigel™ supported significantly higher synthesis of alkaline phosphatase ( $7.7 \times 10^{-3} \pm 0.8$  vs  $6.6 \times 10^{-3} \pm 0.8$  units/liter/cell, respectively,  $P=0.01$ ), overall expression of activated caspase-3 following exposure to 5, 10, 50, 100 and 500 parts per billion (ppb) sodium arsenite ( $P < 0.0001$ ), and percent development to beating cardiomyocytes at P<sub>7</sub> ( $P=0.01$ ). Together, our findings suggest that Matrigel™ shows promise as a substrate for feeder-free propagation of undifferentiated mES cells for embryotoxicity endpoints.

ALTERED TRANSCRIPTIONAL RESPONSES IN MOUSE EMBRYOS EXPOSED TO BISINDOLYLMALEIMIDE I (BIS I) IN WHOLE EMBRYO CULTURE.

E. D. Karoly<sup>1,2</sup>, J. E. Schmid<sup>2</sup>, M. R. Blanton<sup>2</sup> and E. S. Hunter III<sup>2</sup>.

<sup>1</sup>*Curriculum in Toxicology, UNC Chapel Hill, Chapel Hill, NC* and <sup>2</sup>*Reproductive Toxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC*.

Protein kinase C (PKC) comprises a large family of serine/threonine kinases which are involved in a multitude of physiological processes regulating cell proliferation and differentiation. Bisindolylmaleimide I (Bis I), a specific PKC inhibitor, was utilized in this study to examine the transcriptional responses to PKC inhibition in mouse embryos during neurulation. CD-1 mouse embryos (3 to 6 somite stage) were exposed to 10µM Bis I for 0, 1, 3 or 6h using whole embryo culture. At these times 10-15 embryonic heads were removed and pooled for total RNA isolation. Biotinylated cRNA was prepared using GeneChip one-cycle target labeling and hybridized to GeneChip Mouse Genome 430 2.0 arrays (Affymetrix, Inc., Santa Clara, CA). Two-way ANOVA identified 3, 207 genes (of 34, 000 transcripts on the array) as being differentially expressed across dose and/or time. Pathway analysis of these genes identified numerous pathways as affected by the treatment with Bis I including apoptosis, Wnt signaling and oxidative phosphorylation. Gene Ontology (GO) analysis of molecular function identified an extensive list of genes associated with binding events and catalytic activity. Cluster analysis and linear models were used to further identify the transcriptional responses in mouse embryos exposed to Bis I and their association with embryotoxicity. *This is an abstract of a proposed presentation and does not necessarily reflect EPA policy. FOLATE PREVENTION OF OXIDATIVE STRESS IN FUMONISIN-INDUCED NEURAL TUBE DEFECTS.

J. B. Gelineau-van Waes, J. Wilberding, F. Aleman, L. Bauer and J. Maddox. *Department of Genetics, Cell Biology & Anatomy, University of Nebraska Medical Center, Omaha, NE*. Sponsor: G. Bennett.

Fumonisins B1 (FB1) is a mycotoxin produced by *F. verticillioides*, a common contaminant of corn worldwide. An association between maternal FB1 exposure and increased risk for neural tube defects (NTDs) has recently been observed in human populations relying on corn as a dietary staple. FB1 disrupts sphingolipid biosynthesis by inhibiting ceramide synthase, resulting in elevated sphinganine levels, and depletion of downstream glycosphingolipids. We have previously demonstrated that early gestational exposure to FB1 results in NTDs in 80% of exposed inbred LMBC mouse fetuses. FB1 depletion of ganglioside GM1 altered plasma membrane microdomains, compromising folate uptake via the GPI-anchored folate receptor. Daily maternal folate supplementation reduced the incidence of NTDs, while replacement therapy with ganglioside GM1 restored folate uptake and rescued the phenotype. FB1 exposure has been shown to increase expression of inflammatory cytokines such as TNF $\alpha$ . Preliminary microarray data from FB1-exposed embryos indicate altered expression of sphingolipid and TNF $\alpha$  receptor superfamily genes, as well as numerous genes involved in modulating oxidative stress and nitric oxide production. Atypical expression of TNF $\alpha$  is seen in the developing neural tube following FB1 exposure, corresponding to positive TUNEL staining in the ventricular zone. The apoptotic cells also stain positive for iNOS and nitrotyrosine. Maternal folate supplementation reverses the nitrosylation, and prevents against excessive apoptosis in the neural tube. Folate is structurally similar to tetrahydrobiopterin (BH4), the endogenous co-factor for iNOS, and maternal administration of BH4 is effective in protecting against FB1-induced NTDs in our mouse model. Inadequate levels of BH4 result in uncoupling of iNOS, production of reactive oxygen species, and protein nitrosylation. Supplemental folate may functionally replace BH4 as a co-factor for iNOS in order to maintain redox homeostasis under conditions of oxidative stress.

MATERNAL IMMUNE STIMULATION REDUCES DIABETES INDUCED CRANIOFACIAL MALFORMATIONS.

S. D. Holladay<sup>1,2</sup>, T. C. Hrubec<sup>2,1</sup>, R. Prater<sup>2,1</sup> and K. Toops<sup>1</sup>. <sup>1</sup>*Veterinary Medicine, Virginia Tech, Blacksburg, VA* and <sup>2</sup>*Biomedical Sciences, College of Osteopathic Medicine, Blacksburg, VA*.

Maternal diabetes can induce a number of developmental abnormalities in offspring of both laboratory animals and humans, including facial deformities, defects in neural tube closure, and alterations in cardiac, renal, optic and auricular development. The incidence of birth defects in newborns of diabetic women is approximately 3 to 5 times higher than among non-diabetics. In mice, non specific activation of the maternal immune system can reduce fetal abnormalities caused by

diverse etiologies, including diabetes induced neural tube defects. This study was conducted to determine the effects of non-specific maternal immune stimulation on diabetes induced craniofacial defects. Maternal immune function was stimulated prior to induction of hyperglycemia by one of three methods: 1. maternal footpad injection with FCA; or 2. maternal IP injection with GM-CSF; or 3. maternal IP injection with IFNg. Streptozocin (200 mg/kg IP) was then used to induce hyperglycemia (26-35 mmol blood glucose) in female ICR mice prior to breeding. Fetuses from 10-14 litters per treatment group, (over 100 fetuses per group) were collected at day 17 of gestation. Craniofacial defects were observed in fetuses from all groups, and consisted of severe clefting of the rostral maxillary region, reduced maxillary length, altered maxillary to mandibular ratio, and agnathia. Clearing and staining of the fetal heads revealed alterations in the frontal, parietal, interparietal, nasal, maxillary and premaxillary and mandibular bones. Maternal stimulation with IFNg and GM-CSF reduced the incidence and severity of facial deformities to a greater extent than did FCA. These exciting findings set the ground work for further studies into the mechanisms involved in the prevention of diabetes induced birth defects by maternal immune stimulation. Supported by NIH K01RR16241-01A1.

ARSENIC TOXICITY: MOLECULAR AND DEVELOPMENTAL MECHANISMS IN MISCARRIAGE.

J. Coffin<sup>1</sup>, W. He<sup>2</sup>, R. J. Greenwell<sup>1</sup>, J. C. Pfau<sup>1</sup>, D. Brooks<sup>1</sup>, M. Bently<sup>3</sup>, T. J. Poole<sup>3</sup> and H. D. Beall<sup>1</sup>. <sup>1</sup>CEHS, University of Montana, Missoula, MT,

<sup>2</sup>University of Pittsburgh, Pittsburgh, PA and <sup>3</sup>SUNY Upstate Medical University, Syracuse, NY.

**Rationale:** Human arsenic (As) exposure is linked to developmental defects in the nervous system and limbs, pregnancy complications and miscarriage. The goal of this project is to define the developmental and molecular mechanisms for how As exposure causes developmental defects and miscarriage. **Hypothesis:** As exposure *in utero* causes endothelial dysfunction leading to defective vasculogenesis that results in terogenesis and miscarriage. **Aims & Methods:** 1. Determine how As exposure affects fecundity, placentation and vascular morphogenesis. Timed-pregnant mice were exposed to sodium arsenite (As III; 150, 75, 37.5, 20, 10 ppm) in their drinking water. Pregnancy rate, birth rate, litter size, and pup/embryo weight were compared to controls. Embryos and placentas were examined for vascular abnormalities. Cultured quail embryos were exposed to AsIII and analyzed for alterations in vascular development. 2. Determine how As exposure causes endothelial dysfunction. Human microvascular endothelial cells were exposed to AsIII and analyzed for alterations in cell viability (MTT assay), proliferation (BrdU assay), apoptosis (TUNEL & caspase assays) and growth factor/cytokine expression (Luminex). **Results:** AsIII exposure causes miscarriage between E7.5 and E12.5, when the placenta and embryo become vascularized. Histology shows abnormal neovascularization in the embryo and placenta. The mouse results are consistent with the quail results; where the latter show abnormal yolk sac and embryonic neovascularization. As exposure experiments in microvascular endothelial cells (HMEC) reveal a loss of viability due to enhanced apoptosis and decreased proliferation; commensurate with altered VEGF and FGF-2 expression. **Conclusions:** These data suggest that As exposure causes angioblast and endothelial dysfunction during vascular development. ELISA and histological data suggest that these effects are likely due to changes in vascular morphogens/growth factors involving the VEGF regulatory pathway.

SYNERGISTIC DEVELOPMENTAL TOXICITY OF POLYCYCLIC AROMATIC HYDROCARBONS: TOWARDS A MECHANISTIC UNDERSTANDING.

R. Di Giulio<sup>1</sup>, S. Billiard<sup>1</sup>, J. Meyer<sup>3</sup>, D. Wassenberg<sup>1</sup> and P. Hodson<sup>2</sup>. <sup>1</sup>Duke University, Durham, NC, <sup>2</sup>Queens University, Kingston, ON, Canada and <sup>3</sup>NIEHS, Research Triangle Park, NC.

Polyyclic aromatic hydrocarbons (PAHs) invariably occur in the environment as complex mixtures of non-substituted PAHs, alkyl-PAHs, and N-, S-, and O-ring substituted PAHs (such as carbazoles, thiophenes, and furans, respectively). Recent studies in our laboratories with real world mixtures derived from pollution events in marine and estuarine systems (the Exxon Valdez oil spill in AK and a wood treatment facility in the Elizabeth River, VA) revealed potent developmental toxicities in fish embryos. Developmental perturbations included head and tail deformities, and most pronounced were cardiovascular defects. Collectively these effects are consistent with the blue sac syndrome associated with embryo exposures to planar halogenated aromatic compounds, notably dioxin. These dioxin-mediated effects are associated with the binding of dioxin to the aryl hydrocarbon receptor (AHR), although mechanisms downstream of receptor binding remain unresolved. PAH mixtures include AHR agonists and we initially hypothesized that developmental effects observed were via this mechanism. However, aqueous exposures of rainbow trout embryos to a suite of PAHs with varying affinities for the AHR and potency

as CYP1A inducers failed to support a correlation between either binding or induction and toxicity. Other experiments with killifish embryos examined interactions between PAH-type AHR agonists (BNF and BaP) and a variety of CYP1A inhibitors (ANF, PBO, fluoranthene, carbazole and dibenzothiophene). In the majority of cases, we observed synergistic toxicity between AHR agonists and CYP1A inhibitors, which contrasts to the protective effect reported for CYP1A inhibition on the developmental toxicity of dioxin and PCB126. This observed synergy has important implications for accepted additive models of PAH toxicity. Current work is exploring mechanisms underlying these interactions, including alterations in PAH metabolism and gene expression, and oxidative stress.

ARSENIC TRIOXIDE INHIBITS NUCLEAR EXPRESSION OF RXR AND BINDING OF RXR-CONTAINING HETERODIMERS.

K. K. Mann, A. M. Padovani and W. H. Miller. *Lady Davis Institute for Medical Research, McGill University, Montreal, QC, Canada.*

Recently, arsenic exposure has been linked to an increased risk for atherosclerosis and diabetes as well as cancer. We have previously shown that arsenic trioxide ( $As_2O_3$ ) inhibits the transactivation of those nuclear receptors that heterodimerize with RXR and control the expression of many genes, including those involved in cholesterol metabolism (via LXR) and glucose regulation (via PPAR). Here, we confirm that several downstream targets of nuclear receptors, such as ABCA1, CYP3A4, and vitamin D3 24-hydroxylase, are also inhibited by  $As_2O_3$ .  $As_2O_3$  treatment does not alter the levels of total RXR mRNA or protein, but we find RXR is a target of  $As_2O_3$ -induced phosphorylation. Through site-directed mutagenesis,  $As_2O_3$ -induced phosphorylation of RXR was linked to inhibition of nuclear receptor transactivation. Although total RXR levels are not altered,  $As_2O_3$  treatment decreases binding to retinoid response elements in a dose- and time-dependent manner. In addition, we see an increase in the cytoplasmic expression of RXR and concomitant decrease in nuclear expression. These data suggest a mechanism by which  $As_2O_3$  exposure might lead to the development of disease and even has implications to those leukemia patients being treated with  $As_2O_3$ .

P53 MODULATES ARSENITE-INDUCED MITOTIC DISRUPTION AND ALTERED GENE EXPRESSION.

S. C. McNeely<sup>1</sup>, B. Taylor<sup>1</sup>, X. Xu<sup>1</sup>, W. Zacharias<sup>2,1</sup>, M. J. McCabe<sup>3</sup> and J. States<sup>1</sup>. <sup>1</sup>Pharmacology & Toxicology, University of Louisville, Louisville, KY,

<sup>2</sup>Medicine, University of Louisville, Louisville, KY and <sup>3</sup>Environmental Medicine, University of Rochester, Rochester, NY.

Arsenic is both a carcinogen and an efficacious chemotherapeutic for acute promyelocytic leukemia. The underlying mechanism of arsenic-induced carcinogenesis or chemotherapy is unknown. Arsenic disrupts mitosis, induces mitotic delay, and alters chromosome segregation. Our data suggest p53 status is a determinant in response to mitotic disruption by arsenic. Arsenic-treated p53 deficient cells are prone to mitotic arrest associated apoptosis (MAAA). P53 wt cells are more resistant to MAAA and survive an aberrant, aneuploidogenic mitosis. To examine how p53 status impacts mitotic entry and exit in arsenic-treated cells, we used TR9-7 cells which express p53 from a tet-off regulated vector. TR9-7 cells expressing (p53+) or not expressing (p53-) p53 were synchronized in G2 and released with or without 5  $\mu$ M NaAsO<sub>2</sub>. Arsenite delayed mitotic entry independent of p53. Arsenite-treated p53+ cells exited mitosis normally, while treated p53- cells had delayed kinetics. To test if differential gene expression altered exit kinetics, microarray analysis was performed on mRNAs from G2 synchronized p53+ and p53- cells after 0 and 3 h arsenite exposure. Heme oxygenase and metallothionein, two oxidative stress response genes, were induced independent of p53 status. Inhibitor of DNA binding 1 (ID1) was induced 6.9-fold in p53+ cells and 4.3-fold in p53- cells. Immunoblotting confirmed induction that was more extensive and sustained in p53+ cells. As a dominant negative inhibitor of transcription, ID1 represses genes involved in cell cycle arrest. ID1 is elevated in many tumors and its overexpression immortalizes primary human keratinocytes and induces abnormal centrosome numbers. ID1 induction may play a role in the survival of arsenite-treated p53+ cells and contribute to the carcinogenicity of arsenic. (Support: USPHS grants R01ES011314, R01ES06460 F30ES013372, T32ES011564, R25CA44789, P30ES01247, Brown Cancer Center)

P53 SUPPRESSION OF ARSENITE INDUCED MITOTIC ARREST IS MEDIATED BY P21.

B. Taylor<sup>1</sup>, S. C. McNeely<sup>1</sup>, H. L. Miller<sup>1</sup>, M. J. McCabe<sup>2</sup> and J. States<sup>1</sup>.

<sup>1</sup>Pharmacology & Toxicology, University of Louisville, Louisville, KY and

<sup>2</sup>Environmental Medicine, University of Rochester, Rochester, NY.

Arsenite is a chemotherapeutic for acute promyelocytic leukemia and may be efficacious in treatment of many forms of cancer depending on p53 pathway status. Therapeutic levels of NaAsO<sub>2</sub> (5  $\mu$ M) induce mitotic arrest associated apoptosis

(MAAA) in p53- cells. However, p53+ cells show delayed G2 exit and progress through M into G1. The purpose of this study was to examine the role of p53 in escaping arsenite induced mitotic arrest. TR9-7 cells expressing p53 from a tetracycline-off regulated vector were used as a model system. In this model, p21 correlated with p53 expression. Inactivation of cyclin B/CDC2 is necessary for mitotic exit and occurs by proteasomal degradation of cyclin B through anaphase promoting complex (APC) dependent ubiquitination. Arsenite treated p53- cells exhibit cyclin B stabilization and CDC2 phosphorylation on tyr15. Arsenite reduces CDC27 expression, a subunit of APC, independent of p53 expression. Remaining CDC27 becomes hyperphosphorylated, which may contribute to mitotic arrest. Wee1 and p21 activities are both p53 regulated and inhibit cyclin B/CDC2 by CDC2 tyr15 phosphorylation and direct binding, respectively. Activated p53 (ser15 phosphorylated) and p21 were induced by arsenite in p53+ cells. Arsenite induced cleavage of caspase 3 was higher and prolonged in p53- cells compared to p53+ cells. Therefore, p21 inactivation of cyclin B/CDC2 may allow mitotic exit and subsequent cell survival despite presence of stabilized cyclin B. CDC2 phosphorylation on tyr15, however, is not sufficient to allow escape from arsenite induced mitotic arrest. P21 siRNA knockdown caused p53+ cells to assume a p53- phenotype with an increase in mitotic index, cyclin B stabilization and CDC2 phosphorylation in response to arsenite treatment. We conclude that p53 mediated cyclin B/CDC2 inactivation and mitotic blockade release is not via Wee1 activation but via p21 induction and direct inhibition of CDC2. (Support: USPHS grants R01-ES011314, R01-ES06460, F30-ES013372, T32-ES011564, P30-ES01247)

### ARSENIC EXPOSURE ACCELERATES ATHEROGENIC CHANGES IN APOE-/- MICE.

J. States<sup>1</sup>, S. Srivastava<sup>3</sup>, U. Sen<sup>2</sup>, H. L. Miller<sup>1</sup> and S. E. D'Souza<sup>2</sup>.

<sup>1</sup>Pharmacology & Toxicology, University of Louisville, Louisville, KY, <sup>2</sup>Physiology & Biophysics, University of Louisville, Louisville, KY and <sup>3</sup>Medicine, University of Louisville, Louisville, KY.

Chronic arsenic ingestion causes atherosclerosis in humans. Acceleration of aortic lesion formation and alteration of vascular responsiveness in atherosclerosis prone ApoE-/- mice maintained on normal chow by fetal and post-natal arsenic exposure was examined. Mice were divided into 4 exposure groups: controls given tap water (T/T), transplacental gestational day 8-birth only exposure (A/T), 21 days post-natal to sacrifice exposure only (T/A), gestational plus post-natal exposure (A/A). Pregnant dams or weanling mice were given drinking water containing 85 mg/L NaAsO<sub>2</sub>. Fatty streak formation was examined throughout the aortic tree of mice sacrificed at age 10 weeks. Post-natal only arsenic-exposed mice displayed a 4- to 6-fold increase in lesion formation in the aortic sinus and arch compared to controls. Gestationally exposed mice showed no increase. Plasma cholesterol was unaltered by arsenic exposure suggesting that arsenic feeding exacerbates atherosclerotic lesion formation in ApoE-/- mice independent of plasma cholesterol concentration. Vasomotor function of the thoracic aorta from 10-12 week old animals was examined utilizing aortic rings to measure contractile force. Vessel contraction with either cumulative doses ( $10^{-9}$  -  $10^{-5}$  M) of phenylephrine (Phe) or buffer containing 80 mM KCl was unaltered by arsenic exposure. However, there were significant differences in the relaxation of arsenic exposed vessels induced with cumulative doses ( $10^{-9}$  -  $10^{-5}$  M) of acetylcholine following maximal contraction with  $10^{-5}$  M Phe, but not in the presence of sodium nitroprusside. Relaxation was reduced by 10-12% in T/A and A/T vessels and by 20% in A/A vessels compared with controls (T/T). These results indicate that nitric oxide availability becomes compromised in arsenic-treated vessels suggesting a likely defect in endothelial eNOS. We conclude that even brief arsenic exposures can induce atherosgenic changes in ApoE-/- mice independent of high fat diet. Supported by University of Louisville Center for Genetics and Molecular Medicine.

### EXAMINING BIOMARKERS OF EXPOSURE AND PREPARATION TECHNIQUES FOR ARSENIC QUANTITATION IN BIOLOGICAL STUDIES.

B. M. Adair<sup>1</sup>, E. E. Hudgens<sup>2</sup>, R. L. Calderon<sup>2</sup> and D. J. Thomas<sup>1</sup>.

<sup>1</sup>Experimental Toxicology Division/NHEERL, USEPA, Research Triangle Park, NC and <sup>2</sup>Human Studies Division/NHEERL, USEPA, Chapel Hill, NC.

Accurate quantitation of any contaminant of interest is critical for toxicity and metabolism studies that support risk assessment. A first step in an arsenic exposure assessment study in Nevada quantified total arsenic (TAs) concentrations in biomarkers of exposure. Participants in this IRB approved study (N=95) were at least 45 years old, had lived in the area for more than 20 years, and were exposed to a wide range of arsenic concentrations in drinking water (3 ppb to 2100 ppb). Concentrations of arsenic in drinking water were determined for each subject by graphite furnace-atomic absorption spectrometry. Concentrations of TAs in urine, blood, and toenails were determined by hydride generation-atomic fluorescence spectrometry (HGAFS); toenail TAs was also determined by neutron activation

analysis (NAA). TAs concentrations in blood, urine, and toe nail samples ranged from below HGAFS detection to 0.03 ppm, 0.76 ppm, and 12 ppm, respectively. TAs in blood rarely exceeded the limit of detection. A good correlation was found between the TAs concentration in nails and in drinking water ( $r^2=0.46$ ,  $p<0.001$ ); a poorer correlation was found between TAs concentrations in urine and drinking water ( $r^2=0.19$ ,  $p<0.001$ ). Analyses of TAs in toenails by HGAFS and NAA yielded highly concordant estimates ( $r^2=0.84$ ,  $p<0.001$ ). These results suggest that toenails are a better biomarker of exposure than urine because the sequestration of As in toenails provides an integration of exposure over time that does not occur in urine. (This abstract does not reflect USEPA policy.)

## 693

### BIOMONITORING OF A COMMUNITY FOR SOIL ARSENIC EXPOSURE.

J. S. Tsuji<sup>1</sup>, M. D. Van Kerkhove<sup>2</sup>, C. G. Scrafford<sup>3</sup> and R. S. Kaetzel<sup>1</sup>. <sup>1</sup>Exponent, Bellevue, WA, <sup>2</sup>Exponent, New York, NY and <sup>3</sup>Exponent, Washington, DC.

In response to community concerns over arsenic in soil from a pesticide manufacturing plant, a cross-sectional biomonitoring study was conducted of young children less than age 7, the age group most exposed to soil. Two first morning void samples from 77 children (47 percent of the population in this age range) were composited for analysis of total arsenic and urinary arsenic species related to ingestion of inorganic arsenic. Older ages (N=362) also participated, but were not targeted for the study. A subset of these older participants also provided toenail samples for total arsenic analysis. Soil (41 young children; soil arsenic <60 ppm), house dust (52 young children), and garden vegetable samples were collected and analyzed for arsenic. Speciated urinary arsenic levels were well below the reference level of 40  $\mu$ g/L denoting upper limit of background exposure and results for young children (GM=4.0, GSD=2.2; 0.89-17.7  $\mu$ g/L range) were similar to older participants (GM=3.8, GSD=1.9; 0.91-19.9  $\mu$ g/L range). Total arsenic levels in 26 participants exceeded the total arsenic reference level of 50  $\mu$ g/L; however, urinary species profiles indicated ingestion of dietary organic arsenic forms. Arsenic levels in all 67 toenails samples analyzed were below the reference level of 1 ppm, even though samples with higher arsenic levels showed evidence of external soil contamination. Correlations between speciated urinary arsenic levels and arsenic in soil ( $r=0.137$ ,  $p=0.39$ ) or house dust ( $r=0.049$ ,  $p=0.73$ ) were not significant for young children. Including older age groups did not change these results. Similarly, indirect indicators of soil exposure obtained from the geographic distribution of urinary levels within the community and from questionnaire responses (e.g., mouthing rates, eating garden vegetables, time spent outdoors) did not indicate increases in speciated or inorganic urinary arsenic levels due to arsenic in soil. In conclusion, no consistent evidence of increased arsenic exposure from soil was found for this community.

## 694

### CARCINOGENIC EFFECTS OF CADMIUM CHLORIDE, CISPLATIN AND NICKEL SUBSULFIDE IN METALLOTHIONEIN-I/II DOUBLE KNOCKOUT MICE.

M. Waalkes<sup>1</sup>, J. Liu<sup>1</sup>, K. Kasprzak<sup>3</sup> and B. Diwan<sup>2</sup>. <sup>1</sup>Laboratory of Comparative Carcinogenesis, NCI at NIEHS, Research Triangle Park, NC, <sup>2</sup>NCI at Frederick, Frederick, MD and <sup>3</sup>BRP, SAIC-Frederick, NCI at Frederick, Frederick, MD.

Metallothionein (MT) is a high-affinity metal binding protein thought to mitigate the toxicity of various metals. MT may detoxicate a metal by direct binding or through action as an antioxidant for metals that generate reactive oxygen species. Cadmium, cisplatin and nickel have carcinogenic potential in humans and/or animals. Exactly how MT deficiency might impact the carcinogenic effects of these metals is unknown. Thus, groups (n = 25) of male MT-II/I double knockout (MT-null) or MT wild type (WT) mice received a single treatment with cadmium (1 or 5  $\mu$ mole Cd/kg, s.c.; as CdCl<sub>2</sub>), cisplatin (5 or 10 mg/kg, i.p.), or nickel (0.5 or 1.0 mg Ni<sub>3</sub>S<sub>2</sub>/site, i.m., into both hind legs), or were left untreated (control) and observed over the next 104 weeks. There were no differences in the incidence of spontaneous tumors in MT-null and WT mice. In cisplatin-treated MT-null mice a dose-related increase in hepatocellular tumors, including carcinoma (control 0%, 5 mg/kg 16.7%, 10 mg/kg 36.4%), occurred that was not seen in WT mice. Similarly, cadmium treated MT-null mice showed a dose-related increase in hepatocellular tumors (control 8.3%, 5  $\mu$ mole/kg 20.0%, 10  $\mu$ mole/kg 33.3%) that did not occur in WT mice. Nickel-treated MT-null mice developed lung adenocarcinomas not observed in WT mice, while pulmonary tumors were induced by cisplatin in both MT-null and WT mice. Lung tumors developed after cadmium treatment in WT mice but not in MT-null mice. Harderian gland adenocarcinomas were induced by cisplatin but only in MT-null mice. Nickel induced injection site fibrosarcomas in a dose-related fashion in both WT and MT-null mice. Overall, MT-null mice appear more sensitive to the carcinogenic effects of cadmium, cisplatin, and, to a lesser extent, nickel, but only in certain tissues. Thus, poor MT production may be a predisposing factor for cadmium, cisplatin and nickel carcinogenesis, at some, but not all, target sites.

## LEAD IS A RISK FACTOR FOR OSTEOARTHRITIS: MOLECULAR MECHANISMS.

J. E. Puzas, K. Hochberg, M. Zuscik, T. Sheu, E. Schwarz, R. O'Keefe and R. Rosier. *Department of Orthopaedics, University of Rochester School of Medicine, Rochester, NY.*

Evidence in the medical literature supports the notion that lead exposure is a risk factor for osteoarthritis. The observations are: i) sustained chronic exposure leads to joint pain, ii) lead in synovial fluid from bullet fragments induces a marked degeneration of the articular surface and iii) animal studies have documented that it is, in fact, the lead rather than other heavy metals or a mechanical impingement that causes the arthritis. Articular chondrocytes maintain a phenotype that allows for preservation of a normal matrix. A key regulator of the chondrocyte phenotype is TGFbeta. Interruption of TGFbeta signaling induces chondrocyte cloning, hypertrophy, mineralization and apoptosis. This change in cell behavior progresses to an arthritic pathology. Our data indicate that lead blocks the TGFbeta pathway in articular chondrocytes by blocking Smad phosphorylation and by up regulating Smurf levels. These effects cause a chronic but progressive degradation of the articular matrix. Methods Isolated articular chondrocytes were exposed to lead over a range of concentrations. TGFbeta signaling was measured by monitoring Smad activity with a specific reporter construct. Phosphorylated Smad and Smurf levels were measured with Western blots and RT-PCR. The knee joints of mice exposed to lead (blood level: 40 ug/dl, 12 weeks) were histologically evaluated for arthritic changes. Results: Lead significantly depressed TGFbeta signaling in articular chondrocytes at concentrations as low as 0.1  $\mu$ M. Phospho Smad levels were also markedly depressed. This effect was mediated by a reduction Smad kinase activity and an increase in Smurf function. The incidence of arthritic changes in untreated mice was 6%. The incidence in lead-treated mice was 40%. Discussion Our data provide evidence that the pathological features of osteoarthritis can be evoked in articular chondrocytes and animals by lead exposure. Isolated cells, when treated with low levels of lead are inhibited in TGFbeta signaling leading to osteoarthritis in an animal model.

## DISSOLUTION RATES OF NANOPARTICULATE METALLIC SPECIES IN ARTIFICIAL HUMAN SWEAT UNDER PHYSIOLOGICALLY RELEVANT CONDITIONS.

N. J. Szabo, S. C. Wasdo, G. Brubaker, C. M. Jenkins and S. M. Roberts. *University of Florida, Gainesville, FL.*

The ability of nano-sized Al particles to improve the efficiency and power of combustion reactions when mixed with propellants and explosives has generated substantial interest and research over the past decade. As a result, a greater amount of nano-sized Al is being manufactured and the potential for human exposure to this material is increasing. One potentially significant route of exposure is dermal absorption. Given the extremely high surface area, nano-sized Al particles have the potential to dissolve in aqueous solution at a higher rate and produce greater numbers of Al ions on the skin surface than is generated by larger Al objects. As an initial investigation, dissolution rates of 150-nm and 20- $\mu$ m Al particles in artificial human sweat solutions were compared at biologically relevant temperature and pH levels. 1 mM suspensions were prepared in artificial human sweat adjusted to pHs 2.1, 4.5, and 6.9. The suspensions were placed in a 37°C water bath and agitated for 72 h. Sample aliquots were removed at 0, 3, 6, 12, 24, 48 and 72 h, filtered through a 0.02  $\mu$ m syringe filter and analyzed by ICP-AE. Additional materials, including MnO<sub>2</sub>, MoO<sub>3</sub> and SnO<sub>2</sub>, were also studied. For each material tested, dissolution rate was dramatically affected by pH, with rates in the pH 2.1 sweat solution more than ten times greater than dissolution rates in the pH 6.9 sweat. For workers exposed to powdered metals, dissolved species may prove to be a significant source of exposure.

## GENETIC TOXICOLOGY TESTING IN HTS.

R. M. Walmsley<sup>1,2</sup>, P. Cahill<sup>2</sup>, A. Knight<sup>2</sup> and N. Billinton<sup>2</sup>. <sup>1</sup>*Biomolecular Sciences, UMIST, Manchester, England, United Kingdom* and <sup>2</sup>*Product Development, Gentronix Ltd, Manchester, United Kingdom.* Sponsor: S. Dean.

Many analytical tests have been reduced to simple high throughput screening assays. The battery of regulatory genetic toxicology tests do not lend themselves to HTS since they are not readily automated and require too much compound. There are some bacterial screening tests with good Ames prediction, but they lack key eukaryotic targets for known genetic toxins. More recently a validated yeast test has been introduced which like the bacterial tests is suitable for screening large number of compounds, but also provides chromatin and key enzyme targets (polymerases, topoisomerases etc). We reviewed data from both the battery of regulatory genetic toxicity tests, and the bacterial and yeast screening tests, published in the peer-reviewed literature and Internationally recognised databases. The data were used to compare the effectiveness of prediction of rodent carcinogenicity for the screening

and analytical tests, as well as an estimate of the effectiveness of the screening tests in predicting a positive result in the regulatory battery. In a previous study of 102 compounds (SOT2004: Kitching et al) a combination of bacterial and yeast tests was shown to predict 80% of rodent cancer data, and a similar figure was found in the same dataset for cancer prediction by the regulatory test battery. This wider study will include data from more than 250 compounds. Our principal conclusion from these data is that the tools now available for genotoxicity screening are now sufficiently well established to allow their routine use in both pharmaceutical screening and environmental testing. For the former, the data will be of real value in candidate choice (hits-to-leads) as well as lead optimisation programmes. For the latter, far more sampling should be possible so that full analytical resources need only be used where hazards are present.

## AMES II AND DEREK VERSUS THE STANDARD AMES PROTOCOL: A COMPARATIVE STUDY.

C. Andreas, K. Braun, I. Stammberger, H. Spirk and A. Amberg. *Sanofi-Aventis, Hattersheim, Germany.* Sponsor: M. Bonnefoi.

The Ames II Assay is used as screening tool in early drug development due to the low amount of compound (5 mg) that is needed, the high throughput and its described overall predictivity for the Standard Ames Test. The purpose of this study was to compare the results of the Ames II Assay using 16 compounds representing 9 different DEREK alerts with results published for the Standard Ames Test. As the predictivity is not supposed to be 100 %, the study was performed to identify compound classes resulting in lower concordance between Ames II and the Standard Ames. In addition, the predictivity of DEREK for the outcome of the Ames II assay should be investigated. It could be demonstrated that 12 out of 16 compounds of different structural classes showed congruent results between the Ames II and standard Ames. 3 compounds were found to be negative in the Ames, but positive in the standard Ames (5-Amino-4-imidazolcarboxamide, N, N-Dimethylnitrosamine and Glutaraldehyde). All these compounds were detected in the standard protocol in the strains detecting base pair substitutions. One of the compounds (N-Hydroxymethylacrylamide) was found to be positive in the Ames II but not in the Standard Ames. We identified three classes of compounds for which further investigations should be conducted to improve the predictivity of the Ames II. In conjunction with DEREK analysis it seems to be possible to provide differentiated alerts for a mutagenic potential of a drug candidate.

## STUDY IN VITRO OF THE TUMORIGENIC ACTION OF ACRYLAMIDE ON THYROID CELLS.

J. DUMONT<sup>1</sup>, J. Van Sande<sup>1</sup>, C. Massart<sup>1</sup>, M. Friedman<sup>2</sup> and V. CHICO-GALDEZ<sup>1</sup>. <sup>1</sup>*I.R.I.B.H.M., ULB, Brussels, Belgium* and <sup>2</sup>*Free Consultant, Orlando, FL.*

The main consequence of chronic administration of acrylamide to rats is the generation of thyroid tumors. There is no a priori reason for this relative specificity. The present work aimed at explaining the mechanism of the acrylamide effect. FRTL5 and PCC13 rat thyroid cell lines were used as model systems and primary human thyroid cell cultures for validation. As TSH acting through cyclic AMP is the main physiological growth control agent acting on the thyroid, the first hypothesis tested and rejected was that acrylamide could stimulate cAMP accumulation in these cells. The thyroid cell is one of the most active in the generation of H<sub>2</sub>O<sub>2</sub> which could act as growth or mutagenic signal. The second hypothesis rejected was that acrylamide would stimulate H<sub>2</sub>O<sub>2</sub> generation. A third hypothesis was that tumorigenesis resulted as in the case of chronic TSH or oncogenic stimulation: acrylamide would act as a mitogenic stimulant, by whatever mechanism, on these cells. As evaluated by FACS counting of cells having incorporated bromodeoxyuridine in their DNA, no such stimulation was observed *in vitro*. A fourth hypothesis was that acrylamide could induce DNA damage and consequently mutations in thyroid cells. To test this hypothesis cells were treated with acrylamide and DNA damage tested by the comet assay after permeabilization and chromatin dissociation. H<sub>2</sub>O<sub>2</sub> was used as positive control. Acrylamide at rather low concentrations (1 microg/ml) and after a relatively short time (one hour) indeed induced comet generation. This is not due to the induction of DNA double strand breaks as H<sub>2</sub>Ax phosphorylation, as evaluated by immunohistochemistry and Western blotting was negative. Thus, at this stage, the only effect of acrylamide discovered that could account for the generation of thyroid tumors is a DNA damage leading to mutagenesis.

## UNEXPECTED CLASTOGENICITY OF SOME PHARMACEUTICALS IS DUE TO DNA INTERCALATION.

R. D. Snyder<sup>1</sup>, G. B. Zairov<sup>1</sup> and L. B. Hendry<sup>2</sup>. <sup>1</sup>*Investigative and Molecular Toxicology, Schering-Plough, Lafayette, NJ, <sup>2</sup>Schering-Plough, Lafayette, NJ and <sup>3</sup>Accelerated Pharmaceuticals, Augusta, GA.*

Rigorous genotoxicity testing of pharmaceuticals is mandated prior to FDA approval. Early pre-development genotoxicity screening prior to regulatory GLP genotoxicity testing is generally adequate to provide an indication of any complica-

tions that might be encountered in these later studies. Occasionally, however, positive responses are seen in the mouse lymphoma assay (MLA) and/or the *in vitro* chromosome aberration assay that were not predicted by early studies or by standard computational analysis of structural alerts (e.g., MCASE or DEREK) for clastogenicity. A previously published evaluation of marketed pharmaceuticals revealed nearly 70 such examples. Our previous studies have suggested that non-covalent drug/DNA interactions, notably DNA intercalation, may account for some of these unexpected positive results. In the present study, we investigate 30 commercially available pharmaceuticals previously shown to be clastogenic despite not being alerting for DNA intercalation ability in the cell-based V79 bleomycin amplification assay as well as by computational 3-D DNA docking studies. It is demonstrated that many, but not all, of these drugs appear to have intercalative activity which could explain their clastogenicity. These results are discussed with respect to mechanism of genotoxicity and the value of early predictivity of non-covalent DNA interactions.

## 701

### PHOSPHOTRIESTER ALKYLATION OF DNA BY MNU AND MMS.

L. H. Pottenger, F. Zhang, M. J. Bartels, M. R. Schisler and B. B. Gollapudi. *Toxicology and Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.*

Recent *in vitro* data from our laboratory have shown that N-methyl-N-nitrosourea (MNU) and methyl methanesulfonate (MMS) yield different alkylation profiles for model proteins, although their alkylation patterns for nucleosides are similar. Alkylation of DNA bases by mutagenic/carcinogenic chemicals has been investigated for many years, however, much less information is available on alkylation of the deoxyribose-phosphate backbone of DNA, and the subsequent formation, biological fate, and significance of these phosphotriester (PTE) adducts. A new analytical methodology to quantify PTE adducts, using liquid chromatography/electrospray ionization tandem mass spectrometry (LC/ESI-MS/MS) was developed and applied to compare the formation of alkylated bases and PTE adducts in DNA. MNU and MMS were incubated with DNA from salmon sperm and calf thymus. The alkylated DNA samples were enzyme-digested to release nucleosides or dinucleotides, depending on the alkylation (phosphotriesters are resistant to nuclease P1). Samples were analyzed by LC/ESI-MS/MS. Results demonstrated that 24 hr treatment of calf thymus DNA with 10 mM MNU or MMS yielded different profiles *vis-à-vis* both base alkylation and PTE adduct formation. MNU treatment resulted in higher levels of methyl-deoxyguanosine adducts than MMS, while methyl-deoxyadenosine was higher following MMS treatment. Salmon sperm DNA treatment also resulted in similar, chemical-specific alkylation patterns. Both alkylating agents caused formation of PTE adducts, however MNU treatment resulted in an order of magnitude higher levels of the PTE alkylated dinucleotide Tp(Me)T than MMS. Preliminary data from cell cultures indicates that PTE adducts are also present following 4 hr exposures to MNU (treatment concentration range: 2-200  $\mu$ M). In light of their different biological effects, where MNU is considered a 'super mutagen' and MMS a 'super clastogen', this difference in formation of PTE adducts may play a role in the mechanism of mutagenicity/carcinogenicity of these alkylating agents.

### RECOGNITION AND REPAIR OF BUTADIENE EPOXIDE DNA ADDUCTS: INVOLVEMENT OF NUCLEOTIDE EXCISION REPAIR.

J. Wickliffe<sup>1</sup>, O. Masters<sup>2</sup>, S. Herring<sup>1</sup>, M. Ammenheuser<sup>1</sup>, L. Galbert<sup>1</sup>, J. Xie<sup>1</sup>, R. S. Lloyd<sup>3</sup> and J. Ward<sup>1</sup>. <sup>1</sup>*University of Texas Medical Branch, Galveston, TX*, <sup>2</sup>*University of Oklahoma, Norman, OK* and <sup>3</sup>*Oregon Health and Science University, Portland, OR*.

Reactive epoxides, butadiene monoepoxide (BDO) and diepoxide (BDO2), are formed during the biotransformation of 1, 3-butadiene (BD). Both can react with DNA to form potentially mutagenic adducts. Mutations resulting from exposure to BD include single to multinucleotide deletions and point mutations (A/T?T/A transversions, A/T?G/C transitions). We examined the role that nucleotide excision repair (NER) has in recognizing and repairing BD-DNA adducts. Transgenic mice deficient in NER with a targeted knockout of the Xpc gene were exposed to BDO (300 mg/kg) and BDO2 (45 mg/kg) by intraperitoneal injection. Mice exposed to benzo-a-pyrene (BaP, 150 mg/kg) or cisplatin (6 mg/kg) were used as positive NER controls. Mutation induction was measured using the Hprt gene mutation assay. BaP significantly increased the frequency of Hprt mutations in Xpc knockout mice in support of the critical role this enzyme has in repairing bulky DNA adducts. The dose of cisplatin we chose proved to be acutely toxic to both Xpc proficient and deficient mice. BDO significantly increased the frequency of Hprt mutations as a function of Xpc status. In contrast, BDO2 did not increase the frequency of Hprt mutations. This apparent paradox may be explained by a reduced biologically effective dose reaching the target tissue (i.e. lymphocytes) because of the high reactivity

of the injected BDO2. We conclude that NER plays a role in recognizing and repair BD-induced DNA adducts. DNA sequence analysis of induced Hprt mutants as well as investigating other DNA repair pathways will elucidate the type(s) of mutations repaired by NER. Investigating BD-induced mutagenesis in additional mouse models of DNA repair deficiency will aid in understanding if other repair pathways are involved in repairing BD-induced DNA damage.

## 703

### BENZO[A]PYRENE-DNA ADDUCTS DERIVED FROM DIOL-EPOXIDE AND QUINONE PATHWAYS.

Q. Ruan<sup>1</sup>, Q. Dai<sup>2</sup>, H. Kim<sup>1</sup>, R. G. Harvey<sup>2</sup>, T. M. Penning<sup>1</sup> and I. A. Blair<sup>1</sup>.

<sup>1</sup>*Department of Pharmacology, University of Pennsylvania, Philadelphia, PA* and <sup>2</sup>*Ben May Institute for Cancer Research, University of Chicago, Chicago, IL*. Sponsor: S. Burchiel.

Benzo[a]Pyrene (BaP), a well-known representative of polycyclic aromatic hydrocarbons (PAH), can be activated by cytochromes P450s (CYPs) and epoxide hydrolase to the dihydrodiol metabolite 7, 8-dihydroxy benzo[a]pyrene (BaP-D). BaP-D can be further metabolized by CYPs to 7, 8-dihydroxy-9, 10-epoxy-benzo[a]pyrene (BaP-DPE), which can covalently bind to DNA and form stable adducts. [<sup>15</sup>N] stable isotope-labeled (+/-)-anti-BaPDE- $N^6$ -dAdo and  $N^2$ -dGuo adduct standards were synthesized. Reverse phase HPLC method was developed for fast separation of all the adduct stereoisomers. The stereochemistry of these stereoisomers was determined by a combination of LC/MS, UV, and CD spectroscopy. (+/-)-anti-BaPDE was reacted with single-stranded and double-stranded calf thymus DNA *in vitro*. After successive enzyme digestion, the fully hydrolyzed adducts were analyzed by LC/MS/MS. The relative abundance of each adduct stereoisomer in the BaP-DPE-DNA reaction was quantified by using the isotope adduct standards. In both single-stranded and double-stranded DNA reaction, the tendency of BaP-DPE- $N^6$ -dGuo adduct formation is stronger than that of BaP-D- $N^6$ -dAdo adducts. (+)-trans-BaPDE- $N^6$ -dGuo, (-)-trans-BaPDE- $N^6$ -dGuo and (+)-cis-BaPDE- $N^6$ -dAdo are the major adduct stereoisomers. BaP-D can also be metabolized by aldo-ketose (AKR) to the corresponding quinone (BaP-7, 8-dione or BaPQ) in the quinone pathway. The adducts formed from the reaction of BaPQ and mononucleosides or DNA were studied by developed LC/MS/MS methods. The yield of adducts derived from diol-epoxide pathway and quinone pathway was compared. (Supported by NIH grant PO1 CA92537)

### SIGNALING PATHWAYS FOR DNA DAMAGE AND REPAIR, APOPTOSIS AND LYMPHOID PROGENITOR CELL SURVIVAL ARE DYSREGULATED BY N-ACETYL-L-CYSTEINE.

J. E. French<sup>1</sup>, K. R. Martin<sup>2</sup>, F. W. Kari<sup>1</sup> and J. C. Barrett<sup>3</sup>. <sup>1</sup>*Laboratory of Molecular Toxicology, NIEHS, NIH, Research Triangle Park, NC*, <sup>2</sup>*Nutrition and Cancer Laboratory, Pennsylvania State University, University Park, PA* and <sup>3</sup>*Laboratory of Biosystems and Cancer, NCI, Bethesda, MD*.

Radiation induced free radicals induce DNA breaks and apoptosis of hematopoietic progenitor cells. N-acetyl-L-cysteine (NAC) scavenges free radicals and modulates free radical mediated signal transduction pathways. Thus, NAC may alter radiation induced DNA damage and repair. We have observed an increase in lymphoid tumors in 0-6 Gy gamma-irradiated wildtype and p53 haploinsufficient mice. The prevalence of lymphoma and loss of heterozygosity was increased by NAC in the diet. Specifically, an increase in the loss of the p53 wildtype allele was observed when NAC was added to the diet. To investigate, we irradiated mice after acclimation to a basal or basal plus 3% NAC diet. Three hours post-irradiation, mice were killed by CO<sub>2</sub> narcosis and bone marrow cells were removed and cultured or RNA isolation for gene expression analysis. Altered patterns of mRNA expression were observed in pathways that showed NAC suppression of Rb and NF- $\kappa$ B while inducing the transcription factor E2F1, Trp53 dependent Gadd45, Bax and Mdm2, but not p53. Bad, Bcl-w and caspases, but not Bax, Bcl-2, or Trail, expression was increased by NAC. Although the total number of cells/femur and total myeloid colony forming units (CFU)/femur were not significantly reduced, pre-B and pre-T CFU survival were greatly reduced. We speculate that high levels of intracellular NAC alters signaling pathways in pre-B and pre-T cells alters survival in radiation induced DNA damaged progenitor CFU in the bone marrow permitting selection and clonal amplification of pre-malignant lymphoid cells.

## 705

### PREVENTION OF ARSENIC CO-CARCINOGENESIS BY SELENIUM COMPOUNDS.

T. G. Rossman, A. N. Uddin and F. J. Burns. *Environment Med., New York University School of Medicine, Tuxedo, NY*.

Epidemiological studies show that inorganic arsenic (arsenite, arsenate) in drinking water increases skin, lung, bladder, and possibly other cancer risk in humans, but arsenite alone does not cause skin cancer in animals. Since arsenite is comutagenic and inhibits DNA repair, we hypothesized that arsenite is a cocarcinogen requiring a carcinogenic partner. This concept was tested in hairless mice. Mice given a suberythemic dose of solar UV (3 times a week) and 1.25-5 mg/l sodium arsenite in

drinking water for 26 weeks had a dose-related increase in skin cancers compared with mice given solar UV alone. The maximum cocarcinogenic effect occurred at 5 mg/l arsenite. Tumors arising in mice given UV arsenite appeared earlier and were larger and more invasive than those in mice given UV alone. Thus, arsenite may be able to partner with UV or other genotoxic insults to increase various cancers in humans. Selenium deficiency maybe one such insult. It has been suggested that in some parts of the world with high arsenic in the drinking water, the low Se levels in soil may exacerbate the arsenic toxicity and carcinogenicity. In HOS cells, organoselenium compounds blocked both spontaneous and arsenite-induced delayed mutagenesis. In the hairless mouse, the synthetic selenium compound p-XSC prevented the arsenite enhancement of solar UV-induced skin cancer, but had a much smaller effect on UV-induced skin cancer. Selenium is reported to counteract some of the effects of arsenic *in vivo* and *in vitro*. We suggest that the antimutagenic effects of selenium may occur via the antioxidant action of selenoproteins. The anticarcinogenic effect may have additional mechanisms that are specific to arsenic-selenium interactions, such as stimulation by selenium of arsenic excretion or other affects on arsenic metabolism.

CELLULAR DISTRIBUTION OF SELECTIVE AGE DEPENDENT TESTICULAR CYTOCHROME P450-DEPENDENT ALKOXYRESORUFIN O-DEALKYLATION IN SPRAGUE-DAWLEY RATS.

J. E. Seng<sup>1</sup>, J. Gandy<sup>2</sup>, R. Ansari<sup>2</sup> and J. Leakey<sup>3</sup>. <sup>1</sup>Charles River Laboratories, Discovery and Developmental Services, Redfield, AR, <sup>2</sup>Department of Pharmacology & Toxicology, University of Arkansas Medical Sciences, Little Rock, AR and <sup>3</sup>National Center for Toxicological Research, Jefferson, AR.

This study examines the cellular localization and the constitutive cytochrome P450 (CYP) isoforms, which may play a role in 7-ethoxresorufin or 7-benzylxyresorufin O-dealkylase (EROD or BROD) activities in rat testes. In the absence of Leydig cells, neither EROD nor BROD activities are detectable in the testes, whereas enriched Leydig cells have a 4 to 5-fold increase in activities when compared to whole testes. Hepatic EROD and BROD activities in rodents have been associated with CYP1A1 and CYP1A2, but these isoforms were not immunochemically detectable in testicular microsomes. However, significant levels of CYP1B1 immunoactive protein was detectable. CYP1B1 mRNA was isolated from rat testes and expressed in human lymphoblastoid cells. The CYP1B1 recombinant cells expressed both BROD and EROD activity in relative amounts to testicular microsomes from young sexually-mature rats (approximately 3-fold more BROD than EROD). Preparations of recombinant cells expressing CYP2A1 were obtained commercially and found to express EROD, but not BROD activity. Testes from older rats expressed significant levels of CYP2A1 in addition to CYP1B1 and also expressed more EROD activity relative to BROD. CYP2A1 and CYP1B1 were the major CYP isoforms expressed in sexually mature Sprague-Dawley rat testes and appear to be responsible for the observed testicular alkoxyresorufin O-dealkylase activities. Knowledge of which CYP isoforms are expressed in testes from animal strains used in reproductive toxicology testing, in comparison to those expressed in human testes, is important for the evaluation of human risk to developmental toxicants, particularly those requiring metabolic activation.

**707**

ORAL ADMINISTRATION OF EGCG IS NON-TOXIC AND MODULATES CYP19 AND CYP2E1 IN THE FEMALE BALB/C MOUSE.

M. J. Scandlyn, M. G. Goodin and R. J. Rosengren. *Pharmacology & Toxicology, University of Otago, Dunedin, New Zealand.*

Epigallocatechin gallate (EGCG) is a polyphenolic catechin that exhibits anti-carcinogenic properties in a variety of *in vitro* and *in vivo* cancer models. The exact mechanism responsible for the biological effect produced by EGCG has not been conclusively proven. We have previously postulated that changes in the metabolism of estradiol may be an important component of the action of EGCG as an inhibitor of breast cancer. In previous studies we demonstrated that EGCG modulates various CYP450 isoforms in the female mouse. However, EGCG (50 mg/kg, ip) also induced significant mortality and hepatotoxicity. Therefore, we have examined the ability of EGCG to modulate CYP450 isoforms and elicit hepatotoxicity following oral administration. Female BALB/c mice were administered EGCG (25 and 50 mg/kg) or saline (8 ml/kg) by oral gavage for 7 days. Ovarian and hepatic microsomes were prepared on day 8. Aromatase activity was determined in ovarian microsomes, while CYP3A, CYP1A and CYP2E1 catalytic activity and polypeptide levels were determined in hepatic microsomes. Hepatotoxicity was assessed by plasma ALT activity. The results demonstrated that EGCG was well tolerated by the mice as all mice survived the treatment regimen and there was no significant change in body weight, organ weight or hepatotoxicity elicited by EGCG. However, ovarian aromatase (CYP19) activity was decreased 31 and 46%, following 25 and 50 mg/kg of EGCG (CYP19 catalytic activity of 15 ± 2, 10 ± 1 and 8 ± 1 pmol/mg/h for saline, 25 mg/kg and 50 mg/kg EGCG, respectively. Additionally CYP2E1 catalytic activity and polypeptide levels were increased 2-fold following 50 mg/kg of EGCG (0.45 ± 0.05 and 0.91 ± 0.06 nmol/mg/min, for saline and 50

mg/kg of EGCG, respectively). However, no relevant changes in either CYP3A or CYP1A activity occurred. The results demonstrate that when EGCG is administered orally inhibition of aromatase is retained and importantly its lethality and hepatotoxic properties are lost. Therefore, EGCG when administered orally may have a future use as a non-toxic aromatase inhibitor.

MAJOR DETERMINANTS IN SEX DIFFERENCE ON DAILY RHYTHM OF HEPATIC P450 MONOOXYGENASE ACTIVITIES IN RATS.

J. Hirao<sup>1</sup>, S. Arakawa<sup>1</sup>, M. Nishimura<sup>2</sup>, N. Niino<sup>1</sup>, K. Ito<sup>1</sup>, N. Kiyosawa<sup>1</sup>, K. Muramatsu<sup>1</sup> and T. Furukawa<sup>1</sup>. <sup>1</sup>Medicinal Safety Research Laboratories, SANKYO CO., LTD., Fukuroi, Shizuoka, Japan and <sup>2</sup>Biomedical Research Laboratories, SANKYO CO., LTD., Shinagawa, Tokyo, Japan. Sponsor: N. Matsunuma.

There is a sex difference in the daily rhythm of the hepatic cytochromes P450 (CYP) monooxygenase activities in rats. Briefly, the activities of CYP enzymes assessed by measurement of 7-alkoxycoumarin O-dealkylase (ACD) showed obvious daily fluctuations with high values during the dark period in males but not in females. Here we examined what kinds of CYP isoforms were greatly involved in the sex difference. Using an Affymetrix GeneChip system, Fourier transform was applied to analyze the daily fluctuation for each CYP probe. According to the results, many CYP probes showed obvious daily fluctuations with high values during the dark period in males but not in females. In particular, probes for CYP2B2, CYP2B15, CYP2D18 and especially CYP2E1 were extracted as the periodic probes specific to males. Moreover, the Western blot analysis for CYP2E1 was conducted to confirm the protein expression level. Consequently, the protein expression level of CYP2E1 at ZT18 was approximately 1.6 times as high as that at ZT6 in males. In contrast, there were no differences detected between at ZT6 and at ZT18 in females. Indeed, the CYP2E1 activity during the dark period was significantly higher than that during the light period in males. These results indicate that CYP2B2, CYP2B15, CYP2D18, and especially CYP2E1 might be the major determinants in the sex difference on the daily rhythm of hepatic ACD activities in rats.

**709**

INTERINDIVIDUAL VARIATION OF EXPRESSION LEVEL OF CYP3A4 AND ITS RELATED PHARMACOGENETIC GENES IN JAPANESE LIVER TISSUE.

A. Miyajima-Tabata<sup>1</sup>, S. Ozawa<sup>1</sup>, J. He<sup>1</sup>, H. Tanaka<sup>2</sup>, K. Nakai<sup>2</sup>, M. Sunouchi<sup>1</sup>, Y. Kamikawa<sup>3</sup>, K. Kubota<sup>4</sup>, H. Ogata<sup>2</sup> and Y. Ohno<sup>1</sup>. <sup>1</sup>Division of Pharmacology, National Institute of Health Sciences, Setagaya, Tokyo, Japan, <sup>2</sup>Department of Biopharmaceutics, Meiji Pharmaceutical University, Kiyose, Tokyo, Japan, <sup>3</sup>Department of Pharmacology, Dokkyo University School of Medicine, Mibu, Tochigi, Japan and <sup>4</sup>Second Department of Surgery, Dokkyo University School of Medicine, Mibu, Tochigi, Japan. Sponsor: M. Ema.

The CYP3A4 expression level analysis in Japanese liver mRNA was performed by the real-time reverse-transcription polymerase chain reaction method (RT-PCR) with TaqMan probe. The liver tissues were obtained from patients at Dokkyo University School of Medicine and Health Science Research Resources Bank (HSRRB) Japan after getting written informed consents. The interindividual variations of CYP3A4-related drug metabolizing enzyme, transporter, nuclear receptor and transcription factor genes were analyzed. The microsomal fractions were prepared from the same liver tissues and the protein levels of CYP3A4 and 3A5 were also investigated by Western blotting analysis. The expression level variation of CYP3A4 mRNA in 24 Japanese liver sample was correlated with CYP3A43, 2B6, 2C9, MRP2, OATP2, PXR and CAR mRNA ( $p < 0.0001$ ). As the result of the nuclear receptor mRNA, the level of PXR was correlated with CYP3A4, 3A43, 2B6, 2C9, MRP2, OATP2 and CAR and the level of CAR was correlated with CYP3A4, 3A43, 2B6, 2C9, PXR and HNF4A. The transcription factor HNF4A mRNA level was correlated with CYP2B6, 2C9 and CAR. The CYP3A5 levels of both mRNA and protein showed clear bimodal distribution: high and low expression groups. This expression level corresponds to the CYP3A5 allele frequency. These results showed that the expression level of CYP3A4 mRNA was correlated with not only the nuclear receptors but also the various drug metabolizing enzyme and transporter genes. The accumulated data on CYP3A4 expression might explain the difference of interindividual variation in the Japanese population.

**710**

USE OF NOVEL MULTIPLEXED QPCR ASSAYS TO ACCURATELY QUANTIFY HUMAN CYTOCHROME P450 EXPRESSION.

R. D. Larsen<sup>1</sup>, C. Chang<sup>1</sup>, M. Tan<sup>1</sup>, C. Patten<sup>2</sup> and S. Parikh<sup>2</sup>. <sup>1</sup>BD Biosciences Clontech, Palo Alto, CA and <sup>2</sup>BD Biosciences Discovery Labware, Billerica, MA. Sponsor: D. Stresser.

A novel real-time qPCR system based on the activity of a DNAzyme (a catalytically active DNA sequence) was used for the quantification of three human cytochrome P450 transcripts including CYP1A2, CYP2B6, and CYP3A4. Quantifying a cy-

tochrome P450 target, a housekeeping gene, and a spiked synthetic target simultaneously in one triplex reaction generates more accurate and reproducible data than when each gene-specific assay is run separately. Use of triplex qPCR assays allows for accurate quantification of P450 expression that is both normalized to housekeeping gene expression and monitored for overall PCR efficiency via inclusion of a synthetic template in the assay. Additionally, use of a multiplex qPCR approach reduces experimental variation due to liquid handling errors, increases sample throughput, and conserves valuable experimental samples. Cytochrome P450 expression profiles were determined for induced and non-induced human primary hepatocytes. Rifampicin (RIF),  $\beta$ -naphthoflavone ( $\beta$ -NF), and phenobarbital (PB) were used as chemical inducers in a 72 hr induction study. There was a strong correlation between the level of induction of P450 CYP1A2, CYP2B6, and CYP3A4 as measured by traditional enzyme assays and real-time quantitative PCR. Likewise, in a RIF induction time course study there was a marked correlation between the level of induction of P450 CYP3A4 at each time point as measured by traditional enzyme assays and the quantitative PCR triplex assay. Triplex qPCR assays provide a robust, rapid, accurate, and reproducible method to measure the induction of cytochrome P450 expression in treated human primary hepatocytes.

## 711 USING P450-GLO<sup>TM</sup> LUMINESCENT ASSAYS TO SCREEN FOR XENOBIOTIC EFFECTS ON CYTOCHROMES P450.

J. Cali<sup>1</sup>, D. Liu<sup>1</sup>, R. Bulliet<sup>1</sup> and D. Ma<sup>1</sup>. <sup>1</sup>Promega Corp, Madison, WI and R&D, Promega Biosciences, Sac Louis Obispo, CA.

P450-Glo<sup>TM</sup> luminescence-based assays were used to characterize CYP450 enzyme inhibition, positive cooperativity and gene induction by xenobiotics. Inhibition and positive cooperativity were studied in recombinant CYP450 fractions and liver microsomes where the method was validated by testing compounds previously known to influence CYP450 activity. CYP450 gene regulation was studied in cultured rat and human hepatocytes where CYP450-Glo<sup>TM</sup> was used to measure changes in CYP450 enzyme activity as an end-point of gene expression. PXR, GR, AHR and PPAR $\alpha$ -dependent CYP450 gene inductions were observed and the CYP450 isoforms affected were inferred by sensitivity to isoform-selective inhibitors. Since the P450-Glo<sup>TM</sup> cell-based assay method left cells intact it was also possible to test for toxicity of the gene inducers by performing a luminescent cell viability assay subsequent to P450-Glo<sup>TM</sup>. The P450-Glo<sup>TM</sup> method measures CYP450 enzyme activity as light output from a luciferase reaction that is driven by the CYP450-catalyzed conversion of luciferase pro-substrates to D-luciferin. Luminogenic substrates for this method exist for human CYP450 isoforms CYP1A1, 1A2, 1B1, 2C8, 2C9, 2C19, 2D6, 2J2, 3A4, 3A7, 4A11, 4F3B, 4F12 and 19. The same substrates also react with rat isoforms including CYP1A1, 1A2, 2C6, 2C11, 3A1 and 4A. These homogenous assays were sensitive, simple to perform and readily configured in multi-well plate formats for rapid screening of multiple compounds against CYP450 activities.

## 712 DIOXIN AND DIET EFFECTS ON GROWTH AND P450 INDUCTION.

M. La Merrill<sup>1</sup> and D. W. Threadgill<sup>2,1</sup>. <sup>1</sup>Curriculum in Toxicology, UNC-CH, Chapel Hill, NC and <sup>2</sup>Genetics, UNC-CH, Chapel Hill, NC.

Weight gain is retarded by 2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) and we attempted to rescue this wasting syndrome with a high fat diet. TCDD is a lipophilic toxin that is metabolized by CYP1A1, CYP1A2, and CYP1B1, and acts through the Ah Receptor (AhR). A lipophobic toxin, 7, 12-dimethylbenz[a]anthracene (DMBA), is also metabolized by CYP1A1, CYP1A2, and CYP1B1 and acts through the AhR. We examined the competitive inhibition of TCDD on DMBA induction of P450s. Pregnant mice were dosed with 1  $\mu$ g/kg of TCDD (or vehicle control) on gestational day 12.5. When pups were born, the cage was put on a high or low fat diet. Pups were weaned at post natal day (PND) 21. On PND 35, pups were dosed with 60 mg/kg DMBA on PND 31 to allow for gland involution, and sacrificed 24 hours later. Dams were given 60 mg/kg DMBA on PND 31 to allow for gland involution, and sacrificed 24 hours later. Livers were collected, and induction of CYP1A1, CYP1B1, and CYP2A1 was evaluated. Induction levels were different among groups.

## 713 DIOXIN INDUCTION OF CYP1A1 EXPRESSION IS SUPPRESSED IN HEPATITIS C VIRUS REPLICATING CELLS.

G. R. Anderson, A. Hasan, I. Qadri and L. C. Quattrochi. Medicine, University of Colorado Health Sciences Ctr, Denver, CO.

Hepatitis C Virus (HCV) is a positive-stranded RNA virus that belongs to the Flaviviridae family. At least 400 million people worldwide are infected with the virus, and up to 85% of these people progress to chronic carriers, and can develop

cirrhosis and hepatocellular carcinoma. Although many processes are involved in the development of liver damage, the mechanism leading to cell injury is unclear. This study was initiated to test the hypothesis that chronic HCV infection modulates hepatic cytochrome P4501A1 (CYP1A) expression and function. CYP1A1 catalyzes the metabolism of numerous toxins to reactive intermediates, and is highly inducible by xenobiotics (e.g. polycyclic aromatic hydrocarbons and 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD; dioxin)) through the activation of the aryl hydrocarbon receptor (AhR). Using a human hepatoma cell model for HCV replication (Huh.8) for induction studies, we demonstrated that the induction in Huh.8 cells of CYP1A1 expression by TCDD, but not by  $\beta$ -naphthoflavone or 3-methylcholanthrene, was substantially diminished. TCDD exposure of Huh.8 cells resulted in greater than 50% suppression of CYP1A1 transcription compared to the parent cell line Huh-7; while protein levels and enzyme activities were further diminished. Time course and dose response experiments indicated suppression of TCDD-induced CYP1A1 mRNA in Huh.8 cells occurs as early as 6 hr following exposure and at all doses tested (0.1-10 nM). Nuclear AhR binding, as assessed by gel mobility shift assays, was reduced in extracts from TCDD-treated Huh.8 cells compared to Huh-7, although the decrease was considerably less than the magnitude of the transcription response. These findings demonstrate that TCDD-mediated AhR signaling is impaired in hepatocytes in which HCV is present, and that exposure of HCV-infected hepatocytes to xenobiotics can have the potential to perturb the cellular defense balance of the infected cell. Investigations into the molecular mechanisms responsible for these observations are ongoing.

## 714 DIFFERENTIAL REGULATION OF LIVER MITOCHONDRIAL CYTOCHROME P4501A1 (P450MT2) BY 3-METHYLCHOLANTHRENE IN MICE DEFICIENT IN THE CYTOCHROME P4501A2 GENE.

B. Moorthy, S. Kondraganti and W. Jiang. Pediatrics, Baylor College of Medicine, Houston, TX.

Cytochrome P4501A (CYP1A) enzymes play important roles in the activation of carcinogens such as 3-methylcholanthrene (MC) to genotoxic metabolites. Recent studies have demonstrated that CYP1A1 is also present in the mitochondria. Mitochondrial CYP1A1 (450MT2) is targeted to mitochondria after proteolytic N-terminal cleavage of 32 amino acids from microsomal CYP1A1. The physiological significance of mitochondrial P450MT2 is not well understood. In this investigation, we tested the hypothesis that MC, which elicits a persistent induction of hepatic microsomal CYP1A1, would also elicit sustained induction of mitochondrial P450MT2 in wild type, but not CYP1A2-deficient mice. Eight week-old female wild-type (C57BL/6) mice or CYP1A2-null mice were treated with MC (100  $\mu$ mol/kg) or vehicle (corn oil), once daily for 4 days. Enzymatic activities [ethoxresorufin-O-deethylase (EROD)] and apoprotein contents of P450MT2 were determined in liver mitochondria of these animals at 1, 8, or 15 days after MC withdrawal. At each of the time points, MC-treated wild-type animals displayed a 5-6-fold induction of mitochondrial EROD (P450MT2) activities over those of control animals. On the other hand, exposure of CYP1A2-null animals to MC led to 8-10 fold induction of EROD activities at the 1 and 8 days, respectively. By 15 days, the elevation of P450MT2 expression in these animals declined to about 2-fold over control, suggesting that targeted CYP1A2 gene disruption alters the expression of mitochondrial P450MT2. Western blot experiments yielded data that correlated with those of CYP1A1 enzyme activities. Overall, the results were similar to those obtained with microsomal CYP1A1. Since persistent induction of P450MT2 in the mitochondria may lead to enhancement of oxidative stress and persistent damage of mtDNA, further studies on the mechanisms of persistent up-regulation of P450MT2 by MC would be of relevance to carcinogenesis mediated by polycyclic aromatic hydrocarbons. (Supported by NIH grant ES09132.)

## 715 ENDOGENOUS SUBSTRATES OF CYP1B1 WHICH MAY BE ENDOGENOUS LIGANDS OF THE ARYL HYDROCARBON RECEPTOR.

B. Stapleton<sup>1</sup>, A. Annalora<sup>1</sup>, C. Chiaro<sup>5</sup>, M. Doshi<sup>3</sup>, A. Bailey<sup>1</sup>, J. Omahl<sup>2</sup>, B. Bejjani<sup>4</sup>, D. Edward<sup>3</sup>, G. Perdew<sup>5</sup> and C. Marcus<sup>1</sup>. <sup>1</sup>Toxicology, University New Mexico, Albuquerque, NM, <sup>2</sup>Biochemistry, University New Mexico, Albuquerque, NM, <sup>3</sup>Ophthalmology & Visual Sciences, University IL, Chicago, IL, <sup>4</sup>Genetics & Pediatrics, WA. St. University, Spokane, WA and <sup>5</sup>Cell & Molecular Biology, Penn. St. University, University Park, PA.

Cytochromes P450 (CYP) catalyze many oxidative reactions for both xenobiotics and endogenous substrates. Altered CYP expression/function is implicated in a variety of human disease states including cancer. Frame-shift mutations in the human CYP1B1 gene have been linked to primary congenital glaucoma (PCG). Using a polyclonal antibody against human CYP1B1, we localized CYP1B1 protein primarily within the non-pigmented ciliary epithelium in human adult and fetal eyes, suggesting CYP1B1 in these tissues metabolizes a substrate that regulates development of the trabecular meshwork (generally considered the target tissue for PCG).

We also utilized an AhR-Luciferase reporter construct (responsive to Aryl Hydrocarbon Receptor (AhR) ligands) stably transfected into HepG2 cells to attempt to identify AhR ligands which may also be CYP1B1 substrates. Extracts from African Green Monkey CV-1 cells not expressing CYP1B1 were found to be highly active, while extracts from CV-1 cells stably transfected with human CYP1B1 were much less active. AhR activity was restored in a dose-dependent manner (0 - 750 nM) when 1B1-expressing CV-1 cells were grown in the presence of the CYP1B1 inhibitor 2, 4, 3', 5'-tetramethoxystilbene, suggesting CYP1B1 can metabolize an endogenous AhR ligand present in CV-1 cells. Tissue extracts from wild-type, AhR null and cyp1b1 null mouse heart, eye, liver, kidney and lung were tested for AhR activity. Highest activity was recovered from eye and heart of AhR null mice. Partial purification of mouse tissue extracts by HPLC generated AhR-active fractions. These results support the existence of endogenous AhR ligands that are also CYP1B1 substrates, thus constituting a regulatory feedback loop for CYP1B1.

716

#### THE RESPONSE OF THE RAT HEPATIC P450 SYSTEM TO FIVE ARCHETYPAL HUMAN MICROSOMAL ENZYME INHIBITORS.

S. J. Schomaker, S. E. Boldt and D. E. Amacher. *Safety Sciences Groton, Pfizer Inc., Groton, CT.*

Human enzyme inhibition following xenobiotic administration is an important phenomenon in drug development. Secondary effects of enzyme inhibition can include decreased catabolism of endogenous substrates or altered bioavailability of co-administered chemicals potentially leading to untoward drug-drug interactions. Although inhibition of the human P450 drug metabolizing isozymes is well documented, little is known in regard to the response of preclinical species to these inhibitors. The purpose of this study was to assess the effects of five human microsomal enzyme inhibitors on the cytochrome P450 system of the CD® rat liver. Male and female rats were dosed with ellipticine (ELP), yohimbine (YOH), 4-methylpyrazole (MET), 1-aminobenzotriazole (AMB), cimetidine (CIM), or the appropriate vehicle. Liver microsomal samples were prepared from all animals and assayed for the following general indicators of microsomal enzyme activity: cytochrome P450 content, NADPH cytochrome c reductase, and p-nitroanisole O-demethylase. In addition, samples were assayed for ethoxresorufin O-dealkylase, pentoxysresorufin O-dealkylase, methoxresorufin O-dealkylase, p-nitrophenol hydroxylase, ethylmorphine N-demethylase activity, and 3-[2-(N, N-diethyl-N-methylamino)ethyl]-7-methoxy-4-methylcoumarin demethylase activity. These enzymes were used as specific indicators of the isozymes CYP1A1, CYP2B, CYP1A2, CYP2E1, CYP3A and CYP2D2, respectively. Microsomes from a subset of animals were assayed by HPLC analysis for the metabolism of progesterone. Progesterone 21- and 2 $\alpha$ -hydroxylase are associated with CYP2C6 and male specific CYP2C11, respectively. While a reduction in enzyme activity was noted after dosing with CIM, MET and AMB, only AMB caused a reduction of activity in the majority of isozymes. In conclusion, these five xenobiotics affect the cytochrome P450 system of the CD® rat liver indicating the value of preclinical testing in rodents, but the specific isozyme response may differ from the published data for the human.

717

#### EFFECTS OF DIESEL EXHAUST PARTICLES ON CYTOCHROME P450 ACTIVITIES IN PRIMARY CULTURES OF ADULT RAT HEPATOCYTES: A USEFUL INDICATOR FOR THE STUDY OF HEALTH RISK.

T. Jeon<sup>1</sup>, S. Hyun<sup>1</sup>, S. Lee<sup>1</sup>, C. Jin<sup>1</sup>, D. Lee<sup>1</sup>, G. Kim<sup>1</sup>, I. Jun<sup>1</sup>, K. Chung<sup>2</sup>, C. Moon<sup>2</sup> and T. Jeong<sup>1</sup>. <sup>1</sup>*College of Pharmacy, Yeungnam University, Kyungsan, South Korea*, <sup>2</sup>*College of Pharmacy, Sungkyunkwan University, Suwon, South Korea* and <sup>3</sup>*College of Pharmacy, Seoul National University, Seoul, South Korea*.

Diesel exhaust particles (DEPs) are one of the major air pollutants in urban areas. The estimated health risk from air pollutants is considered to be very high. We investigated the effect of DEP extracts on health risk by measuring the activities of cytochrome P450 enzymes in the primary cultures of adult rat hepatocytes. For this examination, DEPs were fractionated into water-soluble and organic fractions. The organic portion was consecutively divided into fractions of crude extract, acidic, basic, aliphatics, aromatics, slightly polar compounds, moderately polar compounds and highly polar compounds. Hepatocytes were isolated and cultured in AB medium for up to 3 days. DEP extracts at 0.1, 1.0 and 10  $\mu$ g/ml in dimethyl sulfoxide were added directly to the medium from the initiation of culture. Treatment with fractions of acidic, basic, aliphatics, aromatics and slightly polar compounds produced significant dose- and time-dependent inductions of ethoxresorufin O-deethylase (EROD) activities. Treatment with crude extract maximally induced the EROD activity from the lowest dose at 72 hr after treatment. Treatment with fractions of acidic, aliphatics and aromatics compounds showed significant dose-dependent increases in benzoyloxyresorufin O-debenzylase (BROD) activities. In addition, treatment with fractions of basic and slightly polar

compounds induced the BROD activities from 1.0  $\mu$ g/ml at 72 hr after treatment. Treatment with fractions of water-soluble, moderate and high polar compounds did not alter these enzymes. Our results suggest that the activities of EROD and BROD in primary cultures of rat hepatocytes might be useful indicators for the study of health risk caused by air pollutants, such as DEPs. #### IN VITRO EVALUATION OF HISTAMINE AND ITS MAJOR METABOLITES AS INHIBITORS OR INDUCERS OF CYTOCHOME P450 EXPRESSION IN HUMAN LIVER.

S. A. Tonetta<sup>1</sup>, F. Nodikum-Moffor<sup>2</sup>, B. L. Paris<sup>2</sup> and B. M. Richard<sup>1</sup>.

<sup>1</sup>*Nonclinical, Maxim Pharmaceuticals, San Diego, CA* and <sup>2</sup>*Metabolism, Xenotech LLC, Lenexa, KS.*

Histamine dihydrochloride (Ceplene™, 2-(1H-imidazol-4-yl)ethanamine) is a synthetic analog of histamine, which is being tested as a subcutaneous formulation in cancer patients. Histamine seems likely to play a role in gene function and cell growth regulation via certain CYP450 enzymes. We have investigated the ability of histamine and its major metabolites, N-methylhistamine (NMH) and imidazoleacetic acid (IAA) to inhibit or induce the major CYP450 enzymes in humans. In order to examine their ability to act as direct inhibitors, each test article (TA) was added together with the marker substrates to human liver microsomes. The TA concentrations were 0, 0.1, 0.3, 1.0, 3.0, 10, 30, and 100  $\mu$ M. Each marker substrate concentration was approximately equal to its respective Km. The following CYP450 enzymes were evaluated: 1A2, 2A6, 2B6, 2C8, 2C9, 2C19, 2D6, 2E1, 3A4/5 and 4A11. In the induction protocol, human hepatocytes were treated with vehicle, positive control inducers,  $\beta$ -naphthoflavone (33  $\mu$ M) as a strong inducer of CYP1A2 and rifampin (20  $\mu$ M) as a strong inducer of CYP3A4 or one of 3 concentrations of each TA (1.0, 10, and 100  $\mu$ M). The results of IC50 values for histamine, IAA or NMH indicate little or no inhibition of the CYP450 enzymes examined. In addition, the results indicate that treatment of cultured human hepatocytes with histamine, NMH, and IAA did not cause an increase in 7-ethoxyresorufin O-dealkylation (CYP1A2 activity) and testosterone 6 $\beta$ -hydroxylation activity (CYP3A4/5 activity) in human hepatocytes. As expected, treatment of cultured human hepatocytes for 3 consecutive days caused appropriate increases in CYP1A2 and CYP3A4/5 activity in hepatocytes treated with  $\beta$ -naphthoflavone and rifampin (6.5- and 9.0-fold, respectively). In conclusion, these results provide no evidence that histamine has the potential to inhibit or induce CYP450 enzymatic activities in human liver suggesting that histamine is unlikely to interact with the metabolism of CYP450 substrates.

719

#### COMPARATIVE STUDIES OF CYTOCHROME P4503A4 INDUCTION RESPONSE IN PRIMARY CULTURES OF CRYOPRESERVED AND FRESH HUMAN HEPATOCYTES.

J. Johnson<sup>1</sup>, C. M. Chandler<sup>1</sup>, S. Kim<sup>2</sup>, L. Tarabelsi<sup>1</sup>, D. M. Stresser<sup>1</sup>, M. Sinz<sup>2</sup> and J. G. Zhang<sup>1</sup>. <sup>1</sup>*BD Discovery Labware, woburn, MA* and <sup>2</sup>*Bristol Myers Squibb Co., Wallingford, CT.*

One important and well-established *in vitro* system for determining cytochrome P450 (CYP) induction, a major cause of drug-drug interactions, is fresh primary human hepatocyte cultures. However, the availability of donor hepatocytes is limited and unpredictable and, therefore, the use of cryopreserved hepatocytes is increasing. This study examined whether cryopreserved hepatocytes exhibit similar induction responses of CYP3A4, a predominant isoform of P450 family, to that of fresh hepatocytes. A prototypical CYP3A4 inducer rifampicin (RIF) and five new molecule entities (NMEs) were tested in one cryopreserved and two fresh hepatocyte cultures. The preparations were incubated with RIF (20  $\mu$ M) or varying concentrations of the test compound for 3 days. After treatment, CYP3A4 activity was determined by measuring the formation of 6-beta hydroxytestosterone *in situ*. The cells were then lysed and CYP3A4 mRNA levels were determined using one-step real-time RT-PCR. The results of CYP3A4 activity and mRNA levels revealed that the CYP3A4 induction response to RIF and the test compounds was consistent in both cryopreserved and fresh human hepatocyte cultures in this limited donor set. RIF treatment resulted in an average of 92 +/- 34 fold induction in CYP3A4 activity in fresh hepatocytes and 31 +/- 7 fold induction in cryopreserved hepatocytes. CYP3A4 mRNA levels increased concurrently to 192 +/- 147 fold in fresh hepatocytes and 23 +/- 6 fold in cryopreserved hepatocytes. Moreover, four out of five test compounds showed induction responses in both CYP3A4 activity and mRNA levels, which were consistent between the fresh and cryopreserved preparations. Our results demonstrate that cryopreserved hepatocytes are a comparable alternative to fresh hepatocytes for testing the *in vitro* P450 induction potentials of NMEs.

## REGULATIONS OF HUMAN CYP3A4 PROXIMAL AND XREM PROMOTER ACTIVITIES IN HEPA I AND HEPG2 CELLS.

Y. Y. Sheen, K. N. Min, J. Y. An, K. E. Joung, Y. W. Kim and D. Kim. *Pharmacy, Ewha Womans University, Seoul, Seoul, South Korea.* Sponsor: J. Chung.

In order to gain the insight of the molecular mechanism of CYP3A4 gene expression, study has been undertaken to investigate the regulation of CYP3A4 gene expression by proximal promoter in human hepatoma HepG2 cells. HepG2 cells were transfected with a plasmid pCYP3A4-Luc containing 1kb of the CYP3A4 proximal promoter region (-863 to +64 bp) in front of a reporter gene, luciferase, in the presence or absence of pSAP-SXR. In HepG2 cells, CYP3A4 inducers, such as rifampicin, PCN and RU486 showed minimal stimulation of CYP3A4 proximal promoter activity in the absence of SXR and histone deacetylase (HDAC) inhibitors. 4-Dimethylamino-N-[4-(2-hydroxycarbamoylvinyl)benzyl]benzamide (IN2001), a new class HDAC inhibitor significantly increased CYP3A4 proximal promoter activity over untreated control cells and rifampicin concomitant treatment with IN2001 increased further CYP3A4 proximal promoter activity that was stimulated by IN2001. The results of this study demonstrated that both acetylated histone and SXR are essential to increase of CYP3A4 proximal promoter activity by CYP3A4 inducers such as PCN, rifampicin, and RU486. In Hepa-I cells, CYP3A4 inducers and estradiol increased modestly the luciferase activity when TSA was co-treated, but this increment was not enhanced by SXR cotransfection. Also, effects of HNFs and ER on CYP3A4-XREM-proximal promoter activity were investigated in HepG2 cells and results would be discussed. Taken together, these results indicated that the inhibition of histone deacetylation was required to SXR-mediated increase in CYP3A4 proximal promoter region when rifampicin, or PCN was treated. Also this data suggested that HDAC inhibitors seemed to facilitate the CYP3A4 proximal promoter to be activated by chemicals. [This research has been supported by biochallenger program MOST Korea.]

ROLE OF NF- $\kappa$ B IN REGULATION OF PXR TRANSCRIPTIONAL ACTIVITY: A MECHANISM FOR THE SUPPRESSION OF CYTOCHROME P450 3A4 BY INFLAMMATORY AGENTS.

X. Gu<sup>1</sup>, T. Sheng<sup>2</sup>, S. Ke<sup>1</sup>, P. E. Thomas<sup>3</sup>, M. A. Gallo<sup>3</sup>, W. Xie<sup>4</sup> and Y. Tian<sup>1</sup>. <sup>1</sup>*Interdisciplinary Faculty of Toxicology, College Station, TX*, <sup>2</sup>*The University of Texas Medical Branch, Galveston, TX*, <sup>3</sup>*EOHSI, Rutgers University, Piscataway, NJ* and <sup>4</sup>*University of Pittsburgh, Pittsburgh, PA*.

Cytochrome P450 3A4 (CYP3A4) is the predominant isoform of cytochromes P450 in adult human liver. It is responsible for the metabolism of more than 50% of current prescription drugs. Many physiological and pathological factors have effects on CYP3A4 gene expression. It is a long-standing observation that inflammatory conditions decrease drug metabolism capacity in human and experimental animals. CYP3A4 expression levels are known to be suppressed in human and rodent hepatocytes by the inflammatory agents such as endotoxin, TNF- $\alpha$  and IL-1 $\beta$ . However the mechanism of the suppression remains poorly understood. In the current study, utilizing a human PXR-driven reporter system, we investigate the mechanism of suppression of PXR-mediated CYP3A4 expression. We demonstrated that LPS, dsRNA and TNF- $\alpha$  down-regulated the PXR-driven reporter gene. We observed that in HepG2 cells overexpression of p65, the transcriptionally active component of NF- $\kappa$ B which is activated in hepatocytes by inflammatory agents, has the same suppressive effect on PXR-mediated CYP3A4 expression as LPS, dsRNA and TNF- $\alpha$ . These suppressive effects could be reversed by the dominant super repressor I $\kappa$ B $\alpha$  as well as pyrrolidine dithiocarbamate, which is a known chemical inhibitor of NF- $\kappa$ B. Mammalian one-hybrid and two-hybrid assay show that there is functional interaction between PXR and p65. Our results strongly suggest that NF- $\kappa$ B activation plays an important role in mediating the suppression of CYP3A4 gene expression. (Supported in part by NIEHS Grants ES09859, ES09106 and American Heart Association Grant 0355131Y.)

DOWN-REGULATION OF HEPATIC CYTOCHROME P450S IN ENDOTOXEMIC MICE IS INDEPENDENT OF PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR ALPHA (PPAR $\alpha$ ).

T. Richardson and E. T. Morgan. *Pharmacology, Emory University, Atlanta, GA.*

Inflammatory agents such as bacterial lipopolysaccharide (LPS) down-regulate the expression of many cytochrome P450 mRNAs and proteins. Previous studies in LPS-treated PPAR $\alpha$  mice indicated that some effects on P450 mRNAs were attenuated or blocked in PPAR $\alpha$  knockout mice (analyzed by Northern blotting), implicating PPAR $\alpha$  in the down-regulation of P450s during inflammation. To confirm these findings, adult female wildtype and PPAR $\alpha$  knockout mice were administered either saline or 1 mg/kg LPS, and hepatic and renal mRNA and protein ex-

pression of four P450 isoforms were examined by quantitative reverse transcriptase PCR and western blotting 16 hours later. mRNA expression of the proinflammatory cytokines interleukin (IL)-1 $\beta$ , IL-6 and tumor necrosis factor alpha (TNF $\alpha$ ), and the acute phase proteins  $\alpha$ 1-acid glycoprotein and fibrinogen were also investigated. LPS administration significantly decreased the hepatic expression of CYP2A5 (each reduced to 7% of control), 2C29 (46 and 25%), 3A11 (17 and 15%), and 4A10 (each 19%) in both PPAR $\alpha$  wildtype and knockout mice, respectively. LPS also down-regulated hepatic P450 proteins detected of both strains using rat P450 2C, 3A and 4A antibodies, and these results correlated with effects on mRNA. Treatment with LPS significantly increased renal CYP4A10 mRNA expression (224% of control) in PPAR $\alpha$  wildtype mice and 2C29 expression (226% of control) in PPAR $\alpha$  knockout mice, with little effect on renal CYP2A5 and 3A11 expression. LPS significantly increased mRNA expression of IL-1 $\beta$ , IL-6, and TNF $\alpha$  in both wildtype (380, 712, and 2615%) and PPAR $\alpha$ -deficient (1013, 378, and 928%) mice. Expression of  $\alpha$ 1-acid glycoprotein and fibrinogen were also significantly increased after LPS treatment in wildtype (652 and 745%) and knockout (397 and 355%) mice, respectively. Because decreases in hepatic P450 mRNA expression were essentially identical in both wildtype and knockout mice, these data indicate that down-regulation of P450s during inflammation is PPAR $\alpha$  independent. (Supported by NIH Grant GM46897)

## GENERATION AND CHARACTERIZATION OF A TRANSGENIC MOUSE MODEL WITH HEPATIC EXPRESSION OF HUMAN CYP2A6.

J. Gu, Q. Zhang, T. Su, H. Cui, X. Zhuo, P. J. Swiatek, L. Zhang, W. Yang and X. Ding. *Wadsworth Center, Albany, NY.*

CYP2A6 is a human cytochrome P450 enzyme active in the metabolic activation of numerous xenobiotic compounds, including procarcinogens. CYP2A6, which is polymorphic, is mainly expressed in the liver, and it is believed to play an important role in systemic clearance of nicotine. The aim of this study was to prepare and characterize a CYP2A6-transgenic mouse model, a model that should be valuable for studying the *in vivo* function of this polymorphic human enzyme in drug metabolism and chemical toxicity. The transgene construct contained the mouse transthyretin promoter/enhancer, a full-length CYP2A6 cDNA, and a downstream neomycin resistance gene for positive selection in embryonic stem cells. Liver-specific expression of transgenic CYP2A6 was confirmed by immunoblotting and RNA-PCR. The transgenic mouse, originally generated on a mixed C57BL/6 and 129/Sv genetic background, has been backcrossed to the C57BL/6 strain for seven generations. This was necessary because the orthologous mouse Cyp2a5 genes of the two parental mouse strains have structural and regulatory differences that would confound the analysis of the transgenic CYP2A6. Hepatic microsomes from homozygous transgenic mice (on a C57BL/6 background) had significantly higher activities than that of wild-type controls toward coumarin and nicotine. For example, with 0.05 mM nicotine, microsomes from the transgenic mice were >2-fold more active than those of either C57BL/6 or 129/Sv mice in the formation of cotinine. Experiments are currently under way to determine the *in vivo* capacity of transgenic CYP2A6 to activate various drugs and other xenobiotic substrates, including nicotine and coumarin. Preliminary studies with coumarin indicated that, following intraperitoneal administration of a single dose (150 mg/kg), coumarin was eliminated at a higher rate in the transgenic mice than in the WT strains, a finding that is consistent with the reported role of CYP2A6 as the major coumarin hydroxylase in human liver. (Supported in part by NIH grant ES07462)

## AFFINITY LABELING OF SER-57 IN RAT CYTOCHROME P450C24A1 (CYP24A1) OF THE VITAMIN D PATHWAY: MUTATION AND CHARACTERIZATION.

A. J. Annalora<sup>1,2</sup>, A. Pastusyn<sup>2</sup>, R. Ray<sup>3</sup>, C. B. Marcus<sup>1</sup> and J. L. Omdahl<sup>2</sup>.

<sup>1</sup>*College of Pharmacy, University of New Mexico, Albuquerque, NM*, <sup>2</sup>*Department of Biochemistry and Molecular Biology, University of New Mexico, Albuquerque, NM* and <sup>3</sup>*Vitamin D Laboratory, Boston University-SOM, Boston, MA*.

Cytochrome P450C24A1 or CYP24A1 is a multifunctional regulatory enzyme that mediates homeostasis within the vitamin D endocrine system. CYP24A1, an inner-mitochondrial membrane hemoprotein, regulates vitamin D hormone levels by removing 25(OH)D3 from the circulation and excess 1, 25(OH)2D3 from kidney and target tissues. The development of safe and efficacious vitamin D-based therapeutics will require a detailed understanding of the structure-and-function of CYP24A1. In the current study, binding of substrate to recombinant rat CYP24A1 was investigated using a <sup>3</sup>H-radiolabeled 3 $\beta$ -25(OH)D3 affinity analog. MS/MS analysis of labeled sample identified Ser-57 as the only residue covalently modified by the affinity probe. Site-directed mutagenesis was conducted to explore the role

of Ser-57 in substrate-binding and catalytic function. A neutral S57A mutant displayed impaired binding of the endogenous substrate 1, 25(OH)D3 and altered metabolism of the pro-hormone 25-OH-D3. In contrast, a charged S57D mutant strongly enhanced binding affinity and side-chain oxidation of endogenous vitamin D substrates. The S57D mutant also displays enhanced stability and altered biophysical properties compared to wild-type enzyme. Our results suggest that Ser-57 mediates substrate interactions via hydrogen bonding with the A-ring of vitamin D substrates. However, because the affinity probe fails to induce substrate-induced spectral perturbations of the enzyme's heme center, it is unclear if Ser-57 is an active site residue. A computer-based homology model of rat CYP24A1 suggests that Ser-57 resides on the enzyme's surface, near the mouth of the substrate-access channel, where it may coordinate substrate recognition and accessibility. We hypothesize that Ser-57 is key contact residue within a hydrophobic, peripheral binding site that mediates the high-affinity-binding of vitamin D substrates.

725

THE USE OF THE MECHANISM BASED INHIBITOR 2-ETHYNYLNAPHTHALENE (2EN) TO PROBE THE ACTIVE SITE OF CYP2B4.

D. Cheng, J. R. Reed, R. W. Kelley and W. L. Backes. *Pharmacology, LSUHSC, New Orleans, LA.*

Mechanism-based inhibitors are metabolically converted by an enzyme to reactive metabolites that covalently bind and inactivate that enzyme. 2-Ethylnaphthalene (2EN) has been reported to be a mechanism-based inhibitor of CYP2B4. However, there are two components to the inhibition, (1) the inactivation of CYP2B4 by 2EN, which requires prior metabolism and covalent binding of the 2EN metabolite, and (2) an inhibitory component that does not require prior metabolism of the inhibitor. The goal of this study is to characterize both inhibitory components of 2EN with different CYP2B4 substrates. CYP2B4 dependent metabolism of p-nitroanisole (PNA), 7-ethoxycoumarin (7-EC), 7-ethoxy-4-trifluoromethylcoumarin (7-EFC), benzphetamine (BZP), 7-pentoxyresorufin (7-PR), 7-benzyloxyresorufin (7-BR), and testosterone were examined in the absence and presence of 2EN. Preincubation of the reconstituted system with 2EN led to a time dependent inactivation of each of the CYP2B4-dependent activities examined, with the Kinact being similar with each of the substrates used. However, the ability of 2EN to reversibly inhibit CYP2B4-dependent activities was dependent on the substrate employed. Interestingly, the degree of reversible inhibition was roughly related to the molecular size of the substrate. With a small substrate such as PNA, which contains a single aromatic ring, only a small degree of inhibition (about 3%) was observed. Larger substrates exhibited a larger degree of reversible inhibition. In conclusion, the inhibition of cytochrome P450 2B4 by 2EN was substrate-dependent and the degree of reversible inhibition seemed related to the molecular size of substrate. The results are consistent with both 2EN and the smaller substrates being able to simultaneously fit within the CYP2B4 active site. As the size of the substrate is increased, the ability of both the substrate and 2EN to fit into the site is more restricted, leading to greater inhibition of substrate metabolism.

726

INHIBITION OF THE HUMAN LIVER MICROSOMAL AND HUMAN CYTOCHROME P450 1A2 AND 3A4 METABOLISM OF ESTRADIOL BY DEPLOYMENT-RELATED CHEMICALS.

K. A. Usmani, R. L. Rose and E. Hodgson. *Environmental & Molecular Toxicology, North Carolina State University, Raleigh, NC.*

Cytochrome P450 enzymes (CYPs) are major catalysts involved in metabolism of xenobiotics and endogenous substrates such as estradiol (E2). It has previously been shown that E2 is predominantly metabolized by CYP1A2 and 3A4 with 2-hydroxyestradiol (2-OHE2) being the major E2 metabolite. The purpose of this study was to examine possible effects of deployment-related chemicals on the metabolism of E2. Use of phenotyped human liver microsomes (HLM), 6 male and 11 female, demonstrated that individuals with high levels of CYP1A2 and 3A4, regardless of gender, have the greatest potential to metabolize E2. Preincubation of human liver microsomes (HLM) with a variety of ligands, including pesticides, resulted in varying levels of inhibition of E2 metabolism. The greatest inhibition was observed with organophosphorus compounds, including chlorpyrifos (CPS) and fonofos, with up to 80% inhibition observed for 2-OHE2 production. Carbaryl, a carbamate pesticide, and naphthalene, a jet fuel component, inhibited ca. 40% of E2 metabolism. Preincubation of CYP3A4 with CPS, fonofos, deltamethrin, or permethrin under the same conditions resulted in 94, 87, 58, and 37% inhibition of E2 to 2-OHE2, respectively. The Ki values indicated that fonofos and CPS were the most potent inhibitors of E2 metabolism to 2-OHE2 and inhibited E2 metabolism noncompetitively. Preincubation of CYP1A2 with CPS, fonofos, carbaryl, or naphthalene resulted in 96, 59, 84, and 87% inhibition of E2 to 2-OHE2, respec-

tively. The Ki values indicated that CPS, naphthalene, 1-naphthol, carbaryl, 4-hydroxy carbaryl were the most potent inhibitors of E2 metabolism to 2-OHE2 followed by carbaryl methylol and fonofos. CORRELATIONS BETWEEN ACTIVITIES OF CYPs 2E1/1A2 AND HISTOLOGIC FIBROSIS IN HCV PATIENTS.

S. I. Shedlofsky<sup>1,3</sup>, R. T. Tosheva<sup>1</sup>, C. Hallberg<sup>2</sup> and K. E. Anderson<sup>2</sup>. <sup>1</sup>*Medicine, University of Kentucky, Lexington, KY*, <sup>2</sup>*University of Texas Medical Branch, Galveston, TX* and <sup>3</sup>*General Clinical Research Center, Lexington, KY*.

Liver injury in HCV very likely involves increased hepatic oxidative stress. Hepatic cytochromes P450 could represent a source of excess oxidative stress. We report results of the activities of two P450 isoforms, CYPs 2E1 and 1A2, in untreated HCV patients whose liver biopsies were ranked for degree of histologic injury. METHODS: Chlorzoxazone (CZX) and theophylline (TH) oral clearances were determined as markers of CYP2E1 and 1A2 respectively in 41 HCV patients. Portal (P) and lobular (L) inflammation and fibrosis (F) score were graded according to Ludwig. The histologic score (HS) was formed by adding P+L+2xF. Correlations were made between histologic score (HS) and CYP 2E1 and 1A2 activities, plasma hyaluronic acid (HA), procollagen propeptide III (PPIII), and TGF $\beta$ 1. RESULTS: CYP 2E1 activities for HCV patients with mild, moderate and severe histologic injury were 4.9 $\pm$ 2 (n=14), 5.5 $\pm$ 3 (n=16) and 6.4 $\pm$ 4 (n=11) respectively with correlation coefficient r=0.211. For 1A2 all patients were additionally divided into two groups – non-smokers and smokers. There were no differences between mild, moderate and severe groups for non-smokers. In smokers however the activities were 0.46 $\pm$ 0.1, 0.77 $\pm$ 0.1 and 0.63 $\pm$ 0.2 (n=9, 8, 5) with r=0.240. For HA, PPIII and TGF $\beta$ 1 r=0.272, 0.206 and -0.311 respectively. CONCLUSIONS: As expected, HS is associated with increased markers of endothelial dysfunction (HA) and fibrosis (PPIII). Surprisingly, TGF $\beta$ 1 values were negatively associated. With regard to hepatic P450s, our results suggest that greater degrees of histologic injury (HS weighted to emphasize fibrosis stage) correlate with increased activities of CYP2E1 and, in smokers, of CYP1A2. This may be because these P450s contribute to increased hepatic oxidative stress. Whether decreasing the activities of these P450s will be of benefit to HCV patients will require further study. Acknowledgments: This work was supported by NIH Grant RO1 AA12852-01, GCRC Grants MO1 RR02602, MO1 RR00073.

ROLE OF CYTOCHROME P450 2E1 (CYP2E1) IN TRICHLOROETHYLENE (TCE) METABOLISM AND DISPOSITION: COMPARATIVE STUDIES USING CYP2E1-/- AND WILD-TYPE MICE.

D. Kim and B. J. Ghanayem. *Laboratory of Pharmacology and Chemistry, NIEHS/NIH, Research Triangle Park, NC.*

TCE is a known rodent carcinogen and was classified as probable human carcinogen. Metabolism of TCE occurs via glutathione conjugation and CYPs-dependent oxidation. While a number of CYPs were implicated, CYP2E1 is considered the primary high affinity enzyme responsible for TCE metabolism. The objective of this work is to assess the role of CYP2E1 in the metabolism and disposition of TCE using CYP2E1-null (KO) vs. wild type (WT) mice. Mice were administered 1, 2-<sup>14</sup>C-TCE by gavage at 1000 mg/kg and placed in glass metabolism cages that allowed for the collection of expired air, urine, and feces. At 24 after dosing, animals were euthanized and blood and tissues were collected and frozen for analysis. Exhalation of TCE derived <sup>14</sup>CO<sub>2</sub> accounted for 17-18% of dose, and was not significantly different in KO Vs. WT mice. Elimination of TCE-derived organic volatiles in the expired air accounted for 23 and 49% of the administered dose in WT and KO mice, respectively. In contrast, excretion of TCE-derived radioactivity in the urine was approximately 17 and 40% of the administered dose in KO and WT mice, respectively. Pretreatment of mice with 1-aminobenzotriazole (ABT), a universal CYPs inhibitor, prior to TCE administration significantly inhibited <sup>14</sup>CO<sub>2</sub> exhalation to 2-3% of the administered dose, and increased the exhalation of TCE-derived organic volatiles to 70-77% of the dose in mice of both genotypes. Preliminary analysis suggested that parent TCE is the primary constituent of the expired organic volatiles in ABT pretreated mice. Urinary excretion in ABT-pretreated mice was significantly decreased in KO and WT mice and accounted for approximately 4 and 12% of the dose, respectively. In conclusion, these data suggest that while CYP2E1 plays an important role in TCE metabolism and disposition, other CYPs play an important role as well. Additional studies are in progress to compare the identity of TCE metabolites in the urine and expired air of KO and WT mice in order to quantify the contribution of various CYPs to TCE metabolism.

CYTOCHROME P450 2E1 (CYP2E1) INDUCTION BY PYRIDAZINE PRODUCES QUALITATIVE AND QUANTITATIVE CHANGES IN THE METABOLISM OF TRICHLOROETHYLENE TO POTENTIALLY CARCINOGENIC METABOLITES.

S. Lee, S. Muralidhara, C. A. White and J. V. Bruckner\*. *Department of PBS, University of Georgia, Athens, GA.*

CYP2E1, an isozyme of cytochrome P450, is expressed mainly in the liver. It is inducible by a variety of xenobiotic compounds such as ethanol, acetone and aspirin. CYP2E1 catalyzes the oxidation of many small and hydrophobic volatile organic chemicals (VOCs), including trichloroethylene (TCE). It is generally accepted that CYP2E1 induction will result in increased production of metabolites from TCE, and an attendant increase in cancer risk. The objective of the current study was to investigate the influence of CYP2E1 induction by pyridazine (PZ) on TCE oxidation as well as its subsequent effects on downstream metabolites that have been implicated in hepatocarcinogenesis. Groups of 6 male Sprague-Dawley rats of 175 g body weight were gavaged with a series of doses of TCE up to 200 mg/kg. Other groups of 6 animals were induced with PZ (200 mg/kg, ip) for 3 days before being challenged with TCE 24 hrs after the last PZ dose. Serial blood samples were collected for up to 24 or 48 hrs via an indwelling carotid artery catheter. TCE and its major metabolites were analyzed in the headspace of the micro blood samples by gas chromatography. TCE Cmax values were substantially lower in the induced animals, reflecting increased first-pass hepatic elimination of TCE. The PZ-dosed animals had higher trichloroethanol (TCOH) AUCs, but markedly lower trichloroacetic acid (TCA) AUCs, when compared to those of uninduced rats. Dichloroacetic acid (DCA) levels, which were barely detectable blood in uninduced rats, were prominent in induced groups, suggesting increased conversion of TCA to DCA. Whereas, chloral hydrate (CH) levels were unaffected by PZ, but TCOH formation appeared to be favored over TCA. Additional work will be needed to determine whether CYP2E1 induction is of consequence with very low TCE exposure levels.

PROTECTIVE EFFECT OF DIALLYL SULFONE AGAINST LUNG MUTAGENESIS INDUCED BY VINYL CARBAMATE.

L. G. Hernandez and P. Forkert. *Department of Anatomy and Cell Biology, Queen's University, Kingston, ON, Canada.*

Alliin, a major component in garlic, is converted by the enzyme allinase to organosulfur compounds including diallyl sulfide. Diallyl sulfide is a competitive inhibitor of CYP2E1 and undergoes sequential oxidation to yield diallyl sulfoxide and diallyl sulfone (DASO<sub>2</sub>). DASO<sub>2</sub> is further oxidized by CYP2E1 to diallyl monooxide, which mediates the autocatalytic destruction of CYP2E1. In this study, we tested the hypothesis that DASO<sub>2</sub> protects against vinyl carbamate (VC)-induced *in vivo* mutagenesis. VC is a potent lung carcinogen that is also metabolized by CYP2E1 to an epoxide, a metabolite that is believed to be the ultimate mutagenic and carcinogenic species. Our studies used Big Blue® transgenic mice and the lambda (λ) cII positive selection system that detects mutations in the λ cII transgene by infecting an hfr strain (*E. coli* G1250); only phages with cII mutations lyse at low temperatures (24°C) while all infected bacterial cells lyse at 37°C, allowing determination of mutant frequency. Eight-week old F<sub>1</sub> mice (BigBlue® x A/J) were gavaged with 200 mg/kg of DASO<sub>2</sub>, treated with 60 mg/kg VC (i.p.) 2 h later, and sacrificed four weeks after VC treatment. A 3-fold significant reduction (P < 0.01) in mutant frequency in the VC-treated mice (mean ± SEM; 11.23 ± 2.3 per 10<sup>5</sup> plaques) versus DASO<sub>2</sub>/VC-treated mice (3.82 ± 1.0 per 10<sup>5</sup> plaques) was observed. Pretreatment with DASO<sub>2</sub> completely eliminated VC-induced mutations since DASO<sub>2</sub>/VC mice had nearly identical mutant frequencies as control mice (3.7 ± 1.3 per 10<sup>5</sup> plaques). Mice treated with DASO<sub>2</sub> alone had a 1.8-fold reduction in mutant frequency (2.04 ± 0.6 per 10<sup>5</sup> plaques) versus control mice; although not statistically different, these data suggested some degree of protection against spontaneous mutations. The inactivation of CYP2E1 by DASO<sub>2</sub> oxidation most likely prevented or decreased the formation of the mutagenic VC-epoxide *in vivo*. These results supported the hypothesis that DASO<sub>2</sub> protects against VC-induced mutagenesis. (Supported by NCIC Grant No. 014061).

ROLE OF TOXICOKINETICS IN THE BIOACTIVATION-MEDIATED LIVER INJURY OF THIOACETAMIDE IN *AD LIBITUM* FED AND DIET RESTRICTED RATS.

J. Chilakapati, M. C. Korrapati and H. M. Mehendale. *Toxicology, University of Louisiana at Monroe, Monroe, LA.*

Thioacetamide (TA) is bioactivated by CYP2E1 to TA sulfoxide (TASO), and further to highly reactive sulf dioxide (TASO<sub>2</sub>), that initiates hepatic necrosis by covalent binding. Studies showed that bioactivation-mediated injury of TA does not

obey dose-response. Despite higher bioactivation-mediated (Stage I) injury of TA due to induction of CYP2E1, moderate diet restriction (DR) protects rats from a normally lethal dose. TA causes disproportionately higher increase in liver injury after a low dose (50 mg/kg) compared to a 12-fold higher lethal dose (600 mg/kg) in the DR rats. Low dose produces a 6-fold higher injury whereas the high dose produces a delayed and mere 2.5-fold higher liver injury compared to the *ad libitum* (AL) fed rats. The present objective was to determine if lack of dose response in AL and DR rats between low and lethal doses could be explained by saturable toxicokinetics of TA. Rats maintained on 35% DR for 21 days and AL regimen were given 50 or 600 mg TA/kg ip. TA and TASO were quantified in plasma, liver, and urine. With increasing doses, the half-lives of TA and TASO increased, revealing zero order kinetics for TA metabolism. At higher dose, covalent binding of <sup>14</sup>C-TA to liver macromolecules was lower indicating that bioactivation of TASO to TASO<sub>2</sub> is inhibited and consequently, urinary excretion of TASO increased. These results explain the inverse dose response for Stage I injury of TA. Microsomal metabolism of TA over a concentration range (0.01-10 mM) showed saturation of TA conversion to TASO at and above 0.5 mM TA concentration, equaling the *in vivo* plasma and liver levels found at the high dose. Incubation with CYP2E1 supersomes confirmed saturation of TA metabolism to TASO. Low dose showed two-fold higher covalent binding in DR, explaining higher Stage I liver injury in DR rats vs AL rats. These findings suggest saturation of CYP2E1 at the first step (TA to TASO) and substrate inhibition at the second step (TASO to TASO<sub>2</sub>) of TA bioactivation in the AL and DR rats. (Supported by ES09870)

CYP2E1 OXIDATION MEDIATES THE SPERM TOXICITY OF 1-BROMOPROPANE IN MICE.

C. Garner<sup>1</sup>, J. Davis<sup>1</sup>, C. Sloan<sup>1</sup>, J. Burgess<sup>1</sup>, A. Jeffcoat<sup>1</sup>, A. Hughes<sup>1</sup>, A. Parham<sup>1</sup>, J. Mathews<sup>1</sup>, L. Burk<sup>2</sup> and B. Ghanayem<sup>2</sup>. <sup>1</sup>DMPK, RTI International, Research Triangle Park, NC and <sup>2</sup>NIEHS, Research Triangle Park, NC.

1-Bromopropane (1-BrP) has been demonstrated to induce dose and time dependent reproductive organ toxicity and reduce sperm motility in rodents. The contribution of CYP2E1 metabolism to 1-BrP induced reproductive toxicity has now been investigated using wild type (WT) and CYP2E1-/- mice. Sperm motility was determined following inhalation exposure (conc.) to universally <sup>13</sup>C-labeled 1-BrP. In inhalation studies (800 ppm), the half-life of elimination of 1-BrP from the chamber was significantly greater in CYP2E1 -/- mice relative to WT (3.2 vs. 1.3 hr). Despite a 170% increase in 1-BrP exposure and a 250% increase in 1-BrP mean residence time in CYP2E1-/- vs. WT mice, sperm motility in CYP2E1-/- mice did not change relative to control. This suggests that CYP2E1-mediated oxidation is responsible for 1-BrP induced sperm toxicity. In these same animals, urinary metabolites were identified by LC-MS/MS and one and two-dimensional <sup>13</sup>C-NMR. Regardless of route or dose, the mercapturic acid and of 1-bromo-2-hydroxypropane (2OHBrP) was the major urinary metabolite (>80%) and direct GSH conjugation of 1-BrP was insignificant in WT mice. In CYP2E1 -/- mice, 2OHBrP-GSH conjugate levels were decreased with concurrent increases in direct conjugation of parent compound. This NMR data showed that the ratio of direct conjugation to 2-hydroxylation increased 5 fold in CYP2E1 -/- mice relative to WT. Both 1-BrP and 2OHBrP inhibited WT mouse sperm motility *in vitro*. However, only 2OHBrP reduced the motility of sperm obtained from CYP2E1-/- mice *in vitro*, suggesting conversion of parent to 2OHBrP within the spermatozoa themselves is critical to reduction of motility. Overall, these data suggest that reduction in sperm motility may be mediated by the CYP2E1-dependent metabolism of 1-bromopropane to 1-bromo-2-hydroxypropane.

HEPATIC METABOLISM OF AROMATIC AMINE HAIR DYE COMPONENTS AS COMPARED WITH THAT OF 2-AMINOFLUORENE.

L. Stanley<sup>1</sup>, J. Skare<sup>2</sup>, E. Doyle<sup>1</sup>, R. Powrie<sup>1</sup>, D. D' Angelo<sup>2</sup> and C. Elcombe<sup>1</sup>. <sup>1</sup>CXR Biosciences Ltd., Dundee, United Kingdom and <sup>2</sup>Central Product Safety, Sharon Woods Technical Center, Procter & Gamble Company, Cincinnati, OH.

p-Phenylenediamine (PPD) and p-toluenediamine (PTD) are widely used ingredients in permanent hair dyes; however, little has been published on their hepatic cytochrome P450 (CYP)-mediated oxidation. N-hydroxylation by CYPs is regarded as a key step in the activation of arylamines that leads to the development of bladder cancer. Although most epidemiology studies evaluating the relationship between personal use of hair dyes and bladder cancer do not show a significant association, it has been reported that the risk of bladder cancer was increased in women who were frequent users of permanent hair dyes (1, 2). The purpose of the present study was to determine whether PPD and PTD are metabolised by human hepatic CYPs to form N-hydroxyamines. The metabolism of <sup>14</sup>C-PPD and <sup>14</sup>C-PTD was evaluated using intact human hepatocytes, human liver microsomes, and heterologously expressed human CYPs. Analyses were by LC and LC-MS/MS. p-Phenylenediamine was N-acetylated by human hepatocytes to form N-acetyl-PPD

and N, N-diacyl-PPD. There was no evidence for the formation of mono-oxygenated metabolites of 14C-PPD or 14C-PTD by hepatocytes, microsomes or recombinant CYPs, or for enzyme-mediated covalent binding to microsomal protein. In contrast, experiments with 2-aminofluorene (2-AF) showed evidence of CYP-mediated metabolism to at least four different hydroxylated metabolites. The lack of evidence for hepatic CYP-mediated metabolism of PPD and PTD is inconsistent with the hypothesis that these compounds play a causal role in the development of bladder cancer in users of permanent hair dyes via a mode of action involving hepatic metabolism to N-hydroxyarylamines. 1. Gago-Dominguez et al (2001). Use of permanent hair dyes and bladder-cancer risk. *Int. J. Cancer* 91, 575-579. 2. Gago-Dominguez et al (2003). ### 734 DECHLORINATION OF PCB IUPAC #101 BY HUMAN CYP 2B6 TRANSFECTED INSECT CELL MICROSOMES.

D. P. Waller and J. E. McGraw. *Biopharmaceutical Sciences, University of Illinois at Chicago College of Pharmacy, Chicago, IL.*

Identification of specific human CYP isoform metabolism of PCBs is important to our understanding of PCB kinetics and health effects in humans. PCB IUPAC #101 is a non-coplanar PCB for which oxidative metabolism has been well characterized in the literature. Non-coplanar PCBs are the most abundant congeners found in human and animal tissues. PCB 101 was an abundant congener in original Aroclor mixtures and is found in numerous environmental matrices. It has been described as a rapidly metabolized PCB congener in mammals. Low or undetectable concentrations of PCB 101 are found in most human serum samples. The CYP families involved in PCB metabolism of non-coplanar congeners are CYP 3A and CYP 2B found primarily in liver. The CYP 3A family metabolizes a large number and variety of xenobiotics and endogenous substrates while the CYP 2B family has a limited substrate spectrum and is found in low baseline concentrations. Because of human CYP 3A's lack of substrate specificity, human CYP 2B6 mediated metabolism of PCBs was chosen for initial investigation. Because PCB 101's metabolism has been well characterized it was chosen as the initial congener to be studied by human CYPs in-vitro. Reaction mixtures containing Gentest super-somes (CYP2B6 + b5), PCB 101 (reaction concentrations 12-122 nM) and a NADPH regenerating system were incubated for various times at 37°C under ambient atmospheric and low oxygen saturation conditions. No hydroxylated products were identified in our studies, however, significant concentrations of dechlorination products, eg, PCB 70, were identified under the low oxygen saturation conditions. Reductive dechlorination has not been described as a major mechanism of PCB metabolism in humans. However, these data show that CYP enzyme mediated dechlorination may occur in humans under low oxygen conditions. Dechlorination of PCBs requires further investigation to better understand their impact on biomarker, risk assessment, pharmacokinetic, and human health effects studies of PCBs.

### 735 REGIO-SPECIFIC ( $\omega$ TO $\omega$ -6) FATTY ACID (LAURIC, MYRISTIC AND PALMITIC) HYDROXYLATION IN HUMAN POOLED LIVER AND RECOMBINANT MICROSOMES.

M. L. Haasch and J. C. Allgood. *National Center for Natural Products Research, Environmental Toxicology Research Program, Pharmacology, The University of Mississippi, University, MS.*

Most studies of lauric acid hydroxylation have focused on only two hydroxylation products,  $\omega$  and  $\omega$ -1. Modifications of an HPLC method (Lemaire et al., 1992) to include GC-MS (Buhler et al., 1997) have allowed more sub-terminal hydroxylation products including  $\omega$ -2 to  $\omega$ -6 to be quantified. Further modifications now allow the measurement of not only lauric acid hydroxylation but also the hydroxylation of myristic and palmitic acids (Holmes et al., 2004). We have used a modification of the method to allow measurement of not only  $\omega$  and  $\omega$ -1 but also  $\omega$ -2 to  $\omega$ -6 sub-terminal hydroxylation products of lauric, myristic and palmitic fatty acids. Previously we have shown regio-specific lauric acid hydroxylation in human pooled liver and recombinant microsomes. Preliminary evidence indicated significant lauric acid sub-terminal hydroxylation, specifically  $\omega$ -2,  $\omega$ -5 and  $\omega$ -6 by both human liver male and female pooled microsomes, with only female microsomes catalyzing  $\omega$ -1 while products of  $\omega$ -3,  $\omega$ -5, and  $\omega$ -6 were produced by human recombinant CYP4A11. Interestingly, CYP2B6 produced significant lauric acid sub-terminal hydroxylation at the  $\omega$ -1,  $\omega$ -2, and  $\omega$ -3 positions with high  $\omega$ -6 activity. Additionally the source of the recombinant enzyme and the source of the cytochrome P450 reductase influenced the lauric acid hydroxylation pattern by CYP2E1. The sub-terminal hydroxylation of myristic and palmitic acids has not previously been reported. There is potential for sub-terminal hydroxylation products to act as second messengers in cellular signal transduction or to interfere with steroid biotransformation. These hypotheses will be investigated in future research.

### 736 ROLE OF CYTOCHROME P450 3A IN

### HEPATOTOXICITY OF THE CHLOROACETANILIDE HERBICIDE ALACHLOR.

S. R. Miranda and S. A. Meyer. *Toxicology, University of Louisiana at Monroe, Monroe, LA.*

Alachlor [2-chloro-2', 6'-diethyl-*N*-(methoxymethyl)acetanilide] a chloroacetanilide herbicide is used in agriculture for pre-emergent weed control of corn and soybeans. Previous studies have shown that alachlor is acutely hepatotoxic to rats at doses > 400mg/kg and suggest a role for CYP3A1/2. Also, human CYP3A4 catalyzes alachlor *N*-dealkylation to 2-chloro-*N*-(2, 6-diethylphenyl)acetamide (CDEPA; Coleman et al. *Chem.Biol.Interactions*, 122:27-39, 1999), the putative rate limited precursor to formation of a reactive metabolite, diethylbenzoquinoneimine (DEBQI). Therefore, the objectives of this study were to examine the role of CYP3A in alachlor hepatotoxicity and to determine the toxicity of the intermediate metabolites CDEPA and 2, 6-diethylaniline (DEA). HepG2 human hepatoblastoma cells were chosen as a model system since these cells express constitutive and dexamethasone-inducible CYP3A7 and can be further induced by dexamethasone (DEX) to express CYP3A4 (Krusekopf et al. 2003. *Eur. J. Pharmacology* 466:7-12). Release of lactate dehydrogenase into the culture medium was used as the endpoint for cytotoxicity. In our studies, we observed that alachlor hepatotoxicity (24hr, 0-800 $\mu$ M) was time-dependent and unaffected by pretreatment with 25 $\mu$ M DEX (EC50s $\mu$ M): mean  $\pm$  SEM = 253  $\pm$  7.8 vs. 249.8  $\pm$  14.7 for - vs. + DEX. Further triacetyloleandomycin a CYP3A4 inhibitor, and triazolam a CYP3A7 inhibitor, did not alter alachlor toxicity. The alachlor metabolite DEA was not toxic, while toxicity of CDEPA was evident only in the presence of an arylamidase inhibitor, PMSF. Collectively, these data do not support hepatotoxicity of alachlor initiated by the CYP3A4/7 isoforms through a pathway including DEA as an intermediate. Support: Johnston Science Foundation and Louisiana Board of Regents.

### INTERINDIVIDUAL VARIABILITY IN P450-MEDIATED METABOLISM OF 4-(METHYLNITROSAMINO)-1-(3-PYRIDYL)-1-BUTANONE(NNK) IN HUMAN WHOLE PERIPHERAL LUNG MICROSOMES.

P. J. Brown<sup>1</sup>, K. R. Reid<sup>2</sup>, D. Petsikas<sup>2</sup> and T. E. Massey<sup>1</sup>. <sup>1</sup>*Pharmacology and Toxicology, Queen, Kingston, ON, Canada* and <sup>2</sup>*Surgery, Queen's University, Kingston, ON, Canada.*

NNK is a potent tobacco-specific carcinogen that is believed to play an important role in lung cancer induction in humans. The objective of this study was to determine if interindividual variability in pulmonary NNK metabolism could be attributed to differences in P450 contributions and whether these differences are influenced by P450 genetic polymorphisms. Human whole peripheral lung microsomes were incubated with [<sup>5</sup>-<sup>3</sup>H]NNK and NNK metabolism was assessed by HPLC with radiometric detection. The keto-reduced form of NNK, NNAL, was the major metabolite, with production ranging from 0.0087 to 0.443 %/mg protein/min. Total NNK bioactivation ranged from 1.67 $\times$ 10<sup>-3</sup> to 6.33 $\times$ 10<sup>-3</sup> % total  $\alpha$ -hydroxylation/mg protein/min. Total NNK detoxification by N-oxidation ranged from <6.67 $\times$ 10<sup>-4</sup> to 6.00 $\times$ 10<sup>-3</sup> % total N-oxidation/mg protein/min. Consistent with our previous observations, subjects could be classified as either high (8 subjects) or low (8 subjects) bioactivators (5.00 $\times$ 10<sup>-4</sup>-9.23 $\times$ 10<sup>-4</sup> and 1.93 $\times$ 10<sup>-3</sup> $\pm$ 1.01 $\times$ 10<sup>-3</sup> % total  $\alpha$ -hydroxylation/mg protein/min, n=16, P< 0.05). Similarly, for detoxification, subjects could be grouped into high (4 subjects) and low (12 subjects) categories (4.25 $\times$ 10<sup>-3</sup> $\pm$ 1.66 $\times$ 10<sup>-3</sup> and 6.94 $\times$ 10<sup>-4</sup> $\pm$ 5.01 $\times$ 10<sup>-4</sup> % total N-oxidation/mg protein/min, n=16, P< 0.05). Subjects (n=84) were genotyped for the CYP2A13 Arg257Cys polymorphism and NNK metabolism for the one variant (Arg/Cys) was similar to that for other subjects. Distribution of subjects between bioactivation categories is not consistent with reported frequencies of established P450 genetic polymorphisms, suggesting environmental contributions to the variability in NNK metabolism. Identification of high and low categories for bioactivation and detoxification may be useful for predicting susceptibility of individuals to NNK-induced carcinogenesis. (Supported by CIHR Grant No.MOP-10382).

### COMPARATIVE METABOLISM OF AFLATOXIN B1 (AFB1) BY ZEBRAFISH, RAINBOW TROUT AND HUMAN CYTOCHROMES P450.

C. L. Miranda, W. Chung, J. Wang and D. R. Buhler. *Environment & Mole. Toxicology, Oregon State University, Corvallis, OR.*

The zebrafish is one of the non-mammalian models used to investigate mechanisms of AFB1-induced carcinogenesis. To understand mechanisms of AFB1-induced carcinogenesis in zebrafish, the key enzymes involved in the activation and detoxification of AFB1 has to be identified in this fish model. The present work was carried out to determine the ability of cDNA-expressed zebrafish P450s to metabolize

AFB1 *in vitro*. The enzyme activities of three recombinant zebrafish P450s (zCYP2K6, zCYP1A and zCYP3A65) were compared with those of the rainbow trout (tCYP2K1) and human P450s (hCYP1A1, hCYP1A2 and hCYP3A4) that are known to metabolize AFB1. The oxidation of AFB1 mediated by the various P450s was evaluated by examining the formation of AFB1 epoxide (as a GSH conjugate), AFM1, AFQ1, DNA adducts and protein adducts. Trout CYP2K1 was 3 times more active than the zebrafish ortholog, zCYP2K6, in catalyzing the formation of AFB1-GSH conjugate, DNA adducts and protein adducts. However, zCYP2K6 was 4.4 times more active than hCYP1A1 and was as active as hCYP1A2 in forming the AFB1-GSH conjugate. Zebrafish CYP1A was comparable to hCYP1A1 in forming the AFB1-GSH conjugate. Human CYP3A4 was 12 times more active than zCYP2K6 and 4.7 times more active than tCYP2K1 in mediating the formation of the GSH conjugate. Furthermore, the rate of formation of the AFB1-GSH conjugate mediated by hCYP3A4 was 54-fold and 14-fold higher than with hCYP1A1 and hCYP1A2, respectively. Zebrafish CYP3A65 was inactive toward the formation of AFB1-GSH conjugate. Human CYP3A4 oxidized AFB1 to AFQ1 whereas the zebrafish ortholog, zCYP3A65, did not form AFQ1. Human CYP1A1 and hCYP1A2 catalyzed the formation of AFM1 but zCYP1A, zCYP2K6, zCYP3A65, and tCYP2K1 produced little or no AFM1. These findings indicate that zebrafish P450s were less efficient than trout CYP2K1 and human CYP3A4 in forming the AFB1-8, 9-epoxide which might partially explain the relative insensitivity of zebrafish compared to trout to AFB1-induced carcinogenesis. (Supported by NIH grants Nos. ES 00210 and ES 11587).

#### EXPRESSION AND CHARACTERIZATION OF CHANNEL CATFISH CYP 2X1.

S. MOSADEGH, B. FURNES, C. WONG and D. SCHLENK. *Environmental Toxicology, University of California, Riverside, CA.*

Previous studies of channel catfish identified a novel cDNA encoding the cytochrome P450 isoform, CYP2X1. To better characterize CYP2X1, the protein was expressed in Sf9 cells and examined for catalytic ability. A pFastBac<sup>TM</sup> 1 donor plasmid, containing the CYP2X1 reading frame, was transferred to the bacmid DNA (Baculovirus genome) at the Tn7 site-specific transposition in DH10Bac competent cells. Isolated microsomes from Sf9 cells demonstrated a maximum CO reduced spectrum at 450nm, and exhibited a band at approximately 57 kD on SDS-PAGE. CYP2X1 catalyzed Benzphetamine demethylase activity at 0.790  $\mu$ M/min/ $\mu$ M of CYP2X1. However, enzymatic activity was not observed following incubation with p-Nitrophenol, Fenthion or Testosterone. Studies are currently underway to evaluate alkoxy resorufins as substrates. These results indicate CYP2X1 displays activities consistent with other piscine CYP2 isoforms.

740

#### CHARACTERIZATION AND COMPARISON OF METHODS FOR VESICULAR RECONSTITUTION OF CYTOCHROME P450 2B4 AND NADPH P450 REDUCTASE.

J. R. Reed, R. W. Kelley and W. L. Backes. *Pharmacology, Louisiana State University Health Science Center, New Orleans, LA.*

The gel filtration and cholate dialysis methods for vesicular preparations of liver phosphatidylcholine (PC), cytochrome P450 2B4 (P450), and P450 reductase were compared with respect to protein incorporation and catalytic activity. FPLC size-exclusion chromatography on a Superose 6 column (MW cutoff 5, 000, 000) showed that the majority of P450 (>90%) eluted in the void volume (indicating vesicular incorporation). However, a significant proportion of the reductase (>50%) was not incorporated in the PC vesicles under typical reconstitution conditions (> 1 mg PC and 0.5% cholate (w/v)). The proportion of reductase incorporation was increased by lowering the lipid to detergent ratio used in the solubilization steps of the methods. The vesicular preparations derived from the gel filtration method were significantly more active than reconstitutions where the proteins were preincubated with sonicated dilauryl phosphatidylcholine (DLPC) or PC. The rates of benzphetamine demethylation from these preparations were 3 to 4 fold higher, respectively, than with the reconstituted systems prepared using sonicated DLPC. Although the rates of benzphetamine metabolism using the vesicular samples prepared by cholate dialysis also tended to be higher than those catalyzed by the non-vesicular DLPC reconstitutions, the results were more variable, and in some cases rates catalyzed by the cholate dialysis were similar to those of the DLPC controls. These high rates of metabolism were attained despite the fact that the reductase to P450 ratios in the CD and GF preparations were lower (due to the < 60% incorporation of reductase) than those of the sonicated reconstituted system. These results suggest that the CD and GF methods produced a more catalytically effective incorporation of P450 and reductase into the liposomes, than with the more conventional reconstitutions with DLPC.

741

#### QUANTITATIVE DOSE-RESPONSE EFFECTS OF ACETYLAMINOFLUORENE HEPATOCARCINOGENESIS IN RATS.

A. M. Jeffrey, M. J. Iatropoulos, J. Duan and G. M. Williams. *New York Medical College, Valhalla, NY.*

We have conducted a series of dose-response studies using 2-acetylaminofluorene (AAF) in order to delineate liver tumor initiating effects and their practical thresholds at very low doses. AAF was delivered 3 times per week for up to 16 weeks intragastrically in carboxymethylcellulose (CMC) to F344 male rats. The individual doses were 0 (group I), 0.0026 (II), 0.026 (III), 0.87 (IV), 2.61 mg/kg (V). The following parameters were measured at 4, 8, 12 and 16 weeks: DNA adducts in 108 nucleotides (nts) by 32P-postlabeling; the hepatocellular replicating fraction (RF) as percent proliferating cell nuclear antigen-positive (PCNA+) hepatocytes; glutathione S-transferase-placental type-positive (GST-P+) foci per cm<sup>2</sup> of liver tissue (HAF/cm<sup>2</sup>). At 16 weeks, the values for DNA adducts were 0.4 (group I, CMC), below the limit of quantitation (II), 0.6 (III), 6 (IV), and 21 (V) in 108 nts. The values of RF were 1.4 (I), 1.6 (II), 1.8 (III), 1.7 (IV) and 8.2 (V). Lastly, the values of HAF/cm<sup>2</sup> were 1.1 (I), 1.5 (II), 1.3 (III), 0.6 (IV), and 10.4 (V). The DNA adduct values of groups IV and V were statistically significant compared to control values. These values indicate that the most sensitive parameter to be RF proliferation was evident only in group V, as was the increase in preneoplastic HAF/cm<sup>2</sup>. In previous studies, the cumulative dose of group IV was below the threshold of promotable (with 24 weeks of Phenobarbital) hepatocellular neoplasia, whereas the cumulative dose of group V was above the threshold of promotable neoplasia, yielding an incidence of 100% neoplasms. Thus, 42 mg/kg (group IV) could be considered a practical threshold for promotable hepatocellular neoplasia, despite the occurrence of significant DNA adducts per 108 nts. Moreover, the DNA adduct values of group III were 10 times lower than the values of group IV (cumulative dose of 1.25 mg/kg). These findings indicate that hepatocellular integrity, including repair capability, and proliferation are pivotal in chemical carcinogenesis.

742

#### INFLUENCE OF STRAIN AND DIET ON HEPATOCARCINOGENICITY OF N-BUTYL-N-(4-HYDROXYBUTYL)NITROSAMINE (BBN) IN RATS.

A. Hagiwara<sup>1</sup>, T. Murai<sup>2</sup>, E. Miyata<sup>1</sup>, Y. Toda<sup>1</sup>, M. Sano<sup>1</sup>, S. Mori<sup>2</sup> and S. Fukushima<sup>2</sup>. <sup>1</sup>Daiyu-kai Institute of Medical Science, Ichinomiya, Japan and <sup>2</sup>Department of Pathology, Osaka City University Medical School, Osaka, Japan.

While BBN is widely used as a specific initiator of urinary bladder carcinogenesis for initiation/promotion (I/P) bioassays, our previous investigation clearly demonstrated that it also can act as an initiator of hepatocarcinogenesis. Formalin-fixed and paraffin-embedded liver tissues from two I/P studies were cut, immunohistochemically stained for glutathione S-transferase placental form (GST-P), and quantitatively analyzed. In experiment 1, male Sprague-Dawley (SD)/cShi strain rats (highly sensitive to bladder carcinogenesis by BBN) exhibiting spontaneous hydronephrosis and hydroureter and SD/gShi rats (insensitive), with a genetic predisposition for small testes, were treated with 0.05% BBN in the drinking water for 4 weeks and then housed for up to week 36, with or without exposure to bladder tumor promoters. Slightly higher quantitative values for small GST-P positive (GST-P+) foci were found in SD/gShi (8.57/cm<sup>2</sup>) compared to SD/cShi rats (2.48/cm<sup>2</sup>). In experiment 2, F344 and Lewis rats, subjected to a urinary bladder I/P study, were maintained with MF diets or CA-1 diets for 36 weeks. Higher quantitative values of GST-P+ hepatocytic foci (more than 1 mm in diameter) were found in Lewis rats (9.51/cm<sup>2</sup> for MF diet; 7.95/cm<sup>2</sup> for CA-1 diet) compared to the F344 strain (2.82/cm<sup>2</sup> for MF diet; 1.30/cm<sup>2</sup> for CA-1 diet). Slightly higher values were also noted in rats receiving the MF rather than the CA-1 diet in both strains of rats. No modifying effects on GST-P+ foci were apparent in rats receiving bladder tumor promoters in either experiment. Thus, it was confirmed that the selective bladder carcinogen BBN also acts as a liver carcinogen. The results, from quantitative analysis of small GST-P foci as end point marker lesions, indicate that liver tumor modifying potential of test chemicals can be evaluated in the I/P protocol for urinary bladder carcinogenesis using any strain of rat.

#### THIAMETHOXAM INDUCED MOUSE LIVER TUMORS AND THEIR RELEVANCE TO HUMANS 1. MODE OF ACTION STUDIES IN THE MOUSE.

S. Lloyd<sup>2</sup>, T. Green<sup>2</sup>, A. Toghill<sup>2</sup>, R. Lee<sup>2</sup>, F. Waechter<sup>2</sup>, J. Noakes<sup>2</sup> and T. P. Pastoor<sup>1</sup>. <sup>1</sup>Syngenta Crop Protection, Greensboro, NC and <sup>2</sup>Syngenta Central Toxicology Laboratory, Alderley Park, United Kingdom.

Thiamethoxam, a neonicotinoid insecticide, which is not mutagenic either *in vitro* or *in vivo*, caused an increased incidence of liver tumors in mice when fed in the diet for 18 months at concentrations in the range 500 to 2500 ppm. A number of dietary studies of up to 50 weeks duration have been conducted in order to identify

the mode of action for the development of the liver tumors seen at the end of the cancer bioassay. Both thiamethoxam and its major metabolites have been tested in these studies. Over the duration of a 50 week thiamethoxam dietary feeding study in mice, the earliest change, within one week, is a marked reduction (by up to 40%) in plasma cholesterol. This was followed 10 weeks later by evidence of liver toxicity including single cell necrosis and an increase in apoptosis. After 20 weeks there was a significant increase in hepatic cell replication rates. All of these changes persisted from the time they were first observed until the end of the study at 50 weeks. They occurred in a dose dependent manner and were only observed at doses (500, 1250, 2500ppm) where liver tumors were increased in the cancer bioassay. There was a clear no-effect level of 200ppm. The changes seen in this study are consistent with the development of liver cancer in mice and form the basis of the mode of action. When the major metabolites of thiamethoxam, CGA322704, CGA265307 and CGA330050 were tested in dietary feeding studies of up to 20 weeks duration, only metabolite CGA330050 induced the same changes in the liver as those seen with thiamethoxam. It was concluded that thiamethoxam is hepatotoxic and hepatocarcinogenic as a result of its metabolism to CGA330050. Metabolite CGA265307 was also shown to be an inhibitor of inducible nitric oxide synthase and to increase the hepatotoxicity of carbon tetrachloride. It is proposed that CGA265307, through its effects on nitric oxide synthase, exacerbates the toxicity of CGA330050 in thiamethoxam treated mice.

THIAMETHOXAM INDUCED MOUSE LIVER TUMORS AND THEIR RELEVANCE TO HUMANS 2. SPECIES DIFFERENCES IN RESPONSE.

C. Waterfield<sup>2</sup>, T. Green<sup>2</sup>, R. Lee<sup>2</sup>, A. Toghill<sup>2</sup>, F. Waechter<sup>2</sup>, R. Peffer<sup>1</sup>, J. Noakes<sup>2</sup>, M. Robinson<sup>2</sup> and T.P. Pastoor<sup>1</sup>. <sup>1</sup>Syngenta Crop Protection, Greensboro, NC and <sup>2</sup>Syngenta CTL, Alderley Park, Cheshire, United Kingdom.

Thiamethoxam is a neonicotinoid insecticide that is not a mutagen, but it caused a significant increase in liver cancer in mice, but not rats, in chronic dietary feeding studies. Previous studies in mice have characterised a carcinogenicity mode of action which involved depletion of plasma cholesterol, cell death, both as single cell necrosis and as apoptosis, and sustained increases in cell replication rates. In a dietary feeding study, female rats were exposed to thiamethoxam at 0, 1000 and 3000ppm for 50 weeks, a study design directly comparable to the mouse study in which the mode of action changes were characterised. In rats, thiamethoxam had no adverse effects on either the biochemistry or histopathology of the liver at any time point. Cell replication rates were not increased, in fact they were significantly decreased at several time points. The lack of effect on the rat liver is entirely consistent with the lack of liver tumor formation in the 2 year cancer bioassay. Comparisons of the metabolism of thiamethoxam in rats and mice have shown that concentrations of the parent chemical were no lower in rat blood than in mouse blood in both single dose and dietary studies, strongly indicating that thiamethoxam itself is unlikely to play a role in the development of liver tumors. In contrast, the concentrations of the two metabolites, CGA265307 and CGA330050, shown to play a role in the development of liver damage in the mouse, were 140 (CGA265307) and 15 (CGA330050) fold lower in rats than in mice following either a single oral dose, or dietary administration of thiamethoxam for up to 50 weeks. Comparisons of the major metabolic pathways of thiamethoxam *in vitro* using mouse, rat and human liver fractions have shown that metabolic rates in humans are even lower than those in the rat, suggesting that thiamethoxam is unlikely to pose a hazard to humans exposed to this chemical at the low concentrations arising from its use as an insecticide.

THIAMETHOXAM INDUCED MOUSE LIVER TUMORS AND THEIR RELEVANCE TO HUMANS 3. WEIGHT OF EVIDENCE EVALUATION.

T.P. Pastoor<sup>1</sup>, P. Rose<sup>2</sup>, S. Lloyd<sup>2</sup>, R. Peffer<sup>1</sup> and T. Green<sup>2</sup>. <sup>1</sup>Syngenta Crop Protection, Greensboro, NC and <sup>2</sup>Syngenta CTL, Alderley Park, Cheshire, United Kingdom.

Thiamethoxam was shown to increase the incidence of mouse liver tumors in an 18 month study; however, thiamethoxam was not hepatocarcinogenic in rats. Thiamethoxam is not genotoxic, and, given the late life generation of mouse liver tumors, suggests a time-related progression of key hepatic events that leads to the tumors. These key events were identified in a series of studies of up to 50 weeks that showed the time-dependent evolution of relatively mild liver dysfunction within 10 weeks of dosing, followed by frank signs of hepatotoxicity after 20 weeks, leading to cellular attrition and regenerative hyperplasia. Metabolite CGA330050 was identified as generating the mild hepatic toxicity, and metabolite CGA265307 exacerbated the initial toxicity by inhibiting inducible nitric oxide synthase. This combination of metabolite-generated hepatotoxicity and increase in cell replication rates is postulated as the mode of action for thiamethoxam-related mouse liver tumors. The relevance of these mouse-specific tumors to human health was assessed by using the framework and decision logic developed by ILSI-RSI. The postulated

mode of action was tested against the Hill criteria and found to fulfill the comprehensive requirements of strength, consistency, specificity, temporality, dose-response, and the collective criteria of being a plausible mode of action that fits with known and similar modes of action. Whereas the postulated mode of action could theoretically operate in human liver, quantitation of the key metabolites *in vivo* and *in vitro* showed that mice, but not rats or humans, generate sufficient amounts of these metabolites to initiate the hepatic toxicity and consequent tumors. Indeed, rats fed 3000ppm thiamethoxam for a lifetime did not develop hepatotoxicity or tumors. In conclusion, the coherence and extent of the database clearly demonstrates the mode of action for mouse liver tumorigenesis and also allows for the conclusion that thiamethoxam does not pose a carcinogenic risk to humans.

ESTIMATION OF A NO OBSERVED EFFECT LEVEL FOR 4, 4'-OXYDIANILINE, A GENOTOXIC LIVER CARCINOGEN, IN A 16-WEEK FEEDING STUDY USING MALE F344 RATS.

Y. Doi<sup>1</sup>, N. Imai<sup>1</sup>, A. Hagiwara<sup>1</sup>, H. Yoshino<sup>1</sup>, S. Tamano<sup>1</sup>, H. Wanibuchi<sup>2</sup>, K. Morimura<sup>2</sup> and S. Fukushima<sup>2</sup>. <sup>1</sup>Daiyu-Kai Institute of Medical Science, Inc., Ichinomiya, Japan and <sup>2</sup>Department of Pathology, Osaka City University Medical School, Osaka, Japan.

We have already reported the presence of practical no observed effect levels for the genotoxic hepatocarcinogens, 2-acetylaminofluorene and 2, 4-diaminotoluene. In the present study the carcinogenic potential of 4, 4'-oxydianiline (ODA) at very low doses was evaluated in male F344 rats. Groups of 90 or 30 animals (21-days old at the commencement) received 0 (as control), 0.1, 1, 10, 25, 50, 100 and 200 ppm ODA in their diet for 16 weeks. Liver weights were measured and quantitative values for glutathione S-transferase placental form (GST-P) positive hepatocytic foci, considered as preneoplastic lesions, were analyzed. During the dosing period no adverse effects were found in terms of survival, clinical signs, body weights and blood biochemistry in any of the treated groups. Statistically significant elevation of relative liver weights was found in the 200 ppm group, but not in animals fed diet containing 100 ppm or less. GST-P positive foci, consisting of 2 or more cells were significantly increased at doses of 10 ppm and above, but values for 0.1 and 1 ppm demonstrated no differences from the controls. These results suggest that 1 ppm (average intake; 0.0068 mg/kg/day) is a practical no-observed effect level for hepatocarcinogenesis by ODA.

**747**

MUTAGENICITY OF PYRROLIZIDINE ALKALOIDS IN RAT LIVER.

T. Chen, N. Mei and R. H. Heflich. Division of Genetic and Reproductive Toxicology, NCTR/FDA, Jefferson, AR.

Plants containing pyrrolizidine alkaloids (PAs) are found world-wide and have the potential to poison livestock, wildlife, and humans. PAs are rodent carcinogens and induce mutations in a number of *in vitro* systems. However, the mutagenicity of PAs has not been evaluated in tumor target tissue. In this study, we determined the mutagenicity of riddelliine, a widely studied PA, and comfrey, a perennial plant containing more than 9 different PAs in rat liver, the target tissue for their carcinogenicity. Groups of 6 transgenic Big Blue rats were treated for 12 weeks either by gavage with 0.1 to 1 mg/kg riddelliine or by feeding a diet containing 2% comfrey root. The animals were sacrificed one day after the last treatment and liver DNA was isolated for analysis of mutations in the transgenic cII gene. A significant dose-dependent increase in MF was found for riddelliine treatment, increasing from 30 x 10-6 in the control animals to 47, 55, and 103 x 10-6 in the 0.1, 0.3, and 1.0 mg/kg dose groups, respectively. The MF for rats fed with comfrey was 146 x 10-6, a 5-fold increase over the control ( $p < 0.001$ ). Molecular analysis of the mutants indicated that there were statistically significant differences between the mutational spectra of the control rats and the rats treated with riddelliine and comfrey, while the riddelliine and comfrey spectra were quite similar. G:C > T:A transversion was the major type of mutation in rats treated with PAs (35% of riddelliine mutants and 42% of comfrey mutants), whereas 55% of mutations from control rats were G:C > A:T transitions. In addition, mutations from the PA-treated rats included an unusually high frequency (8% for riddelliine, 17% for comfrey) of GG > TT and GG > AT tandem base substitutions, while none of these mutations were in the control spectrum. These results indicate that PAs are genotoxic carcinogens in rat liver and that different types of PAs produced a similar and unique mutational spectrum.

EXPERIMENTAL STUDY ON CARCINOGENESIS INDUCED BY CYANOBACTERIAL MICROCYSTINS AND ORGANIC EXTRACTS OF TAP WATER.

J. ZHAO<sup>1,2</sup>, S. Jiang<sup>1</sup>, W. Qu<sup>1</sup> and H. Zhu<sup>1</sup>. <sup>1</sup>EOH, Fudan University, Shanghai, China and <sup>2</sup>EOH, University of Pitt, Pittsburgh, PA. Sponsor: J. Jiang.

Conventional drinking water treatment processes are not sufficient to remove Cyanobacterial Microcystins (MCs), and chronic exposure to MCs via drinking water may have tumour-promotion effect. Certain disinfections by-products

(DBPs) in drinking water were found to be mutagenic. Coexistence of DBPs and MCs in drinking water may lead to potential synergistic effects during carcinogenesis. In order to investigate the synergistic effects of MCs and organic extractions of water (OEWS) and its potential mechanism during carcinogenesis, a two-stage hepatocarcinogenesis rat model (Solt-Farber Model) was established using OEWS and MCs applied as the initiator and promoter, respectively. The histopathological changes in liver were observed, and expressions of GSTPi and other genes involved in MAPKs signals pathway were detected, and DNA binding activity of AP-1 and GEPI binding activity of nuclei proteins were analyzed by EMSA as well. The results showed that OEWS and MCs could induce hyperplastic and precancerous foci as well as nodule in livers of rats. MCs alone could up-regulate the expressions of PELK-1, c-jun, and c-fos, and enhance DNA binding activity of AP-1 and GEPI binding activity of nuclei protein in hepatocytes of rats. Further promoted up-regulation of related gene expressions were also seen in this study when rats were initiated with OEWS before the administration of MCs ( $p<0.05$ ). It was also indicated that OEWS alone could induce expressions of GSTPi mRNA and protein in livers. While compared to OEWS, MCs alone could not induce the expression of GSTPi, but could promote the expressions of GSTPi mRNA and protein induced by OEWS ( $p<0.05$ ). The results suggested that MCs possessed tumor-promoting activity while OEWS were mutagenic and possessed initiation activity. MCs and OEWS have synergistic effects during experimental hepatocarcinogenesis in rats. Inhibiting of protein phosphates activity and up-regulating of MAPKs signals pathway may be potential tumour promotion mechanism of MCs during carcinogenesis.

749

#### INHIBITION OF GAP JUNCTIONAL INTERCELLULAR COMMUNICATION BY CHLOROHYDROXYFURANONES IN WB-F344 CELLS.

E. Rintala, P. Hakulinen, J. Maki-Paakkonen and H. Komulainen. *Department of Environmental Health, National Public Health Institute, Kuopio, Finland. Sponsor: J. Tuomisto.*

Chlorohydroxyfuranones (CHFs) are mutagenic by-products in chlorinated drinking water. The CHFs MCA (3, 4-dichloro-5-hydroxy-2(5H)-furanone), CMCF (3-chloro-4-(chloromethyl)-5-hydroxy-2(5H)-furanone), and MCF (3-chloro-4-methyl-5-hydroxy-2(5H)-furanone) have been shown to be genotoxic *in vitro* in bacteria and in mammalian cells. In a two-stage cell transformation assay MCA and MCF promote transformation foci formation. All three CHFs inhibit gap junctional intercellular communication (GJIC) in mouse Balb/c 3T3 fibroblasts. Inhibition of GJIC is supposed to be one mechanism in tumor-promotion. In the present study, the effects of MCA, CMCF, and MCF on GJIC were measured in rat WB-F344 liver cells using the scrape loading dye transfer technique. The cells were exposed to MCA (10, 20, 40, and 80  $\mu$ M), CMCF (6.25, 12.5, 25, and 50  $\mu$ M), and MCF (50, 150, 450, and 1350  $\mu$ M) for 1 hour and 12 hours. All three CHFs inhibited GJIC up to 67-73%, in a dose-dependent fashion, in the order of potency CMCF~MCA>MCF. The inhibition by MCA and MCF augmented during the 12 hours exposure period, whereas CMCF inhibited GJIC to the same extent at both exposure times. After 1 hour exposure, the GJIC recovered slowly in CHF-free medium. These results indicate that all these three CHFs inhibit GJIC in rat liver cells *in vitro*.

#### $\alpha$ 2-MACROGLOBULIN: A NOVEL CYTOCHEMICAL MARKER CHARACTERIZING PRENEOPLASTIC AND NEOPLASTIC RAT LIVER LESIONS NEGATIVE FOR HITHERTO ESTABLISHED CYTOCHEMICAL MARKERS.

T. Sukata<sup>1,2</sup>, S. Uwagawa<sup>1,2</sup>, K. Ozaki<sup>1,2</sup>, K. Sumida<sup>1</sup>, M. Kushida<sup>1,2</sup>, K. Saito<sup>1</sup>, K. Morimura<sup>2</sup>, K. Oeda<sup>1</sup>, N. Mikami<sup>1</sup> and S. Fukushima<sup>2</sup>.

<sup>1</sup>*Environmental Health Science Laboratory, Sumitomo Chemical Co., Ltd., Osaka, Japan* and <sup>2</sup>*Pathology, Osaka City University Medical School, Osaka, Japan.*

In risk assessment of compounds targeting the liver one problem has been that well established cytochemical markers of preneoplastic lesions such as glutathione S-transferase (GST-P) are inadequate to detect some types of altered foci. In the present study, we tried to identify a novel marker characteristic for rat hepatocellular preneoplastic and neoplastic lesions, undetectable by well established cytochemical markers. GST-P negative hepatocellular altered foci (HAF), hepatocellular adenomas (HCAs), hepatocellular carcinomas (HCCs) were generated by two initiation-promotion models with N-nitrosodiethylamine (NDEN) and peroxisome proliferators, Wy-14, 643 and clofibrate. Total RNAs isolated from laser-microdissected GST-P negative HAF (amphophilic cell foci) and adjacent normal tissues were applied to microarray analysis. As a result, 5 upregulated genes were identified, and further detailed examinations of the gene demonstrating most fluctuation, i.e., that for  $\alpha$ 2-macroglobulin ( $\alpha$ 2M) were performed. In RT-PCR,  $\alpha$ 2M mRNA was overexpressed not only in GST-P negative HAF but also in GST-P negative HCAs and HCCs. *In situ* hybridization showed accumulation of  $\alpha$ 2M mRNA to be evenly

distributed within GST-P negative HAF (predominantly amphophilic cell foci). Distinctive immunohistochemical staining for  $\alpha$ 2M could be consistently demonstrated in GST-P negative HAF, HCAs and HCCs induced not only by peroxisome proliferators but also NDEN alone. Moreover quantitative analysis of the number of  $\alpha$ 2M mRNA positive foci revealed that  $\alpha$ 2M was a sensitive marker for detection of GST-P negative HAF as compared to conventional histopathological examination. Thus our findings suggest that  $\alpha$ 2M is an important novel cytochemical marker to identify hepatocellular preneoplastic lesions, undetectable by established cytochemical markers and is tightly linked to rat hepatocarcinogenesis.

#### MECHANISMS OF 2-BUTOXYETHANOL CARCINOGENESIS.

S. M. Corthals, L. M. Kamendulis and J. E. Klaunig. *Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Chronic exposure to 2-butoxyethanol increases liver hemangiosarcomas in mice. We proposed that the production of liver hemangiosarcomas result from Kupffer cell activation, secondary to hemolysis from 2-butoxyethanol exposure. The present studies examined the effect of 2-butoxyethanol and its metabolites, 2-butoxacetaldehyde and 2-butoxyacetic acid, along with the contribution of the Kupffer cell, on mouse endothelial cell DNA damage (measured by the Comet Assay). 2-Butoxyethanol, 2-butoxyacetic acid (1-10mM), or 2-butoxyacetaldehyde (0.1-1.0mM) did not induce an increase in endothelial cell DNA Damage over control after 2, 4, or 24 hrs of exposure. The effect of hemolyzed RBCs on the induction of endothelial cell DNA damage was also examined and produced an increase in damage after 4 hrs of treatment. Similarly, ferrous sulfate (0.1-1.0 $\mu$ M; 2-24 hrs) and hydrogen peroxide (50-100 $\mu$ M; 1-4 hrs) induced DNA damage in the endothelial cells. Our proposed mode of action argues that Kupffer Cell activation plays a central role in the development of the 2-butoxyethanol induced hemangiomas. To address this, the effect of 2-butoxyethanol, 2-butoxyacetic acid and/or hemolyzed RBCs on macrophage activation was studied. 2-Butoxyethanol and 2-butoxyacetic acid did not activate macrophages (TNF- $\alpha$  release) after 4 hrs treatment. However, hemolyzed RBCs (10 x 10 $^6$ ) increased TNF- $\alpha$  concentrations. The effect of activated macrophages on endothelial cell DNA damage and cell proliferation were also studied. Co-culture of endothelial cells with activated macrophages resulted in increased endothelial cell DNA Damage after 4 or 24 hrs of treatment. Activated macrophages also increased endothelial cell DNA synthesis after 24 hrs compared to control. These data suggest that iron from hemolyzed RBCs and/or products from Kupffer cell activation (possibly ROS), lead to the production of DNA damage in endothelial cells. In addition, the increases in cytokines from the activated Kupffer cells may stimulate endothelial cell proliferation, contributing to the induction of hemangiosarcomas.

#### EVIDENCE FOR THE INVOLVEMENT OF THE KUPFFER CELL IN HEPATIC CARCINOGENESIS.

L. M. Kamendulis, S. M. Corthals and J. E. Klaunig. *Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

The induction of hepatocellular neoplasia in rodents is a multistep process involving a series of cellular modifications. Historically, studies have focused on the hepatocyte as the target cell of chemical carcinogens, however, recent studies are emerging that suggest a role for non-parenchymal cells, specifically Kupffer cells, as mediators for the induction of cell proliferation by tumor promoters. The present studies further defined the role of the Kupffer in hepatocarcinogenesis through examining the effect of Kupffer cell modulation on hepatocellular growth. Kupffer cell depletion was achieved using liposomal delivery of clodronate. Initial studies demonstrated that clodronate liposome treatment reduced the number of Kupffer cells and inhibited lipopolysaccharide-mediated TNF $\alpha$  production. LPS (0.25 mg/kg i.p.; 1x or 2x/week) in male B6C3F1 mice resulted in an increase the number of Kupffer cells and DNA synthesis. Co-treatment with clodronate liposomes decreased the number of Kupffer cells to levels below control values in all groups. Kupffer cell depletion produced a 50% reduction in the basal level of DNA synthesis in liver, and prevented LPS-induced DNA synthesis (~80% reduction). Hepatic focal lesions were produced in B6C3F1 mice using diethylnitrosamine. Following preneoplastic lesion development, LPS (0.25 mg/kg i.p., 1x/week) for 7 or 28 days increased the relative number of hepatic focal lesions (~ 2.7-fold compared to control), as well as an increase in focal lesion volume (3.5-fold increase). In addition, LPS produced a 3-fold increase in focal lesion DNA synthesis. Inactivation of Kupffer cells reduced the number, volume and DNA synthesis in diethylnitrosamine-induced hepatic focal lesions. These data provide evidence supporting the involvement of the Kupffer cell in hepatic carcinogenesis, and suggest that this cell type may function at the tumor promotion stage of the cancer process.

MECHANISTIC ANALYSIS OF CARCINOGENIC AND NONCARCINOGENIC LIVER TOXICANTS USING TOXICOGENOMIC DATA DERIVED FROM RAT LIVER OR PRIMARY RAT HEPATOCYTES.

M. S. Orr, K. K. Daniels and W. B. Mattes. *Toxicogenomics, Gene Logic Inc., Gaithersburg, MD.*

The ability to rapidly identify agents that have the potential to induce carcinogenicity is critical for selecting safe drugs. The current study was designed to identify the similarities and differences at the gene expression level for a panel of agents that induce carcinogenicity via genotoxic or nongenotoxic mechanisms. Specifically, DNA damage response, cell proliferation/cell death, and DNA repair genes will be evaluated in both the rat liver and primary rat hepatocyte model systems using Affymetrix RGU34 Gene Chip® set. In addition, the study will include two negative controls. The two negative controls are Rosiglitazone, which is pharmacologically active in the liver and it is currently being examined as a chemopreventive agent and Acetaminophen, which induces liver damage via necrosis and is not considered to be a carcinogen. Acetaminophen is interesting from the perspective that there are elevations in genes associated with DNA repair such as BTG2, PCNA, and GADD45a. Furthermore, there were elevations in numerous p53 target genes such as cyclin G1, mdm2, and BTG2 following exposure to acetaminophen, similar to the response observed following the administration of genotoxic carcinogens such as ethionine. However, acetaminophen lacked a robust gene expression response for DNA repair genes such as MGMT and APEX1 that are routinely overexpressed following treatment with many genotoxic carcinogens. Interestingly, samples exposed to rosiglitazone lack both the DNA damage and DNA repair response. Is the overexpression of p53-regulated genes enough information to assume that DNA damage has been induced or should other genes associated specifically with DNA repair be dysregulated in combination with the p53-regulated gene sets? The results from this analysis will shed light on similarities and differences in the gene expression responses correlated with carcinogenicity for genotoxic, nongenotoxic carcinogens and negative control compounds.

DEVELOPMENT OF A GENE SIGNATURE THAT DISCRIMINATES BETWEEN GENOTOXIC AND NON-GENOTOXIC COMPOUNDS.

G. Vansant, P. Pezzoli, C. Duffy and J. Monforte. *Althea Technologies, San Diego, CA.* Sponsor: F. Ferre.

Efforts are underway to develop multiple gene signatures of toxicity including hepatotoxicity, nephrotoxicity, oxidative stress, inflammation response and carcinogenicity. This study describes the efforts and results to develop a gene signature that identifies carcinogens and classifies them as genotoxic or non-genotoxic. Moreover, this assay is being developed to characterize compounds as genotoxic or non-genotoxic using *in vivo* or *in vitro* platforms. Primary rat hepatocytes in culture, C9 liver cells, and Sprague-Dawley rats were treated with a set of genotoxic or non-genotoxic compounds including clofibrate, fenofibrate, estradiol (non-genotoxic) and 2-acetylaminofluorine, benzo[*a*pyrene, methyl methanesulfonate, mitocycin C, cyclophosphamide, and cisplatin (genotoxic). After treatment for 7 days in the live rats and 24 hours in the hepatocytes and C9 cells in culture, RNA was isolated from the livers of the rats, and the cells in culture and expression of selected genes was measured relative to the expression of control genes. Genes related to xenobiotic metabolism, proliferation, apoptosis, and DNA damage were part of the panel of genes whose expression was measured. Statistically significant correlations were found in rats and cells treated with the same compounds. The data support the use of gene expression in conjunction with *in vitro* platforms as a replacement for *in vivo* platforms in some early screens. Successful cross platform carcinogenic gene signature development and utilization suggests genotoxicity or nongenotoxicity of a compound determined *in vitro* would correlate with its potential to have the same toxicity *in vivo*. Finally, understanding the functions of genes whose expression changes *in vivo* and *in vitro* are similar in response to the same perturbations should be helpful in determining for future studies which physiological responses observed *in vitro* systems are relevant *in vivo*.

A GENE EXPRESSION SIGNATURE FOR NON-GENOTOXIC CARCINOGENS.

A. Y. Nie, M. K. McMillian, A. M. Leone, J. B. Parker, L. Piechta, S. Bryant, J. Herlich, M. Kemmerer, N. Raghavan, D. Amarantunga, L. Yieh, A. Bittner, J. Wan, M. D. Johnson and P. G. Lord. *Mechanistic Toxicology, Johnson & Johnson PRD, LLC, Raritan, NJ.*

There are a number of rapid, predictive assays for DNA damaging carcinogens, but about half of tumors in rodents are due to non-genotoxic carcinogens, and these compounds are not so easily predicted, with definitive results requiring two years of high dose compound administration. Unexpected discovery that a compound is a

non-genotoxic carcinogen can be a devastating, expensive failure. While establishing a database of liver gene expression responses to over 100 paradigm hepatotoxins, many of the compounds were noted to be non-genotoxic carcinogens, and a gene expression signature for this type of toxicity was determined using data collected 24 hours after compound administration. Although liver is not always the target organ for tumor development, this tissue frequently shows broad gene expression changes to non-genotoxic carcinogens; many of these changes are probably adaptive to prevent hepatic tumor formation. Two classes of hepatotoxins, PPAR $\alpha$  agonists and macrophage activators, produce strong gene expression signatures that overwhelm the responses of other compounds in the database. Both classes of compounds lead to characteristic liver tumors (peroxisome proliferators induce adenomas, macrophage activators lead to carcinomas), but were removed from the database before characterizing other non-genotoxic carcinogens. Gene selection methods were as previously published. Briefly, compounds identified in the literature as non-genotoxic carcinogens were split into training (65%) and testing (35%) sets, and training set compounds were compared to known non-carcinogens to select the best distinguishing genes. Accuracy of prediction was tested using testing compounds; other novel compounds are presently being tested. Some of the best genes for distinguishing non-genotoxic carcinogens from other compounds confirmed literature reports (for example, Ddb1 - damage-specific DNA binding protein 1), but many were surprises (for example, G6pt1 - glucose-6-phosphatase).

EFFECTS OF 3-METHYLCHOLANTHRENE ON HEPATIC GENE EXPRESSION PATTERNS IN RATS USING CDNA MICROARRAY ANALYSES.

S. Kondraganti, W. Jiang, K. Muthiah and B. Moorthy. *Pediatrics, Baylor College of Medicine, Houston, TX.*

3-Methylcholanthrene (MC), a polycyclic aromatic hydrocarbon (PAH), is one of the most potent carcinogens known to date. In experimental animals, MC induces the expression of cytochrome P4501A1 (CYP1A1) and CYP1A2, which play important roles in the bioactivation of MC to genotoxic metabolites. In this study, we tested the hypothesis that treatment of rats with MC would lead to persistent induction of genes encoding CYP1A1/1A2, phase II enzymes, as well as other genes that may play a role in MC-mediated carcinogenesis. Adult female Sprague-Dawley rats were treated with MC (93  $\mu$ mol/kg), i.p., once daily for 4 days, and gene expression patterns were investigated using hepatic RNA isolated from animals at 1, 15, and 28 days after MC withdrawal. Gene expression was monitored by hybridization of the RNA with a chip containing 4608 unique clones from liver-derived EST libraries fortified with clones of known liver genes representing ~4000 genes. Following hybridization, the chips were scanned using Agilent Microarray scanner, and the data were analyzed using Agilent Feature Extraction. Several Ah receptor-regulated genes encoding phase I (CYP1A1, 1A2, 1B1) and phase II (glutathione-S-transferase- $\alpha$ , NAD(P)H:quinone reductase, epoxide hydrolase, UDP-glucuronosyltransferase, and aldehyde dehydrogenase) enzymes were persistently induced (3-13-fold) by MC for 15-28 days. The induction of these drug metabolism genes correlated well with enzymatic, protein and mRNA studies. MC also elicited sustained induction (5-7-fold) of acute phase genes, i.e. haptoglobin and alpha-1-acid glycoprotein (AGP) for up to 28 days, and this was accompanied by sustained liver damage in the MC-exposed rats. Elevation of acute phase proteins is observed in many cancerous tissues. Thus, determining the mechanisms of persistent induction of the above-mentioned genes might lead to new strategies in the prevention/treatment of cancers induced by chemical carcinogens. (Supported in part by NIH grant ES009132 to BM and DOD grant BC021962 to SK.)

GENE EXPRESSION PROFILING IDENTIFIES GENE CHANGES INDICATIVE OF POTENTIAL EARLY NEOPLASTIC LIVER LESIONS CAUSED BY THE RODENT HEPATOCARCINOGEN METHYLEUGENOL.

J. T. Auman, J. Foley and R. S. Paules. *National Center for Toxicogenomics, NIEHS, Research Triangle Park, NC.*

Methyleugenol is a potent rodent carcinogen used widely as a fragrance and flavoring additive that caused liver tumors in both rats and mice in the 2 year NTP bioassay. To determine if gene expression profiling can be used to identify indicators of preneoplastic lesions, we examined hepatic gene expression in male Fisher rats following exposure to methyleugenol and in hepatocellular carcinomas obtained from rats in the methyleugenol NTP study. Methyleugenol was administered by gavage for 1 to 14 days, with hepatic gene expression measured at various times during the treatment regimen, as well as 6 months after the last dose. Hepatic gene expression of treated samples or tumors was measured with the Agilent rat 60-mer oligonucleotide microarray compared to time matched controls. Comparison of gene expression changes during high dose methyleugenol treatment with hepatocellular carcinomas revealed significant overlap of differentially expressed genes. Surprisingly, two of the gene expression profiles generated from livers 6 months

after low dose methyleugenol treatment were markedly similar to those obtained from hepatocellular carcinomas, as determined by hierarchical clustering. Histological analysis of liver samples 6 months after methyleugenol treatment showed a dose-dependent increase in the number of animals with subtle GST-pi positive foci. Preliminary analysis of additional 6 month liver samples from animals exposed to intermediate doses of methyleugenol suggests gene expression alterations are present and persist for 6 months after the last exposure that reflect the potential preneoplastic lesions. These gene expression alterations should provide insight into the mechanisms of hepatocarcinogenesis induced by methyleugenol.

#### GENE REGULATION PATTERNS IN RAINBOW TROUT AFLATOXIN B<sub>1</sub>-INDUCED HEPATOCELLULAR CARCINOMA COMPARED TO NORMAL ADJACENT LIVER.

S. C. Tilton<sup>1,2</sup>, J. D. Hendricks<sup>1</sup>, G. S. Bailey<sup>1,2</sup> and D. E. Williams<sup>1,2</sup>.

<sup>1</sup>Environmental & Molecular Toxicology Department and Marine & Freshwater Biomedical Sciences Center, Oregon State University, Corvallis, OR and <sup>2</sup>Linus Pauling Institute, Oregon State University, Corvallis, OR.

Hepatocellular carcinoma (HCC) is one of the most common malignancies in humans worldwide particularly in Southeast Asia, Japan and Africa, although incidence of HCC in the United States is rising and exhibits the fastest increase among solid tumors. The rainbow trout has proven an excellent model for the study of aflatoxin B<sub>1</sub> (AFB<sub>1</sub>)-induced human hepatocarcinogenesis and chemoprevention because it exhibits mechanisms of metabolism, DNA adduction, oncogene activation and pathology similar to mammalian models. Recently, a number of studies have examined differential gene expression in HCC to identify genes responsible for tumor formation and to further understand the underlying molecular mechanism for disease. In this study, we examined, for the first time, gene expression by microarray in the trout tumor model. Rainbow trout embryos were initiated with 50 ppb AFB<sub>1</sub> and then tumors were isolated from 13 month old juvenile fish following our standard tumor protocol. Global gene expression was determined in HCCs compared to normal adjacent liver utilizing a rainbow trout oligonucleotide array containing approximately 1500 genes for toxicology, comparative immunology, carcinogenesis and stress physiology. We observed distinct gene regulation patterns in HCC compared to adjacent normal tissue including upregulation of genes important for cell cycle control, transcription and cytoskeleton formation and down regulation of genes involved in detoxification and drug metabolism, lipid metabolism and retinol metabolism. These gene classes have previously been observed to be important in the regulation of HCC in human and rodent models. Overall, these findings may lead to a better understanding of the mechanism of AFB<sub>1</sub>-induced hepatocarcinogenesis in the trout model and to identify conserved genes important in carcinogenesis across species. Supported by NIH grants ES03850, ES07060, ES00210 and CA90890.

#### TOXICOGENOMIC ANALYSIS OF NUCLEAR RECEPTOR-MEDIATED AND -INDEPENDENT RESPONSES TO PEROXISOME PROLIFERATORS.

C. G. Woods<sup>1</sup>, B. U. Bradford<sup>1</sup>, M. L. Cunningham<sup>2</sup>, M. Kadiiska<sup>3</sup>, R. P. Mason<sup>3</sup>, A. M. Burns<sup>4</sup>, J. M. Peters<sup>4</sup> and I. Rusyn<sup>1</sup>. <sup>1</sup>Environmental Science and Engineering, UNC, Chapel Hill, NC, <sup>2</sup>NCT and NTP, NIEHS, Research Triangle Park, NC, <sup>3</sup>Laboratory of Pharmacology and Chemistry, NIEHS, Research Triangle Park, NC and <sup>4</sup>Veterinary Science, PSU, University Park, PA. Sponsor: I. Rusyn.

Use of microarray technology is a rapid and efficient method for profiling gene expression changes that can be used to elucidate the mode of action of toxicants. Advances in microarray data analysis now allow for construction of detailed molecular maps displaying pathways associated with a specific toxic response. These capabilities can be useful when studying agents that are suspected to have similar modes of action. In the case of some nongenotoxic carcinogens, there appears to be a large degree of similarity in the mode of action which involves activation of a nuclear receptor, and induction of genes associated with metabolism, cell proliferation, DNA damage and oxidative stress. In this study, we investigated peroxisome proliferator-induced response in mouse liver, which is mediated by nuclear receptor PPAR-alpha. The current body of knowledge surrounding these compounds reports an increase in oxidants, induction of mitogenic cytokines in Kupffer cells, increased cell proliferation, and PPAR-alpha dependent molecular events. PPAR-alpha null mice, NADPH oxidase-deficient mice (p47 phox-null) and wild-type C57BL/6J mice were fed WY-14, 643 (0.5% w/w) for up to 5 weeks. Liver tissue was used to measure gene expression levels and phenotypic response. A map of microarray gene expression data for treated wild-type and p47 phox null mice revealed an induction of metabolism, cell proliferation and DNA repair pathways. This response was not observed in PPAR-alpha null mice. Phenotypic anchoring of gene expression data was conducted by measuring oxidant production and induction of lipid metabolism and other genes. We show that while PPAR-alpha is required for these processes, the Kupffer cell-mediated responses are diminished after weeks of peroxisome proliferator treatment. (Supported by ES11391, ES11660).

#### COMPARATIVE EFFECTS OF TRICHLORACETIC ACID ON RODENT AND HUMAN HEPATOCYTES: ROLE OF PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR $\alpha$ (PPAR $\alpha$ ).

D. J. Smith, X. Pu, L. M. Kamendulis and J. E. Klaunig. *Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Trichloroethylene (TCE) and trichloroacetic acid (TCA), a metabolite of TCE, belong to the peroxisome proliferator class of chemicals and induce liver tumors in mice following chronic exposure. The carcinogenic effect of peroxisome proliferators is believed to involve agonist binding to the peroxisome proliferator activated receptor  $\alpha$  (PPAR $\alpha$ ). Whether TCE and TCA induce hepatic cancer through this mode of action was evaluated in the present studies. Induction of DNA synthesis and apoptosis by TCA was examined in hepatocytes from B6C3F1, PPAR $\alpha$  knockout and 129/Sv wildtype mouse strains. TCA (0.1 - 5.0 mM) produced a concentration-related increase DNA synthesis in both B6C3F1 and 129/Sv hepatocytes at 24, 48 and 72 hrs. In hepatocytes from PPAR $\alpha$  knock mice, TCA failed to increase DNA synthesis at any time point examined. In human hepatocytes, TCA decreased DNA synthesis. Apoptosis was increased by 2.5 and 5.0 mM TCA (-2-fold) in B6C3F1 hepatocytes after 48 and 72 hrs and by 5.0 mM TCA (1.5-2.5-fold) in 129/Sv hepatocytes at 48 and 72 hr exposure. No changes in apoptosis were seen in PPAR $\alpha$  null or human hepatocytes. In addition, peroxisomal  $\beta$  oxidation, a measure of peroxisome proliferation was increased by TCA in hepatocytes from B6C3F1 (- 2-4-fold over control), and 129/Sv (-2-fold) mice, whereas no induction was seen in hepatocytes from PPAR $\alpha$  null mice or in human hepatocytes. In a 7 day *in vivo* study, TCA (0.5 and 2.0 g/L) and TCE (250 and 1000 mg/kg) increased DNA synthesis (2.0-5.7-fold) and peroxisomal  $\beta$  oxidation in the 129/Sv mouse, while no changes in these endpoints were seen in the PPAR $\alpha$  null mice. Neither TCA nor TCE altered levels of apoptosis in either strain of mice. These data demonstrate that (1) human hepatocytes are refractory to the induction of DNA synthesis and apoptosis by TCA and that (2) the PPAR $\alpha$  is required for the induction of DNA synthesis observed following TCA and TCE exposure.

761

#### THE EFFECTS OF AMMONIUM PERFLUOROOCTANOATE (APFO) ON THE TRANSCRIPTIONAL PROFILE OF PANCREAS AND LIVER OF MALE RATS.

S. Plummer, O. Vassieva and C. Elcombe. *CXR Biosciences Ltd., Dundee, United Kingdom.*

APFO is a PPAR ligand which has been shown to induce pancreatic acinar cell, liver and testicular tumours in rats. The mechanism(s) of pancreatic carcinogenesis is poorly understood but evidence suggests that direct genotoxicity is not involved. In order to investigate pancreatic gene expression changes that may be associated with pancreatic carcinogenesis 6 male Sprague-Dawley rats (6-7 weeks old) were fed APFO in the diet at a concentration of 300 ppm for 4 weeks and transcriptional profiling using a rat cDNA array containing 14, 000 genes was performed in pancreas and liver. 577 and 617 APFO treatment-regulated genes were identified in the pancreas and liver respectively. 267 pancreas genes and 294 liver genes were up-regulated and 310 pancreas and 323 liver genes were down-regulated. In the liver many of the transcriptionally induced genes were found to be regulated by the transcription factor PPAR alpha. In the pancreas, a marked up-regulation of phosphoenolpyruvate carboxykinase (PEPCK), a PPAR gamma-regulated gene in adipose tissue, was observed. Groups of genes involved in MAP kinase and Notch signaling, together with target genes for these signaling pathways, were also up-regulated. Gene expression changes which could lead to metabolic acidosis and perturbations in glutamine metabolism and apoptosis were also observed. Examining the broad transcriptional effects of APFO in the liver generated a profile of gene expression changes indicative of increases in hepatic beta-oxidation and fat metabolism. This observation is consistent with the compound acting as a PPAR alpha agonist and peroxisome proliferator. By contrast gene expression changes observed in the pancreas were quite different and suggested possible effects on gluconeogenesis and glutamine metabolism. The profile of regulated genes associated with carcinogenesis were indicative of metabolic acidosis, oxidative stress and endogenous processes of DNA damage against a background of increased mitogenesis. These studies were funded by Plastics Europe Fluoropolymers Committee.

#### EFFECT OF 6MONT'S ADMINISTRATION OF HEPATIC TUMOR PROMOTERS ON IGF SIGNALING PATHWAY EXPRESSION IN THE RAT LIVER.

A. Naito, S. Dial and Y. Dragan. *Division of System Toxicology, NCTR, Jefferson, AR.*

The aim of this study is to determine the integrity of the insulin and insulin-like growth factor signaling pathway in the rat liver following 6 months exposure to the hepatic tumor promoting agents, tamoxifen, mestranol and phenobarbital. Female

Spague-Dawley rats were administered the promoting agent admixed into the basal diet (Phenobarbital at 500 mg/kg diet; mestranol at 0.2 mg/kg diet; and tamoxifen at 250 and 500 mg/kg diet) and fed to the rats for six months prior to sacrifice. The expression levels of 28 genes related to IGF signaling pathway were analyzed by real time PCR. For each treatment, an N=5 samples was analyzed. Expressions of IGFBP1 and IGFBP5 were increased, while IGFBP2 was decreased by mestranol and tamoxifen administration. However, phenobarbital administration resulted in a decreased expression of only IGFBP2. Receptor genes, IGF-II receptor (IGF-IIIR), Insulin receptor (InR) and Insulin receptor-related receptor (IRR), were increased in all cases. Glycogen synthase kinase-3 (GSK3), which mediates cell growth, was also increased in all cases. Specifically, GSK3 beta was increased 10 fold by phenobarbital, while about 2 fold change was induced by the others, indicating that different regulatory system might exist. In order to determine the relative changes in the IR and TR pathways, IGF-I and SPOT14 expression was monitored and the results showed decrease of SPOT14 by tamoxifen treatment. In conclusion, these tumor promoters may alter the expression of receptors in the insulin signaling pathway and the downstream gene, GSK3, required for cell proliferation.

763

#### DIFFERENTIAL CHANGES OF GENE EXPRESSION PROFILES IN MALE LONG-EVANS CINNAMON AND F344 RATS BY THE ADMINISTRATION OF N-NITROSOMORPHOLINE.

Y. Kawano<sup>1</sup>, K. Nakayama<sup>1</sup>, D. Nakae<sup>2</sup>, A. Maekawa<sup>2</sup>, M. Tsuchitani<sup>1</sup> and M. Sekijima<sup>1</sup>. <sup>1</sup>*Mitsubishi Chemical Safety Institute Ltd., Ibaraki, Japan* and <sup>2</sup>*Sasaki Institute, Sasaki Foundation, Tokyo, Japan*.

The Long-Evance Cinnamon (LEC) rat is an inbred strain with a mutation at the ATP7b gene leading to hepatic copper accumulation and spontaneous hepatitis. Additionally the LEC rat develops a high incidence of spontaneous liver tumor and is highly susceptible to chemical carcinogens, but the comprehensive molecular response to hepatocarcinogens remain largely obscure. In this study we analyzed the gene expression profiles by the administration of a hepatocarcinogen, N-nitrosomorpholine (NM), in LEC rats before hepatitis compared with F344 rats. Male LEC and F344 rats, 3 each at 5 weeks old, were orally administrated a daily dose of NM (10 mg/kg/day) or vehicle for 4 weeks, and were sacrificed. According to serological and liver histological examinations, NM induced moderate hepatocellular damage in both LEC and F344 rats at similar magnitudes. Gene expression profiles were analyzed by using GeneChip® RAE230A. It revealed clearly different profiles between vehicle-treated LEC and F344 rats, 32 genes being higher, while 42 genes were lower, expressed in the former rather than in the latter. By the treatment of NM, several genes were up or downregulated in both rats. Whereas the expression of 15 and 2 genes increased and decreased, respectively, in both rats, the expression of 7 and 19 genes increased and decreased, only in LEC rats, and the expression of 33 and 28 genes increased and decreased only in F344 rats. From the results of comprehensive gene expression analysis of LEC rat liver, typical apoptosis-related genes were found to be induced by NM. Particularly, the expression levels of GADD45, caspase3 and p21 activated kinase1 genes were remarkably up regulated in NM-treated LEC rats liver. These results suggested that NM causes different molecular responses in the liver of LEC rats before inducing various serological or histological responses, which may be one of the mechanisms underlying the high susceptibility toward chemical carcinogenesis.

764

#### DOWN-REGULATION OF E-CADHERIN BY THE INTEGRIN-LINKED KINASE PATHWAY (ILK) IN HEPATOCYTES: A POSSIBLE MECHANISM FOR HEXACHLOROBENZENE-INDUCED TUMOR PROMOTION.

I. Plante, D. G. Cyr and M. Charbonneau. *INRS-Institut Armand-Frappier, Université du Québec, Montréal, QC, Canada.*

The ILK pathway is overexpressed in tumors of various tissues. We have previously shown an activation of the ILK pathway in the liver of female rats given hexachlorobenzene (HCB), an environmental epigenetic carcinogen. This was accompanied by a down-regulation of E-cadherin, an adhering junction protein, and connexin32 (Cx32), a gap junction protein. The aim of this study was to demonstrate the role of the ILK pathway in the regulation of adhering and gap junctions in liver cells. MH<sub>1</sub>C<sub>1</sub> rat hepatocytes exposed to HCB for 7 days showed increased levels of the inactive form of GSK3β, i.e. phospho-GSK3β, an important messenger of ILK activation, and a decrease in Cx32, as observed *in vivo* exposed rats. Two different GSK3β specific inhibitors were used to confirm the role of the ILK pathway in E-cadherin and Cx32 regulation. Both inhibitors (kenpaulone 5 and 10 μM, SB-415286 125 and 150 nM) markedly reduced GSK3β activity and caused an approximately 50% decrease in E-cadherin mRNA levels, whereas Cx32 mRNA levels were unchanged. This suggests that in MH<sub>1</sub>C<sub>1</sub> cells, Cx32 expression is not modulated by GSK3β, but depends on either another messenger of the ILK pathway,

such as Akt, or another pathway. Stable transfections of MH<sub>1</sub>C<sub>1</sub> cells with Cx32 expression vector to increase Cx32 expression levels resulted in a marked increased E-cadherin mRNA levels thereby suggesting a link between Cx32 and E-cadherin regulation. Together, these data demonstrate that in rat hepatocytes E-cadherin is down-regulated by the ILK pathway via GSK3β inhibition and up-regulated by Cx32 overexpression. Clearly, both Cx32 and E-cadherin are regulated differently in hepatocytes suggesting that HCB may modulate several signalling pathways in the promotion of hepatocarcinogenesis. (Supported by The Canadian Liver Foundation, NSERC, and the Fondation Armand-Frappier).

#### TOXICOGENOMIC APPROACH FOR PREDICTION OF HEPATOCARCINOGENS USING RAT HEPATOMA CELLS AND COMPARISON OF GENE EXPRESSION PATTERNS WITH CHEMICAL-TREATED RAT AND HUMAN HEPATOMA CELLS.

K. TSUJIMURA<sup>1,2</sup>, M. Asamoto<sup>1</sup>, S. Suzuki<sup>1</sup>, K. Ogawa<sup>1</sup> and T. Shirai<sup>1</sup>.

<sup>1</sup>*Department of Experimental Pathology and Tumor Biology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Aichi, Japan* and <sup>2</sup>*Chemicals Assessment Center, Hita laboratory, Chemicals Evaluation and Research Institute, Hita, Oita, Japan.*

The long-term rodent bioassay is the standard method to predict carcinogenic hazard of chemicals for human beings. However, this assay takes a long time and high costs. Our aim has been to develop a rapid and reliable prediction method for carcinogenicity based on microarray technology in cultured cells. We selected 39 chemicals that have been well characterized for carcinogenicity. Rat hepatoma cells (MH1C1) and human hepatoma cells (HepG2) were treated with the chemicals for 3 days. A set of genes for prediction of carcinogenicity were selected with statistical methods using a support vector machine (SVM). As a test set, six external samples underwent prediction of carcinogenicity based on the results of the SVM analysis and comparison with actual findings. Twenty-four of 39 chemicals were compared for expression responses between MH1C1 and HepG2 in ortholog genes. As the result of cross-validation, the predictive ratio for carcinogenicity was over 80%. With the six test set samples, the results predicted by SVM were reasonable. In contrast to MH1C1, the pattern of gene expression induced by chemicals was very different in the human (HepG2) case. These results indicate that toxicogenomic approach on hepatoma cells can be useful for carcinogenicity. With interspecies analysis, careful consideration is needed for the application of rat data to the human situation. #### EVALUATION OF A VACCINE DELIVERY SYSTEM FOR RECOMBINANT ANTHRAX PROTECTIVE ANTIGEN IN RABBITS.

J. M. Blonder<sup>1</sup>, C. Coeshott<sup>1</sup>, E. Verderber<sup>1</sup>, A. Samaniego<sup>1</sup>, S. Smithson<sup>2</sup>, M. Westerink<sup>2</sup> and G. Rosenthal<sup>1</sup>. <sup>1</sup>*RxKinetix, Louisville, CO* and <sup>2</sup>*Department Medicine, Medical College of Ohio, Toledo, OH.*

Vaccine candidates such as recombinant proteins and synthetic peptides often lack the intrinsic adjuvant activity of traditional vaccines. The safety and adjuvant activity of aluminum compounds and new adjuvants also remain questionable. We developed a vaccine delivery system (F127/CpG) using Pluronic® F127 for sustained release and a CpG motif as adjuvant. F127/CpG demonstrated safe and efficacious delivery of recombinant anthrax protective antigen (rPA) to mice with improved responses compared to aluminum hydroxide (alum). Measures of safety and efficacy of rPA/F127/CpG were presently assessed in rabbits to determine if the beneficial characteristics of F127/CpG were maintained in a second and more sensitive animal used for inhalation anthrax studies. Rabbits received a primary (week 0) and booster (week 4) SC injection of 6.25 μg rPA in alum, F127/CpG/alum, or F127/CpG. Potential adverse effects were measured by following weight gain, clinical chemistries, and blood cell differentials for 8 weeks. Protective immunity was assessed by measuring biologically active antibody to rPA via a toxin neutralization assay. Injection of rPA/F127/CpG caused no overt adverse effects when compared to rPA/alum, rPA/F127/CpG/alum, or vehicles. Rabbits in all groups had similar gains in body weights. Clinical chemistries and blood cell differentials did not vary among the rPA or vehicle groups and were within normal ranges. At 8 weeks, relative levels of neutralizing antibodies to anthrax lethal toxin were 209, 167, and 153 for rPA/alum, rPA/F127/CpG/alum, and rPA/F127/CpG and did not differ significantly among groups. These data demonstrate that injection of rPA in F127/CpG is well tolerated and induces an effective immune response in rabbits as in mice. In contrast to mice, the efficacy of rPA/F127/CpG immunization in rabbits is not significantly improved compared to rPA/alum. This may be due to inherent differences in immune systems between species and the antigen dose tested. (Supported by NIH grant #1R43 A/52891-01)

HISTOLOGICAL RESPONSE OF RAT ORGANS TO REPEATED BLAST OVERPRESSURE EXPOSURE. EFFECTS OF NUMBER OF EXPOSURES AND TIME AFTER EXPOSURE.

N. Elsayed<sup>1,2</sup>, N. Gorbunov<sup>3</sup>, A. Januszkiewicz<sup>3</sup> and J. Atkins<sup>3</sup>. <sup>1</sup>*Hurley Consulting Associates, Chatham, NJ*, <sup>2</sup>*SUNY Downstate Medical Center, Brooklyn, NY* and <sup>3</sup>*Walter Reed Army Institute of Research, Silver Spring, MD*.

Blast overpressure (BOP) is the sharp rise in ambient pressure from explosive detonation, firing of high-powered weapons or from terrorist bombings and accidental occupational explosions. Exposure to BOP can cause auditory and nonauditory injury such as hearing loss, lung contusion and other manifestations of blunt trauma. We have previously evaluated and scored lung injury from 1 BOP exposure. To further assess the health risks of BOP, we examined the histological response to repeated BOP exposures in 5 organs. Anesthetized rats were exposed from 1-6 consecutive BOP exposures (- 62 kPa) at 3 min interval then euthanized after 5 min, 1, 6, and 24 h. After each exposure, the lungs were fixed inflated at 25-cm water pressure with 10% formaline-phosphate buffer. Heart, kidneys, small intestines, and brain were also extracted and fixed. All organs were stained with hematoxylin/eosin and examined microscopically. The results indicated minimal cumulative effect from repeated BOP exposure, although animals exposed to 6 blasts exhibited slightly greater damage to the affected organs. The lungs displayed the greatest changes showing mild to moderate focal and multifocal hemorrhage and congestion that continued to increase moderately up to 24 h even with a single exposure. The small intestines had mild multifocal hemorrhage and congestion, the brains displayed minimal focal to multifocal hemorrhage, and the hearts had focal to diffuse congestion and hemorrhage. The kidneys were the least affected displaying only slight congestion. We conclude that BOP-induced injury increases only slightly after repeated exposure, but moderately beyond 1 h. These observations have occupational and military implications re-emphasizing the need for protection from any BOP exposure, and stressing the importance of injury management within the first hour after exposure to minimize further risk of multiple organ failure.

DEVELOPMENT OF A MICROBIAL RISK ASSESSMENT METHODS COMPENDIUM AND ASSESSMENT OF SECONDARY DATA U.

M. Coleman<sup>1</sup>, P. McClure<sup>1</sup>, P. McGinnis<sup>2</sup>, R. Starmer<sup>1</sup>, P. Rodgers<sup>3</sup>, I. Baumel<sup>4</sup>, J. Choich<sup>4,5</sup> and E. Brady-Roberts<sup>4,5</sup>. <sup>1</sup>*Environ Sciences Ctr, Syracuse Research Corp, Syracuse, NY*, <sup>2</sup>*Syr Res Corp, Philadelphia, PA*, <sup>3</sup>*Battelle Mem Inst, Columbus, OH*, <sup>4</sup>*NHomeland Sec Res, USEPA, Washington, DC*, <sup>5</sup>*NHomeland Sec Res, USEPA, Cincinnati, OH*, <sup>6</sup>*USEPA, Washington, DC* and <sup>7</sup>*Amer Assn Adv Sciences, Washington, DC*.

The threat of a microbial terrorist attack on buildings and drinking water systems has elevated the urgency for a method to assess and mitigate the possible human health impact of exposure to deliberate biological contamination. A critical need for achieving this objective is the development of microbial risk assessment methodology that leverages and extends aspects of recent work to incident based biothreat assessment. Therefore, a compendium of relevant studies and methods for microbial risk assessment has been developed based on literature and technical reports published from 1994 to 2004. The objectives of this effort were to identify, compile and evaluate existing studies for exposure assessment, dose-response assessment, or risk characterization for microbial agents that might subsequently be extended to support decision making process to decontaminate buildings and drinking water systems. Comprehensive literature searches were conducted of commercial electronic data bases and selected web sites for government agencies and international organizations. More than sixteen hundred titles were evaluated, including published manuscripts, books, and reports subjected to various levels of peer-review. The poster provides a tutorial example for assessing the applicability of secondary data largely in the absence of sufficient primary sources using data utility criteria. In addition, the poster will address data gaps and potential solutions for modeling airborne, waterborne, foodborne, and dermal hazards of concern for indoor air and drinking water distribution systems. The state of the science reflected in the microbial risk assessment methods compendium is the foundation for further development and testing of novel methods in this rapidly evolving field.

MICROARRAY ANALYSIS OF RAW264.7 CELLS EXPOSED TO BACILLUS ANTHRACIS- EVIDENCE OF VOLLUM 1B-INDUCED MACROPHAGE APOPTOSIS.

B. W. Gutting and R. S. Mackie. *NSWC Dahlgren, Dahlgren, VA*.

*Bacillus anthracis* is the causative agent of anthrax disease. Inhalational anthrax is the most severe form of the disease and the lungs are the likely route of exposure during a terrorist attack. Following deposition of *B. anthracis* spores, alveolar macrophages (Mφ) phagocytose the bacteria and transport them to the draining

lymph system. En route, the spores germinate into vegetative bacteria, become metabolically active, secrete several known toxins and ultimately kill the host Mφ. The mechanisms by which *B. anthracis* spores evade destruction by the Mφ defenses and escape from them into the circulation remain unknown. Defining these mechanisms will lead to a better understanding of the infection stage of anthrax and may contribute to novel therapies for the disease. To this end, we have developed and applied microarray techniques to an *in vitro* Mφ-*B. anthracis* spore model using RAW264.7 Mφs infected with the virulent Vollum 1B strain (V1B) of *B. anthracis*. In this model, RAW Mφs are 50% viable 7 hours after phagocytosis of V1B spores and 100% dead at 15 hours. The mechanism of RAW cell death remains unknown, but was reversed by the addition of anti-lethal factor antibody, suggesting the V1B-derived toxin mediated, in part, RAW cell death. Microarrays were conducted 2 hours after the addition of V1B spores. Categories of genes increased by V1B in Mφs include those involved in cytoskeletal rearrangements, metabolism, gene transcription and reactive oxygen species generation. Additionally, several genes identified are directly linked to apoptotic pathways: Rhot-1, Rhot-2, LIMK2, Card10 and Rai 3. These observations suggest V1B germinates in Mφs, expresses lethal toxin in sufficient quantity to kill the Mφ and the mechanism of Mφ death is via an apoptotic pathway.

DECONTAMINATION OF BACILLUS ANTHRACIS SPORES ON INDOOR BUILDING SURFACES USING FORMALDEHYDE GAS.

W. R. Richter, Y. W. Choi, C. L. Sabourin, M. L. Taylor and J. V. Rogers. *Battelle Memorial Institute, Columbus, OH*.

The intentional release of *Bacillus anthracis* spores in the mail prompted extensive remediation and clean-up efforts. The USEPA (EPA) has recently established the Building Decontamination Technology Center to test the performance of technologies intended to decontaminate biological agents from indoor building surfaces. This study assessed laboratory-scale decontamination efficacy of *B. anthracis* Ames spores with the surrogates *B. subtilis* and *Geobacillus stearothermophilus* deposited on porous and non-porous indoor surface materials. *B. anthracis*, *B. subtilis*, and *G. stearothermophilus* spores ( $1 \times 10^8$  CFU) were dried on seven types of indoor surfaces (carpet, wood, painted concrete, glass, laminate, galvanized metal, and painted wallboard) and exposed to 1100 ppm formaldehyde gas for 10 hours. Formaldehyde exposure significantly decreased viable *B. anthracis*, *B. subtilis*, and *G. stearothermophilus* spores on all test materials. The log reduction in viable spores across all seven test materials ranged from  $\geq 5.2$  to  $\geq 7.9$ , 6.0 to  $\geq 8.0$ , and 5.7 to  $\geq 7.6$  for *B. anthracis*, *B. subtilis*, and *G. stearothermophilus*, respectively. Significant differences in spore log reduction were observed between *B. anthracis* and both surrogates. Microorganisms from commercial biological indicators and spore strips having spore loads of approximately  $1 \times 10^6$  CFU were evaluated in parallel as a qualitative decontamination assessment. These biological indicators and spore strips were partially inactivated ( $\geq 50\%$  for all exposures) by formaldehyde. These results provide information for correlating the decontamination of virulent *B. anthracis* spores with surrogates on indoor surfaces using formaldehyde gas. Supported by the USEPA National Homeland Security Research Center.

DECONTAMINATION OF BACILLUS ANTHRACIS SPORES ON INDOOR BUILDING SURFACES USING HYDROGEN PEROXIDE GAS.

Y. W. Choi, W. R. Richter, C. L. Sabourin, M. L. Taylor and J. V. Rogers. *Battelle Memorial Institute, Columbus, OH*.

In 2001, mailed *Bacillus anthracis* spores contaminated mail processing and distribution centers and the Hart Senate Office Building, which led to extensive remediation and clean-up efforts. The USEPA (EPA) responded to US homeland security concerns by establishing the Building Decontamination Technology Center to test the performance of technologies intended to decontaminate biological agents from indoor building surfaces. This study assessed laboratory-scale decontamination efficacy of *B. anthracis* Ames spores with the surrogates *B. subtilis* and *Geobacillus stearothermophilus* deposited on porous and non-porous indoor surface materials. *B. anthracis*, *B. subtilis*, and *G. stearothermophilus* spores ( $1 \times 10^8$  CFU) were dried on seven types of indoor surfaces (carpet, wood, painted concrete, glass, laminate, galvanized metal, and painted wallboard) and exposed to  $\geq 1000$  p.p.m. hydrogen peroxide gas for 20 minutes. Hydrogen peroxide exposure significantly decreased viable *B. anthracis*, *B. subtilis*, and *G. stearothermophilus* spores on all test materials except for *G. stearothermophilus* on carpet. The log reduction in viable spores across all seven test materials ranged from 3.0 to  $\geq 7.9$ , 1.6 to  $\geq 7.7$ , and 0.8 to 6.0 for *B. anthracis*, *B. subtilis*, and *G. stearothermophilus*, respectively. Significant differences in spore log reduction were observed between *B. anthracis* and both surrogates. Microorganisms from commercial biological indicators and spore strips (having spore loads of approximately  $1 \times 10^6$  CFU), evaluated in parallel as a qualitative decontamination assessment, were inactivated by hydrogen peroxide exposure. These

results provide new information for correlating the decontamination of virulent *B. anthracis* spores with surrogates on indoor surfaces using hydrogen peroxide gas. Supported by the USEPA National Homeland Security Research Center.

#### A METHOD FOR THE SIMULTANEOUS MEASUREMENT OF SPECIFIC IgGS TO FIVE CDC SELECT BIOTERRORISM AGENTS IN SERUM.

R. E. Biagini<sup>1</sup>, D. L. Sammons<sup>1</sup>, J. P. Smith<sup>1</sup>, B. A. MacKenzie<sup>1</sup>, C. A. Striley<sup>1</sup>, S. A. Robertson<sup>1</sup>, J. E. Snawder<sup>1</sup> and C. P. Quinn<sup>2</sup>. <sup>1</sup>*CDC/NIOSH, Cincinnati, OH* and <sup>2</sup>*CDC/NCID, Atlanta, GA*.

The Centers for Disease Control and Prevention has classified several agents which may be used in a bioterrorism attack as select agents. They are classified as such based on ease of dissemination, mortality/morbidity rate, and potential for social disruption. A subset of these agents include *Bacillus anthracis* (Ba), *Yersinia pestis* (Yp), *Francisella tularensis* (Ft), ricin toxin (RT) and staphylococcus enterotoxin B (SEB). Exposure/infection with these agents has been shown to cause the production of specific serum IgG antibodies. Comparison of pre- and post-incident IgG antibody levels has been shown to be a useful method to biologically monitor decontamination and clean-up workers for potential exposure to bioterrorism agents (*Occ Environ Med*. 61: 703-708, 2004). We describe a fluorescent covalent microsphere immunoassay (FCMIA) to measure specific IgG antibodies to Ba (protective antigen [PA] and lethal factor [LF]), Yp (F1 and V antigens), Ft, RT and SEB simultaneously in human Ba vaccinee sera which had been fortified with animal select agent specific IgG antibodies. Intra- and interassay coefficients of variation were <15% (N=3). There were no significant differences (P>0.70) in dilution curves when the assays were performed individually vs. multiplexed. When the observed vs. expected dilution curves were compared, highly linear relationships were observed (mean  $r^2=0.985 +/- 0.006$  [SD], P<0.001). Finally, the curves yielded linear responses for most analytes upon serum dilution from  $1 \times 10^2$  to  $1 \times 10^5$ . These data indicate that multiplexed FCMIA is a method to measure specific IgGs in serum to CDC select agents and may be of value in screening either decontamination workers or the general population for exposures/infections to these agents.

#### GENERATION, METHODOLOGY AND ANALYSIS OF VX VAPOR.

J. S. Anthony<sup>1</sup>, E. M. Jakubowski<sup>1</sup>, R. J. Mioduszewski<sup>1</sup>, S. A. Thomson<sup>1</sup>, K. L. Matson<sup>2</sup>, R. A. Evans<sup>2</sup>, C. L. Crouse<sup>2</sup> and J. M. McGuire<sup>2</sup>. <sup>1</sup>*Edgewood Chemical Biological Center, Department of the Army, Aberdeen Proving Ground, MD* and <sup>2</sup>*Geo-Centers, Inc., Abingdon, MD*.

Low vapor concentrations of VX were generated to assess dosages at which threshold clinical signs (e.g., miosis) occur as a result of whole-body exposures in rodents. Saturated VX vapor streams were generated by directing nitrogen carrier gas through a glass vessel (multi-pass saturator cell) containing liquid VX. The saturator cell body was submerged in a water bath to help maintain a constant temperature. VX vapor concentration was manipulated through controlling the water bath temperature and the nitrogen gas flow. In order to facilitate calibration of saturator cell output, data was collected to validate previously published data on VX vapor pressure. Unlike other agents, it was also observed that passivation, or coating of the chamber was critical before analytical concentration determinations could be made. Furthermore, a constant flow through the chamber was necessary in order to maintain the passivation. Concentration uniformity was confirmed at several locations in the chamber to assure an even distribution. Steps were taken to verify that the agent generated was vapor with no measurable signs of aerosol. Analytical methodology was developed to verify generated concentrations. Performing inhalation vapor exposures of low volatility materials also introduced potential contamination hazards to personnel handling exposed animals, or performing routine operation with the chamber. Test methods have been developed to address these additional hazards created and how to safely generate these agents. In order to address residual contamination of animals and cages, swab samples were collected following exposure and analyzed for the presence/absence of the generated material. In addition, contaminated animal carcasses were dipped in a solvent to extract any residual VX, and the extract analyzed by large volume liquid injection/gas chromatography. As higher concentrations will be generated in support of additional studies, these contamination issues will become of greater importance.

#### CORRELATING GENE EXPRESSION PROFILES WITH THERAPEUTIC EFFICACY OF POTENTIAL VESICANT MEDICAL COUNTERMEASURES.

J. F. Dillman<sup>1</sup>, L. M. Dorsch<sup>1</sup>, A. I. Hegel<sup>1</sup>, A. J. Sylvester<sup>1</sup>, C. S. Phillips<sup>1</sup>, R. C. Kiser<sup>2</sup>, Y. W. Choi<sup>2</sup> and C. L. Sabourin<sup>2</sup>. <sup>1</sup>*Applied Pharmacology, USAMRIID, Aberdeen Proving Ground, MD* and <sup>2</sup>*Medical Research and Evaluation Facility, Battelle Memorial Institute, Columbus, OH*.

Sulfur mustard (SM) is a potent alkylating agent. We are developing medical countermeasures to reduce the injury caused by SM exposure. Screening in the mouse ear vesicant model has identified three effective compounds: dimercaprol (British

anti-lewisite), indomethacin, and octyl homovanillamide (OHV). To identify gene expression changes that correlate with compound efficacy we used oligonucleotide microarrays to compare gene expression profiles in vehicle-exposed skin, SM-exposed skin, and skin pretreated with each compound before SM exposure. Mice were topically exposed on the inner surface of the right ear to SM alone or pretreated for 15 min with one of the compounds and then exposed to SM. Left ears were vehicle-exposed. Ear tissue was harvested 24 hr later for ear weight determination (an endpoint indicating compound efficacy). RNA was extracted from the tissues and used to generate oligonucleotide microarray probes. Principal component analysis of the gene expression data revealed partitioning of the samples based on drug treatment and SM exposure. Vehicle-exposed mouse ears clustered away from the other treatment groups. SM-exposed mouse ears pretreated with dimercaprol or OHV clustered more closely with vehicle-exposed ears, while SM-exposed mouse ears pretreated with indomethacin clustered more closely with SM-exposed ears. This clustering of the samples is supported by the ear weight data, in which the indomethacin group has ear weights closer to the SM-exposed group, whereas the dimercaprol and OHV groups have ear weights closer to the vehicle-exposed group. Correlation coefficients were calculated for each gene based on the correlation between gene expression level and ear weight. These data provide the basis for understanding what gene expression changes are important in the development of effective SM medical countermeasures.

#### FLUORIDE ION REGENERATION OF CYCLOSARIN (GF) FROM MINIPIG TISSUE AND FLUIDS FOLLOWING WHOLE BODY GF MIOSIS LEVEL VAPOR EXPOSURE.

E. M. Jakubowski<sup>1</sup>, J. M. McGuire<sup>2</sup>, R. A. Evans<sup>2</sup>, S. W. Hulet<sup>1</sup>, D. C. Burnett<sup>1</sup>, R. A. Way<sup>1</sup>, B. P. Gaviola<sup>1</sup>, J. A. Scotto<sup>1</sup>, W. T. Muse<sup>1</sup>, D. B. Miller<sup>1</sup>, R. J. Mioduszewski<sup>1</sup> and S. A. Thomson<sup>1</sup>. <sup>1</sup>*Toxicology Team, Edgewood Chemical Biological Center, APG-Edgewood, MD* and <sup>2</sup>*Geo-Centers, Inc., Edgewood, MD*.

Recent developments to improve nerve agent biomarker techniques include methods for measuring fluoride regenerated Sarin (GB) in blood and tissue. Our efforts extend the fluoride ion regeneration method to be able to determine cyclosarin (GF) in red blood cell and tissue of minipig blood samples after whole body exposure to GF at miosis levels. Blood samples were taken serially before, during, and after whole body GF exposure from the minipig via venous catheter allowing agent exposure profiles to be generated. After processing the samples with fluoride ion and extracting with C-18 solid phase extraction cartridges the ethyl acetate extract was analyzed by GC/MS. The GC/MS method utilized an autoinjector, a large volume injector port (LVI), positive ion ammonia chemical ionization detection in the SIM mode, and a 2H11-GF stable isotope internal standard. Results indicated that the method range was 10-1000 pg on column. The detection limit was 3 pg of GF on column despite the complexity of the red blood cell/tissue matrix. Conditions that needed to be optimized for the LVI included injection volume, initial temperature, pressure, and flow rate. The regenerated GF (R-GF) profiles differ greatly from the regenerated GB (R-GB) profiles in the minipig at similar exposure levels. The onset of the appearance of R-GF in the blood seems to be delayed and maximum levels are reached at much later times as compared to GB exposures. Quantities of R-GF were recovered from minipig blood during the first several hours of inhalation exposure that were one-fifth to one-tenth of R-GB recovered at equimolar exposure concentrations and equal exposure duration times.

776

#### CHOLINESTERASE AND SARIN (GB) REGENERATION PROFILE FOLLOWING LOW LEVEL GB IN GUINEA PIGS: USEFULNESS FOR PBPK MODELING.

L. A. Lumley<sup>1</sup>, C. Whalley<sup>2</sup>, J. McGuire<sup>3</sup>, M. O'Malley<sup>1</sup>, A. D'Ambrozio<sup>1</sup>, C. Robison<sup>1</sup>, E. Mason<sup>1</sup>, C. Krauthauser<sup>2</sup>, E. Jakubowski<sup>1</sup>, S. McAvoy<sup>1</sup>, T. Rowland<sup>1</sup>, C. Clark<sup>1</sup>, R. Evans<sup>3</sup>, D. Miller<sup>3</sup>, T. Belski<sup>3</sup>, J. Renner<sup>3</sup>, J. Scotto<sup>2</sup>, J. Jarvis<sup>2</sup>, J. Anthony<sup>2</sup>, C. Crouse<sup>3</sup>, J. McDonough<sup>1</sup>, R. Mioduszewski<sup>2</sup>, S. Thomson<sup>2</sup> and T. Shih<sup>1</sup>. <sup>1</sup>*USAMRIID, Aberdeen Proving Ground, MD*, <sup>2</sup>*ECBC, Aberdeen Proving Ground, MD* and <sup>3</sup>*Geo-Centers, Aberdeen Proving Ground, MD*.

Physiologically based pharmacokinetic (PBPK) modeling may be a useful risk assessment tool for interspecies extrapolation and prediction of response to chemical warfare nerve agent (CWNA) exposure. The current study was performed to integrate CWNA toxicity data across different routes of exposure in guinea pigs. Animals were given a single subcutaneous (sc) dose of GB (0.1 & 0.4 LD50). Arterial blood was drawn from the right carotid artery at time intervals between 1 min and 4 hr post-exposure. Blood levels of acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE), and blood and tissue levels of regenerated sarin (rGB) were assayed. AChE and BuChE were significantly inhibited 1 min following 0.4LD50 GB, and remained inhibited at 4 hr, with the greatest level of inhibition

at 40 min. Following 0.1 LD50 GB, AChE was decreased at 40 and 60 min, while BuChE was not affected. In plasma, rGB reached maximal levels 20 min after 0.1 and 0.4 LD50 GB and gradually declined over 4 hr. In red blood cells (RBC), rGB reached maximal levels 10 min after 0.4 LD50 GB exposure and remained elevated over the course of 4 hr; however, RBC rGB was not as great as plasma rGB. After 0.1 LD50 GB exposure, rGB in RBC was not significantly elevated. These findings suggest that both plasma and RBC measures of rGB and cholinesterase indicate low level exposure, but that plasma rGB and RBC AChE may be more sensitive measures of extremely low level GB exposure. In the 2-4 hr after low level GB exposure, the highest levels of rGB were in lung and kidney. A future goal is to compare the pharmacokinetics of low dose GB in guinea pigs exposed by acute inhalation with our current measures following sc exposure. PBPK modeling will then be used to extrapolate these findings to different routes of administration and to compare similar exposures in other species.

779

## EFFECT OF TOPICAL IODINE TREATMENT ON EARLY SULFUR-MUSTARD-INDUCED CUTANEOUS CHANGES AND EPIDERMAL-CELL PROLIFERATION.

S. Trivedi<sup>1</sup>, U. Wormser<sup>2</sup>, N. Flagler<sup>1</sup>, B. Brodsky<sup>2</sup>, S. Peddada<sup>2</sup> and A. Nyska<sup>1</sup>.  
<sup>1</sup>Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC and  
<sup>2</sup>School of Pharmacy, Faculty of Medicine, Institute of Life Sciences, The Hebrew University of Jerusalem, Jerusalem, Israel.

Exposure of skin to sulfur mustard (SM), a potent chemical-warfare and strong alkylating agent, results in severe damage. Topical iodine treatment reduces SM-induced skin lesions. The aims of the present study were to test the effect of topical iodine on SM-induced skin toxicity at an early stage after exposure and to analyze the effect of SM followed by iodine treatment on cellular proliferation. The treatment groups included SM + iodine, SM + iodine vehicle, and SM only. Control groups received iodine only or iodine vehicle only. One animal with 6 separate application sites was used for each type of treatment. One microliter of SM was applied on 6 sites on the back of the animal. Iodine or vehicle was applied 20 min later for a duration of 2 hours. One hour before the end of the experiment, 150 mg/kg bromodeoxyuridine (BRDU) was injected intraperitoneally. Animals were sacrificed 5 hours after SM exposure. Histopathology showed that only iodine significantly reduced dermal infiltration of neutrophils induced by SM. Visualization of cellular proliferation was accomplished by BRDU staining and blind labeling index (LI) counting in epidermal cells along a fixed unit of length. No significant difference occurred between the groups of SM + iodine and SM + vehicle or SM only. We concluded that iodine did not reverse the significantly-reduced LI parameters induced by SM. The results indicate that iodine exerts its protective activity predominantly by its anti-inflammatory activity, not through a primary effect on epidermal-cell proliferation. (This study was supported by the US Army Medical Research and Material Command under Cooperative Agreement DAMD17-03-2-0013 of the Binational Science Foundation Research Project 2001186.)

## PRETREATMENT OF HUMAN EPIDERMAL KERATINOCYTES WITH D, L SULFORAPHENE PROTECTS AGAINST SULFUR MUSTARD CYTOTOXICITY.

C. L. Gross, E. W. Nealey, M. T. Nipwoda and W. J. Smith. *USAMRICD, APG-EA, MD*. Sponsor: A. Sciuto.

Sulfur mustard (SM) is a powerful cytotoxic agent in addition to being a potent vesicating agent, mutagen, and carcinogen. This insidious chemical agent reacts with glutathione (GSH) and forms GSH conjugates which appear to be excreted through the mercapturic acid pathways in mammals. The question of whether glutathione-S- transferases (GST) are involved in the formation of these conjugates remains unresolved. In previous studies, ethacrynic acid (EAA), a putative inhibitor of GST and Oltipraz (OLT), a known inducer of GST were ineffective in modulating this enzyme in HEK so this hypothesis could not be tested. Higher levels of intracellular GSH appeared to be responsible for the resistance of EAA-pretreated HEK to SM. A more efficient inducer of GST was needed to test whether this enzyme could be used to modify cytotoxicity following SM exposure. D, L- sulforaphene (DLS), a compound from broccoli extract known to be a potent inducer of GST was tested for GST induction in HEK. GST levels increased optimally (40%) in 24-well plates of HEK within 4 hours using 0.5 µg DLS/ well over a 48-hour incubation period. When the drug was removed by washing, and the pre-treated cells were challenged with 0-200 µM SM, there was an approximate 10-15% increase in survival at 24 hours compared to non-pretreated controls. This protective effect due to increased levels of GST was overcome at 300 µM SM, where there was no difference in survival between pretreated and non-pretreated controls. Glutathione levels were also assessed and showed no increase at 4 hours in HEK with DLS pretreatment. Higher levels of glutathione appear not to be responsible for this protection against SM as shown with EAA. More efficient compounds that can increase glutathione-S-transferase levels in target cells may be helpful in designing a medical pretreatment countermeasure against sulfur mustard.

## THE MATRIX METALLOPROTEINASE INHIBITOR GM 1489 REDUCES MMP-9 ACTIVITY AFTER SULFUR MUSTARD EXPOSURE *IN VIVO*.

D. R. Gerecke<sup>1</sup>, P. Bhatt<sup>1</sup>, Y. Chang<sup>1</sup>, C. L. Sabourin<sup>2</sup>, T. L. Rudge Jr.<sup>2</sup>, R. C. Kiser<sup>2</sup>, S. L. Casbohm<sup>2</sup>, M. K. Gordon<sup>1</sup>, D. J. Riley<sup>3</sup>, M. P. Shakarjian<sup>3</sup> and R. P. Casillas<sup>2</sup>.<sup>1</sup>Pharmacology & Toxicology, Rutgers University, Piscataway, NJ, <sup>2</sup>Battelle Memorial Inst., Med. Res. & Eval. Fac., Columbus, OH and <sup>3</sup>Medicine, UMDNJ-Robert Wood Johnson Med. School, Piscataway, NJ.

Bis(2-chloroethyl)sulfide (sulfur mustard, SM) is a chemical warfare agent that penetrates the skin rapidly, causing extensive blistering within several hours. The damage includes separation of the dermis from the epidermis, potentially as a result of collagen degradation in the basement membrane zone by matrix metalloproteinases (MMPs). We hypothesize that skin damage is increased by upregulation of the MMPs following mustard-induced inflammation. MMP-2 (gelatinase A) and MMP-9 (gelatinase B) in the absence or presence of MMP inhibitors were investigated to better assess their role in SM-induced skin injury. Mouse ears were treated with 80 µg of liquid SM and ear specimens collected 24, 72, and 168 hours after exposure. Specimens were examined for the expression of MMP-2 and MMP-9 by histology, real-time PCR, gelatinase activity assays, and Western blot analysis. SM exposure increased mRNA levels for MMP-9 by 2-fold, 8-fold, and 21-fold for 24, 72, and 168 hours, respectively, when compared to the control untreated ears. There were no observable changes in the MMP-2 mRNA levels between treated and controls. A time-related increase in overall gelatinase activity was observed in SM treated ears. Western blot analysis confirmed the increased gelatinase activity was due to MMP-9. Pretreatment with the MMP inhibitor GM 1489 N-[(2R)-2-4-methylpentanoyl]-L-tryptophan-(S)-methyl-benzylamide resulted in a 50% reduction of MMP-9 mRNA at 72 and 168 hours after SM treatment when compared to samples without pretreatment with MMP inhibitor. These studies demonstrate that the MMP inhibitor GM 1489 is a promising candidate as an effective pharmacological countermeasure against SM injury. \*This work is supported by the US Army Medical Research and Materiel Command under Contract No. DAMD17-02-C-0091

## THE EFFECT OF SULFUR MUSTARD EXPOSURE ON THE PERCENT, SIZE AND DENSITY OF HUMAN T CELLS (CD3+).

H. L. Meier and M. S. Oravitz. *Biochemical Pharmacology Research Institute of Chemical Defense, Aberdeen Proving Ground, MD*. Sponsor: S. Baskin.

Isolated human leukocytes from normal human volunteers were exposed to 0, 10, or 100 µM sulfur mustard (SM) at 1, 4, and 24 hrs. The effects of the SM on the percentage, size, and density of the human T cells were determined by flow cytometry and analyzed using the FlowJo program (Tree Star Inc., Stanford U, CA). The results showed a time- dependent decrease in the percent of T cells among exposed cells. At 1 hr post-SM exposure, there was no discernable change in the CD3+ cells. By 4 hrs post-SM exposure, there was a concentration-dependent decrease in percent of CD3+ cells; but no shift in the peak channel of the forward scatter pattern. At 24 hrs post-SM exposure, there was both a large decrease in the percent of CD3+ cells and a shift to the left in the peak channel. The concentration-dependent shift to the left of the peak channel in the SM-exposed cells indicated a decrease not only in the percent of CD3+ cells but also in the size of the remaining T cells. When the side scatter parameter was studied at 1, 4, and 24 hrs post-SM exposure, there was no difference of the SM-exposed T cells at either the 1 or 4 hr time points. At the 24 hr time point, there was a SM-induced, concentration-dependent shift to the right indicating an increase in cell density. When lymphocytes are exposed to SM, T cells become smaller and denser in a concentration-dependent manner between 4 and 24 hrs after exposure. These changes are consistent with the hypothesis that SM-exposed lymphocytes die by an apoptotic mechanism.

781

## OBSERVATIONS ON THE INTERACTION OF SULFUR MUSTARD WITH CYTOCHROME P450.

A. A. Brimfield<sup>1</sup> and E. Hodgson<sup>2</sup>.<sup>1</sup>Biochemical Pharmacology, USAMRICD, Aberdeen Proving Ground, MD and <sup>2</sup>Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.

The potential for interactions at the level of metabolism among chemicals encountered during military deployment is an area that has gained interest since the advent of Gulf War Syndrome. Sulfur mustard is one of the compounds of concern. However, the characteristics of the interaction of sulfur mustard with cytochrome

P450 have received little attention. We tested p-nitroanisole-O-demethylase activity using liver microsomes (0.5 mg microsomal protein/ml) from male CD1 mice induced with phenobarbital as our enzyme source. The complete incubation mixture included NADP and the standard NADPH regenerating system. In the presence of 3.4 mM sulfur mustard we observed a 55% reduction in the uninhibited reaction rate, indicating sulfur mustard interaction with the microsomal oxidative drug metabolizing system at some level. We followed this up with an experiment to determine whether sulfur mustard was interacting with NADPH-cytochrome P450 reductase or with cytochrome P450 itself. We assayed human NADPH-cytochrome P450 reductase using bovine heart cytochrome c as an electron acceptor in place of the cytochrome P450. The system was further simplified by the use of NADPH and omission of the NADPH regenerating system. We followed cytochrome c reduction spectrophotometrically by measuring the increase in OD at 550 nm. The inclusion of 2.4 mM sulfur mustard yielded a 30% drop in the rate of cytochrome c reduction. We conclude that sulfur mustard interacts with NADPH-cytochrome P450 reductase in a manner that reduces the rate of substrate oxidation by the P450. If this effect generalizes to all CYP isoforms, as might be expected, an overall reduction in the rate of oxidative drug and xenobiotic metabolism could be possible in anyone exposed to sulfur mustard.

PUTATIVE ROLE OF PLATELET ACTIVATING FACTOR (PAF) ANALOGS IN CELL CYCLE ABBERRATIONS IN HUMAN ENDOTHELIAL CELLS *IN VITRO*.

O. E. Clark, E. W. Nealey, K. W. Leiter, K. L. Finke, A. L. Miller and W. J. Smith. *Pharmacology, USAMRIICD, Aberdeen Proving Ground, MD.*

Our laboratory studies the mechanism of toxicity of the chemical blister agent sulfur mustard (SM) for the purpose of developing medical countermeasures to this chemical threat agent. SM is a cytotoxic alkylating agent with mutagenic and vesicant properties. A major feature of SM tissue injury is inflammation. Platelet activating factor (PAF), one of the inflammatory mediators potentially involved in the cell death cascades induced by SM, was studied for its effect on human pulmonary artery endothelial cells (HPAEC). PAF is known to effect pulmonary vasculature. We evaluated the effect of several PAF analogs on cell growth and cell cycle via incorporation of 5-bromo-2-deoxyuridine (BrdU). PAF C-16 is a naturally occurring phospholipid produced upon stimulation through two distinct pathways known as the 'remodeling' and 'de novo' pathways. It is a potent mediator of neutrophil migration, reactive oxygen species production, and IL-6 secretion. PAF C-16 (10 uM) caused greater than 20% increased cell death and lysis at 24 hrs, with the remaining cells exhibiting reduced cytoplasm. 2-Thio PAF C-16 (10 uM) caused greater than 30% cell death at 24 hrs after exposure. PAF C-16 and azelaoloy PAF increased S-phase from 24% in controls to 56% and 52% respectively. They also decreased G1 from 62% in controls to below 49% and eliminated G2, suggesting a block at or near the S/G2 interface. Several other PAF analogs did not cause increased cell death, altered morphology or changes in cell cycle. PAF analogs are potent stimulators of inflammatory response which in our laboratory caused G2 cell cycle blockade and cellular toxicity in the absence of SM. The resemblance of the morphological and cell cycle changes seen with PAF to those seen with SM suggest that these mediators may play a key role in the pathology following SM exposure.

ORAL DOSING WITH N-ACETYL-L-CYSTEINE SIGNIFICANTLY INCREASES GLUTATHIONE LEVELS AND GLUTATHIONE-S-TRANSFERASE ACTIVITY IN RAT SKIN.

E. Wilfong, A. J. Bobb, E. W. Johnson, S. L. Lohrke, R. H. Casavant and D. P. Arfsten. *Naval Health Research Center Detachment Environmental Health Effects Laboratory, Wright-Patterson AFB, OH.*

Sulfur mustard (2, 2-dichlorodiethyl sulfide, HD), a vesicant, remains a major chemical threat to troops and civilians; yet no specific medical countermeasures are currently available. Phases of dermal HD toxicity range from erythema to blistering and ultimately necrosis, however the mechanism of HD-induced damage remains unclear. Glutathione (GSH), a free-radical scavenger in cells which is decreased following HD exposure, may be involved. N-acetyl-L-cysteine (NAC), a synthetic cysteine derivative, has been shown to not only increase GSH levels in animals and humans but also reduce the toxicity of certain chemicals. To determine if NAC could be a potential prophylaxis for HD exposure, adult Sprague-Dawley rats were orally dosed with 600 or 1200 mg/kg NAC containing 6  $\mu$ Ci/g  $^{14}$ C-NAC or water (control vehicle). Significant levels of  $^{14}$ C were detected in rat skin 30 minutes after a single oral dose of  $^{14}$ C-NAC (600 or 1200 mg/kg) and levels remained elevated for up to 6 hrs. Skin GSH levels and glutathione-S-transferase activity were significantly increased in rats following daily oral NAC administration (600 or 1200 mg/kg) for 30 days. Gene expression analysis is ongoing to determine if GSH associated genes were significantly affected by repeat-oral NAC exposure. Since NAC distributes to the skin and increases GSH, daily oral administration may prevent GSH depletion and subsequent tissue damage following HD exposure.

TOPICAL IODINE SUPPRESSES SULFUR-MUSTARD-INDUCED TUMOR NECROSIS FACTOR-ALPHA INDUCTION IN MOUSE-EAR MODEL.

U. Wormser<sup>1</sup>, B. Brodsky<sup>1</sup>, E. Proscra<sup>1</sup>, J. F. Foley<sup>2</sup>, T. Jones<sup>2</sup> and A. Nyska<sup>2</sup>.

<sup>1</sup>*Pharmacology, The Hebrew University Jerusalem, Israel* and <sup>2</sup>*Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC.*

Sulfur mustard (SM), also termed mustard gas, is a potent vesicant that elicits an inflammatory response upon exposure of the skin. Evaluation of mouse ear 3 hours after exposure to 0.318 mg SM revealed acute inflammatory-cell aggregates in the vascular beds accompanied by strongly TNF-alpha-positive neutrophils as measured by immunohistochemistry. Eight hours after SM exposure, this phenomenon became intensified and associated with infiltration into the adjacent dermis. In ear skin topically treated with iodine, however, no inflammatory cells were observed 3 hours after SM exposure; 8 hours postexposure, blood vessels contained very few TNF-alpha-positive inflammatory cells. Administration of 1 and 2 micrograms per 30 gram body weight anti-TNF-alpha antibodies significantly reduced ear edema by 49% and 30%, respectively. These findings were corroborated by quantitative analysis of the histological findings. Iodine pretreatment of peritoneal mouse neutrophils elicited a concentration-dependent reduction in the oxidative burst of the activated cells. Iodine also scavenged hydroxyl radicals generated by glucose oxidase in a concentration-dependent manner. Since TNF-alpha may be induced by oxygen radicals, iodine-induced protection against SM might result from hydroxyl-radical scavenging by iodine and its suppression of the oxidative burst of activated neutrophils. The combination of iodine and anti-TNF-alpha antibodies might constitute a new approach for treatment of SM-exposed individuals. (This study was supported by US Army Medical Research and Material Command under Cooperative Agreement DAMD17-03-2-0013 and the Binational Science Foundation Research Project 2001186).

DEVELOPMENT OF INTERSPECIES AND MULTI-EXPOSURE ROUTE DOSE METRICS FOR SARIN VIA PHYSIOLOGICALLY BASED PHARMACOKINETIC/PHARMACODYNAMIC MODELLING.

J. Gearhart<sup>1</sup>, K. Yu<sup>2</sup>, P. Robinson<sup>1</sup>, E. Jakubowski<sup>3</sup>, R. Mioduszewski<sup>3</sup>, C. Whalley<sup>3</sup>, S. Thompson<sup>3</sup>, T. Shih<sup>4</sup>, L. Lumley<sup>4</sup> and J. McDonough<sup>4</sup>. <sup>1</sup>*ManTech Environmental Technology, Inc., Wright-Patterson AFB, OH*, <sup>2</sup>*AFRL/HEPB, Wright-Patterson AFB, OH*, <sup>3</sup>*US Army Edgewood Chem Bio Center, Aberdeen Proving Ground, MD* and <sup>4</sup>*US Army MRICD, Aberdeen Proving Ground, MD.*

One of the significant challenges for the relevant application of animal models for studies of chemical warfare agent (CWA) toxicology is to produce actual risk estimates of human response through conversion of pharmacokinetic and pharmacodynamic results. The majority of mechanistic animal studies with CWAs have been at near lethal to supra-lethal doses, by dosing routes (i.e. subcutaneous, intramuscular) that are less applicable to likely human exposure scenarios (i.e. inhalation, dermal), and in animal models that are compromised. This confounds the direct application of these kinds of data to operational risk management processes. One quantitative approach to extrapolate animal study results relevant to human exposure scenarios and best estimate responses is the use of physiologically based pharmacokinetic/pharmacodynamic (PBPK/PD) models. This approach is to simulate potential human responses from CWA exposures through development of mathematical constructs, which incorporate physiologically specific characteristics of both the test species and humans. Using a previously developed PBPK/PD model of sarin inhalation pharmacokinetics and pharmacodynamics in the Gottingen miniature swine, we parameterized the model for the guinea pig and simulated new experimental data with previously published results from studies using subcutaneous, intravenous and inhalation dosing routes. These simulations permitted comparison of the results from CWA studies by different study exposure routes using different species, provided the basis for utilizing extensive data resources for sarin and will be used to extrapolate these PBPK/PD model results to predict human dose-response effects.

**786**

A PBPK REGIONAL MODEL FOR NERVE AGENTS IN THE BRAIN.

P. J. Robinson<sup>1</sup>, J. M. Gearhart<sup>1</sup>, K. O. Yu<sup>1</sup>, E. M. Jakubowski<sup>2</sup>, R. J. Mioduszewski<sup>2</sup> and S. A. Thomson<sup>2</sup>. <sup>1</sup>*Wright-Patterson AFB, Dayton, OH* and <sup>2</sup>*Edgewood Chemical Biological Center, Aberdeen, MD.*

Traditional chemical warfare (nerve) agents, such as sarin, soman and VX, are organophosphorous compounds which bind to acetylcholine esterase (AChE) enzyme, resulting in inhibition of hydrolysis of acetylcholine. Accumulation of acetylcholine at the nerve junction causes continuous stimulation, resulting in observable effects such as miosis, increased tracheobronchial secretions, tremor and convul-

sion. Extended low-level exposures are believed to lead to more subtle mental and behavioral consequences, which may depend on the dose to particular brain regions (dose-response). Physiologically-based pharmacokinetic or toxicokinetic (PBPK/TK) models are accepted tools for data integration and cross-validation of diverse studies. Previous related PBPK models include one by Kim et al for 2, 4-D, which incorporates membrane-limited transfer into brain regions, and transfer from brain regions to cerebrospinal fluid (CSF). The present models are based on a PBPK model for nerve agents developed in our laboratory, extended to incorporate regional brain blood flows, regional flow-limited brain uptake, tissue volumes and CSF flow. Regional brain activity increases regional cerebral blood flow, altering the regional distribution of lipophilic agents and toxins such as nerve agents, thereby altering the response. Limited experimental data has been collected in rat, minipigs, guinea pig and humans, and includes regional AChE inhibition measurements in the frontal, occipital, parietal and temporal cortex, as well as the optic nerve and olfactory bulb in the minipig. Regional brain blood flows and tissue volumes for animals and humans have been collected from the literature. Consistent and defendable data, suitably incorporated into this PBPK/TK modeling framework, will significantly reduce errors currently embedded in various estimates of toxicity, and will provide a consistent basis for extrapolating and integrating experimental data and information on health effects with potential performance decrements resulting from low-level exposure scenarios.

Belski<sup>3</sup>, J. Renner<sup>3</sup>, J. Anthony<sup>1</sup>, C. Crouse<sup>3</sup>, J. Scotto<sup>1</sup>, J. Jarvis<sup>1</sup>, A. Totura<sup>3</sup>, M. O'Malley<sup>2</sup>, A. D'Ambroio<sup>2</sup>, C. Robison<sup>2</sup>, E. Mason<sup>1</sup>, S. McAvoy<sup>2</sup>, T. Rowland<sup>2</sup>, C. Clark<sup>2</sup>, J. H. McDonough<sup>2</sup>, R. J. Mioduszewski<sup>1</sup>, T. M. Shih<sup>2</sup> and S. A. Thomson<sup>1</sup>. <sup>1</sup>ECBC, Aberdeen Proving Ground, MD, <sup>2</sup>USAMRICD, Aberdeen Proving Ground, MD and <sup>3</sup>GEO-Centers, Aberdeen Proving Ground, MD.

A risk assessment tool for interspecies extrapolation and prediction of response to chemical warfare nerve agent (CWNA) exposure is physiologically based pharmacokinetic (PBPK) modeling. This study was performed to integrate CWNA toxicity data using the inhalation route of exposure in guinea pigs (GP). After the 60 min GB LC<sub>50</sub> was determined (239 mg·min/m<sup>3</sup>), GP were exposed to GB vapor (0.1 & 0.4 LC<sub>50</sub>) in a modified whole body inhalation chamber that allowed serial collection of blood from the left carotid artery from as many as eight animals during the 60-min exposure. Arterial blood was also collected at various time intervals post-exposure (up to 24 hrs). Mixed blood was collected at 7 & 14 days post-exposure. Blood gas and other physiological parameters were measured using i-STAT. The onset of miosis (within 6-min) was measured using IR technology while the animals were exposed. Blood levels of acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE)(pre- & post-exposure, during exposure), and blood and tissue levels of regenerated sarin (rGB) were assayed. At the GB concentrations tested, rGB levels were higher in plasma than RBC, but RBC rGB was still measurable while plasma rGB was barely detectable 7 days post-exposure. Post-exposure, high levels of rGB were found in the eyes, lung and kidney. The results suggest that plasma and RBC rGB and cholinesterase are useful indicators of low level exposure. These results combined with data from the subcutaneous route of exposure will be used to refine existing PBPK models and to compare with similar inhalation data in other species. These data will provide important information regarding the relationships between exposure levels, absorption amounts and toxic effects.

ESTIMATING LETHAL AND SEVERE TOXIC EFFECTS IN MINIPIGS FOLLOWING 10, 60 AND 180-MINUTES OF WHOLE-BODY GB VAPOR EXPOSURE.

S. W. Hulet<sup>1</sup>, D. R. Sommerville<sup>1</sup>, P. A. Dabisch<sup>2</sup>, B. J. Benton<sup>1</sup>, D. B. Miller<sup>2</sup>, J. S. Forster<sup>1</sup>, J. A. Scotto<sup>1</sup>, R. B. Crosier<sup>1</sup>, C. L. Krauthausen<sup>2</sup>, J. R. Jarvis<sup>2</sup>, J. H. Manthei<sup>1</sup>, W. T. Muse<sup>1</sup>, D. C. Burnett<sup>1</sup>, R. A. Moretz<sup>1</sup>, B. P. Gaviola<sup>1</sup>, R. J. Mioduszewski<sup>1</sup> and S. A. Thomson<sup>1</sup>. <sup>1</sup>Toxicology, US Army ECBC, Aberdeen Proving Grounds, MD and <sup>2</sup>GEO-Centers, Inc., Abingdon, MD.

Sexually mature male and female Gottingen minipigs were exposed to various concentrations of GB vapor via whole-body inhalation for 10, 60 or 180 minutes. Signs of nerve agent exposure were classified as either lethal, severe, moderate or mild. Maximum likelihood estimation was used to calculate the median effect levels (lethal (LCT<sub>50</sub>) and severe effects (ECT<sub>50</sub>)) for each gender-duration combination. Ordinal regression was used to model the concentration x time profile of the agent toxicity. Contrary to that predicted by Habers rule, LCT<sub>50</sub> and ECT<sub>50</sub> values increased as the duration of the exposures increased. LCT<sub>50</sub> values (with 95% confidence limits) for 10, 60 and 180-minute exposures in male minipigs were 72.5

(57.3-91.6), 105.7 (85.6-130.6) and 182.3 (145.2-228.9) mg·min/m<sup>3</sup> respectively. LCT<sub>50</sub> values (with 95% confidence limits) for 10, 60 and 180-minute exposures in female minipigs were 86.9 (69.2-109.2), 127.1 (100.7-160.4) and 174.3 (134.7-225.5) mg·min/m<sup>3</sup> respectively. The data were best fit using a probit slope of 15.7 and toxic load exponent of 1.38 (95% confidence limits of 1.25-1.51). Although, males were significantly (p =0.01) more sensitive than females to lethal effects of GB vapor, the ratios of lethal to severe concentrations were higher in female minipigs (99% ANOVA confidence) indicating that there is less difference between severely toxic and lethal dosages in the female as compared to male pigs.

PRETREATMENT WITH CARBOXYESTERASE INHIBITOR CBDP SENSITIZES MICE TO SARIN: POTENTIAL MODEL FOR LOW-DOSE EXPOSURE ASSESSMENT.

R. D. Grubbs, W. A. Price, J. B. Lucot and M. Morris. *Pharmacology & Toxicology, Wright State University School of Medicine, Dayton, OH.*

Low-level (sub-clinical) exposure to organophosphates (OPs), both insecticides and chemical warfare agents, continues to be a public health concern. To better understand the effects of such exposures, we have developed a mouse model that utilizes the selective carboxyesterase inhibitor, 2-(O-cresyl)-4H-1:3:2-benzodioxaphosphorin-2-oxide (CBDP), to render the mouse more sensitive to OPs. In this study we pretreated animals for 1 hr with either 1.5 mg/kg CBDP administered sc. or vehicle (propylene glycol/5% EtOH) and then administered sc. saline or sarin (0.05 or 0.1 x LD<sub>50</sub> - 0.4 ug/kg). The animals were sacrificed 24 hr later and cholinesterase activity was determined in blood and several brain areas (brain stem, prefrontal cortex, caudate, and amygdala). Analysis of the blood cholinesterase activity indicated that at the dose used, CBDP had little effect alone, but potentiated the inhibition produced by both doses of sarin. In all of the brain areas examined, neither CBDP nor sarin alone produced inhibition of brain CHE activity; however, CBDP pretreatment enabled sarin to inhibit CHE activity by 38 to 65%, depending on the dose and brain region. We also observed no behavioral effects of CBDP or sarin alone at the doses tested, but the combination produced classic signs of OP toxicity: hypothermia, lethargy, and muscle fasciculations. From these results, we conclude that by inhibiting carboxyesterase with CBDP pretreatment, the mouse becomes sufficiently sensitized to sarin for it to function as a model for human exposure. The advantages of using a mouse model include the ability to employ transgenic animals and microarray technologies to look for subtle changes induced by sub-lethal OP exposures. This research is funded by DoD contract DAMD17-00-C-0020.

**790**

GENISTEIN PROTECTS MICE FROM RADIATION-INDUCED WEIGHT LOSS.

M. R. Landauer, J. Kramer, C. Pham and V. Srinivasan. *AFRR, Bethesda, MD.*

Radioprotectors are chemical compounds that provide protection from ionizing radiation-induced injury. They have applications in clinical oncology, space travel, radiation site cleanup, radiological terrorism, and military scenarios. We demonstrated that the isoflavone genistein protects mice from radiation-induced lethality when administered 24 hr before gamma irradiation (Landauer et al., *J. Appl. Toxicol.*, 23, 379-385, 2003). In a clinical setting, radiation is administered at sub-lethal doses to destroy tumor cells. A frequent side effect of sublethal irradiation is a reduction of body weight. Moreover, weight loss has been demonstrated to be a prognostic indicator of reduced survival rates; therefore, the amelioration of radiation-induced weight loss is an important objective when using radiation therapy. In the present study, we characterized the effects of genistein on gamma radiation-induced weight loss in CD2F1 male mice. Mice were divided into four groups:(1) vehicle + sham irradiation, (2) genistein + sham irradiation, (3) vehicle + 7-Gy irradiation, and (4) genistein + 7-Gy irradiation. A single injection of genistein (200 mg/kg) or vehicle was subcutaneously administered 24 hr before either sham irradiation or a sublethal dose of cobalt-60 gamma irradiation (7 Gy at 0.6 Gy/min). Animals were weighed daily for 30 days after irradiation. We found that mice treated with vehicle or genistein that were sham-irradiated exhibited normal weight gain over the 30 days of the experiment. In contrast, a significant reduction in body weight for both groups of irradiated animals was observed. Beginning on day 3 after irradiation, the genistein/irradiation group exhibited decreased weight loss compared with the vehicle/irradiation group. By day 20 after irradiation, the body weight of the genistein/irradiation group had returned to control levels. However, the body weight of irradiated mice that did not receive genistein remained significantly below that of the other three treatment groups at 30 days after irradiation. These results demonstrate that genistein can mitigate weight loss in mice receiving a sublethal dose of gamma radiation.

## LOW DOSE SARIN PRODUCES LONG LASTING CHANGES IN CARDIOVASCULAR FUNCTION.

V. Farah, S. J. Paton and M. Morris. *Pharmacology and Toxicology, Wright State University, Dayton, OH*. Sponsor: J. McDougal.

Our previous studies showed that sarin, acetylcholinesterase (AChE) inhibitor and chemical warfare agent, has effects on brain gene expression at very low doses. To extend these studies to physiological function, we evaluated the cardiovascular effects of sarin in mice. Male C57BL mice (n=8) with radiotelemetric arterial catheters were injected with sarin subcutaneously (8 µg/kg, 0.05 x LD50) on two consecutive days. Arterial pressure (AP) was recorded (5Hz) under baseline conditions and 5, 12 and 30 days after treatment. We measured blood pressure and heart rate (HR) with analysis of variability in time and frequency domains. AP and pulse interval (PI) time series were submitted to spectral analysis by autoregressive method with variability measured in the low (LF, 0.1-1.0 Hz) and high (HF, 1-5 Hz) frequency ranges. The low dose of sarin did not affect blood cholinesterase activity, HR or AP. However, there was a more than 2 fold increase in PI variance which lasted for at least 30 days. PI variance after sarin was: 40±4, 97±17, 96±13 and 110±24 ms<sup>2</sup> before and 5, 12 and 30 days after treatment, respectively. Sarin also enhanced the LF and HF components of PI variability (19±3, 42±6, 44±8 and 63±12 ms<sup>2</sup>; 16±1, 45±11, 42±6 and 39±10 ms<sup>2</sup> before and days 5, 12 and 30 for LF and HF, respectively). Sarin treatment (12 days, n = 5) combined with muscarinic receptor blockade (atropine, 4mg/Kg, i.p.) produced an increase in HR from 478±14 to 623±34 bpm, while MAP did not change. Atropine markedly reduced PI variability from 97±10 to 9±2 ms<sup>2</sup> and also reduced LF from 41±10 to 1±1 ms<sup>2</sup> and HF from 43±7 to 6±2 ms<sup>2</sup> in sarin treated mice. Our results show that a dose of sarin which exerts no peripheral effects on cholinesterase activity produced marked and long lasting effects on cardiac function. These data raise concerns about possible public health effects of exposure to even sub-clinical levels of sarin. (This work was supported by US Army Medical Research and Materiel Command under contract DAMD17-00-C-0020).

## EVIDENCE OF CYSTEINE LOADING IN SKIN AND OTHER TISSUES IN SPRAGUE-DAWLEY RATS DOSED AT 4-HOUR INTERVALS WITH N-ACETYL-L-CYSTEINE (1, 200 MG/KG).

E. W. Johnson, E. R. Wilfong, A. J. Bobb and D. P. Arfsten. *NHRC EHE Lab., Wright-Patterson AFB, OH*.

Intracellular cysteine levels are a significant, rate-limiting factor for chemical detoxification via glutathione (GSH) conjugation. N-acetyl-L-cysteine (NAC) is an artificial source of cysteine and oral administration of NAC has shown to increase cellular GSH levels and protect against toxic injury from certain exposures. However, NAC has a relatively short half-life of approximately 4-6 hours and it is assumed that the beneficial effect of NAC also diminishes 2-4 hours after oral administration. In this study, we explored whether oral administration of a single bolus dose of 14C-NAC (1, 200 mg/kg in 2 mL d H<sub>2</sub>O) every 4 hours for up to 12 hours resulted in increasing levels of 14C dpm, GSH levels and glutathione-S-transferase (GST) activity in tissues with potential exposure to irritating chemicals. We found that the levels of 14C increased significantly with each successive NAC dose in the serum, skin, kidneys, thymus, lung, and liver at 4, 8, and 12 hours as compared with to tissues from negative control animals dosed with deionized water. 14C dpm for eyes, kidney, liver, serum, and thymus did not increase significantly following a third NAC dose at 8 hours as compared to levels at 4 hours suggesting that cysteine levels in these tissues had reached steady-state after two doses. 14C dpm for the skin and lungs were found to be elevated still further after 3 NAC doses indicating that cysteine levels had not reached steady-state. Studies are continuing to determine if repeat dosing increases GSH levels and GST activities in the tissues analyzed for 14C activity.

## LOW-LEVEL INHALATION EXPOSURE TO GB, GF AND VX INDUCES EXPRESSION OF NEURONAL APOPTOSIS AND REGENERATION GENES IN RAT.

J. W. Sekowski<sup>1</sup>, J. Bucher<sup>1</sup>, M. Orehek<sup>1</sup>, M. Horsmon<sup>1</sup>, J. J. Valdes<sup>1</sup>, C. Whalley<sup>1</sup>, B. Benton<sup>1</sup>, W. Muse<sup>1</sup>, D. Miller<sup>1</sup>, J. Scotto<sup>1</sup>, J. Forster<sup>1</sup>, J. Manthei<sup>1</sup>, R. Way<sup>1</sup>, D. Burnett<sup>1</sup>, B. Gaviola<sup>1</sup>, R. Mioduszewski<sup>1</sup>, S. Thomson<sup>1</sup>, M. Nau<sup>2</sup> and M. Vahey<sup>2</sup>. <sup>1</sup>*Edgewood Chemical Biological Center, US Army RDECOM, APG-EA, MD* and <sup>2</sup>*Walter Reed Army Institute of Research, US Army MRC, Rockville, MD*.

Since the description of Gulf War Syndrome and the terrorist events in Tokyo and Matsumoto in the 1990s, there has been increased interest in the toxic effects of low-levels of chemical warfare (CW) agents. A considerable body of literature suggests that exposures to organophosphorus (OP) compounds result in cognitive and neurological decrements. However, there is a paucity of literature regarding the mo-

lecular effects of low-level exposures to OP nerve agents. Although low-level exposures may not cause obvious pathology at the time of exposure, they may cause genetic alterations or changes in gene expression that may predispose personnel to injury or disease later in life. In the experiments described herein, male and female Sprague-Dawley rats were exposed to low-level levels of the aerosolized nerve agents Sarin (GB), Cyclosarin (GF), and VX. The ranges of exposure levels (0.0001- 0.033 mg/m<sup>3</sup> for 1 or 4 hrs.) used in these experiments are near levels inducing miosis. Control animals were exposed to air for the same time periods. Alteration of gene expression levels in the brain of the exposed animals was assessed using DNA microarray analysis, and was verified by RT-PCR. To date, our results indicate that low-level inhalation exposure to GB, GF, and VX results in the differential expression many genes that participate in neurological injury, cell death, and regeneration. These data reveal both agent specific and general organophosphate nerve agent toxicities. Furthermore, our analyses also reveal many differences in the extent and identities of the differentially expressed genes between the female and male animals. These data, along with parallel physiological measurements, strongly suggest that there are significant gender-associated differences in the toxicity of low-level exposures to organophosphate nerve agents.

## MECHANISM OF THE MIOTIC TOLERANCE OBSERVED FOLLOWING MULTIPLE EXPOSURES TO SARIN VAPOR.

P. A. Dabisch<sup>2,1</sup>, D. B. Miller<sup>3</sup>, D. C. Burnett<sup>1</sup>, E. M. Jakubowski<sup>1</sup>, S. A. Reutter<sup>1</sup>, R. J. Mioduszewski<sup>1</sup> and S. Thomson<sup>1</sup>. <sup>1</sup>*Operational Toxicology, US Army Edgewood Chemical Biological Center, Aberdeen Proving Ground, MD*, <sup>2</sup>*National Research Council Postdoctoral Associate, National Academy of Sciences, Washington, DC* and <sup>3</sup>*Geo-Centers, Inc., Aberdeen Proving Ground, MD*.

One of the first signs of exposure to sarin (GB) vapor is miosis. The present study was undertaken to investigate the ocular effects of repeated low-level exposure to GB vapor. Rats were exposed to GB vapor (3.93 ± 0.18 mg/m<sup>3</sup>) for 1 hour on each of 3 consecutive days. Exposed rats had >97% reduction in the ratio of pupil-to-iris radius following the first two exposures (n=15). However, following the third exposure, tolerance developed to the miotic effect of GB, with the ratio of pupil-to-iris radius only decreased by 40% (n=15). The light reflex in GB-exposed animals was also absent following the third exposure, but gradually returned over the next 7 days. AChE and BChE activity in the eye and blood were inhibited to a similar degree (50-70%) following each exposure, and the amount of GB recovered from the eye was similar following each exposure. Thus, the tolerance observed cannot be attributed to a reduction in the inhibitory effect of GB. Phentolamine (n=4) and propranolol (n=4) were administered to some animals before the third exposure to determine if enhanced sympathetic activity was responsible for the tolerance observed, but neither had an effect on the development of tolerance to GB vapor. Atropine (6 mg/kg i.m.; n=4) was administered to some animals before the first exposure to determine if excessive stimulation and subsequent desensitization of muscarinic receptors following inhibition of AChE may be responsible for the tolerance observed. Atropine pre-treatment prevented both the miosis associated with the first exposure, and the tolerance observed following the third exposure. The results of the present study demonstrate that multiple inhalation exposures to GB vapor result in tolerance to the miotic effect of GB that persists for about 7 days, and is likely the result of excessive stimulation of muscarinic receptors.

## THE URINE CONCENTRATIONS OF 2-AMINO-2-THIAZOLINE-4-CARBOXYLIC ACID AS A BIOMARKER FOR CYANIDE IN SMOKING AND NON-SMOKING MALE AND FEMALE VOLUNTEERS.

B. A. Logue<sup>1</sup>, S. I. Baskin<sup>2</sup>, G. A. Rockwood<sup>2</sup>, N. P. Kirschten<sup>2</sup>, S. Royster<sup>2</sup>, M. Keebaugh<sup>2</sup> and G. E. Platoff<sup>2</sup>. <sup>1</sup>*Drug Assessment, USAMRICD, Aberdeen Proving Ground, MD* and <sup>2</sup>*South Dakota State University, Brookings, SD*.

It is known that 2-amino-2-thiazoline-4-carboxylic acid (ATCA) is a toxic metabolite (Nagasawa et al., OPPI 36, 178-182, 2004) of cyanide which causes tremors, convulsions and brain lesions (Bitner et al., NeuroToxicology 16, 115-122, 1995, NeuroToxicology 18, 191-200, 1997). ATCA inhibits cytochrome c oxidase approximately 200 times greater than cyanide (Kelly et al., 2005). ATCA appears to be a promising biomarker of cyanide as it is far more stable than cyanide (Logue et al., submitted to J. Chromatography B). Concentrations of ATCA were measured in urine of smoking or non-smoking volunteers using gas chromatography-mass spectrometry. Gender urine differences of ATCA were found in smokers indicating that women (319 + 284 ng/ml, N=11) had higher concentrations than men (115 + 36 ng/ml, N=8). In non-smokers, no differences in urine ATCA concentrations as a function of gender were observed in males (87 + 36 ng/ml, N=15) versus females (80 + 53 ng/ml, N=6). It is shown that the cyanide metabolite ATCA could be used to measure cyanide exposure if the factors of smoking and gender are considered.

INTERACTION OF 2-AMINO-2-THIOZOLINE-4-CARBOXYLIC ACID WITH CYTOCHROME C OXIDASE IMMOBILIZED IN AN ELECTRODE-SUPPORTED LIPID BILAYER MEMBRANE.

J. B. Kelly<sup>2</sup>, E. M. Hawkridge<sup>2</sup>, S. I. Baskin<sup>1</sup>, G. A. Rockwood<sup>1</sup> and G. E. Platoff. <sup>1</sup>USAMRICD, Aberdeen Proving Ground, MD and <sup>2</sup>Chemistry, Virginia Commonwealth University, Richmond, VA.

Cyanide inhibition of cytochrome c oxidase (CCO) is thought to be responsible for cyanide toxicity. It has also been shown that the cyanide metabolite 2-amino-2-thiazoline-4-carboxylic acid (ATCA) (Nagasawa et al., OPPI, 36, 178-182, 2004) is formed chemically from cyanide. ATCA itself causes tremors, convulsions, and brain lesions in rodents (Bitner et al., NeuroToxicology, 16, 115-122, 1995, NeuroToxicology, 18, 191-200, 1997). In the current preliminary experiments, potential inhibition of CCO (isolated from bovine) by ATCA (Chem-Impex Interactions, Wood Dale, IL) was investigated using electrochemical sensor technology. Voltammograms were obtained during continuous exposure to CCO by 9.8  $\pm$  M ATCA in phosphate buffer (0.1 M, pH 7.4). The initial experiment found a 91% decrease in oxidative current (using cyclic voltammetry) of CCO after exposure to ATCA for 20 min. The inhibition of CCO by ATCA is generally similar to earlier results found with cyanide spectrophotometrically (Alexander et al., BBA, 912, 41-47, 1987) or electrochemically (Su et al., submitted to J. Electroanalytical Chem.), although the inhibition by ATCA is of greater magnitude than that of cyanide. It is suggested that the cyanide metabolite ATCA is a more potent inhibitor *in vitro* of CCO than cyanide.

VALIDATION OF REAL TIME QUANTITATIVE PCR AND SAMPLE PREPARATION PROCEDURE IN BIODISTRIBUTION STUDY OF ADENOVIRUS VECTORS.

B. Tian, S. S. Rentz, G. S. Gregory, R. Tina and J. G. Page. *Southern Research Institute, Birmingham, AL.*

A reliable real time quantitative PCR (Q-PCR) assay and a standardized sample preparation procedure must be established prior to evaluation of the biodistribution of a gene therapy product. Demonstrated here are strategies implemented to achieve reliable and reproducible data in a biodistribution study of an adenovirus vector (Ad-vector) in mouse tissues. The well-defined primer-probe set and an optimized Q-PCR assay allowed for specific detection of the Ad-vector in mouse tissue samples with a reaction efficiency of greater than 96%. Applying Q-PCR limiting dilution assay, the copy number (1.0) of the Ad-vector DNA calculated from the size and concentration compared well with the experimentally determined value of 1.13 copy numbers. A standard curve ranging from  $10^1$  to  $10^7$  copies per reaction was shown to be reproducible over four-month study period with an average CV% of 2.0% for  $C_T$  ( $n=9$ ). Because a variety of tissue types and multiple steps were involved in the target detection, each step of the procedure was standardized. This included using identical amounts of various tissues for DNA isolation and equal volumes of each DNA sample for the PCR assay to ensure a consistent sample quality among individual samples. Applying these procedures, the concentration of DNA isolated with a Qiagen DNeasy kit was similar for each tissue type. Additionally, DNA samples from various control mouse tissues, each spiked with 10 copies of Ad-vector DNA resulted in an average of  $8.1 \pm 1.8$  (SD) copies being detected. Moreover, data generated from a group of animals treated with Ad-vector ( $n=5$ ), which covered a range from zero to several thousand copies of Ad-vector per  $\mu$ g DNA in eleven different tissues, have been reproduced with the same tissue lysate over a nine-month period. These data demonstrate the reliability and reproducibility of the complete procedure from sample preparation through PCR analysis. (Supported by NGVL, and NIH grant no. RR-01-001)

SINGLE-DOSE TOXICITY STUDY OF AN ONCOLYTIC ADENOVIRUS ADMINISTERED BY INTRAVENOUS INFUSION TO CYNOMOLGUS MONKEYS.

B. McIntyre<sup>1</sup>, S. Thibault<sup>1</sup>, N. Kishnani<sup>2</sup>, D. Compton<sup>1</sup>, R. Veneziale<sup>1</sup>, J. Nelson<sup>3</sup>, R. Ralston<sup>4,2</sup> and R. Morrissey<sup>1</sup>. <sup>1</sup>Schering-Plough Research Institute, Lafayette, NJ, <sup>2</sup>Schering-Plough Research Institute, Kenilworth, NJ, <sup>3</sup>Charles River Laboratories, Sierra Division, Sparks, NV and <sup>4</sup>Canji, San Diego, CA.

Replication of recombinant adenovirus 01/PEME is attenuated in normal human cells by key pathways that control cell growth and apoptosis. However, these pathways, which are often dysregulated in tumor cells, allow 01/PEME to undergo vigorous replication, resulting in release of new 01/PEME to infect other tumor cells and produce oncolysis. The current study was designed to assess the safety of 01/PEME in cynomolgus monkeys. Female monkeys ( $n=2$ /group) were administered a single iv (saphenous) dose of either vehicle,  $1 \times 10^{11}$ ,  $5 \times 10^{11}$ ,  $1 \times 10^{12}$ , or  $5 \times 10^{12}$  viral particles/kg (p/kg). Animals, with the exception of the highest dose

group, were necropsied on study Day 25. Mortality and morbidity were observed at  $5 \times 10^{12}$  p/kg within 4 days of dosing and was associated with increased prothrombin and activated partial thromboplastin time values, mild thrombocytopenia, elevated transaminase values, and diffuse liver necrosis. Monkeys administered  $5 \times 10^{11}$  and  $1 \times 10^{12}$  p/kg exhibited dose-related transient increases in transaminase levels. 01/PEME was detectable in excreta by PCR but only a single incidence of active infectious virus was detected in a monkey administered  $5 \times 10^{12}$  p/kg. 01/PEME was measurable in blood in a dose-dependent manner, exhibiting multiphasic pharmacokinetic profile, and was detected in other necropsied tissues by PCR. Histological examination revealed intranuclear inclusion bodies in the lung and liver and inflammation. Livers from animals administered  $5 \times 10^{12}$  p/kg exhibited mRNA for hexon by rtPCR and transmission electron microscopy was negative for viral structures, thus collectively indicating abortive replication. These findings are consistent with other non-replicative adenoviral studies conducted in nonhuman primates.

FIFTEEN-MONTH REPEATED DOSE SUBCUTANEOUS ADMINISTRATION STUDY OF rhFGF-2 IN ATHYMIC NUDE MICE.

S. Tsunoda<sup>1</sup>, T. Nakamura<sup>1</sup>, T. Sibanushi<sup>1</sup>, K. Kuzutani<sup>1</sup> and M. Takahashi<sup>2</sup>.

<sup>1</sup>Safety Research Department, Kaken Pharmaceutical co., Ltd, Sizuoka, Japan and

<sup>2</sup>Pathology Peer Review Center, Tokyo, Japan.

[Background] Although the importance of the carcinogenicity property of human recombinant growth factors *in vivo* has been widely recognized, repeated dosing study has often been hesitated in concern with antibody production. In the present study, we successfully completed the chronic repeated dose study of recombinant human FGF-2 (rhFGF-2), with special attention to the tumor development, using athymic nude mice. rhFGF-2 was injected subcutaneously at the dose of 0.4, 4 and 40  $\mu$ g/head twice weekly in Crj:CD-1(ICR)-nu male and female athymic nude mice for 15 months and various analyses were performed. [Results] Survival rates attained to 25% at the end of 15-month treatment and it did not differ significantly between the rhFGF-2 groups and the control group treated with saline. As the neoplastic lesions, malignant lymphoma was observed in almost all the mice of all the groups died during the study and the incidence and onset were identical between the rhFGF-2 and the control groups. Additionally, a small number of other neoplastic lesions were observed with no relation to the treatment of rhFGF-2. As the non-neoplastic lesions, incidence of glomerulosclerosis in the kidney increased in number in the 40  $\mu$ g/head group, which might be related the mitogenic potency of FGF-2 on the glomerular epithelial cells. Increase in the subcutaneous fat tissues of dorsal skin in the 4 and 40  $\mu$ g/head groups, which resulted in significant increase in the body weights, was considered the outcome of rhFGF-2 that acted as the mitogen on the fat cells. Anti-rhFGF-2 neutralizing antibody was not detected in all the rhFGF-2 groups after the 15 months of repeated dosing even at the presence of rhFGF-2 in the serum. [Conclusion] The present study clearly indicated that rhFGF-2 did not develop the neoplastic lesions or unexpected toxicities in the systemic organs after the repeated subcutaneous treatment for 15 months in athymic nude mice.

PRECLINICAL SAFETY OF RECOMBINANT HUMAN THROMBIN.

J. K. Heffernan, R. Ponce, L. A. Zuckerman, J. Visich and M. Rogge. *Preclinical Development, ZymoGenetics, Seattle, WA.*

Recombinant human thrombin (rhThrombin) is being developed as an alternative to thrombin products purified from pooled human or bovine plasma and currently-marketed as topical hemostatic agents. Preclinical studies of rhThrombin were conducted prior to its evaluation as a topical adjunct to surgical hemostasis in clinical trials. Innate cynomolgus monkey inhibitors, including antithrombin III, bound  $^{125}$ I-rhThrombin both *in vitro* and after a single IV (3.5 U/kg) or SC (350 U/kg) dose demonstrating inactivation of rhThrombin following entry into the circulation (SE-HPLC detection). Mouse fibroblast cells incubated with 250 or 500 U/mL rhThrombin or bovine thrombin demonstrated viability after 24 and 48 hours with morphologic changes consistent with thrombin's action as a serine protease. Application of rhThrombin or bovine thrombin to rabbits at concentrations of 100, 1000 or 2000 U/mL resulted in no ocular or skin irritation for up to 72 hours. Repeated subcutaneous injection of rhThrombin or bovine thrombin (346 U/kg weekly for four weeks) in monkeys produced no treatment-related findings as assessed by clinical signs, clinical pathology and gross and microscopic pathology. Absorbable gelatin sponges soaked with rhThrombin or bovine thrombin (1000 U/mL), implanted for six weeks in monkeys following creation of a surgical liver wound, showed equivalent gross and microscopic wound healing characteristics with no systemic or local toxicities. Specific anti-rhThrombin antibodies and anti-prothrombin activator (PTA) antibodies were not detected after exposure to rhThrombin. Transient, low-titer antibodies specific to Chinese hamster ovary (CHO) host cell protein were detected in one of ten monkeys. rhThrombin was shown in preclinical studies to be safe when administered topically, subcutaneously or via an absorbable gelatin sponge.

## SAFETY ASSESSMENT OF MONOCLONAL ANTIBODY MAB216 + VINCRISTINE IN RABBITS.

**K. Steinmetz**<sup>1</sup>, D. Fairchild<sup>1</sup>, N. Teng<sup>2</sup>, M. Bieber<sup>2</sup>, K. Schweikart<sup>3</sup>, J. Tomaszewski<sup>3</sup> and J. Mirsalis<sup>1</sup>. <sup>1</sup>SRI International, Menlo Park, CA, <sup>2</sup>Stanford University, Stanford, CA and <sup>3</sup>National Cancer Institute, Bethesda, MD.

The monoclonal antibody MAb216 (VH4-34) is targeted against human B lymphocytes and is proposed for chemotherapy in combination with vincristine (VCR). We have evaluated MAb216 in NZ rabbits to determine a safe dose for human trials and to identify potential target organs of toxicity. Males and females were treated intravenously (iv) with a single dose of MAb216 at 0, 6.25, and 25 mg/kg (75 and 300 mg/m<sup>2</sup>) with or without iv vincristine (0.125 mg/kg, 1.5 mg/m<sup>2</sup>). All rabbits gained weight and had no significant clinical signs or mortality. On Day 3 all rabbits treated with 25 mg/kg MAb216 had reductions in white blood cells (WBC), neutrophils (ANS), and lymphocytes (ALY; females only). Reduced WBC persisted through Day 10. VCR treatment reduced reticulocytes (RET) in both genders. By Day 17, all hematology parameters returned to control values. There was a general trend towards lower platelet counts (PLC) in all MAb216 groups on Days 3 and 10; however, this may be due to increased clumping of samples caused by MAb216 rather than on a direct MAb216-induced thrombocytopenia. Flow cytometry analysis of bone marrow and mandibular lymph nodes showed modest, non-dose-related, but consistent decreases in the percentage of B cells in the bone marrow samples from MAb216-treated animals on Day 10, but not on Day 35. No histopathologic changes were attributed to treatment with MAb216. MAb216 was detected in rabbit sera by ELISA with mean values of 67 and 889 µg/ml at 6.25 and 25 mg/kg, with half-lives of 6 and 9 hrs, respectively. Rabbits produced an antibody response to the human protein, but antibody titer was far less at 10 days than at 35 days, suggesting minimal effect on circulating MAb216 following injection. In conclusion, iv treatment with MAb216 ± vincristine does not appear to induce sustained toxicity in rabbits. The no observable adverse effect level (NOAEL) is approximately 6.25 mg/kg (75 mg/m<sup>2</sup>). (Supported by NCI Contract N01-CM-87101, N01-CM-42203, and RAID Application No. 038).

## RISING DOSE TOLERABILITY STUDIES OF A CHIMERIC ANTI-PHOSPHATIDYL SERINE MONOCLONAL ANTIBODY (TARVACIN™) IN RATS AND CYNOMOLGUS MONKEYS.

**S. Carpenter**<sup>1</sup>, **C. Stewart**<sup>2</sup>, **L. Willis**<sup>2</sup> and **P. E. Thorpe**<sup>3</sup>. <sup>1</sup>Peregrine Pharmaceuticals, Inc., Tustin, CA, <sup>2</sup>MPI Research, Inc., Mattawan, MI and <sup>3</sup>The University of Texas Southwestern, Dallas, TX.

Tarvacin™ is a chimeric (human/murine) monoclonal antibody specific for phosphatidylserine that becomes exposed on the external surface of tumor (but not normal) vascular endothelium. Tarvacin™ is being evaluated for the treatment of human solid tumors. The objective of these studies was to determine the effects of Tarvacin™ administered as a single IV bolus to Sprague-Dawley rats and Cynomolgus monkeys. Four groups of rats (i.e., 3/sex/group) received 0, 2, 20, 60 or 200 mg/kg Tarvacin™ and were monitored for 7 days post-dose. Monkeys were divided into two groups (i.e., 1/sex/group). One group received 1 mg/kg (day 1) and 30 mg/kg (day 13) Tarvacin™. The other group received 10 mg/kg (day 1) and 100 mg/kg (Day 16) Tarvacin™. Monitoring was continued for 7 days post-dose except for monkeys receiving 100 mg/kg Tarvacin™ who were monitored for 14 days post-dose. Samples were collected at various time points for hematology and coagulation parameters. Findings in both species were limited to transient dose-dependent elevations in activated partial thromboplastin time (APTT) and prothrombin time (PT). To further evaluate the coagulation response, a study in rats showed that while APTT and PT were elevated 2.9- and 1.3-fold, respectively at 24 hours post-dose, bleeding time, fibrinogen, thrombin time (TT), and fibrin degradation products (FDP) were not significantly affected. Furthermore, an *in vitro* study with Tarvacin™-spiked rat plasma showed that Tarvacin™ interfered with the analytical determination of APTT. We conclude that Tarvacin™ administered as a single IV bolus is generally well tolerated in rats and monkeys with effects limited to prolonged APTT and PT.

## SAFETY EVALUATION OF A CHIMERIC ANTI-PHOSPHATIDYL SERINE MONOCLONAL ANTIBODY (TARVACIN™) IN MICE USING A FULL-THICKNESS EXCISIONAL DERMAL WOUND MODEL.

**S. Carpenter**<sup>1</sup>, **T. Nguyen**<sup>2</sup> and **P. E. Thorpe**<sup>3</sup>. <sup>1</sup>Peregrine Pharmaceuticals, Inc., Tustin, CA, <sup>2</sup>Explora Biolabs, LLC, La Jolla, CA and <sup>3</sup>The University of Texas Southwestern, Dallas, TX. Sponsor: **L. Kamendulis**.

Tarvacin™ is a chimeric (human/murine) monoclonal antibody specific for phosphatidylserine that becomes exposed on the external surface of tumor (but not normal) vascular endothelium. Tarvacin™ is being evaluated for the treatment of

human solid tumors. The objective of this study was to determine whether Tarvacin™ inhibits wound healing in a full thickness excisional dermal wound model in mice. Three groups of mice (i.e., 6/group/termination time point) received 0, 4, or 200 mg/kg/week Tarvacin™ intravenously. A fourth positive control group received 1 mg/kg/day dexamethasone subcutaneously (SC). All treatments began on day 0. On day 6, two full-thickness circular dermal wounds (6-mm diameter) were surgically created on the lower backs of female BALB/c mice. Twenty-four mice were sacrificed on days 14 and 19, respectively and wounds evaluated for healing. All animals survived until the scheduled time of termination. On day 14, percent wound closure (mean±SD) was 71.2±15.4, 81.8±17.1, and 86.3±4.7% in 0, 4, and 200 mg/kg Tarvacin™ groups, respectively. Wound closure was 57.3±19.3% in dexamethasone-treated controls. Histological evaluation (i.e., trichrome stains) of the wounds showed no qualitative difference in wound healing between the vehicle and Tarvacin™-treated groups. By day 19 all wounds from all groups had re-epithelialized with the exception of 3 out of 12 wounds in the dexamethasone control group. We conclude that repeat doses of Tarvacin™, up to 200 mg/kg/week, does not prolong time-to-healing in this murine model.

## REPRODUCTIVE AND DEVELOPMENTAL EFFECTS OF AVASTIN™, A MONOCLONAL ANTIBODY AGAINST VASCULAR ENDOTHELIAL GROWTH FACTOR.

**C. L. Zuch**<sup>1</sup>, **A. Bricarello**<sup>2</sup>, **J. C. Beyer**<sup>1</sup>, **P. J. Thomford**<sup>3</sup>, **B. J. Christian**<sup>3</sup> and **A. M. Hoberman**<sup>4</sup>. <sup>1</sup>Safety Assessment, Genentech, Inc., South San Francisco, CA, <sup>2</sup>Study Management, Genentech, Inc., South San Francisco, CA, <sup>3</sup>Covance Laboratories, Inc., Madison, WI and <sup>4</sup>Charles River Laboratories, Inc., Argus Research Division, Horsham, PA.

Avastin™ (bevacizumab) is a recombinant humanized monoclonal antibody directed against vascular endothelial growth factor (VEGF) that has been approved for use in colorectal cancer patients. It blocks the interaction of VEGF with its receptors, thereby inhibiting angiogenesis. Angiogenesis plays a role in pathologic processes such as cancer; it is also critical to several normal physiological functions, including corpus luteum development and fetal development. Avastin™ administration was thus expected to interfere with these normal functions. In cynomolgus monkey safety studies, female reproductive tract alterations were observed following administration of 10 or 50 mg/kg Avastin™ once or twice weekly for 13 or 26 weeks; the alterations included significant decreases in ovarian and/or uterine weight and number of corpora lutea, a reduction in endometrial proliferation, and an inhibition of follicular maturation. Importantly, evidence of reversibility was noted upon cessation of treatment. The doses that resulted in these effects were at least 2-fold greater than the human clinical dose. The teratogenic potential of Avastin™ was investigated in New Zealand White rabbits. Administration of 10, 30, or 100 mg/kg Avastin™ during the period of organogenesis induced adverse effects. Effects included decreases in maternal and fetal body weights, an increased number of fetal resorptions, and an increased incidence of specific gross and skeletal fetal alterations. The effects in fetuses were noted at doses below those which caused maternal toxicity, and that approximated the average serum concentration at the clinical dose. Although potentially tolerable in the oncology patient population, decreased reproductive fertility and adverse outcomes of pregnancy are risks associated with the administration of Avastin™.

## ACUTE TOXICITY STUDIES WITH A TRANSFORMING GROWTH FACTOR-BETA ANTAGONIST IN SPRAGUE-DAWLEY RATS AND CYNOMOLGUS MONKEYS.

**E. R. LaCasse**, **R. Pawliuk**, **J. DelCarpini**, **C. Rogers** and **L. Andrews**. *Pharmacology/Toxicology, Genzyme, Framingham, MA.*

Transforming growth factor beta (TGF- $\beta$ ) is a multifunctional cytokine that plays a fundamental role in the regulation of the immune system as well as cell growth and differentiation. The importance of this growth factor is underscored by the role that aberrant TGF- $\beta$  expression plays in the initiation and/or progression of a number of diseases. Overexpression of TGF- $\beta$  has been implicated in the pathogenesis of fibroproliferative disorders, immunosuppression, as well as an increase in metastasis. Monoclonal antibodies have been demonstrated as an effective means by which inappropriate cytokine levels can be antagonized. In collaboration with Cambridge Antibody Technology, we have developed a human IgG4 monoclonal antibody, GC1008, that specifically neutralizes all three isoforms of TGF- $\beta$ . To assess the acute toxicological potential of GC1008, Sprague-Dawley rats and Cynomolgus monkeys were given a single, intravenous administration of vehicle, 0.5, 5 or 50 mg/kg of GC1008 and evaluated for 14 days. Evaluations included cageside observations, body weights, clinical pathology, toxicokinetics, necropsy, and organ weights. In addition, electrocardiograms, blood pressure, heart rate, body temperature, and respiration rate was monitored in monkeys. The half-life of GC1008 in rats and monkeys was dose-dependent and ranged from 6 to 12 days and 3 to 10 days, respectively. A single dose of 50 mg/kg of GC1008 was well tolerated in both

the rats and monkeys. Rats dosed with 50 mg/kg showed a significant, but not adverse increase in reticulocyte levels. In monkeys, there was a small, dose-independent reduction in total T-cytotoxic lymphocytes and CD8+ activated lymphocytes. None of the changes in either species were considered to be toxicologically relevant. Thus, under the conditions of these studies the no observed adverse effects level (NOAEL) for GC1008 in rats and monkeys was 50 mg/kg.

**806**

#### SAFETY EVALUATION OF A HUMAN FUSION PROTEIN PRO97796 (BR3-FC).

T. R. Gelzleichter<sup>1</sup>, T. Kamenosono<sup>2</sup>, D. M. Danilenko<sup>1</sup>, S. Ren<sup>1</sup>, A. Song<sup>1</sup>, S. R. Brignoli<sup>1</sup>, T. M. Watson<sup>1</sup> and Y. Vugmeyster<sup>1</sup>. <sup>1</sup>Genentech, South San Francisco, CA and <sup>2</sup>SNBL, USA, Seattle, WA.

Abnormal signaling through B-cell activating factor (BAFF) has been implicated in the pathology of autoimmune disorders including rheumatoid arthritis and lupus. PRO97796 (BR3-Fc) is a human fusion protein designed to inhibit BAFF signaling by acting as a decoy receptor. To evaluate the safety and biologic activity of this candidate therapeutic, cynomolgus monkeys were administered 0, 2, or 20 mg/kg/week of PRO97796 by IV injection for 18 weeks. Clinical observations, hematology, clinical chemistry, urinalyses, gross pathology and histopathology were evaluated both during dosing and during a 23-week recovery period. Effects on B, T and NK cells were evaluated by FACS analyses of peripheral blood and lymphoid tissues. To evaluate effects on normal immune function, monkeys were given a primary vaccination with Pneumovax 23, a primary and booster vaccination with KLH, and a booster vaccination with tetanus toxoid. As anticipated, PRO97796 induced significant reductions (up to 50%) in peripheral blood B cells. Decreases were evident as early as week 4 post first dose and persisted throughout the dosing period. There were no consistent effects on T or NK cells. By IHC, there was an approximate 40% decrease in the size of lymphoid follicles and a significant decrease in splenic outer marginal zone B cells. All B cell effects were reversible following cessation of dosing. PRO97796 did not inhibit the ability to mount primary or secondary immune responses as measured by Pneumovax-, KLH- and tetanus-specific IgG and IgM responses. There were modest decreases in titers for KLH and tetanus IgG; however, decreases were statistically significant only for tetanus IgG and only at the low dose. Other than the anticipated effects on B cells, there were no drug-related clinical signs or changes in hematology, clinical chemistry, urinalyses, organ weights, gross pathology or histopathology. Overall, PRO97796 has been shown to have a good safety profile at doses up to 20 mg/kg in cynomolgus monkeys.

**807**

#### CJC-1295, A LONG-ACTING GROWTH HORMONE RELEASE FACTOR ANALOGUE, IS WELL TOLERATED IN DOGS UP TO 14 DAYS.

V. Iordanova<sup>1</sup>, S. Wen<sup>1</sup>, B. Lawrence<sup>1</sup>, C. N. Papagiannis<sup>2</sup>, S. Morseth<sup>3</sup> and J. Castaigne<sup>1</sup>. <sup>1</sup>ConjuChem, Inc., Montreal, QC, Canada, <sup>2</sup>MPI Research, Inc., Mattawan, MI and <sup>3</sup>Morseth Consulting LLC, Jefferson, MD.

CJC-1295 is a synthetic modification of growth hormone releasing factor (GRF) which stimulates the secretion of insulin-like-growth factor (IGF-1) and the pulsatile release of growth hormone (GH). By applying the Drug Affinity Complex (DAC) technology to GRF, the peptide selectively and covalently binds to circulating albumin after subcutaneous (SC) administration, thus prolonging its  $t_{1/2}$ , as seen in dogs administered CJC-1295 ( $t_{1/2}=83$  h). CJC-1295 was evaluated SC in Beagle dogs following single doses of 2.5, 8, 24 and 40 mg/kg, 7-day repeat dosing at 40 mg/kg/day, and 14-day repeat dosing at 0, 2, 6 and 18 mg/kg/day. Treatment-related effects included transient decreased activity and emesis at single doses  $\geq 8$  mg/kg. Similar clinical signs were noted in the 7-day repeat-dose phase at 40 mg/kg/day and at  $\geq 6$  mg/kg/day in the 14-day study in Beagle dogs. In addition, the repeat dosing resulted in dose- and pH-dependent injection site irritation, seen at all CJC-1295 doses as scabs, signs of pain/discomfort, redness, swelling, thickening, or microscopically as inflammation, hemorrhage and minimal to mild necrosis. There were no treatment-related effects on survival, body weight, food intake, ophthalmology, ECG, blood pressure, urinalysis, or organ weight. Although decreases in hemoglobin and red-cell mass were noted at  $\geq 2$  mg/kg/day ( $\downarrow 16\%$ ), there was no clear dose-response pattern, making the toxicological significance of the finding unclear. Mild increases in cholesterol at  $\geq 26$  mg/kg/day ( $\uparrow 1.8$ -fold) were suggestive of possible altered lipid metabolism. There was partial or complete recovery of the findings after a 4-week treatment-free period. In conclusion, CJC-1295 was well tolerated in dogs following SC doses up to 18 mg/kg/day for up to 14 days.

**808**

#### RODENT SUBCHRONIC TOXICITY STUDIES WITH THE PEPTIDE ANTIBIOTIC XMP.629.

R. Hawks<sup>1</sup>, S. W. Frantz<sup>2</sup>, J. T. Secrest<sup>2</sup> and K. E. Meyer<sup>1</sup>. <sup>1</sup>XOMA LLC, Berkeley, CA and <sup>2</sup>MPI Research, Mattawan, MI.

XMP.629 is a novel D-linked 9-amino acid peptide based on a natural antimicrobial protein, and has been tested in Phase I/II trials as a topical treatment for acne. Subchronic 30- and 90-day studies have been performed in the rat. Due to low oral

bioavailability, these studies used subcutaneous administration to maximize systemic exposure. In both studies, injection site lesions were noted at gross necropsy and histopathology. These findings included thickened skin, hemorrhage, necrosis and inflammation. Test article deposition at the site of injection was seen in the 30-day study. In both studies, systemic effects were seen that appeared to be indirect, secondary reactions to the injection site inflammation. These systemic effects in the 30-day study included  $\uparrow$  neutrophil and monocyte counts,  $\uparrow$  spleen weights,  $\downarrow$  Hgb, Hct and RBCs, and  $\uparrow$  reticulocyte counts. The 90-day study showed these alterations plus  $\uparrow$  liver weight,  $\uparrow$  lymphocyte, basophil and leukocyte counts, as well as histopathology findings of injection site fibrosis, granulation tissue, macrophage infiltration, Kupffer cell hypertrophy, mesenteric lymph node (LN) histiocytosis and splenic monocyte/macrophage hyperplasia. The  $\uparrow$  spleen weight and hematology alterations in both studies may indicate mild RBC hemolysis mediated by the strong inflammatory response. Some of the 90-day findings (such as injection site fibrosis and granulation tissue) illustrate a transition from acute to chronic inflammation. The 90-day findings of macrophage infiltration, Kupffer cell hypertrophy, and mesenteric LN histiocytosis likely indicate macrophage-mediated clearance of test article. PK data revealed that the mean high dose AUC0-24 seen in the 90-day study was 2110 hr\*ng/mL. By comparison, all patient serum samples from a Phase I trial were below the LOQ of 1 ng/mL. The results from these studies demonstrate a high safety margin and support the use of this novel compound in clinical trials.

**809**

#### SAFETY AND EFFICACY OF GLYCOSYLATED UNDENATURED TYPE II COLLAGEN (UC-II) IN OBESE-ARTHRITIC DOGS.

R. C. Gupta<sup>1</sup>, L. DeParle<sup>1</sup>, T. Canerdy<sup>1</sup>, J. Goad<sup>1</sup>, M. Bagchi<sup>2</sup> and D. Bagchi<sup>2</sup>. <sup>1</sup>Toxicology, Murray State University, Hopkinsville, KY and <sup>2</sup>InterHealth Nutraceuticals Inc., Benicia, CA.

In large breed dogs, arthritis is very common because of obesity, injury, aging, or immune disorder. This study was therefore undertaken to evaluate clinical tolerability and safety of UC-II in obese-arthritic dogs. Fifteen dogs in three groups received either no UC-II (Group I) or UC-II with 1 mg/day (Group II) or 10 mg/day (Group III) for 90 days. Lameness and pain were measured on a weekly basis for 120 days (90 days treatment plus 30 days post-treatment). Blood serum samples were assayed for rheumatoid factor (marker of arthritis); creatinine and blood urea nitrogen (markers of renal function); and alanine aminotransferase- and aspartate aminotransferase (markers of liver function). Dogs receiving 1 mg and 10 mg UC-II/day for 90 days showed marked decline in pain and lameness after physical exertion, and the therapeutic efficacy was dose-dependent. UC-II at either dose did not produce any side effects or significant changes in serum chemistry, and was well tolerated. In addition, dogs receiving UC-II for 90 days showed increased activity level and lost a significant amount of body weight. Following UC-II withdrawal for a period of 30 days, all dogs experienced a relapse of overall pain, pain with limb manipulation, and exercise-associated lameness. These results suggest that daily treatment of arthritic dogs with UC-II ameliorates signs and symptoms of arthritis, and UC-II is well tolerated with no adverse effects (Supported by InterHealth Nutraceuticals Inc. and Beckman Coulter, Inc.).

#### PRECLINICAL SAFETY ASSESSMENT OF RECOMBINANT PLAGUE VACCINE (rF1V) FOLLOWING REPEAT-DOSE ADMINISTRATION.

R. V. House<sup>1</sup>, J. Shearer<sup>1</sup>, S. Manetz<sup>2</sup> and S. Morris<sup>1</sup>. <sup>1</sup>DynPort Vaccine Company LLC, Frederick, MD and <sup>2</sup>Gene Logic Laboratories, Gaithersburg, MD.

A recombinant preventative vaccine conceived by the US Army Medical Research Institute of Infectious Diseases is being developed to provide protection against pneumonic plague. The vaccine comprises the F1 antigen (capsular protein of Y. pestis), genetically fused to the V antigen (virulence protein, secreted by Y. pestis) resulting in a single fusion protein (rF1V). Studies were conducted to evaluate the general toxicity and local reactogenicity of the rF1V vaccine. Toxicity was evaluated in CD-1 mice vaccinated by IM injection with two doses of rF1V in a volume of 100  $\mu$ L with or without Alhydrogel on Days 0, 28, 56 and 70. Total immunizing protein given in each dose was 20 or 60  $\mu$ g/animal. When normalized by the body weight, the amount of rF1V and Alhydrogel given to the mice were  $>1000$ -fold in excess of the anticipated human dose. Local reactogenicity was evaluated in New Zealand White rabbits using the same injection volume (0.5 mL) and formulations (40, 80, 160 and 320 mg/mL total antigen with 0.33% Alhydrogel) intended for use in the Phase 1 clinical trial. Reactogenicity at the vaccination sites was scored for edema, ulcer, and erythema using a scale from 0 for no symptoms to 4 for severe symptoms. Mice gained weight and had normal food consumption during the study. Clinical observations, clinical chemistry, clinical hematology, gross necropsy, organ weights and histopathology in mice indicated no overt toxicity related to rF1V administration. Dermal observation showed no adverse vaccination site reactogenicity in mice or rabbits. Localized inflammation, typical of foreign body host

response, was observed in mice and rabbits vaccinated with rF1V/Alhydrogel combinations. These results indicate a favorable safety profile for rF1V and support its use in a Phase 1 clinical trial. Funded by the Joint Vaccine Acquisition Program, Department of Defense (DoD) Contract DAMD 17-98-C-8024 and does not represent official DoD positions, policies, or decisions.

PRECLINICAL SAFETY ASSESSMENT OF RECOMBINANT BOTULINUM VACCINE A/B (RBV A/B) FOLLOWING REPEAT-DOSE ADMINISTRATION.

J. Shearer<sup>1</sup>, I. Henderson<sup>1</sup>, S. Manetz<sup>2</sup> and R. V. House<sup>1</sup>. <sup>1</sup>*DynPort Vaccine Company LLC, Frederick, MD and*<sup>2</sup>*Gene Logic Laboratories, Inc., Gaithersburg, MD.*

A recombinant preventative vaccine conceived by the US Army Medical Research Institute of Infectious Diseases is being developed to provide protection against the effects of botulism. The two recombinant antigens that comprise the rBV A/B vaccine, Antigen A and Antigen B, are derived from the 50 kDa C-terminal domains of the botulinum neurotoxin serotypes A and B. A comprehensive series of studies were conducted to evaluate the general toxicology, neurotoxicology and local reactogenicity of the rBV A/B vaccine. Toxicity was evaluated in CD-1 mice vaccinated with the three doses of rBV A/B with or without Alhydrogel by IM injection on Days 0, 28, 56 and 70 in a volume of 100  $\mu$ L. Total immunizing protein given in each dose was 0, 2, 4 and 8  $\mu$ g/animal. Local reactogenicity was evaluated in New Zealand white rabbits using the same injection volume (0.5 mL) and formulations (10, 20 and 40  $\mu$ g/mL total antigen with 0.2% (w/v) Alhydrogel) intended for use in the Phase 1 clinical trial. Mice gained weight and had normal food consumption during the study. Clinical observations, inoculation site reactogenicity, clinical chemistry, clinical hematology, gross necropsy, organ weights and histopathology indicated no overt toxicity related to rBV A/B administration. Qualitative and quantitative functional observational battery assessment indicated no adverse neurobehavior related to administration of rBV A/B. Dermal observations showed no adverse vaccination site reactogenicity in rabbits. A microscopic, mild inflammatory response was observed in the Day 28 injection site and was consistent with vaccine-Alhydrogel interaction. There was no indication of chronic inflammation in the Day 0 injection site. Together these results indicate a favorable safety profile for rBV A/B and support its use in a Phase 1 clinical trial. Funded by the Joint Vaccine Acquisition Program, Department of Defense (DoD) Contract DAMD 17-98-C-8024 and does not represent official DoD positions, policies, or decisions.

SPONTANEOUS HEMORRHAGE OF THE PANCREATIC ISLET IN SPRAGUE-DAWLEY RATS.

M. Imaoka, T. Suzuki, K. Nozaki, H. Satoh, T. Sugawara and K. Furuhama. *Drug Safety Research Laboratory, Daiichi Pharmaceutical Co., Ltd., Tokyo, Japan.*

In rats, although there is much information about age-related pancreatic islet changes such as  $\beta$ -cell hyperplasia characterized by enlarged islets, fibrous dissection, and hemosiderin deposition, little report is available on islet hemorrhage. The present study was designed to find the spontaneous hemorrhage in the pancreatic islet of non-treated Sprague-Dawley rats. Groups of 20 male and 20 female Crj:CD(SD)IGS rats each were allowed free access to a commercial diet containing high protein and fat, and were sequentially sacrificed at 8, 12, 18, and 26 weeks of age. During the study, clinical observations and measurements of body weight and food consumption were periodically performed, and hematology and serum glucose, insulin and estradiol levels were examined with histopathology of the pancreas. As results, no changes in blood and serum parameters tested were observed throughout the experimental period. Histopathologically, however, pancreatic islet hemorrhage in males was observed in one animal each at 12 and 18 weeks, and eleven animals at 26 weeks. In females, the same hemorrhage was observed only in one animal each at 18 and 26 weeks. This hemorrhage was accompanied by pigment deposition in the peripheral or central islets which were occasionally dissected by fibrous septa. A special staining revealed that the pigments contain iron, suggesting the previous occurrence of micro-hemorrhage. Other changes, except for hemorrhage, closely resembled the age-related changes reported previously. In conclusion, an obvious sex-difference exists in spontaneous hemorrhage of the rat pancreatic islets, and its incidence increased with aging.

NRF2 ACTIVATION INVOLVES AN OXIDATIVE-STRESS INDEPENDENT PATHWAY IN TETRAFLUOROETHYLCYSTEINE-INDUCED CYTOTOXICITY.

H. Ho<sup>1</sup>, C. White<sup>2</sup>, C. Fernandez<sup>2</sup>, N. Fausto<sup>3</sup>, T. Kavanagh<sup>2</sup>, S. Nelson<sup>1</sup> and S. Bruschi<sup>1</sup>. <sup>1</sup>*Medicinal Chemistry, University of Washington, Seattle, WA,* <sup>2</sup>*Environmental and Occupational Health, University of Washington, Seattle, WA and* <sup>3</sup>*Pathology, University of Washington, Seattle, WA.*

Tetrafluoroethylcysteine (TFEC), a metabolite of the industrial gas tetrafluoroethylene has been known to cause both nephrotoxicity and limited hepatotoxicity that are associated with the covalent modification of specific intramitochondrial pro-

teins including HSP60, mtHSP70, AST, aconitase and  $\alpha$ -ketoglutarate dehydrogenase. Using the murine TAMH cell line as a useful *in vitro* model, we demonstrate a rapid and sustained induction of Nrf2, a cytosolic member of the "cap-and-collar" family of transcription factors, after a cytotoxic dose of TFEC (250  $\mu$ M). A functional correlation of this induction is established with the rapid translocation of cytosolic Nrf2 into the nucleus as assessed by both immunoblot and immunocytochemical methods. We have also detected a corresponding transcriptional and translational upregulation of Nrf2 regulated genes including GCL (both catalytic and modulatory subunits), heme oxygenase-1, and some GSTs. While Nrf2 activation is often linked to perturbation of cellular thiol status and/or oxidative stress, we were unable to detect any significant depletion of cellular glutathione nor oxidation of membrane cardiolipin. These data suggest that Nrf2 activation is likely independent of oxidative-stress, or at best, a result of a transient oxidative stress. Moreover, supporting evidence from DNA microarray and Western blot analysis indicates an early ER response after TFEC treatment, with a time-dependent upregulation of the ER responsive genes gadd34, gadd45, gadd153 and ndrl. These findings suggest an alternative avenue of exploration for Nrf2 activation, i.e. the phosphorylation of Nrf2 through ER-mediated protein kinases such as PERK. Overall, the results implicate a role for Nrf2 in the cellular response to TFEC toxicity, and suggest a novel ER role in a mitochondrially-initiated pathway of cytotoxicity. NRF2-DEPENDENT ARE ACTIVATION IS A GAIN OF FUNCTION ALTERATION SPECIFIC TO DIFFERENTIATED AND FUNCTIONALLY ACTIVATED ASTROCYTES.

J. A. Johnson, J. Li, D. A. Johnson and M. J. Calkins. *School of Pharmacy, University of Wisconsin, Madison, WI.*

The promoter region of several phase II detoxification enzymes contain a cis-acting enhancer known as the antioxidant response element (ARE). Increased expression of these enzymes contributes to the protection of neural cells from oxidative stress. Transgenic reporter mice were created to carry in their genome the core ARE sequence coupled to the human placental alkaline phosphatase (hPAP) reporter gene. Neural stem cells derived from these mice were treated with tert-butylhydroquinone (tBHQ), a potent ARE activator. *In vitro* cell migration assays demonstrated that only fully differentiated, functionally activated astrocytes responded to this ARE-dependent activation. Neither neural stem cells, differentiated neurons, oligodendrocytes, proliferating cells nor apoptotic cells showed this response. Adenovirus-mediated Nrf2 overexpression also revealed a massive increase in ARE activation in astrocytes but not progenitor cells. Transplantation of ARE-hPAP neural stem cells into mouse striatum demonstrated a similar pattern of ARE activation specific to astrocytes after malonate lesioning, suggesting that this gain of function was unique to the astrocytes in response to low-molecular-weight electrophilic compounds. Real-time RT-PCR analysis of Nrf2 dependent, ARE driven genes highlight the different extent of transcriptional upregulation between neural stem cells and their differentiated cultures after tBHQ treatment. This is the first developmental study to show that only differentiated, functionally activated astrocytes are responsible for ARE activation. Developmental expression of Nrf-dependent detoxification enzymes may have a strong impact on early life stage susceptibility to neurotoxicants. Support by: Grants ES08089 and ES10042 from the NIEHS

INDUCTION OF NAD(P)H:QUINONE OXIDOREDUCTASE 1 IN MOUSE LIVER DURING EXTRAHEPATIC CHOLESTASIS IS DEPENDENT UPON NRF2 ACTIVATION.

A. L. Slitt<sup>1</sup>, L. M. Aleksunes<sup>2</sup>, J. M. Maher<sup>1</sup>, M. Z. Dieter<sup>1</sup>, N. J. Cherrington<sup>3</sup>, J. E. Manautou<sup>2</sup>, J. Y. Chan<sup>4</sup> and C. D. Klaassen<sup>1</sup>. <sup>1</sup>*Pharmacology, Toxicology, & Therapeutics, University of Kansas Medical Center, Kansas City, KS,* <sup>2</sup>*Pharmaceutical Sciences, University of Connecticut, Storrs, CT,* <sup>3</sup>*Pharmacology and Toxicology, University of Arizona, Tucson, AZ and* <sup>4</sup>*Pathology, University of California Irvine, Irvine, CA.*

Bile duct ligation (BDL), a rodent model of extrahepatic cholestasis, causes bile acid and conjugated bilirubin accumulation in liver and blood. Elevated levels of bile constituents in liver can cause oxidative stress and inflammation, which may cause hepatic injury if normal bile flow is not restored. Nuclear factor-E2-related factor 2 (Nrf2) induces gene expression in response to administration of antioxidants as well as during conditions of oxidative stress. Nrf2 regulates basal and inducible expression of numerous protective genes in liver, including NAD(P)H: quinone oxidoreductase 1 (Nqo1). We hypothesized that BDL increases mouse liver Nqo1 expression through activation of Nrf2. BDL or sham surgeries were performed on male C57BL/6 mice. Livers were collected at one, three, and seven days after surgery for analysis of Nqo1 mRNA, protein, and activity. BDL increased

Nqo1 mRNA expression in male C57BL/6 mouse livers by 3 fold at one and three days, and 7 fold at seven days, as compared to expression in livers from sham-operated controls. Nqo1 protein expression and activity in livers from male C57BL/6 mice were increased 2-3 fold and 4-5 fold at three and seven days after BDL, respectively. Parallel studies were performed with wild-type and Nrf2-null mice, with livers being collected three days after BDL or sham surgery. BDL increased Nqo1 mRNA and protein expression, as well as enzyme activity, in livers from wild-type mice, but not in livers from Nrf2-null mice. Together these data demonstrate that during BDL-induced extrahepatic cholestasis, Nqo1 expression and activity in mouse liver are induced via a Nrf2-dependent mechanism. ALTERATIONS IN GENE EXPRESSION BY 2378-TETRACHLORO-P-DIBENZODIOXIN (TCDD) IN LIVERS OF NRF2 KNOCKOUT MICE.

M. Matsumoto<sup>1</sup>, H. Sato<sup>2</sup>, K. Itoh<sup>3</sup>, M. Yamamoto<sup>3</sup> and Y. Aoki<sup>1</sup>. <sup>1</sup>National Institute for Environmental Studies, Tsukuba, Japan, <sup>2</sup>Institute of Medicinal Molecular Design Inc., Tokyo, Japan and <sup>3</sup>University of Tsukuba TARA Center, Tsukuba, Japan.

Nrf2 is an essential transcription factor for inducible and/or constitutive expression of a group of phase II detoxification and antioxidant enzymes. Previously we showed that the expression of glutathione S-transferase P1 gene was induced in cultured rat liver cells by dioxins and its expression was dependent on Nrf2/ARE (antioxidant responsive element) system. We aimed to globally identify TCDD-inducible genes that are dependent on Nrf2 exploiting Nrf2 knockout mice. Nrf2(-/-) mice and Nrf2(+/+) mice were produced by intercrossing Nrf2(+/+) mice. Forty micrograms of TCDD per kg body weight were administered orally to female Nrf2(-/-) and Nrf2(+/+) mice, and total RNA was extracted from the livers 24 hrs after the administration. The relative expression levels of genes were analyzed using Codelink DNA array. Identification of genes expressed/suppressed by TCDD and the relation analysis between altered genes were performed under support of KeyMolnet expert system (Institute of Medicinal Molecular Design Inc.). TCDD administration caused over 2-fold increase in the expression levels of 99 genes and 131 genes in Nrf2(-/-) and Nrf2(+/+) mice, respectively. On the other hand, the expression levels of 72 genes and 111 genes in TCDD-treated Nrf2(-/-) and Nrf2(+/+) mice, respectively, were decreased to less than half of untreated mice. Among the genes altered by TCDD, the expression of following genes was increased in both Nrf2(-/-) and Nrf2(+/+) mice, CYP1A1, CYP1A2, CYP1B1 and NQO1. In contrast, the expression of several metabolic enzyme genes (e.g., GSTP1, GSTM2 and UDP glucuronosyl transferase) and c-Jun were elevated only in Nrf2(+/+) mice but not in Nrf2(-/-) mice, suggesting that Nrf2 contributes to the inducible expression of these genes by TCDD. We surmise that the administration of TCDD might provoke the generation of endogenous inducers for the Nrf2/ARE system and activate the expression of phase II and antioxidant enzyme genes.

PHOSPHORYLATION OF NRF2 BY CASEIN KINASE 2 (CK2) REGULATES ACTIVATION AND DEGRADATION.

J. Pi<sup>1,2</sup>, Y. Bai<sup>2</sup>, J. Reece<sup>3</sup>, J. William<sup>4</sup>, D. Liu<sup>5</sup>, M. Freeman<sup>6</sup>, W. Fahl<sup>7</sup>, D. Shugar<sup>8</sup> and M. Waalkes<sup>1</sup>. <sup>1</sup>Lab of Comparative Carcinogenesis, NCI at NIEHS, Research Triangle Park, NC, <sup>2</sup>Division of Biology Sciences, CIIT Centers for Health Research, Research Triangle Park, NC, <sup>3</sup>LST, NIEHS, Research Triangle Park, NC, <sup>4</sup>LSB, NIEHS, Research Triangle Park, NC, <sup>5</sup>LRDT, NIEHS, Research Triangle Park, NC, <sup>6</sup>Vanderbilt University School of Medicine, Nashville, TN, <sup>7</sup>University of Wisconsin, Madison, WI and <sup>8</sup>Polish Academy of Sciences, Warsaw, Poland.

Phosphorylation of transcription factor Nrf2 is a potential mechanism of activation. In this study, we identified two phosphorylated types of Nrf2 and provide evidence that CK2-mediated Nrf2 phosphorylation plays a critical role in activation and proteasome-mediated degradation. Human Nrf2 has a predicted molecular mass (MM) of 66 kDa. However, western blot showed two bands at 96 and 116 kDa are increased in response to Nrf2 inducers, like arsenite (As), in several human cell lines. Over-expression of Nrf2 by transfection results in two similar bands. Nuclear fractions from As-exposed cells treated with  $\lambda$ -phosphatase or PP1 showed the loss of the two higher MM bands and the appearance of a lower MM band, suggesting both the higher MM forms of Nrf2 are phosphorylated. *In vitro* kinase assay using Nrf2 immunoprecipitation products as the substrate for purified CK2 indicated Nrf2 is a CK2 substrate and CK2 mediates two steps of Nrf2 phosphorylation. Although the mechanism of CK2 activation is unknown, our results support a role in which calmodulin (CaM) binding regulates CK2 activity. CaM and  $Ca^{2+}$  dramatically inhibits CK2 activity *in vitro*, suggesting  $Ca^{2+}$  mobilization may affect local CK2 activity. Accordingly, we found cold shock in  $Ca^{2+}$ -free media decrease cellular  $Ca^{2+}$  levels and caused Nrf2 hyper-phosphorylation, which in turn was prevented by CK2 specific inhibitors. Gel-shift assay showed the hyper-phosphorylated type Nrf2 (HP-Nrf2) can not bind to the  $\gamma$ -GCS<sub>h</sub> antioxidant response element, indicating phosphorylated-Nrf2, but not HP-Nrf2, has transcriptional activity. In contrast, HP-Nrf2 is more susceptible to proteasome-mediated degradation.

NRF3 NEGATIVELY REGULATES ARE-MEDIATED EXPRESSION AND ANTIOXIDANT INDUCTION OF DETOXIFYING ENZYME GENES.

S. KANNAN and A. K. JAISWAL. *Pharmacology, Baylor College of Medicine, Houston, TX*. Sponsor: B. Moorthy.

Antioxidant response element (ARE) and nuclear factors Nrf2 and Nrf1 are known to coordinately upregulate expression of a battery of detoxifying enzyme genes including NAD(P)H:quinone Oxidoreductase1 (NQO1) gene in response to antioxidants. This induction is critical in cellular protection against chemically induced oxidative stress and neoplasia. Nrf3 is a third member of Nrf family of proteins that was recently identified and cloned. In this study, we investigated the role of Nrf3 in ARE-mediated NQO1 gene expression and induction in response to antioxidants. Band and super shift assays with *in vitro* transcribed and translated proteins and nuclear extracts from Hep-G2 cells treated with DMSO and antioxidant tert-butyl hydroquinone (t-BHQ) and immunoprecipitation assays demonstrated that Nrf3 forms heterodimers with small Maf proteins that bound to NQO1 gene ARE. Overexpression of Nrf3 in Hep-G2 cells led to concentration dependent decrease in transfected and endogenous NQO1 gene expression and induction in response to t-BHQ. In addition, RNAi specific to Nrf3 reduced intracellular Nrf3 that led to increased expression and induction of transfected and endogenous NQO1 gene expression in response to t-BHQ. Deletion mutation analysis revealed that Nrf3 repression of NQO1 gene expression required heterodimerization and DNA binding domains but not transcriptional activation domain of Nrf3. The cotransfection of Nrf2 with Nrf3 rescued the repression effect of Nrf3. These results combined suggest that Nrf3 is a negative regulator of ARE-mediated gene expression. It presumably interferes with binding of Nrf2 and Nrf1 and/or titrates out small Maf proteins to repress ARE-mediated gene expression.

**819**

ANTIOXIDANT INDUCED NUCLEAR IMPORT AND EXPORT OF OXIDATIVE STRESS-RESPONSE FACTOR NRF2.

A. K. Jain and A. K. Jaiswal. *Pharmacology, Baylor College of Medicine, Houston, TX*. Sponsor: B. Moorthy.

Antioxidants protect cells against oxidative stress and neoplasia. This is achieved by antioxidant response element (ARE)-mediated coordinated induction of genes encoding chemopreventive proteins. These genes include detoxifying enzyme NAD(P)H:quinone oxidoreductase1 (NQO1). Nrf2 (NF-E2 related factor 2) is a transcription factor that binds to ARE and regulates activation of these genes. Under normal conditions, Nrf2 is retained in the cytoplasm by its inhibitor, INrf2. Exposure of cells to antioxidants leads to release of Nrf2 from INrf2. Nrf2 then accumulates in the nucleus leading to ARE-mediated gene expression. Nrf2 exits from the nucleus after it has turned on the gene expression, presumably to bind to INrf2 for its own degradation. In this report, we have characterized the nuclear import and export signals of Nrf2. We demonstrated that Nrf2 contains a bipartite nuclear localization signal (NLS) and a leucine rich nuclear export signal (NES) which regulate its shuttling in and out of nucleus. Immunofluorescence studies revealed that Nrf2 accumulates in the nucleus within 15 min of antioxidant treatment and exits around 6 h after the treatment. An Nrf2 mutant lacking NLS failed to enter the nucleus and displayed diminished expression and induction of downstream genes including NQO1. The Nrf2 NLS sequence fused to green fluorescence protein resulted in the nuclear accumulation of GFP indicating that this signal was sufficient to direct nuclear localization of heterologous protein. A NES was characterized in the C-terminus of Nrf2, deletion of which caused Nrf2 to display more nuclear localization as observed by immunofluorescence. This NES was sensitive to leptomycin B and could function as an independent export signal when fused to heterologous protein. These results led to the conclusion that Nrf2 localization is controlled by both nuclear import and export suggesting that overall distribution of Nrf2 is likely to result from a balance between these two processes. Antioxidants shift this balance in favor of nuclear accumulation of Nrf2 leading to activation of detoxifying genes.

COMPARTMENTAL OXIDATION OF THIOL/DISULFIDE REDOX COUPLES DURING EGF SIGNALING.

P. J. Halvey<sup>1</sup>, J. M. Hansen<sup>1</sup>, W. H. Watson<sup>2</sup>, Y. Go<sup>1</sup> and D. P. Jones<sup>1</sup>. <sup>1</sup>Medicine, Emory University, Atlanta, GA and <sup>2</sup>Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.

Exogenously added reactive oxygen species (ROS) cause generalized oxidation of cellular components whereas endogenously generated ROS induced by physiological stimuli activate discrete signal transduction pathways. An increase in reactive

oxygen species (ROS) accompanies epidermal growth factor (EGF) binding to its receptor and potentiates the phosphorylation cascade that leads to MAP kinase activation and cell proliferation. Compartmentation is an important aspect of such signaling pathways but little is known about redox compartmentation during signal transduction. In the present study we examined the effects of EGF induced redox signaling on specific thiol/disulfide redox pools. We measured the redox states of cytosolic thioredoxin-1 (Trx1), nuclear Trx1 and mitochondrial thioredoxin (Trx2) using Redox Western blot methodologies during endogenous ROS production induced by EGF signaling. Glutathione redox state was measured by HPLC. Results showed that only cytosolic Trx1 undergoes significant oxidation during EGF signaling. Thus we demonstrate that EGF signaling involves subcellular compartmental oxidation of Trx1 in the absence of a generalized cellular oxidation.

UPREGULATION OF MRP3 AND MRP4 BY SULFHYDRYL-MODIFYING COMPOUNDS IS MEDIATED BY THE TRANSCRIPTION FACTOR NRF2.

J. M. Maher<sup>1</sup>, M. Z. Dieter<sup>1</sup>, A. L. Slitt<sup>1</sup>, J. Y. Chan<sup>2</sup> and C. D. Klaassen<sup>1</sup>.

<sup>1</sup>University of Kansas Medical Center, Kansas City, KS and <sup>2</sup>University of California Irvine, Irvine, CA.

The Multidrug Resistance-Associated Protein (Mrp) family is comprised of ATP-dependent transporters that mediate efflux transport of a variety of conjugated and unconjugated compounds from cells. In liver, Mrp3 and Mrp4 transport chemicals from hepatocytes into sinusoidal blood, and may serve to protect the liver from toxicity. Mrp3 and Mrp4 are upregulated by butylated hydroxyanisole (BHA) and oltipraz (OPZ), chemicals that have been shown previously to upregulate a number of genes involved in the protective response to oxidative stress, including NAD(P)H:quinone oxidoreductase 1 and heme oxygenase 1. Collectively this battery of antioxidant genes is transcriptionally regulated via Nuclear Factor E2 related factor 2 (Nrf2). During oxidative homeostasis, Nrf2 is sequestered in the cytosol by Kelch-like Ech-Associated Protein (Keap1); during oxidative challenge, modification of Keap1 sulfhydryl groups results in release and nuclear translocation of Nrf2. The purpose of this study was to determine whether Mrp3 and Mrp4 are part of the Nrf2-regulated antioxidant battery. OPZ and BHA upregulated Mrp3 and Mrp4 mRNA at least three fold in livers of wild-type mice. In Nrf2-null mice, basal expression of Mrp3 mRNA was diminished in liver, and the induction of Mrp3 and Mrp4 by OPZ and BHA was attenuated. In mouse hepatoma cells, known Nrf2 activators, such as diethyl maleate, oltipraz, ethoxyquin, tert-butylhydroquinone, catechol, and catechol dinitrobenzene, all increased expression of Mrp3 and Mrp4. These data suggest that a broad range of chemicals can transcriptionally upregulate Mrp3 and Mrp4, presumably through the actions of Nrf2. In conclusion, during cellular adaptation to an oxidative environment, Mrp3 and Mrp4 respond via Nrf2 to help excrete compounds or metabolites that are harmful to the cell, and therefore may play an important role in prevention of hepatic toxicity. (Supported by NIH grants ES-09716 and ES-07079)

EPIGENETIC EFFECTS OF OXIDATIVE STRESS.

B. Upham<sup>1,2</sup> and J. E. Trosko<sup>1,2</sup>. <sup>1</sup>Pediatrics/Human Development, Michigan State University, East Lansing, MI and <sup>2</sup>National Food Safety & Toxicology Ctr, Michigan State University, East Lansing, MI.

For many years, research on oxidative stress focused primarily on determining how reactive oxygen species (ROS) damage cells by indiscriminate reactions with the macromolecular machinery of a cell, particularly lipids, proteins and DNA. However, many chronic diseases affiliated with oxidative stress, such as cancer, are not always a consequence of tissue necrosis, DNA mutations, or protein damage but rather to altered gene expression. Gene expression is highly regulated by the coordination of extra-, intra- and inter-cellular communication systems that will typically maintain tissue homeostasis by sustaining a balance between proliferation, differentiation and apoptosis. Therefore, much research has shifted to the understanding of how ROS can reversibly control the expression of genes at noncytotoxic doses through cell signaling mechanisms. Cell proliferation typically involves inhibition of gap junctional intercellular communication (GJIC) and the activation of mitogen activated protein kinase pathways (MAPK). We demonstrate that normal rat liver epithelial cells response to epidermal growth factor (EGF) will inhibit GJIC in addition to activating extracellular receptor kinase (ERK), a MAPK. However, inhibition of NADPH oxidase, which reduces oxygen to H<sub>2</sub>O<sub>2</sub>, with the very selective inhibitor, diphenyleneiodonium, prevented EGF from inhibiting GJIC suggesting that the generation of H<sub>2</sub>O<sub>2</sub> is an essential component of the intracellular pathway controlling GJIC. Furthermore, we previously demonstrated that reduced-glutathione (GSH) was also a necessary cofactor of H<sub>2</sub>O<sub>2</sub>-induced inhibition of GJIC. These results demonstrate that ROS and GSH play essential roles in controlling EGF-dependent control of GJIC. Therefore, the overly simplistic approach of either preventing the generation of ROS or accelerate the removal by antioxidants could deleteriously alter normal signaling functions. Funded by NIEHS (PA42ES04911).

HISTONE H3.3 MODIFICATIONS DURING REACTIVE OXYGEN SPECIES INDUCED DNA DAMAGE.

R. Xie, T. T. Monks and S. S. Lau. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

2, 3, 5-Tris-(glutathion-S-yl)hydroquinone (TGHQ), a reactive oxygen species (ROS)-generating toxicant, causes DNA single strand breaks (SSBs), premature chromatin condensation (PCC) and oncotic/necrotic cell death in renal proximal tubular epithelial (LLC-PK1) cells. Previous studies revealed an increase in the phosphorylation of histone H3, in response to TGHQ, concurrent with PCC, and only serine was phosphorylated in this event. However, western analysis revealed a decrease in phosphorylation of histone H3 at both S10 and S28, both of which are well-known sites of S phosphorylation during mitotic chromosomal condensation. Moreover, TGHQ-induced phosphorylation only occurred on the histone H3.3 isoform, and not on histone H3 isoforms H3.1 and H3.2. Comparing the amino acid sequence of all three histone H3 variants, histone H3.3 contains a unique S site at position 31 in the highly modified N-terminal tail region, suggesting that S31 might be an alternate site of histone H3 phosphorylation in response to TGHQ. To ascertain whether S31 is a novel site of histone H3.3 phosphorylation in response to TGHQ, wild-type and four histone H3.3 mutants, S10A, S28A, S31A, and S10/28A were constructed using alanine to substitute for serine residues at position 10, 28, 31, and 10 plus 28, respectively. Transient transfection of LLC-PK1 cells with either wild-type or mutant histone H3.3 constructs resulted in similar levels of his-tagged protein expression. Neutral red analysis revealed a decrease in TGHQ-induced toxicity in LLC-PK1 cells transfected with mutant S31A compared to the wild-type transfection (each with ~70% transfection efficiency). These studies suggest that modification of histone H3.3 at S31 is associated with TGHQ induced oncotic/necrotic cell death. To confirm that S31 is a novel site undergoing phosphorylation in response to TGHQ, current work is focusing on [32P]-orthophosphate incorporation into LLC-PK1 cells transiently expressing H3.3 wild-type or mutant proteins. (DK59491)

EVALUATION OF PLASMA VON WILLEBRAND FACTOR (VWF) AND VWF PROPEPTIDE IN DRUG-INDUCED VASCULAR INJURY.

D. Brott<sup>1,2</sup>, A. Katen<sup>1</sup>, K. Ershaw<sup>1</sup>, G. Evans<sup>3</sup>, H. Jones<sup>3</sup>, S. Gould<sup>3</sup>, G. Betton<sup>3</sup>, J. Valentin<sup>3</sup>, R. J. Richardson<sup>2</sup> and C. Louden<sup>1,2</sup>. <sup>1</sup>Global Safety Assessment, AstraZeneca Pharmaceuticals, Wilmington, DE, <sup>2</sup>Toxicology Program, Environmental Health Science Department, The University of Michigan, Ann Arbor, MI and <sup>3</sup>Global Safety Assessment, AstraZeneca Pharmaceuticals, Alderley, United Kingdom.

Drug-induced vascular endothelial injury in toxicology studies is of concern to regulatory agencies and the pharmaceutical industry. The absence of a reliable marker of endothelial cell injury is an unmet need in experimental and clinical medicine. Plasma levels of von Willebrand factor (vWF) and vWF propeptide (vWFpp) were investigated as biomarkers of activated/injured endothelial cells following physiological and pathological stimuli in beagle dogs. In control dogs, repeat bleeding had no significant effects on vWF and vWFpp. Physiological stimulation of the vascular bed using deamino 8 D arginine vasopressin (5μug/kg DDVAP) caused a rapid but short-lived increase in vWF (30-100%) but no changes of vWFpp. Pathological stimulation of the vascular bed with an endotoxin (2mg/kg Lipopolysaccharide) produced an immediate and prolonged increase of vWF (40-220%) over 24-hours: additionally vWFpp increased markedly (1100-2300%), returning to near baseline by 24-hours. Plasma levels of vWF and vWFpp were measured in dogs following the administration of a novel Endothelin Receptor Antagonist (ETRA) and a novel potassium channel opener known to induce localized injury in the coronary vascular bed of some dogs. Both compounds caused vWF elevations similar to DDAVP even though they induced focal lesions in the coronary bed whereas DDVAP stimulates the entire vascular bed. In addition, both compounds induced a 30-300% increase in vWFpp. vWF and vWFpp were elevated following endothelial cell perturbation and drug-induced vascular injury in these dog studies, and warrant further investigation of these biomarkers for drug-induced vascular injury in preclinical toxicology studies.

MORPHOLOGIC IMAGING OF EXTRACELLULAR MATRIX IN CHEMICAL-INDUCED DEVELOPMENTAL DISSECTING AORTIC ANEURYSM USING MULTIPHOTON FLORESCENCE AND SECOND HARMONIC GENERATION MICROSCOPY.

B. gong<sup>1</sup>, J. Sun<sup>2</sup>, G. Vargas<sup>2</sup> and P. Boor<sup>1</sup>. <sup>1</sup>Pathology, UTMB at Galveston, Galveston, TX and <sup>2</sup>Biomedical Engineering Center, UTMB at Galveston, Galveston, TX.

To reveal the role of the extracellular matrix (ECM) in developmental dissecting aortic aneurysm (DAA), we studied the pathological progression of changes in elastin and collagen using two nonlinear imaging techniques, multiphoton flores-

cence microscopy (MPFM) and second harmonic generation microscopy (SHGM), in a recently-described model of thoracic DAA in newborn rats due to *in utero* exposure to relatively non-toxic doses of semicarbazide (SM). Sprague-Dawley rat dams were given SM (0.10 to 49.6 mg/kg i.p.) from days 14 to 20 of gestation. Fetuses were harvested on day 20 of gestation (E20), as newborns (P1) and at 7 (P7) and 28 days of age (P28); matched controls were from dams treated with saline only. Thoracic organs were removed for histopathology and MPFM and SHGM elastin study at an excitation wavelength of 800 nm. A narrow band pass filter centered at 400 nm with a 14 nm band width was used to collect the SHGM signal from collagen in standard sections. DAA occurred at birth, no E20 fetuses showed lesions in routine sections, although MPFM and SHGM demonstrated that collagen was significantly degraded at doses of 6.13 mg/kg SM. In P1, P7, and P28, DAA occurred in nearly 100% at all doses over 1.15 mg/kg. The massive dissections frequently extended to the carotids and other vessels of the aortic arch. Histologic study revealed healing and healed vascular lesions consisting of localized collections of blood in vascular media. Gradually disorganized or non-fibrillar structures and dose-dependent degradation of elastin and collagen were seen. Conclusion: MPFM and SHGM provide sensitive and high-resolution information on aortic elastin and collagen in developmental DAA. The extracellular matrix potentially plays a crucial role in developmental DAA. (Supported by NIH grants HL45616 and ES013038.)

### EFFECTS OF GONADAL STEROIDS ON CALCIUM CURRENTS AND ACTION POTENTIALS IN GUINEA PIG CARDIAC MUSCLES.

S. Nagayama, K. Yunomae, S. Ichisaki, J. Matsuo, M. Haruyama, K. Fukuzaki, R. Nagata and G. Kito. *Shin Nippon Biomedical Laboratories, Ltd (SNBL), Kagoshima, Japan.*

It is known that there are gender differences in arrhythmia and it is possible that cardiac memory contributes to arrhythmia. Cardiac electrophysiological changes are thought to be important determinants of gender differences and cardiac memory. Previous research in arrhythmia has focused mainly on outward potassium currents that contribute largely to phase 3 of repolarization in action potential (AP). Clinical and basic studies suggest that other currents contributing to AP plateau also determine gender differences in repolarization and cardiac memory. However, in cardiac electrophysiology, it is not clear how gonadal steroids contribute to gender-related differences or how cardiac memory is induced. Accordingly, the purpose of the present study was to determine whether gonadal steroids influence  $\text{Ca}^{2+}$  currents ( $I_{\text{Ca}}$ ) and APs in male and female guinea pig cardiac muscles. [Methods] We evaluated  $I_{\text{Ca}}$  and APs in cardiac muscle using whole-cell patch-clamp and micro-electrode techniques. gonadal steroids used were 5 $\alpha$ -dihydroxytestosterone (DHT) and 17 $\beta$ -estradiol (EST). [Results] There was no difference in APs or L-type  $I_{\text{Ca}}$  ( $I_{\text{Ca},L}$ ) between male and female guinea pig ventricular myocytes. EST (0.1-10  $\mu\text{M}$ ) decreased  $I_{\text{Ca},L}$  in both males and females. In contrast, DHT (10  $\mu\text{M}$ ) had no effect on  $I_{\text{Ca},L}$ . EST (10  $\mu\text{M}$ ) decreased AP duration (APD) in both male and female guinea pig papillary muscle. DHT (10  $\mu\text{M}$ ) slightly increased APD in female guinea pig papillary muscle. DHT had no effect on APD in male guinea pig papillary muscle. Therefore, we evaluated other  $\text{Ca}^{2+}$  currents in cardiac muscles. [Conclusion] These results suggest that the gonadal steroids regulate  $I_{\text{Ca}}$  conditions that constitute AP, and contribute to gender-related differences in ventricular repolarization.

### NUCLEOSIDE ANALOG REVERSE TRANSCRIPTASE INHIBITOR (NRTI)-INDUCED $\rho^-$ RAT CARDIAC MYOCYTES IN CELL CULTURE.

A. Rolo, J. A. Bjork and K. B. Wallace. *Biochemistry & Molecular Biology, University of Minnesota Medical School, Duluth, MN.*

The advent of NRTI antiretroviral therapy has yielded substantial improvements in clinical outcomes for HIV-infected patients; unfortunately, the success of this therapy is constrained by the eventual development of a dose-limiting metabolic failure. Drug-induced interference with metabolic regulation is manifested as systemic-wide alterations in carbohydrate and lipid metabolism, which is believed to have mitochondrial origins of pathogenesis. The prevailing paradigm for NRTI-induced metabolic failure is that the phosphorylated analogs are competitive substrates for mitochondrial DNA Pol  $\gamma$ , thereby inhibiting mtDNA replication by truncating the elongating mtDNA copy. The inferred consequence is a decrease in mtDNA copy number ( $\rho^-$ ) leading to a depletion of mitochondrial-encoded proteins and a loss of aerobic metabolic capability leading to cell death. This paradigm was tested in h9c2 cardiac myocytes cultured in the presence of 0.1-50  $\mu\text{M}$  zidovudine (AZT) or didanosine (ddI); a separate set of cells cultured in 50 ng/ml ethidium bromide (EtBr) was included as a positive control. Cardiac myocytes survived in culture in the presence of up to 50  $\mu\text{M}$  AZT or ddI for up to 10 cell passages. Similar to what was observed with EtBr, both AZT and ddI caused a dramatic time- and dose-dependent depletion of up to 80% mtDNA, which was accompanied by a correspond-

ing and progressive dose and time-dependent decrease in cytochrome oxidase enzyme activity. The associated decrease in ATP concentration is suggestive of a progressive decoupling of mitochondrial oxidative phosphorylation. This bioenergetic phenotype of cardiac myocytes grown in the presence of NRTIs is consistent with the Pol  $\gamma$ -dependent mitochondrial depletion proposed to account for the metabolic failure associated with long-term therapy of HIV infected patients. (Supported by HL72715-02).

### EPHEDRINE AND CAFFEINE CAUSE SIGNIFICANT MORTALITY IN 14 WEEK OLD BUT NOT IN 7 WEEK OLD FISCHER RATS.

P. Hanlon<sup>1</sup>, R. Howden<sup>2</sup>, J. Petranka<sup>1</sup>, S. Kleeberger<sup>2</sup>, J. Dunnick<sup>3</sup>, A. Nyska<sup>4</sup> and E. Murphy<sup>1</sup>. <sup>1</sup>Laboratory of Signal Transduction, NIEHS, Research Triangle Park, NC, <sup>2</sup>Laboratory of Respiratory Biology, NIEHS, Research Triangle Park, NC, <sup>3</sup>Toxicology Branch, NIEHS, Research Triangle Park, NC, <sup>4</sup>Laboratory of Environmental Pathology, NIEHS, Research Triangle Park, NC and <sup>5</sup>NIEHS, Research Triangle Park, NC.

Human consumption of a combination of ephedrine and caffeine has been associated with a number of adverse effects including changes in the electrocardiogram, myocardial infarction, hyperthermia, and in rare instances death. To study potential mechanisms associated with cardiotoxicity heart rate, body temperature, histological and ECG changes were assessed in 7 and 14 weeks old rats treated with a combination of ephedrine (25 mg/kg) and caffeine (30 mg/kg). No mortality was seen in ephedrine and caffeine-treated 7 week old rats, nor was any mortality observed in the 14 week old rats treated with ephedrine or caffeine alone. However, of the 14 week old rats treated with the combination of ephedrine and caffeine, 46% (6 of 13 animals) died within 5 hours of dosing. Treatment of both 7 and 14 week old rats with ephedrine and caffeine caused significant increases in QTc interval (from 116 to 190 msec and 118 to 190 msec, respectively) as well as significant increases in body temperature (from 37.3 to 38.5  $^{\circ}\text{C}$  and from 37.1 to 38.0  $^{\circ}\text{C}$ , respectively). Yet at this timepoint, prior to any signs of distress, the degree of hyperthermia in the 14 week old rats that died was significantly higher (40.6  $^{\circ}\text{C}$ ) than surviving 14 week old rats ( $p<0.0001$ ). Three hours post-treatment the percentage increase in the heart rate of 14 week old animals that died (154%) was significantly larger than the percentage increase in heart rate for both the 7 week old rats (121%,  $p<0.0001$ ) and the 14 week old rats that survived (129%,  $p<0.0001$ ). The combination of ephedrine and caffeine induced an increase in mitochondrial uncoupling proteins (UCP) 2 and 3 expression in 14 week old rats, and a decrease in expression of UCP2 and 1 adrenergic receptor in 7 week old rats. Histopathological data indicated interstitial hemorrhage, myofiber necrosis and vasospasm. These data are consistent with enhancement of catecholamine induced ischemic injury in 14 week old rats due to hyperthermia.

### ACUTE HEMORRHAGIC MYOCARDIAL NECROSIS AND SUDDEN DEATH OF RATS EXPOSED TO A COMBINATION OF EPHEDRINE AND CAFFEINE.

A. Nyska<sup>1</sup>, E. Murphy<sup>2</sup>, J. F. Foley<sup>1</sup>, B. J. Collins<sup>4</sup>, J. Petranka<sup>2</sup>, R. Howden<sup>3</sup>, P. Hanlon<sup>2</sup> and J. K. Dunnick<sup>4</sup>. <sup>1</sup>Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC, <sup>2</sup>Laboratory of Signal Transduction, NIEHS, Research Triangle Park, NC, <sup>3</sup>Laboratory of Respiratory Biology, NIEHS, Research Triangle Park, NC and <sup>4</sup>Environmental Toxicology Program, NIEHS, Research Triangle Park, NC.

Because of possible side effects of herbal medicines containing ephedrine and guarana-derived caffeine, including increased risk of stroke, myocardial infarction, and sudden death, the Food and Drug Administration recently banned the sale of ephedra-containing products, specifically over-the-counter dietary supplements. We report cardiac pathology in pilot studies in 7- and 14-week-old male F344 rats exposed by gavage to ephedrine (25 mg/kg) and caffeine (30 mg/kg) administered in combination for one or two days. The ephedrine-caffeine exposure was approximately 12- and 1.4-fold, respectively, above average human exposure, based on a mg/m<sup>2</sup> body surface-area comparison. Several of the exposed 14-week-old rats died or were sacrificed in extremis 4-5 h after the first dosing. In these hearts, changes were observed chiefly in the interventricular septum but also left and right ventricular walls. Massive interstitial hemorrhage, with degeneration of myofibers, occurred at the subendocardial myocardium of the left ventricle and interventricular septum. Immunostaining for cleaved caspase-3 and anti-phospho-H2AX, a histone variant that becomes phosphorylated during apoptosis, indicated multifocal generalized positive staining of degenerating myofibers and fragmenting nuclei, respectively. The Barbeito-Lopez trichrome stain revealed generalized patchy yellow myofibers, consistent with acute coagulative necrosis. In treated animals terminated after the second dosing, foci of myocardial degeneration and necrosis were already infiltrated by mixed inflammatory cells. The myocardial necrosis may occur secondarily to intense diffuse vasoconstriction of the coronary arterial system with decreased myocardial perfusion. Our work shows the direct relationship between combined ephedrine and caffeine exposure and cardiac pathology.

### EFFECTS OF HYPOKALIEMIA ON THE QT INTERVAL IN DOGS.

A. Yvon, J. Provost, Y. Rabemampianina and G. Hanton. *Pfizer PGRD, Amboise, France.* Sponsor: H. Sterz.

Imbalance in plasma electrolytes, in particular potassium is known to affect ECG. Hypokalemia increases the duration of cardiac action potential; consequently it prolongs QT interval and is a risk factor for arrhythmia. The objective of this study was therefore to estimate the quantitative relationship between plasma potassium concentrations and the QT interval in dogs. Hypokalemia was induced by treatment with furosemide, a potent diuretic. One group of 3 dogs/sex received oral escalating doses of 5, 8, 12, 18, 30, 45 mg/kg of furosemide and one group of 2 dogs/sex received a single dose of 30 mg/kg followed by repeat daily doses of 60 mg/kg for 3 days. ECG were recorded before the start of the treatment and on each day of treatment, before dosing, then 1.5 and 3.5h after dosing. QT was measured from leads II and CV5RL. Blood was sampled immediately after each ECG recording, for measurement of the plasma concentrations of potassium. The slopes of the linear regression between QT and plasma potassium levels were calculated for each animal, with the corresponding coefficient of correlation ( $r$ ) and of determination ( $r^2$ ). Escalating doses of furosemide produced a progressive hypokalemia whereas an abrupt change occurred in animals treated with 60 mg/kg. The change in plasma potassium was paralleled by an increase in QT and QTc interval. There was a clear inverse relationship between  $K^+$  plasma levels and QT or QTc interval in all animals and overall, the correlation was better for QT and QTc recorded in CV5RL lead compared to DII. When  $K^+$  plasma levels were below approximately 3.5 mmol/L, QT was increased above normal values of our historical range. The mean coefficients of determination of the relation between QTc measured in CV5RL and  $K^+$  plasma levels were 0.42 for males and 0.44 for females whereas the mean slopes were -17.4 for males and -24.2 for females. In conclusion, hypokalemia is quantitatively associated with an increase in QT and QTc interval in dogs.

### DOES AUTONOMIC NERVOUS TONE DIRECTLY AFFECT THE QT INTERVAL?

T. Harada, J. Abe, M. Shiotani, Y. Hamada and I. Horii. *PGRD Nagoya Lab., Pfizer Inc., Taketoyo, Aichi, Japan.* Sponsor: M. Kurata.

Changes in the QT interval should be evaluated precisely in the early stages of drug development because QT prolongation can cause torsades de pointes, a life threatening polymorphic ventricular tachycardia. However, it is well known that the QT interval varies with changes in autonomic nervous tone irrespective of heart rate. In this study, we investigated the changes of the QT interval by shifting the RR interval from 400 to 700 msec, and the direct effect of autonomic nervous tone on the QT interval by measuring heart rate variability in dogs. Our result showed that the QT interval at the high HF (high vagal tone) or low LF/HF ratio (low sympathetic tone) was longer than that at the low HF or high LF/HF ratio, respectively, when the RR interval was constant at 400 or 700 msec. Besides, the effect of vagal tone on the QT interval might be somewhat stronger than that of sympathetic tone because HF, which reflects vagal tone, is much higher in dogs than in other animals and the significant differences in the QT interval between low and high LF/HF ratios were not detected in 2 animals. The present observations support the idea that sympathetic as well as parasympathetic tone regulate the QT interval and that the QT interval may be controlled physiologically by both sinus rhythm and myocardial characteristics, that is, autonomic nerves may regulate the QT interval directly as well as via the sinus node.

### SENSITIVITY OF CANINE AND RABBIT CARDIAC REPOLARIZATION ASSAYS FOR DETECTION OF POTENTIAL QT LIABILITY.

J. Kramer. *ChanTest, Inc., Cleveland, OH.* Sponsor: T. Narahashi.

The nonclinical evaluation of the potential for QT prolongation induced by non-antiarrhythmic drugs includes *in vitro* cardiac action potential repolarization assays. These evaluations can be critical for decision-making and their relative predictive value for identifying potential QT and torsade de pointes (TdP) liabilities is of particular importance. We compared the responsiveness of several widely-used test systems: canine and rabbit Purkinje fibers, *ex vivo* rabbit hearts, and hERG potassium channels in a panel of drugs that are known to be either positive or negative for TdP in humans. Torsadogenic compounds such as, cisapride, erythromycin, haloperidol, ketanserin, quinidine, dl-sotalol, and thioridazine gave positive signals in both canine and rabbit Purkinje fibers. However, other torsadogenic compounds such as bepridil, pimozide and terfenadine gave positive signals only in rabbit Purkinje fibers. Terfenadine- and cisapride-induced QT interval prolongation was confirmed in *ex vivo* Langendorff-perfusion rabbit hearts. Non-torsadogenic test compounds (e.g. amoxicillin, aspirin, captopril and loratadine) were negative in both canine

and rabbit Purkinje fibers. Our results indicate that *in vitro* measurements obtained in rabbit-derived test systems give fewer false negative responses and have greater predictive value than those obtained in canine Purkinje fibers.

**833**

### ACCURATE EVALUATION OF QT INTERVAL IN CONSCIOUS CYNOMOLGUS MONKEYS BY USE OF TELEMETRY ECG.

K. Kuwano, T. Jikuzono, S. Otsuka, M. Hijioka, T. Miyake, T. Uchino, M. Shoki, T. Koga, K. Fukuzaki, R. Nagata and G. Kito. *Shin Nippon Biomedical Laboratories, Ltd., (SNBL), Kagoshima, Japan.*

The objective of this study was to determine the best method to evaluate the QT interval with respect to the heart rate in cynomolgus monkeys. Cynomolgus monkeys are widely used in cardiovascular research, but the characteristics of QT-RR formulas in cynomolgus monkeys have not been determined. We analyzed the physiological QT-RR relationship for practical evaluation of the QT interval in conscious cynomolgus monkeys by use of 24-hour telemetry ECG monitoring. As the QT interval varies dependent on the RR interval, 14 QT regression functions were evaluated by use of 12 pairs of QT-RR points per animal in 100 male cynomolgus monkeys. The accuracy of fit with the measured data was assessed according to the minimum Akaike information criterion. Among one-parameter linear regression function,  $QT = s \times (RR)^{1/2}$ , where  $s$  is the regression coefficient, gave the best fit, which was almost comparable to that of all multi-parameter regression functions. Our results also suggest that the QTc formula derived from the square root regression function is the most practical for evaluation of QT intervals in cynomolgus monkeys. Furthermore, ranges in diurnal variation and the patterns of blood pressure (BP), heart rate (HR), body temperature (BT), motor activity (MA) and ECG parameters (PR interval, QRS duration, RR interval, QT interval, JT interval, QTc and JTc) in 100 male cynomolgus monkeys were analysed using telemetry system. We believe that these results in cynomolgus monkeys are very important and quite useful for cardiovascular research of new drugs.

**834**

### NEW SAFETY ASSESSMENT ON LEFT VENTRICULAR VOLUME AND ITS FUNCTION IN MONKEYS USING THREE-DIMENSIONAL ECHOCARDIOGRAPHY.

T. Yamada<sup>1</sup>, H. Tsusaki<sup>1</sup>, H. Yonamine<sup>1</sup>, A. Tamai<sup>1</sup>, M. Shimomoto<sup>2</sup>, G. Kito<sup>1</sup> and R. Nagata<sup>1</sup>. <sup>1</sup>*Shin Nippon Biomedical Laboratories, Ltd., Kagoshima, Japan* and <sup>2</sup>*Philips Medical Systems, Fukuoka, Japan.*

[Background and Purpose] Non-invasive determination of cardiac function over time is potentially important for safety pharmacology study and toxicity study. The objectives of this study are to evaluate the accuracy of three-dimensional echocardiography (3DE) measurement of left ventricular (LV) volume and LV function, and to examine effects of some drugs on LV function in monkeys. [Methods] 3DE (SONOS 7500, Philips Med. Sys.) was performed in isoflurane-inhalated male cynomolgus monkeys before and after intravenous infusion (5 or 10 min) of four drugs (propranolol, verapamil and dobutamine). End-diastolic volume (EDV), end-systolic volume (ESV), ejection fraction (EF), stroke volume (SV), cardiac output (CO) and heart rate (HR) were determined. LV volume was determined using 4D CardioView RT software (TomTec Imaging Sys) by average rotation method. [Results] By using cut sausage at various volumes, there was strong correlation between the actual volume by Archimedes method and volume determined by 3DE (ranging 1.5-7 mL, slope=0.99,  $R^2=0.999$ ), suggesting that 3DE is accurately measured the small-volume-materials. Propranolol (0.1 mg/kg/10 min,  $n=5$ ) caused an increase in ESV, not EDV, resulting in decreases in EF and SV. Verapamil (0.1 mg/kg/10 min,  $n=5$ ) produced increases in both EDV and ESV, and thereby SV maintained almost pre-value despite a slight decrease in EF. Dobutamine (0.01 mg/kg/5 min,  $n=5$ ) produced decreases in both EDV and ESV, and thereby the increased CO resulted from the increased SV and EF. [Conclusion] These results demonstrate that cardiac function can be estimated by LV volume and analytical parameters from 3DE, and that this method is possible to use for evaluation in safety pharmacology study and toxicity study.

**835**

### HERG LIABILITY: THINKING OUTSIDE THE BLOCK.

B. Wible. *ChanTest, Inc., Cleveland, OH.* Sponsor: T. Narahashi.

Direct block of the hERG potassium channel by non-antiarrhythmic drugs (NARDs) is a major cause of QT prolongation and torsade de pointes (TdP). Recently, we showed that certain NARDs may produce hERG liability not by direct block but by inhibition of channel trafficking. Trafficking defects are not detected with the usual patch clamp protocol or any of the surrogate assays such as rubidium flux, ligand displacement, or dye-based methods. We have developed a novel, comprehensive assay called HERG-Lite® that predicts hERG liability for both direct

blockers and trafficking inhibitors. The antibody-based, chemiluminescent assay uses two cell lines to monitor hERG surface expression: hERG-WT (wild-type) is a biosensor for trafficking inhibitors while hERG-SM (single mutant) detects channel blockers. We have screened an 880 compound diverse chemical library and found that ~35% of the compounds have a predicted hERG liability. These compounds fall into three classes. Class B compounds, such as cisapride and pimozide, are direct blockers of the channel and show increased surface expression of the SM. Class C compounds, such as thioridazine and trifluoperazine, are direct blockers but also show a predominant trafficking defect in the HERG-Lite® assay. Our studies show that ~40% of hERG blockers possess this dual liability. Class A compounds such as arsenic trioxide and pentamidine are non-blockers that produce hERG trafficking inhibition. The results of the HERG-Lite® screen indicate that inhibition of hERG trafficking is a prevalent mechanism for NARD-induced hERG liability.

**836**

#### VARIABILITY IN THE MEASUREMENT OF HERG POTASSIUM CHANNEL INHIBITION: EFFECTS OF TEMPERATURE AND STIMULUS PATTERN.

G. Kirsch. *ChanTest, Inc., Cleveland, OH.* Sponsor: T. Narahashi.

*In vitro* evaluation of drug effects on hERG K<sup>+</sup> channels is a valuable tool for identifying potential proarrhythmic side effects in drug safety testing. Patch clamp recording of hERG K<sup>+</sup> current in mammalian cells can accurately evaluate drug effects, but the methodology has not been standardized and results vary widely. Our objective was to evaluate two potential sources of variability: the temperature at which recordings are performed and the voltage pulse protocol used to activate hERG K<sup>+</sup> channels expressed in HEK293 cells. A panel of 15 drugs that spanned a broad range of potency for hERG inhibition and pharmacological class was evaluated at both room temperature and near-physiological temperature using several patch clamp voltage protocols. Concentration-response analysis was performed with three stimulus protocols: 0.5 s step-pulses, 2 s step-pulses or a step-ramp pattern. Block by two of the 15 drugs tested, d, l-sotalol (antiarrhythmic) and erythromycin (antibiotic), was markedly temperature-sensitive. HERG inhibition measured using a 2 s step-pulse protocol underestimated erythromycin potency compared with results obtained with a step-ramp protocol. Using conservative acceptance criteria and the step-ramp protocol, the IC50 values for hERG block differed by less than twofold for 15 drugs. Data obtained at near-physiological temperatures using a step-ramp pattern are highly repeatable and provide a conservative safety evaluation of hERG inhibition.

**837**

#### VALIDATION OF QT EVALUATION IN CONSCIOUS GUINEA PIGS WITH A TELEMETRY SYSTEM.

M. Shiotani<sup>1</sup>, T. Harada<sup>1</sup>, J. Abe<sup>1</sup>, Y. Hamada<sup>1</sup>, K. Hashimoto<sup>2</sup> and I. Horii<sup>1</sup>.  
<sup>1</sup>*PGRD Nagoya Lab., Pfizer Inc., Taketoyo, Aichi, Japan* and <sup>2</sup>*Interdisciplinary Graduate School of Medicine and Engineering, University of Yamanashi, Nakakoma, Yamanashi, Japan.* Sponsor: M. Kurata.

Guinea pigs have constituted an attractive *in vivo* model to evaluate the effect of newly discovered drugs on the QT interval at the pre-clinical stage because of their small size, low cost, an action potential configuration similar to that of humans, and the availability of a lot of *in vitro* data on the animal. But no ECG measurement technique using a telemetry system has been fully established in guinea pigs as yet. The purpose of this study was to validate telemetry data in guinea pigs using drugs that are well known to prolong the QT interval in humans. Bepridil (10 mg/kg), terfenadine (4 mg/kg), cisapride (3 mg/kg), haloperidol (2 mg/kg), pimozide (5 mg/kg), quinidine (30 mg/kg), E-4031 (0.1 mg/kg) or thioridazine (6 mg/kg) were given to 6 animals each. The intravenous route was selected to save the amount of compound used. The pharmacokinetics of the drugs was also investigated using other animals. All the drugs clearly prolonged the QT interval 10-60 min post-dose, with 7 of the 8 drugs tested inducing a statistically significant prolongation. In the animals treated with haloperidol, flattening of the T-wave was also observed, which is liable to cause torsades de pointes. When QT interval changes were plotted against the serum concentrations of the drugs, the resulting curves indicated a delayed distribution of the compounds into the ventricle. In summary, the present study demonstrated that use of conscious guinea pigs with an implanted telemetry device is useful to detect drug-induced QT interval changes and evaluate their potential to cause arrhythmia in humans at an early stage of drug development using only a small amount of chemicals.

**838**

#### ASTEMIZOLE : SPECIES DIFFERENCES IN QT PROLONGATION AND ARRHYTHMOGENESIS.

J. Le Bigot, P. Lainee, A. Betat, G. Froget, L. Camus and R. Forster. *CIT, Evreux, France.*

The current draft ICH S7B guideline requires that the potential of new drugs to provoke QT prolongation and cardiac arrhythmias should be investigated in conscious animal models. In order to compare the sensitivity of different non-rodent

species, 6 female beagle dogs and 6 female cynomolgus monkeys implanted with telemetric devices received a single oral administration of 30 mg/kg astemizole (an H2 receptor antagonist) or vehicle. ECG was recorded continuously for 12 hours, and checked 24 hours after administration. QTf (QT corrected with Fridericia's formula) and the occurrence of arrhythmias were monitored over the same period. QTf was prolonged in both species but primates were more sensitive than dogs (42±18% vs 14±4%, p<0.05). The maximal effect was observed after 10 hours in both species and QTf prolongation was still present at 24 hours (15±12% in primates; 7±3% in dogs). In primates, ECG shape was modified with the appearance of a U wave from 45 minutes after treatment in all animals. Isolated extrasystoles were observed in two animals, and more severe arrhythmias (bigeminism and polymorphic tachycardia including Torsades de pointe) were noted in one animal, leading to transient syncope. No arrhythmias were observed in dogs. Based on these results, primates would be considered as more sensitive to astemizole-induced QT prolongation. Nevertheless, the use of either species would have allowed identification of the QT prolongation hazard. The choice of dogs would have led to underestimation of the potential for arrhythmogenesis. Since the new guidelines emphasize both QT prolongation and the potential for arrhythmogenesis, the choice of species for *in vivo* investigation should ideally be discussed on a case-by-case basis, taking account of the response of the animal models to different chemical or pharmacological classes.

**839**

#### VALIDATION OF THE ISOLATED RABBIT HEART FOR CARDIOVASCULAR SAFETY ASSESSMENT.

E. Tanhehco, P. Senese and M. Gralinski. *CorDynamics, Inc., Chicago, IL.*

The potential to cause arrhythmias has become a major concern during lead optimization and assessment of all potential drug candidates, regardless of their therapeutic target. Unlike other experimental procedures such as those examining hERG channel binding and isolated Purkinje fiber assays, both hemodynamic and electrophysiologic effects of compounds can be observed simultaneously in our application of the isolated rabbit heart. In this screening study, we examined the hemodynamic and electrophysiologic effects of nine compounds with known cardiovascular actions. Hemodynamic function was assessed by measuring left ventricular pressure, coronary perfusion pressure, +dP/dt, and -dP/dt. Changes in electrophysiologic characteristics were determined by monitoring heart rate, monophasic action potential duration, and by measurements of PR, QT and QRS intervals. The compounds studied included flecainide, propranolol, dobutamine, amiodarone, E4031, terfenadine, sotalol, and verapamil. These compounds represent a wide range of mechanisms that affect cardiac electrophysiologic and/or hemodynamic function. Penicillin was used as a negative control. Each compound altered the function of isolated rabbit hearts in a similar manner to what is observed in humans, or in the case of E4031, consistent with what has been observed in other pre-clinical models. For example, terfenadine increased QT interval and verapamil decreased contractility. Our results demonstrate that our use of the isolated rabbit heart can serve as an effective cardiovascular toxicity screen, and as a physiologically relevant bridge between the typical ion channel assay, and *in-vivo* telemetry studies.

#### NON-SURGICAL TELEMETRY TECHNIQUES FOR ELECTROCARDIOGRAM (ECG) DETERMINATION IN DOGS AND MONKEYS DURING TOXICOLOGY STUDIES.

P. Shaver-Walker, M. Vezina, N. Leblond and C. Copeman. *IPN, CTBR Bio-Research Inc., Senneville, QC, Canada.*

Manual ECG recordings can be difficult to interpret due to movement artefact and excitement during restraint. The relatively large numbers of animals/study (avg 32-40) also creates logistical difficulties in obtaining the ECG at the appropriate time-points (around Cmax). Non-surgical telemetry was selected as an alternative to allow undisturbed ECG recording simultaneously from multiple animals. ECGs were obtained from 12 dogs (60 seconds) and 12 monkeys (30 seconds) during restraint in a sling (limb leads). The same animals were then fitted with specially designed jackets with an integrated pocket. A DSI telemetry transmitter with 2 biopotential leads was placed in the pocket and the 2 leads connected to stick-on gel electrodes in a cutaneous axial formation under the jacket. Jacketed animals were placed in their cages and the following day simultaneous ECGs were recorded from an anteroom at a time similar to the restrained recording. The ECGs were evaluated for quality (presence of artefact, readability of the ECG complexes) as well as heart rate (HR). Telemetry-derived ECGs exhibited little or no excitement-induced tachycardia, compared to most restrained ECGs, and improved readability due to reduced artefact. HR was reduced by ~ 80 BPM (45%) and ~ 120 BPM (40%) in dogs and monkeys, respectively. In dogs, the lower HR resulted in an expected increased incidence of sinus arrhythmia and other common dog-related ECG changes. It was concluded the non-surgical telemetry improved both the dog and

monkey ECG and reduced the time to record the ECGs. It allowed evaluation at more physiologically relevant HR in both species, but had a more profound improvement in readability for the monkey.

#### GENERATION OF BACKGROUND

#### ELECTROCARDIOGRAM (ECG) TELEMETRY DATA IN DOGS USING A POSITIVE CONTROL SUBSTANCE (DL-SOTALOL) FOR QT PROLONGATION.

**M. Vezina**, N. Leblond, K. Tenneson and C. Copeman. *IPN, CTBR Bio-Research Inc., Senneville, QC, Canada.*

As part of the validation of a computerized telemetry data acquisition system (Ponemah P3 v. 3.23 and DSI Open Art v 2.2), data from the CTBR telemetry dog colony were obtained to evaluate the systems ability to analyze ECG waveforms from live animals. ECGs were continuously monitored using telemetry from six previously implanted beagle dogs for an approximate 24-hour period for baseline determination. The dogs then received oral doses of dl-sotalol at 5 and 10 mg/kg, with a one week washout between doses. On the day of dosing, the ECG was continuously recorded for 2 hours pre-dose and up to 24 hours post dose. Heart rate and the PR, QRS and QT intervals were measured and the QT was also corrected for heart rate using the Van de Water equation (QTcv). As expected, administration of dl-sotalol resulted in a dose-related prolongation of the QT and QTcv intervals as evidenced using values adjusted for baseline and also direct QT-HR plots. At 5 mg/kg, the QT interval was prolonged by an average of approximately 25 milliseconds (ms) and at 10 mg/kg by an average of approximately 90 ms. Most of the dogs also exhibited slight shortening of the QRS interval when plotted against the heart rate at the 10 mg/kg dose, but not the 5 mg/kg dose. The Ponemah software successfully detected the ECG waveform components when the heart rate was constant, but had some trouble when the heart rates were slower and sinus arrhythmia more prevalent. Therefore, the data generated by the system required verification and correction of the ECG data as needed. Although time consuming, it was considered to provide much more accurate data since every complex is measured compared to manual measurement techniques.

#### THE ROLE OF CALPAIN-CALPASTATIN SYSTEM IN 2-BUTOXYETHANOL-INDUCED HEMOLYSIS.

**P. S. Palkar**, **V. S. Bhave**, **B. K. Philip**, **P. B. Limaye** and **H. M. Mehendale**.

*Department of Toxicology, University of Louisiana at Monroe, Monroe, LA.*

Administration of 500 mg/kg of 2-butoxyethanol (2-BE) to female Sprague-Dawley (SD) rats leads to hemolysis via its reactive metabolite, 2-butoxyacetic acid (2-BAA). This study was designed to test the hypothesis that calpain released from lysed red blood cells (RBCs) mediates the progression of hemolysis initiated by 2-BAA. Hematocrit was measured at 0, 3, 6, 9, 12, 24, 72, 120, 168 h after the oral intubation of 500 mg 2-BE/kg to female SD rats (200-250 g). Hemolysis evident as early as 3 h after 2-BE treatment, progresses until 24 h, well after the elimination of 2-BAA ( $t_{1/2} = 3$  h). Plasma calpain levels peaked at 3 h and remained high until 9 h after 2-BE intubation. Presence of high levels of calpain in the plasma during and after BAA elimination, suggests its role in the progression of injury. Incubation of RBCs (250  $\mu$ l buffer) with 5.6 U of calpain led to significant hemolysis by 2 h. It is known that after the low dose of 2-BE, rats and hematocrit values recover from the hemolytic episode by 168 h due to erythropoietic stimulation. Erythropoiesis leads to the production of new RBCs, known to be resilient to hemolysis, explaining much lower hemolysis on subsequently administered normally lethal dose of 2-BE given 7 days later. We hypothesized that overexpression of calpastatin, an endogenous inhibitor of calpain in the new RBCs will impart resistance to calpain-mediated degradation of RBCs. Calpastatin expression was assessed by Western blotting in whole RBC lysates from 0 to 120 h after 2-BE administration. Calpastatin increased significantly at 3 h and remained high till 72 h. Collectively, these results suggest that calpain released from lysed RBCs may mediate the progression of hemolysis initiated by 2-BAA while overexpression of calpastatin may explain the underlying mechanism of resiliency of young RBCs against calpain-mediated hemolysis. However, the calpastatin overexpression is not seen after 72 h, which suggests that other death proteins and their inhibitors may be players in mediation of progression/regression of hemolytic injury.

#### ADHESION-MOLECULE CHANGES IN 2-BUTOXYETHANOL (BE) FISCHER F344 RAT MODEL FOR THROMBOTIC SEQUELAE OF HEMOLYTIC ANEMIAS.

**T. L. Ortel**<sup>2</sup>, **A. Potti**<sup>2</sup>, **D. Lewis**<sup>2</sup>, **J. Wu**<sup>2</sup> and **A. Nyska**<sup>1</sup>. <sup>1</sup>*Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC* and <sup>2</sup>*Division of Hematology, Duke University Medical Center, Durham, NC.*

In hemolytic diseases, like sickle cell disease (SCD) and thalassemia, the mechanisms of thrombosis are poorly understood. Appropriate animal models would help increase our understanding of the pathophysiology of thrombosis. Gavage exposure

of female rats to BE leads to the development of hemolytic anemia and disseminated microthrombi. Using red blood cell (RBC) flow analysis, we demonstrated that formation of microthrombi was not secondary to RBC aggregation. Instead, we found that exposure to BE led to enhanced adherence of RBCs to the extracellular matrix, possibly secondarily to the recruitment of cellular adhesion molecules on the endothelial cell (EC)-RBC interface. We exposed female Fischer F344 rats to 250mg/kg of BE for up to 4 days, using 8 groups (5 animals/group) of rats 4 vehicle-treated control and 4 treated groups. One control and one treated group were terminated each day, after the 1st, 2nd, 3rd, and 4th daily dose. Blood was collected on each day for laboratory testing of coagulation markers. Platelet counts, prothrombin times, activated plasma thromboplastin times, fibrinogen, antithrombin-III levels, and D-dimers showed no differences between treated and control rats. The levels of endothelial intercellular adhesion molecule-1 (ICAM-1) in the BE-treated animals were approximately twice those of the control animals on days 2 and 3. On day 4, the levels in treated animals were 1.5 times those in controls. The thrombin-antithrombin levels in the BE-treated rats for all the time points were 3-7 times greater than those in the control rats. We suggest that RBC/EC interaction may be a potent catalyst for thrombosis. This hypothesis is consistent with the observations of increased RBC adherence, RBC/EC interaction, and increased ICAM-1 expression observed in humans during acute sickle-cell crises and provides an explanation for the relative failure of anticoagulant/antiplatelet strategies during acute thrombotic episodes in SCD.

We recently proposed a chemically induced rat model for human hemolytic disorders associated with thrombosis. The objective of the present investigation was to apply a non-invasive, high-magnification x-ray analysis (Faxitron radiography) to characterize the protracted bone damage associated with this model and to validate it by histopathology. Groups of female Fischer 344 rats were given 0, 250, or 300 mg of 2-butoxyethanol/kg body weight daily for 4 consecutive days. Groups were then sacrificed 2 hours or 26 days after the final treatment. The treated animals displayed a darkened purple-red discoloration on the distal tail. Histological examination of animals sacrificed 2 hours after the final treatment revealed disseminated thrombosis and infarction in multiple organs, including bones. Phosphotungstic acid-hematoxylin (PTAH) staining confirmed the presence of ante-mortem thrombosis. Faxitron radiography was used to image selected bones of rats sacrificed in 30 days (26 days after the final treatment). Premature thinning of the growth plate was seen in the calcaneus, lumbar and coccygeal vertebrae, femur, and ilium from the treated animals. Radiolucent areas were seen in the diaphysis of the femur of all treated animals. The bones were then examined histologically and showed a range of changes, including loss or damage to growth plates and necrosis of cortical bone. No thrombi were seen in the animals sacrificed at 30 days, but bone and growth plate changes consistent with prior ischemia were noted. The Faxitron proved to be an excellent non-invasive tool that can be used in future studies with this animal model to examine treatment modalities for the chronic effects of human thrombotic disorders.

#### 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN ALTERS FETAL MURINE CARDIAC GROWTH AND GENE EXPRESSION, AND LEADS TO CARDIAC HYPERTROPHY AND ALTERED CARDIAC FUNCTION AFTER BIRTH.

**E. A. Thackaberry**, **B. A. Nunez**, **I. D. Ivntski-Steele** and **M. K. Walker**. *College of Pharmacy, U of New Mexico, Albuquerque, NM.*

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) and similar environmental contaminants have previously been demonstrated to be potent cardiovascular teratogens in developing piscine and avian species. In the current study, we investigate the effects of TCDD on murine cardiovascular development. Pregnant mice were dosed with 1.5, 3, 6, 12, and 24  $\mu$ g/kg TCDD on gestation day (GD) 14.5. No overt maternal or fetal toxicity was seen at this dose, and litter size and neonatal survival were normal in the offspring of TCDD-treated dams. At day GD17.5, fetal mice exhibited a dose-related decrease in heart-to-body weight ratio that was significantly reduced at a dose as low as 3  $\mu$ g/kg TCDD. In addition, cardiac proliferation, as measured by both proliferating cell nuclear antigen (PCNA) and 5-bromo-

2'-deoxyuridine (BrdU) staining, was reduced in GD17.5 hearts treated with 6 ug/kg TCDD. To determine if this reduction in cardiac weight was transient, or continued after birth, mice treated with 6 ug/kg TCDD were allowed to come to term and remain with the original dam. While heart weights had normalized by post-natal day 7, TCDD-treated mice had increased heart-to-body weight ratios and increased expression of the cardiac hypertrophy markers 21 days after birth. At post-natal day 21, mice from TCDD-treated dams demonstrated a pronounced ST-segment depression in response to isoproterenol, suggesting cardiac ischemia. Furthermore, basal and isoproterenol-responsive heart rate was lower in TCDD-treated mice. These results demonstrate that TCDD reduces heart weight during cardiac development, and results in a compensative cardiac hypertrophy and altered cardiac functionality after birth. SUB-CHRONIC, LOW LEVEL 2, 3, 7, 8-  
TETRACHLORODIBENZO-P-DIOXIN (TCDD)  
EXPOSURE INCREASES BLOOD PRESSURE IN ADULT  
MICE AS MEASURED BY TELEMETRY.

P. G. Kopf, A. K. Lund and M. K. Walker. *College of Pharmacy, University of New Mexico, Albuquerque, NM.*

Hypertension is a prevalent disorder in industrialized regions. If left untreated, prolonged hypertension significantly increases the likelihood of coronary thrombosis, stroke, and renal failure. Previous studies have correlated adult TCDD exposure with increased incidence of cardiovascular disease in humans, including hypertension. The purpose of our study was to determine if sub-chronic, low level TCDD exposure increased arterial blood pressure, a risk factor for future cardiovascular disease-related mortality. An implanted telemeter system was used to monitor the blood pressure of the left carotid artery in 3-4 month old male C57Bl/6N mice. After telemeter implantation and a 7 day recovery period from surgery, baseline blood pressure was measured for 7 days. Following baseline measurement, mice were dosed with vehicle control (corn oil) or 150 ng/kg TCDD by oral gavage three times per week for 2 months, which will result in a steady state body burden of 1 ug/kg after 8 weeks. Within the first 36 hours after the first dose (t36) no change in mean arterial pressure (MAP) was observed. However, within the next 24 hours (t60) a trend for increased MAP was observed which continued up to 9 days (t216). After 9 days, a normalization of MAP occurred which continued through day 18 (t432). Telemeter output will continue to be monitored until the mice attain steady state TCDD body burdens at 8 weeks. These results suggest that low level TCDD exposure increases blood pressure, which is consistent with previous studies that used higher doses of TCDD in mice. However, the mechanism by which TCDD increases MAP followed by normalization remains to be elucidated. Hypertension is the primary risk factor for atherosclerosis. Others have shown that this sub-chronic dose of TCDD promotes atherosclerosis in ApoE null mice. The continuance of this telemetry study will reveal if increasing TCDD body burden continues to effect blood pressure regulation. Supported by ES012335 to MKW; P30ES12072 to UNM.

A HARMONIZED PBPK MODEL FOR  
TRICHLOROETHYLENE RISK ASSESSMENT.

T. R. Covington<sup>1</sup>, H. J. Clewell<sup>1</sup>, J. W. Fisher<sup>2</sup>, D. A. Keys<sup>2</sup>, C. Hack<sup>3</sup> and J. Q. Zhao<sup>3</sup>. <sup>1</sup>*ENVIRON Health Sciences Institute, Ruston, LA*, <sup>2</sup>*University of Georgia, Athens, GA* and <sup>3</sup>*Toxicology Excellence for Risk Assessment, Cincinnati, OH.*

The most recent EPA cancer risk estimates for trichloroethylene (TCE) were derived in part using PBPK models. In particular, risks of liver cancer based on tumors in mice were estimated using two different PBPK models, as well as with "calibrated" versions of these two models using re-estimated parameters obtained from Markov chain Monte Carlo analysis. In this effort, the developers of the two previous models have collaborated to develop a single harmonized PBPK model for TCE, and to characterize the reliability of the resulting model in providing dosimetry estimates in support of a risk assessment for TCE. The harmonized PBPK model provides a comprehensive description of all of the data used in the development of both of the previous models on the kinetics of trichloroethylene (TCE) and its metabolites, trichloroethanol (TCOH), and trichloroacetic acid (TCA), in the mouse, rat, and human, for both oral and inhalation exposure. Dose metrics that can be calculated with the model include the area under the concentration curve (AUC) for TCA in the plasma or liver, the peak concentration and AUC for chloral (CHL) produced in the tracheo-bronchial region of the lung, and the production of a thioacetyating intermediate from dichlorovinylcysteine (DCVC) in the kidney. It was concluded that there is currently not adequate data available with which to confidently parameterize a description for another metabolite of interest,

dichloroacetic acid (DCA). Model predictions of TCE, TCA, and TCOH concentrations in rodents and humans are consistent with variety of experimental data, suggesting that the model should provide a useful basis for evaluating cross-species and cross-route differences in pharmacokinetics for these chemicals. In the case of the lung and kidney target tissues, however, only limited data are available for establishing cross-species pharmacokinetics. As a result, PBPK model calculations for these dose metrics are highly uncertain.

PHYSIOLOGICAL MODELING OF THE DERMAL  
ABSORPTION OF  
OCTAMETHYLCYCLOTETRASILOXANE (D4) AND  
DECAMETHYLCYCLOCLOPENTASILOXANE (D5).

M. B. Reddy<sup>1</sup>, K. P. Plotzke<sup>2</sup>, J. R. Looney<sup>3</sup>, M. J. Utell<sup>3</sup>, M. L. Jovanovic<sup>2</sup>, J. M. McMahon<sup>2</sup>, D. A. McNett<sup>2</sup> and M. E. Andersen<sup>4</sup>. <sup>1</sup>*Colorado State University, Fort Collins, CO*, <sup>2</sup>*Dow Corning Corporation, Midland, MI*, <sup>3</sup>*University of Rochester, Rochester, NY* and <sup>4</sup>*CIIT, Research Triangle Park, NC.*

Studies have been conducted to assess the dermal absorption of D4 and D5 through human axilla skin *in vivo* and abdominal skin *in vitro*. A physiologically based pharmacokinetic (PBPK) model was previously developed to examine the dermal absorption of D4 in the rat and human. Here, we describe extension of the published PBPK model for inhalation of D5 in humans by adding a skin compartment for dermal application. The compartment model for D5 dermal absorption, based on the D4 model, included (1) volatilization of applied chemical from the skin surface, (2) a storage compartment in the skin tissue, (3) diffusion of absorbed chemical within the skin back to the skin surface, (4) evaporation of this chemical from the skin surface even though the applied dose was no longer present, and (5) uptake from the skin compartment into blood. Time course of blood and exhaled breath data from human volunteers were used to estimate model parameters. Based on model calculations, 0.05 % of the applied dose of D5 absorbed through the skin and into the body over a 24 hour period. Modeling results for the *in vivo* human dermal absorption study were generally consistent with the results of *in vitro* human dermal studies. A smaller proportion of applied D5 absorbed through axilla skin than absorbed with D4, although neither was very well absorbed by the dermal exposure route. For D4 and D5, more than 83% of the small amount of systemically absorbed chemical was eliminated by exhalation in the 24 hour period after application. With these compounds having low blood:air partitioning, extensive first-pass loss by exhalation reduces systemic exposures after dermal absorption. Sponsored by the Silicones Environmental, Health and Safety Council of North America.

ALTERATION OF HEXACHLOROBENZENE  
DISPOSITION BY PCB126 COEXPOSURE AND  
APPLICATION OF PBPK MODELING IN A MEDIUM-  
TERM LIVER FOCI BIOASSAY.

Y. LU, M. Lohitnavy, O. Lohitnavy, E. Perrigo and R. Yang. *Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO.*

Hexachlorobenzene (HCB) is a probable human carcinogen which still exists in the environment despite the curtailment of its production and use. Human exposure to HCB is often accompanied by PCB126, a dioxin-like compound and the most potent congener of polychlorinated biphenyls. Earlier, we observed that PCB126 altered the kinetics of coexposed lipophilic chemicals. Here, we report our studies on HCB pharmacokinetics, with or without coexposure to PCB126. Our experiments included two separate kinetic studies (HCB alone and HCB+PCB126) integrated into a time-course medium-term liver foci bioassay. In both studies, fat had the highest concentrations of HCB, followed by the other tissues. The kinetics of tissue distribution of HCB are dramatically different between HCB alone group and the HCB+PCB126 combination group, suggesting complex interaction mechanisms. Using PBPK modeling as a hypothesis-testing tool, we carried out computer simulations based on the assumptions that PCB126 induced disruption at the levels of absorption, exsorption (i.e., the diffusion from blood to the lumen of GI tract), and fat metabolism. We utilized a previously constructed PBPK model for HCB to describe these altered disposition patterns. The model was composed of fat, liver, erythrocytes, blood plasma, GI lumen, and rapidly and slowly perfused tissues and incorporated the physiological changes related to partial hepatectomy in the time-course medium term liver foci bioassay protocol. The model adequately described the pharmacokinetics of HCB singly and in combination with PCB126. From our modeling exercises, we propose that the kinetic alterations were the results of a combination of the modification of HCB absorption and exsorption and the disruption of fat metabolism by PCB126. (This research was supported, in part, by a grant from CDC/NIOSH, 1 RO1 OH07556-01.)

PREDICTIVE PHYSIOLOGICALLY BASED  
PHARMACOKINETIC (PBPK) MODELING OF  
PYRETHRHOID PESTICIDES.

S. J. Godin<sup>1</sup>, R. Tornero-Velez<sup>2</sup>, E. J. Scollon<sup>3</sup>, M. F. Hughes<sup>3</sup> and M. J. Devito<sup>3</sup>. <sup>1</sup>Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, <sup>2</sup>NERL, USEPA, ORD, Research Triangle Park, NC and <sup>3</sup>NHEERL, USEPA, ORD, Research Triangle Park, NC.

Pyrethroids are a class of neurotoxic pesticides that have many different applications in agriculture, horticulture, and homes, and medicinal uses for animals and humans. Differences in the toxicity of pyrethroids are the result of their pharmacokinetic and/or pharmacodynamic properties. Rat LD<sub>50</sub> values for three type II pyrethroids, deltamethrin-105mg/kg, esfenvalerate-95mg/kg, and  $\beta$ -cyfluthrin-450mg/kg have been reported by their manufacturers. In an effort to develop human exposure-dose-response models for pyrethroid pesticides we have determined *in vitro* metabolism parameters in rat liver microsomes using a parent depletion approach. We are interested in whether intrinsic hepatic clearance (CLint) is a major determinant of target organ (brain) concentration and therefore a potential determinant of the relative toxicity of these three pyrethroids. We have determined Kmapp, Vmax and, CLint for deltamethrin (Km 3.09 $\mu$ M  $\pm$  0.82; Vmax 435.86 pmoles/min/mg MSP  $\pm$  27.79; CLint = 8.47E-3 L/hr/mg MSP), esfenvalerate (Km = 7.13 $\mu$ M  $\pm$  0.15; Vmax = 353.00 pmoles/min/mg MSP  $\pm$  28.15; CLint = 2.97E-3 L/hr/mg MSP), and  $\beta$ -cyfluthrin (Km = 16.13 $\mu$ M  $\pm$  2.43; Vmax = 810.40 pmoles/min/mg MSP  $\pm$  28.15; CLint = 3.02E-3 L/hr/mg microsomal protein). Deltamethrin is cleared nearly 3-fold more rapidly than esfenvalerate or  $\beta$ -cyfluthrin. These results do not indicate any correlation between the rate of hepatic clearance and the relative toxicity of these three pyrethroids. From literature derived data and these calculated CLint values; a preliminary PBPK model of exposure to deltamethrin was developed. Based on model predictions it appears that for these three pyrethroids in addition to CLint, critical determinants of pyrethroid target organ concentration include absorption/metabolism in the G.I. tract, and partitioning into and metabolism in the brain. (SJG was funded by NHEERL-DESE, USEPA CT826513. This abstract does not represent EPA policy)

ROUTE-TO-ROUTE EXTRAPOLATION OF METABOLIC  
INTERACTIONS IN MIXTURES OF ALKYLBENZENES  
USING A PBPK MODEL.

R. Tardif, A. Nong and K. Krishnan. *Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada.*

PBPK models facilitate the conduct of route-to-route extrapolation of the extent of metabolism and tissue dose of chemicals. This aspect of the PBPK models has not been particularly well explored with chemical mixtures. The objective of this work was to evaluate the extent and consequence of competitive metabolic interactions in a ternary mixture of alkylbenzenes (toluene (T), m-xylene (X), and ethyl benzene (E)) following dermal, inhalation and oral routes of exposure considered individually or together. A previously validated human PBPK model for TEX mixture was used to simulate the area under the venous blood vs time curve (AUC) as well as the amount metabolized of each mixture component. The AUC associated with inhalation exposure (7 hr) increased from 1.1, 4.2 and 3.1 mg/L.hr to 1.3, 4.6 and 4.3 mg/L.hr, respectively for T (17 ppm), E (33 ppm) and X (33 ppm) due to interactions. Based on equivalent 24 hr AUCs, oral doses of 2.2, 4.8, and 4.6 mg/kg of T, E and X were calculated to be equivalent to the above inhalation exposures. At these oral doses, the AUCs of T, E and X were altered from 1.1, 4.2, and 3.1 mg/L.hr to 1.6, 5.3, and 4.9 mg/L.hr due to interactions during mixed exposures. Dermal exposure to TEX vapors at the same atmospheric concentrations as the inhalation study did not result in any significant metabolic interactions. In fact, further simulations indicated that the impact of interaction on AUC would be negligible following dermal exposures, at levels below the saturable vapor concentrations of TEX. The multiroute human PBPK model for TEX was then applied to simulate the pharmacokinetics of T, E and X for various exposure scenarios (inhalation and dermal exposure, inhalation and oral exposure, and all three routes of exposures together). This study demonstrates the unique usefulness of PBPK models in predicting tissue dose of mixture components during multimedia and multiroute exposures, on the basis interaction mechanism evaluated following a single route of exposure.

A PBPK MODEL FOR A MIXTURE OF DIOXIN-LIKE  
CHEMICALS.

M. Easterling<sup>1</sup>, N. J. Walker<sup>2</sup>, F. M. Parham<sup>2</sup> and C. J. Portier<sup>2</sup>. <sup>1</sup>Constella Group, Durham, NC and <sup>2</sup>NIEHS, Durham, NC.

A physiologically based pharmacokinetic (PBPK) model for TCDD was used as the framework for models of TCDD, PCB126, PeCDF, and a mixture of these three chemicals. A goal was to assess how a model developed specifically for TCDD

would serve as a general Ah receptor model for individual dioxin-like chemicals as well as a mixture of dioxin-like chemicals. The model builds on previous TCDD models by linking P450s to measured activity (EROD, A4H). The model structure is the same for each chemical while parameters related to binding, metabolism, cytotoxicity, and absorption vary by chemical. The mixture model links the individual chemicals by competitive binding to the Ah receptor and CYP1A2. The National Toxicology Program (NTP) chronic bioassay data includes lung, liver, blood and fat concentrations as well as EROD and A4H activity. The individual chemical models were fit to the NTP data. The fit parameters were used in the mixture model to make predictions to compare with mixture data. The predictions for fat and liver concentration are very good, while the predictions of the other data are reasonable. The results suggest areas to further refine a general Ah receptor PBPK model.

A HUMAN PBTK MODEL DESCRIBING ACETONE  
KINETICS IN BREATH AND BLOOD AT DIFFERENT  
WORKLOADS.

A. Mork and G. Johanson. *Work Environment Toxicology, Karolinska Institute, Stockholm, Sweden.*

Typically, human PBTK models are developed by scaling animal PBTK models to man, based on animal and, at best, human blood data. We have over several years measured solvents in blood, breath and urine sampled from human volunteers. PBTK modeling of these data suggests difficulties to simultaneously describe the time courses of solvent in blood and breath. We attribute this to a washin-washout effect in the airways, an effect that may lead to erroneous exposure and risk estimates. The aim of this study was to develop a PBTK model that correctly describes blood, mixed-exhaled and end-exhaled breath acetone levels in humans experimentally exposed to acetone vapors at various workloads. A series of previously published 26 controlled exposures to acetone (Wigaeus et al 1983, Ernstgard et al 1999) in 18 male volunteers were used as a starting point. The exposures were carried out at rest and various levels of exercise (50, 100, 150 W) and pulmonary ventilation was measured. Arterial, venous and arterialized capillary blood and end- and mixed-exhaled air was analyzed for acetone. A PBPK model was developed in Berkeley Madonna based on previously published ones (Kumagai and Matsunaga 1995, Clewell et al 2001). These models include a mucous compartment to account for washin-washout in the airways. Both previous models were unable to simultaneously predict the experimental blood and end-exhaled and mixed-exhaled breath levels. No improvement was achieved by deleting the mucous compartment while freely adjusting alveolar ventilation. In contrast, a good fit to all experiments was achieved by setting the mucous clearance proportional to, rather than independent of, pulmonary ventilation. This exercise suggests that (1) washin-washout phenomena affects the kinetic behaviour of acetone considerably and (2) an adequately designed mucous compartment in the airways may be used to describe the blood and breath kinetics also at elevated workloads (supported by grants from the Swedish council for working life and social research).

EVALUATION OF ORAL AND INTRAVENOUS ROUTE  
PHARMACOKINETICS, PLASMA PROTEIN BINDING  
AND UTERINE TISSUE DOSE METRICS OF BISPHENOL  
A: A PHYSIOLOGICALLY BASED PHARMACOKINETIC  
APPROACH.

J. G. Teeguarden<sup>1</sup>, J. M. Waechter<sup>3</sup>, H. J. Clewell<sup>2</sup>, T. R. Covington<sup>2</sup> and H. A. Barton<sup>4</sup>. <sup>1</sup>Biological Monitoring and Modeling, Pacific Northwest National Laboratory, Richland, WA, <sup>2</sup>ENVIRON International, Ruston, LA, <sup>3</sup>The Dow Chemical Company, Midland, MI and <sup>4</sup>NHEERL, USEPA, Research Triangle Park, NC.

Bisphenol A (BPA) is a weakly estrogenic monomer used in the production of polycarbonate plastics and epoxy resins. A physiologically based pharmacokinetic (PBPK) model of BPA pharmacokinetics in rats and humans was developed to provide a physiological context in which the processes controlling BPA pharmacokinetics (e.g. plasma protein binding, enterohepatic recirculation of the glucuronide (BPAG)) could be incorporated. A uterine tissue compartment was included to allow the correlation of simulated ER binding of BPA with increases in uterine wet weight (UWW) in rats. Intravenous and oral-route blood kinetics of BPA in rats and oral-route plasma and urinary elimination kinetics in humans were well described by the model. Simulations of rat oral-route BPAG pharmacokinetics were less exact, most likely the result of over simplification of the GI tract compartment. Comparison of metabolic clearance rates derived from fitting rat i.v. and oral-route data implied that intestinal glucuronidation of BPA is significant. In rats but not humans, terminal elimination rates were strongly influenced by enterohepatic recirculation. In the absence of BPA binding to plasma proteins, high ER occupancy was predicted at doses without uterine effects. Restricting free BPA to the measured unbound amount demonstrated the importance of including plasma binding in BPA kinetic models. The relationship between ER occupancy and UWW increases

fit expectations for a receptor mediated response with low ER occupancy at doses with no response and increasing occupancy with larger increases in UWW. (This abstract does not necessarily reflect USEPA policy.)

#### LACK OF BIOACCUMULATION WITH REPEATED, PERIODIC EXPOSURES OF CYCLIC SILOXANES.

M. E. Andersen<sup>1</sup>, M. B. Reddy<sup>2</sup> and K. P. Plotzke<sup>3</sup>. <sup>1</sup>*CIIT, Research Triangle Park, NC*, <sup>2</sup>*Colorado State University, Fort Collins, CO* and <sup>3</sup>*Dow Corning Corporation, Midland, MI*.

Cyclic siloxanes, such as octamethylcyclotetrasiloxane (D4) and decamethylcyclotetrasiloxane (D5), have uses in a variety of consumer products. These siloxanes have unusual physical properties that make them attractive for their specific applications and give rise to novel pharmacokinetic properties. D4 and D5 have moderate volatility, high lipophilicity, and are cleared from the circulation by exhalation and methyl-group oxidation. High lipophilicity (fat:blood partition coefficients in the 1000 to 2000 range) typically leads to concern for bioaccumulation. Multi-dose route, multi-species physiologically based pharmacokinetic (PBPK) models for D4 and D5 have integrated physical chemical, metabolic and partitioning information to provide an understanding of the expected time course concentrations of D4 and D5 in tissues, including fat, during various usage scenarios. We simplified these models to evaluate time course plasma and fat concentrations during periodic daily exposures, likely to occur with low level exposures to consumers. The model was calibrated with blood and tissue concentrations in rats arising from 6 hr/day exposures of various durations of, 1 day, 14 day, and 6 months. The model had a central compartment with first-order metabolic clearance and either a single or two fat compartments that had variable diffusion-limitations for uptake. The fat concentrations at steady state were equal to the steady-state concentrations expected for a continuous exposure times the ratio of the daily exposure duration/24 hours. The approach to steady state and persistence after cessation for all exposure scenarios depended on the characteristic diffusional clearance from the deeper fat compartment. These siloxanes, despite high lipophilicity, do not bioaccumulate because they are rapidly cleared by exhalation and metabolism.

856

#### IMPACT OF MODEL MISSPECIFICATION ON A PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR DMA.

C. R. Eklund, M. V. Evans and E. M. Kenyon. *ORD/NHEERL/ETD, U. S. EPA, Research Triangle Park, NC*.

Inorganic arsenic in drinking water and organic arsenic used as herbicides both pose health risks. Using experimental data, a Physiologically Based Pharmacokinetic (PBPK) modeling has been applied to dimethylarsinic acid (DMA) in order to quantify dose metrics associated with health effects. A nine compartment intravenous PBPK model (venous, lung, lung blood, skin, kidney, urine, bladder, liver, and rest-of-body) was developed for mice that can be extrapolated to humans. This work describes part of the process of model development, and potential errors that can arise. To describe the pharmacokinetics, we initially assumed the simplest case, blood flow-limited distribution in every organ. However, this type of mathematical description was incomplete in that the amounts of DMA in the organs exceeded the dose. After examining the assumptions used for the lung, we decided that the blood flow-limited case was inappropriate for this organ. When we added membrane-limited terms to the lung blood equation, we could then account for lung tissue accumulation. Since the lung is a target organ, we wanted to ensure that we were describing accumulation correctly. The next organ to be described mathematically was the kidney. The fits obtained assuming zero order transport through the glomerular capsule were not satisfactory. An additional improvement included in the model is a saturable mechanism for the clearance of DMA in the kidney. In summary, this model describes the inclusion of more complex descriptions of the lung and kidney, resulting in a combination of different approaches used in PBPK modeling. (This abstract does not reflect EPA policy).

#### HUMAN PBPK MODELING OF CLINICAL CASE REPORTS OF ETHYLENE GLYCOL OVERDOSING: INCORPORATION OF THERAPEUTIC INTERVENTIONS.

R. A. Corley<sup>1</sup> and K. E. McMurtin<sup>2</sup>. <sup>1</sup>*Battelle Northwest, Richland, WA* and <sup>2</sup>*Louisiana State University Health Sciences Center, Shreveport, LA*.

The acute toxicity of ethylene glycol (EG) in humans and animals can proceed through three stages, each associated with a different metabolite: central nervous system depression (EG), cardiopulmonary effects associated with metabolic acidosis (glycolic acid; GA) and ultimately renal toxicity (oxalic acid; OX), depending upon

the total amount consumed and effectiveness of therapeutic interventions. A recently developed PBPK model for rats and humans was refined to include clinically relevant treatment regimens for EG poisoning such as hemodialysis and metabolic inhibition with ethanol or fomepizole. These modifications enabled the model to describe several human case reports which included analysis of EG and/or GA in blood or urine. Such data and model simulations provide important confirmation that the previously developed PBPK model can adequately describe the pharmacokinetics of EG in humans following low, occupational or environmentally relevant inhalation exposures, as well as after massive oral doses, even under conditions where treatments have been employed that markedly affect the disposition of ethylene glycol and glycolic acid. By integrating the case report data sets with controlled studies in this PBPK model, it was demonstrated that fomepizole, if administered early enough in a clinical situation, can be more effective than ethanol or hemodialysis in preventing the metabolism of ethylene glycol to more toxic metabolites. Hemodialysis remains an important option, however, if treatment is instituted after a significant amount of EG is metabolized or if renal toxicity has occurred. (Sponsored by the Ethylene Glycol Panel of the American Chemistry Council).

#### DEVELOPMENT OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODEL TO COMPARE DIFFERENCES IN DISPOSITION OF TRICHLOROETHYLENE(TCE), AND METABOLITES IN ADULT VERSUS ELDERLY RATS.

M. V. Evans<sup>1</sup>, R. Tornero-Velez<sup>2</sup>, M. J. DeVito<sup>2</sup>, M. Okino<sup>3</sup>, A. Geller<sup>2</sup>, J. Blancato<sup>2</sup> and L. Birnbaum<sup>2</sup>. <sup>1</sup>*USEPA/NHEERL, Research Triangle Park, NC*, <sup>2</sup>*USEPA/NERL, Research Triangle Park, NC* and <sup>3</sup>*USEPA/NERL, LV, NV*.

Due to the increasing number of elderly in the American Population, the question as to whether the aged have different susceptibility to environmental contaminants needs to be addressed. Physiologically based pharmacokinetic (PBPK) models are used to extrapolate between rodents (toxicological database) and humans. We used an established PBPK model for TCE, a common environmental contaminant. The PBPK comparisons were made in two different F344 rat age groups: 6 months and 2 years old. A single inhalation exposure of 100 ppm for 1 hour was simulated as the basis for the comparison. The compartments evaluated were: brain, lung, adipose, kidney, liver, rapidly perfused and slowly perfused tissues. Both organ flow and organ size changes were examined. The metabolic scheme involved P450 oxidation of the parent TCE to both trichloroethanol (TCOH) and trichloroacetic acid (TCA). TCOH was further metabolized to TCA, and glucuronidated trichloroethanol(TCOG) for excretion by the kidneys. Acute neurotoxicity is related to the parent chemical concentration present in the brain, while chronic nephrotoxicity is related to TCOG in the kidneys. Simulation results show no differences in the concentration of TCE present in the brain for the two ages studied. There were obvious differences between ages in the time course of TCOG excretion, both at the early part of the time course and for the steady state component. In comparison to the young, the amount of TCOG excreted by the kidney in elderly rats was decreased by 12%, 24 hours after exposure. After repeating a second 1 hour exposure, the differences between the adult and elderly simulations were more obvious. In summary, the PBPK modeling results suggest that metabolite amount excreted may be different in the elderly, and that PBPK modeling should play a role in predicting potential experiments needed to confirm these predictions. (This abstract does not reflect EPA policy).

859

#### A PBPK MODEL TO EVALUATE VARIABILITY IN RENAL CLEARANCE.

R. S. DeWoskin<sup>1</sup> and C. M. Thompson<sup>2</sup>. <sup>1</sup>*ORD/NCEA, USEPA, Research Triangle Park, NC* and <sup>2</sup>*Risk Policy Fellow / NCEA, AAAS, Washington, DC*.

A PBPK model was developed to better characterize human variability in renal clearance, and its contribution to overall variability in chemical disposition. Renal clearance is a function of filtration and secretion from the arteriolar circulation, minus reabsorption. Variability in renal clearance is relatively low in healthy adults due to the kidney's autoregulation of filtration and reabsorption, and its large functional reserve capacity. Based on recent data for clearance rates of various pharmaceuticals in healthy adults (Dorne et al. 2003), an adjustment factor of 1.8 times the mean accounted for 99 percent of the variability in renal clearance. This suggests that the standard default adjustment factor of 3.16, which is used in EPA's RfD/RfC process for intrahuman variability in pharmacokinetics, is adequate for renal clearance, although the default factor must also account for other kinetic processes including absorption and metabolism. The question arises as to how variability in renal clearance might increase when subpopulations are considered such as the aged, developmentally immature (neonates), or diseased individuals; or when a nephrotoxin compromises renal function. As a first step in evaluating variability

in renal clearance for subpopulations or nephrotoxicity, the renal compartment typical of most PBPK models was expanded to include terms for glomerular filtration and reabsorption, as well as simplified representations of kidney feedback controls based upon target levels of sodium and glucose in plasma and filtrate, and target levels for plasma and urine volume. Secretion is modeled as a first order elimination of free chemical (organic acids or bases) from plasma. Using this approach, the PBPK model provides a reasonably good simulation of normal adult renal clearance and response to perturbation. The next step is to apply the model to evaluate variability in chemical specific renal clearance due to reductions in filtration, reabsorption, or secretion, or reduced ability to maintain homeostatic control. [This abstract does not necessarily reflect EPA policy.]

## 860 DEVELOPMENT OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR SCH-D IN THE RAT.

G. Pastino<sup>1</sup>, C. Rosenfeld<sup>1,2</sup>, C. Cox<sup>1</sup>, I. Knemeyer<sup>1</sup>, K. Fellows<sup>1</sup> and L. Sulfato<sup>2</sup>. <sup>1</sup>Schering Plough research Institute, Lafayette, NJ and <sup>2</sup>University of Medicine and Dentistry of New Jersey, Newark, NJ.

SCH-D, a CCR-5 receptor antagonist, is currently in development for the treatment of HIV and will be used in combination with several other anti-viral drugs. The possibility of pharmacokinetic and metabolic interactions exists as many of these compounds either inhibit or induce the enzymes responsible for the metabolism of SCH-D. In an effort to assess the other medications on the pharmacokinetic profile of SCH-D, a physiologically based pharmacokinetic model for SCH-D was developed in the rat. Compartments for this model included the brain, kidney, liver, fat, and rapidly perfused and slowly perfused. Pharmacokinetic data, including SCH-D plasma concentration-time profiles following both oral and iv administration, and SCH-D urinary excretion data, were used to estimate the oral absorption (KA), metabolic (KMET) and urinary excretion (KEX) rate constants. The data used for the pharmacokinetic analysis had been previously collected as part of the preclinical development program for SCH-D. The only data that was not already available were the SCH-D tissue:blood partition coefficients, which were determined using equilibrium dialysis. The model was validated against single and multiple dose toxicokinetic data that were also available. Application of the model indicated that following a single oral administration of 10 mg/kg peak SCH-D plasma concentrations increased by 12% when hepatic metabolism (Kmet) was reduced by half and decreased 19% when hepatic metabolism was doubled. In addition, the SCH-D plasma AUC(0-24 hr) increased 35% when hepatic metabolism was reduced by half and decreased by 43% when hepatic metabolism was doubled. This model represents the initial step in the development of a PBPK model for SCH-D in humans that will be used to more fully characterize potential pharmacokinetic and metabolic interactions between SCH-D and other anti-retroviral drugs.

## 861 PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR ALL-TRANS RETINOIC ACID IN PREGNANT CD-1 MICE.

J. L. Campbell<sup>1</sup>, D. Warren<sup>2</sup>, M. Smith<sup>1</sup> and J. W. Fisher<sup>1</sup>. <sup>1</sup>Environmental Health Science, University of Georgia, Athens, GA and <sup>2</sup>Program in Environmental Science, University of South Carolina-Beaufort, Beaufort, SC.

all-trans Retinoic acid (RA) is a well documented teratogen in laboratory animals as well as humans. When administered to mice on gestation day 11 (GD-11), RA causes severe alterations in fetal forelimbs and cleft palate. A nine compartment physiologically-based pharmacokinetic model (PBPK) for RA and a 4 compartment PBPK model for its metabolite, the 13-cis retinoic acid (13-cis RA) isomer, are under development to describe the uptake, fetal transfer, and systemic clearance of RA in the pregnant CD-1 mouse on GD 11. This model was adapted from a previously published RA model (Clewel, 1997) to include endogenous production of RA and induction of RA metabolism in the maternal liver. Maternal blood and fetal tissue kinetic data was collected from pregnant CD-1 mice on GD 11 after a single oral bolus dose (10, 30, 60, and 100 mg/kg) of RA suspended in soybean oil. Analysis of tissues and blood was by HPLC for RA and 13-cis retinoic acid (13-cis RA). The systemic clearance of RA by metabolism was described by two metabolic pathways; isomerization to 13-cis RA and a composite pathway representing both p450 and glucuronidation metabolic pathways. Placental transfer of RA and 13-cis RA to the fetal compartment were described as diffusion limited. Metabolism of 13-cis RA was described as a composite pathway including p450 and glucuronidation. To obtain adequate fits to the kinetic data the composite metabolic pathway for RA was assumed to be induced 5 fold by 4 hours after dosing. Diffusion limited transfer of RA and 13-cis RA to the embryo were also well described by the model for all doses tested. Dose-response analyses are ongoing to determine the relationship between fetal exposure and incidence or severity of malformation.

## 862 PREDICTION OF DI-N-BUTYLPHthalate (DBP) LEVELS IN PREGNANT RATS USING A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODEL.

J. J. Kremer, R. A. Clewell and S. J. Borghoff. CIIT Centers for Health Research, Research Triangle Park, NC.

DBP is a widely used phthalic acid ester and a reproductive toxicant. The monoester metabolite monobutyl phthalate (MBP) is the primary circulating form in rodents and is responsible for the adverse effects from DBP exposure. We previously developed a PBPK model to predict MBP levels in maternal and fetal rats during reproductive development (gestation days GD12-20). Physiological and chemical-specific parameters were obtained from peer-reviewed literature or fitted to data. Metabolism of DBP to MBP was modeled to occur in the gastrointestinal (GI) tract. Subsequent uptake of MBP, but not DBP, from GI was calculated using a first-order rate constant. Metabolism of MBP to MBP-glucuronide (MBP-G) occurs in liver and was modeled using Michaelis-Menten kinetics. Model predictions were compared to *in vivo* data from published studies that utilized oral dosing of DBP. This preliminary model predicted MBP levels qualitatively, but not quantitatively, primarily due to a lack of data on metabolism of MBP to MBP-G. To address this gap, we measured MBP and MBP-G levels in pregnant rats on GD19 following MBP intravenous (iv) administration. MBP to MBP-G metabolic parameters were fit to MBP plasma data following iv doses of 10, 30, and 60 mg/kg MBP. Our PBPK model was revised to incorporate these improved metabolic parameters and expanded to predict MBP-G levels after we observed that MBP-G accumulated in the fetus and amniotic fluid. The revised model effectively predicted initial MBP and MBP-G distribution and clearance but still underpredicted MBP and MBP-G levels at later time points. Sensitivity analysis indicated that maternal MBP levels were affected by the rate of uptake from GI; fetal plasma MBP and MBP-G levels were affected by placental diffusion and placenta-to-blood partition coefficient. This quantitative description of the critical determinants of MBP dosimetry and transport of MBP and MBP-G to the developing fetus will enable a better assessment of potential risks from DBP exposure.

## 863 PULMONARY FUNCTION IN RATS DURING PREGNANCY.

T. Leavens, C. Parkinson, A. James, D. House and D. Dorman. CIIT Centers for Health Research, Research Triangle Park, NC.

Minute ventilation and tidal volume increase in humans during pregnancy. Currently little data exists on pulmonary function in rats during pregnancy, an animal model often used for developmental studies. Respiration will affect the pharmacokinetics of volatile compounds, and accurate estimates of minute ventilation will improve physiologically based pharmacokinetic models that predict target tissue concentrations for extrapolation to human exposure scenarios. We conducted a longitudinal study to evaluate pulmonary function in rats during pregnancy. Whole-body plethysmography was used to measure the breathing frequency, tidal volume, and minute ventilation approximately every other day from gestation day (GD) 1 to 21 in 8 timed pregnant and 8 nonpregnant female, Sprague-Dawley rats. Scaled minute ventilation was calculated from the minute ventilation and body weight of each rat. Multivariate analysis of variance methods for a repeated measures design were used to analyze the collected data. On GD 1, breathing frequency, tidal volume, minute ventilation, and scaled ventilation were  $97 \pm 2.7$  bpm,  $1.46 \pm 0.06$  ml,  $139 \pm 4.9$  ml/min, and  $34.1 \pm 1.2$  L/hr/kg for pregnant rats, and  $96 \pm 4.7$  bpm,  $1.42 \pm 0.04$  ml,  $134 \pm 5.5$  ml/min, and  $35.3 \pm 1.3$  L/h/kg for nonpregnant rats. On GD 21, breathing frequency, tidal volume, minute ventilation, and scaled ventilation were  $106 \pm 4.7$  bpm,  $1.95 \pm 0.06$  ml,  $204 \pm 12.4$  ml/min, and  $29.4 \pm 1.7$  L/hr/kg for pregnant rats, and  $92 \pm 4.7$  bpm,  $1.75 \pm 0.08$  ml,  $157 \pm 10.9$  ml/min, and  $36.3 \pm 2.2$  L/hr/kg for nonpregnant rats. Tidal volume was not significantly different between the two groups. Minute ventilation was significantly greater in pregnant rats compared to nonpregnant rats. The scaled ventilation was significantly lower in pregnant rats compared to nonpregnant rats due to the significantly greater body weight of the pregnant rats. This study provides important reference values to be used in pharmacokinetic models during pregnancy.

## 864 A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODEL FOR THE PESTICIDE MONOMETHYLARSONIC ACID (MMA<sup>V</sup>).

E. M. Kenyon, M. F. Hughes, C. Eklund and M. V. Evans. USEPA, Research Triangle Park, NC.

The monosodium salt of monomethylarsonic acid [MMA(V)] is a widely used organoarsenical herbicide. In lifetime feeding studies with MMA(V), the large intestine (focal mucosal ulceration) was the primary target organ in both male and female mice and rats and no treatment-related neoplastic effects were reported. We

have developed a PBPK model to describe the target tissue dosimetry of MMA in mice that can be extrapolated to humans for ultimate use in risk assessment. The model consists of two separate submodels (for mono- and di-methylated arsenic) linked by methylation in liver; tissue compartments include arterial and venous blood, gastrointestinal tissue, liver, lung, kidney, urinary bladder, skin and residual tissue. Chemical specific parameters for partition coefficients, gastrointestinal absorption, methylation in liver and urinary elimination were estimated using oral and i.v. kinetic data from our studies of MMA(V) and dimethylarsinic acid [DMA(V)] in mice. In general distribution into tissues was modeled assuming blood flow limited kinetics in plasma. Good visual fits were obtained for much of the data used to evaluate the model; however, kidney was often a notable exception, although fits to urinary clearance data were generally quite good. Sensitivity analysis suggests that parameters governing uptake into the kidney are highly influential for both kidney concentration and urinary clearance. This points to the need to further understand and evaluate mechanisms of renal uptake and elimination. (This abstract does not necessarily reflect EPA policy.)

865

#### DEVELOPMENT OF A HYBRID REACTION NETWORK PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL OF BENZO(A)PYRENE AND ITS METABOLITES.

K. F. Reardon<sup>1,2</sup>, K. H. Liao<sup>1,2</sup> and R. S. Yang<sup>1</sup>. <sup>1</sup>Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Colorado State University, Fort Collins, CO and <sup>2</sup>Department of Chemical Engineering, Colorado State University, Fort Collins, CO.

PBPK modeling of mixtures is challenging in part because it requires information not only on the parent chemicals but also on any important metabolites. Such data are rarely available. To address this problem, Reaction Network (RN) modeling was used to describe the mammalian metabolism of benzo[a]pyrene (BaP), a priority environmental carcinogen. A RN model generates the reaction pathways automatically based on the chemical structures of the parent compounds and reaction rules. We have linked a RN model with a PBPK model to describe the distribution and disposition of BaP and seven of its metabolites. In the hybrid RN/PBPK model, BaP metabolism in the lung and liver was described by a RN model for BaP, in which the kinetics parameters were estimated using *in vitro* experiments with rat liver microsomes. In these *in vitro* studies, time-course profiles of BaP and 11 of its metabolites were measured using HPLC methods. The RN/PBPK model for BaP and its metabolites were calibrated using pharmacokinetics data from rats following intratracheal exposure to BaP (*Cancer Res*, 46:5655, 1986). Validation of the RN/PBPK model for BaP was performed using two different data sets in rats with intravenous (*Cancer Res*, 30:2893, 1970) and intraarterial (*J Pharmacol Exp Ther*, 226:661, 1983) exposure to BaP. The quality of the RN/PBPK model prediction demonstrates its ability to extrapolate from one dosing route to another and from low dose to high dose. The major advantages of applying RN/PBPK modeling to study toxicology are: (1) their capabilities of handling complex metabolic systems involving chemical mixtures; (2) their potential for predicting reaction networks of chemicals with limited knowledge on their metabolic pathways; and (3) their abilities to predict the reactive intermediates that are not readily measurable in experiments. (Supported by NIEHS Grant R01 ES09655).

866

#### VALIDATION OF A HUMAN PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR VINYL ACETATE AGAINST HUMAN NASAL DOSIMETRY DATA.

P. M. Hinderliter<sup>1</sup>, K. D. Thrall<sup>2</sup>, R. A. Corley<sup>2</sup>, L. J. Bloemen<sup>3</sup> and B. S. Matthew<sup>1</sup>. <sup>1</sup>Haskell Laboratory for Health and Environmental Sciences, Newark, DE, <sup>2</sup>Biological Sciences Division, Battelle Pacific Northwest Laboratories, Richland, WA and <sup>3</sup>Epidemiology, Health Services, Dow Benelux NV, Terneuzen, Netherlands.

Vinyl acetate has been shown to induce nasal lesions in rodents in inhalation bioassays. A physiologically-based pharmacokinetic (PBPK) model has been used in human vinyl acetate risk assessment but has only previously been validated in rats. To provide validation data for the application of the model in humans, controlled human exposures to vinyl acetate were conducted. Air was sampled by a probe inserted into the nasopharyngeal region of five volunteers. Sampling was carried out during exposure to labeled <sup>13</sup>C<sub>1</sub>, <sup>13</sup>C<sub>2</sub> vinyl acetate during resting and light exercise. Both <sup>13</sup>C<sub>1</sub>, <sup>13</sup>C<sub>2</sub> vinyl acetate and the major metabolite <sup>13</sup>C<sub>1</sub>, <sup>13</sup>C<sub>2</sub> acetaldehyde from the nasopharyngeal region were analyzed in real time utilizing ion trap mass spectrometry (MS/MS). Experimentally determined concentrations of both vinyl acetate and acetaldehyde were then compared to predictions calculated by applying the previously published human model. Model predictions of vinyl acetate nasal extraction compared favorably with measured values of vinyl acetate as did predictions of nasopharyngeal acetaldehyde when compared to measured acetaldehyde. The results showed that the current PBPK model structure and parameterization is appropriate for vinyl acetate. These analyses were conducted from 1 to 10 ppm

vinyl acetate, a range relevant to workplace exposure standards but which would not be expected to saturate vinyl acetate metabolism at low concentrations. A risk assessment based on this model further concluded that 24 hour per day exposures up to 1 ppm do not present concern on cancer or non-cancer toxicity. Validation of the vinyl acetate human PBPK model provides support to these conclusions.

867

#### DEVELOPMENT AND EVALUATION OF A PBPK MODEL FOR THE FATE OF 2-BUTOXYETHANOL IN HUMANS AFTER DERMAL AND INHALATION EXPOSURE.

S. kezic, J. Kruse and I. Jakasa. *Coronel Institute, Academic Medical Centre, Amsterdam, Netherlands*. Sponsor: P. Boogaard.

The objective of this study was the development of a PBPK model to describe the disposition of butoxyethanol (BE) in blood and its main metabolite 2-butoxyacetic acid in urine (BAA) after exposure to BE by inhalation and via the skin. An existing PBPK model for 2-butoxyethanol (Corley, 1994) was implemented and validated with published information and with experimental data obtained in human volunteers who were exposed by inhalation. In this PBPK model a detailed module for systemic uptake of substances via the skin (Kruse et al., 2004) was incorporated. The modeling of dermal permeation was achieved by the use of a multi-compartment model (vehicle, stratum corneum and viable epidermis) and systemic compartment. In the skin module the mass transport through the skin is determined by the thickness of the different layers in the skin and by substance related partition and diffusion coefficients. In a series of experiments the skin of human volunteers was exposed to vaporous BE and aqueous solutions of BE (50-90% w/w) and the resulting time courses of the BE concentrations in blood (during 8 hours) and the excretion rates of BAA in urine (up to 48 hours) were determined. These data were used for the fitting of the skin model in order to assign values to parameters of the model such as partition coefficient and diffusion coefficient. This was both done via a deconvolution method using the systemic response of a reference exposure via inhalation, and by direct fitting of the concentration time courses after dermal exposure using the PBPK model. The results of the two approaches were compared. In conclusion, a refined PBPK model for BE, including a mechanistic module for skin permeation was presented. The model is particularly well suited to simulate the time courses of BE in blood and BAA in urine following a variety of occupational scenarios including exposure via inhalation and/or dermal exposure to vapors or aqueous solution of BE.

868

#### PHYSIOLOGICAL MODELING OF THE TOXICOKINETICS OF METHYL TERT-BUTYL ETHER (MTBE) AND ITS METABOLITE TERT-BUTANOL (TBA) IN HUMANS.

K. Krishnan<sup>1,3</sup>, A. Nihlen<sup>2</sup>, L. Ernstgard<sup>3</sup> and G. Johanson<sup>3</sup>. <sup>1</sup>Universite de Montreal, Montreal, QC, Canada, <sup>2</sup>Active Biotech Research AB, Lund, Sweden and <sup>3</sup>Work Environment Toxicology, Karolinska Institute, Stockholm, Sweden.

MTBE, an oxygenated gasoline additive, has been investigated by several investigators for its pharmacokinetic behavior and toxicity. Animal and human PBPK models for MTBE have also been developed. The existing human PBPK models neither describe the kinetics of the oxidative metabolite (TBA) nor the kinetics of MTBE itself in exercising individuals, typical in work environments. The objective of this study was therefore to develop a physiologically-based (PB) model for simulating the toxicokinetics (TK) of MTBE and TBA in human volunteers performing workload (50 W). The PBTK model consists of five tissue compartments (liver, fat, richly perfused tissues, working muscle and resting muscle) interconnected by systemic circulation. The alveolar ventilation rate, cardiac output, and blood flows to tissues were calculated as a function of the workload exercised by exposed individuals. The human blood:air (17.7) and tissue:air (liver and richly perfused tissues 1.04, fat 5, and muscle 1.18) partition coefficients for the MTBE model were obtained from a previously published experimental study. The kinetics of TBA was simulated using a single compartment model, in which the volume of distribution was approximated to the body weight and the rate of elimination was described as a first order process. The integrated MTBE-TBA model, with its metabolism parameters estimated from the blood concentration vs time profile previously collected in human volunteers exposed for 2 hr to 5, 25 and 50 ppm (50 W workload), adequately described the whole dataset. Model simulations, consistent with the experimental data, indicate linearity in the range of these exposure concentrations and an intermediate hepatic metabolism. The toxicokinetic model developed in this study should be useful as a tool for interpreting the blood concentrations of MTBE and TBA in workers and general population. (Partially supported by Swedish council for working life and social research)

## A HUMAN DIETARY IODIDE PBPK MODEL TO EVALUATE THE EFFECTS OF PERCHLORATE ON THYROIDAL IODIDE CONTENT.

J. W. Fisher<sup>1</sup>, J. L. Campbell<sup>1</sup> and D. Guth<sup>2</sup>. <sup>1</sup>*Environmental Health Science, University of Georgia, Athens GA, GA* and <sup>2</sup>*The Boeing Company, Seattle, WA*.

Perchlorate is an environmental contaminant that is known to act on the thyroid by blocking radiolabeled iodide uptake into the thyroid gland in laboratory animals and humans. Thyroid function has been clearly altered in laboratory animals administered perchlorate, but not in humans. The objective of this research was to construct a dietary iodide PBPK model for the adult human to explore under what conditions perchlorate exposure would be predicted to deplete the thyroidal iodide stores (thyroid hormones) sufficiently to alter thyroid function. A human physiologically based pharmacokinetic (PBPK) model of thyroid hormone production and metabolism was constructed and adapted to an existing PBPK model for perchlorate and radiolabeled iodide (Merrill et al., 2004). The dietary iodide model accounts for a range of iodide diets and includes autoregulation of iodide uptake by the thyroid gland. Under brief perchlorate exposure conditions, such as those of Greer et al. (2002) (500, 100, 20 and 7 ug/kg/day oral administration for 14 days), perchlorate was not predicted to deplete thyroid iodide stores sufficiently to alter thyroid function. If a chronic exposure (years) to perchlorate occurs at these doses, the dietary iodide model predicts that the 100 and 500 ug/kg/day doses would cause depletion of thyroidal iodide stores sufficient to alter thyroid function (increase blood TSH levels in response to a decline in thyroid hormone production). For the two lower doses of perchlorate (7 and 20 ug/kg/day) the PBPK iodide model predicts that thyroid function would not be altered. This dietary iodide PBPK model can assist in policy decisions regarding public health issues with perchlorate in water supplies. The PBPK model for iodide and perchlorate forecasts that chronic exposure to 7 ug/kg day (245 ug/L for a 70 kg person) will not alter thyroid function in the adult euthyroid human.

## USE OF A PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL TO ESTIMATE ABSORBED CARBARYL DOSE IN CHILDREN AFTER TURF APPLICATION.

M. Okino<sup>1</sup>, F. W. Power<sup>1</sup>, J. B. Knaak<sup>4</sup>, R. Tornero-Velez<sup>2</sup>, C. Lunchick<sup>5</sup>, A. Lowit<sup>3</sup>, J. N. Blancato<sup>2</sup> and C. C. Dary<sup>1</sup>. <sup>1</sup>*NERL/EDRB, USEPA, Las Vegas, NV*, <sup>2</sup>*NERL, USEPA, Research Triangle Park, NC*, <sup>3</sup>*Office of Pesticide Programs, USEPA, Washington, DC*, <sup>4</sup>*Pharmacology and Toxicology, SUNY, Buffalo, Buffalo, NY* and <sup>5</sup>*Bayer CropScience, Research Triangle Park, NC*.

A physiologically based pharmacokinetic (PBPK) model was developed to investigate exposure scenarios of children to carbaryl following turf application. Physiological, pharmacokinetic and pharmacodynamic parameters describing the fate and effects of carbaryl in rats were scaled to establish the model structure for exposure to humans. Adjustments were made for differences in metabolism and physiology between children and adults. Michaelis-Menten kinetics were used to describe the metabolism of carbaryl to yield biomarkers of metabolism, including urinary 1-naphthol. Bimolecular rate constants,  $k_i$  (pM<sup>-1</sup> hr<sup>-1</sup>), were used to describe inhibition of acetylcholinesterase by the parent chemical. Rates for enzyme synthesis and reactivation were interposed within compartments to account for depletion of the enzymes. Exposure by hand-to-mouth activities for toddlers, and by dermal exposure for older children resulted in no observable cholinesterase inhibition (>99% of basal activity) in the brain and blood. Peak concentrations of carbaryl in the brain remained below the brain peaks observed in rats at the no observable adverse effect level (NOAEL) by an order-of-magnitude. Corresponding with the absorbed dose and subsequent distribution were the appearance of metabolite biomarkers in urine. Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

## ASSESSING THE RISKS ASSOCIATED WITH CHILDREN INGESTING LEAD IN SCHOOL DRINKING WATER: PBPK MODELING AND RISK COMMUNICATION.

M. K. Peterson, R. C. Pleus and S. M. Hays. *Intertox, Inc., Seattle, WA*.

Communities across the United States have become increasingly concerned about the many recent instances of lead being detected in school drinking water. Given lead's potential for developmental and behavioral toxicity at relatively low levels of exposure, concerns of parents, teachers, and administrators about the potential impact on children's health are understandable. Considering the uncertainties inherent in characterizing children's activity patterns as well as current regulatory debates about what levels of lead exposure are safe, effectively communicating the issues to various stakeholders can be a difficult process. We present the results of physiologically-based pharmacokinetic (PBPK) modeling (using the O'Flaherty model) conducted to predict blood lead levels and assess the risks to children exposed to lead in

school drinking water. This model was considered to be more appropriate for this exposure scenario than the traditional approach using the USEPA's Integrated Exposure and Uptake Biokinetic (IEUBK) Model for Lead in Children because of the episodic nature of the exposures, and allowed the calculation of incremental blood lead increases in any classroom with lead in drinking water sampling data. Our modeling illustrates that the for the school exposure scenarios evaluated, which included lead in drinking water concentrations of up to 1600 ppb (first-draw), virtually none would result in incremental elevations of blood lead greater than 3 micrograms per deciliter above blood lead levels associated with background exposures to lead. In addition to these data, we provide examples of effective risk communication materials and approaches used with various stakeholders, and an assessment of the scientific support for USEPA's action level of 20 ppb in school's drinking water.

## ENFUVIRTIDE DOES NOT IMPAIR HOST RESISTANCE TO INFECTIONS IN RATS.

T. D. Steele<sup>1</sup>, W. Geng<sup>1</sup>, F. Burleson<sup>2</sup> and G. Burleson<sup>2</sup>. <sup>1</sup>*Nonclinical Drug Safety, Hoffmann-LaRoche, Inc., Nutley, NJ* and <sup>2</sup>*Burleson Research Technologies, Raleigh, NC*.

Enfuvirtide (ENF; T-20; Fuzeon) is a 36-amino acid peptide effective for the treatment of advanced HIV. In clinical trials, an increased rate of bacterial pneumonia was observed in patients treated with ENF. To assess whether ENF can suppress immunity and increase susceptibility of an organism to pathogens, two *in vivo* host resistance assays were conducted in Fischer-344 (CDF) rats challenged with infections of either *Streptococcus pneumoniae* or influenza virus. Test doses were 0, 25, 50, and 125 mg/kg ENF given twice daily as a subcutaneous injection. In the *Streptococcus pneumoniae* study, animals were treated with enfuvirtide for 28 days, infected on day 29, and sacrificed at 1, 4, and 24 hours post-infection. In the influenza virus study, animals were treated for seven days prior to infection, and groups were sacrificed at several time points for up to 21 days while continuing enfuvirtide treatment. Groups were composed of 10 females per dose per sacrifice time point. Each study contained a positive control group. The primary endpoint for each study was clearance of the infectious agent. Toxicokinetics were conducted in satellite animals. Cytokines and influenza-specific immunoglobulin G responses were determined in the influenza study. Neither study revealed an immunosuppressive effect of enfuvirtide treatment as clearance of the infectious organism was not impaired in the enfuvirtide-treated rats. Marked impairment of clearance of the infectious agent was observed in animals treated with the positive control agents. Cytokine responses in the influenza study were somewhat variable, but did not suggest any clear treatment-related effects of ENF. Similarly, the IgG levels were not consistent with a treatment-related effect, as levels were lowest in the low-dose treatment group, but similar to or greater than vehicle-controls in the middle and high dose groups. Exposure to ENF was confirmed by the toxicokinetic analysis. In total, these results suggest that enfuvirtide is not immunotoxic in rat host resistance models.

## EFFECTS OF METHYLPREDNISOLONE ON CELL PHENOTYPES IN A MURINE CANDIDA HOST DEFENSE MODEL.

C. Maier, C. Genell, A. Hillegas and D. J. Herzyk. *Safety Assessment, GlaxoSmithKline, King of Prussia, PA*.

*Candida albicans* are dimorphic fungi that establish commensal relationships at mucosal surfaces of healthy individuals but have the potential to be pathogenic in immunocompromised hosts. The opportunistic feature of candidiasis and inclusive roles of different arms of the immune system in host defense makes this a compelling model for evaluating potential drug-dependent immunotoxicity. A murine host defense model, developed for evaluating innate and adaptive immunity by inoculating *C. albicans* intravenously (IV) or intramuscularly (IM), was used to measure changes in specific leukocyte subpopulations in the spleen and draining lymph nodes, respectively, by flow cytometry. Methylprednisolone was given as intraperitoneal injections at 25 mg/kg every other day to female CD1™ mice to determine the effects on the IV and IM candidiasis models. Treatment with methylprednisolone of mice inoculated with *C. albicans* IV resulted in decreased median survival time, body weight and lymphoid organ cellularity relative to control IV inoculated mice, indicating that overall host defense was impaired by this dosing regimen. Flow cytometric analysis of leukocyte subsets indicated changes in innate immune responses in mice given methylprednisolone as decreased absolute counts of MHC class II positive cells and decreased activation of neutrophils (decreased CD11b surface expression). Methylprednisolone-dependent changes in adaptive immune responses were observed in both IV and IM models as decreased lymphocyte (particularly CD4+ T cells and B cells) and dendritic cell counts in the draining lymphoid organs. Therefore, evaluation of the cellular signatures of normal immune responses to *C. albicans* infections can provide insight into the mechanisms of drug-induced impaired host defense.

AH RECEPTOR ACTIVATION ELEVATES INTERFERON GAMMA (IFN $\gamma$ ) AND INDUCIBLE NITRIC OXIDE SYNTHASE (iNOS) LEVELS IN THE LUNGS OF MICE INFECTED WITH INFLUENZA A VIRUS.

H. Neff-LaFord<sup>1</sup> and B. Lawrence<sup>2</sup>. <sup>1</sup>Pharmacology/Toxicology Graduate Program, Washington State University, Pullman, WA and <sup>2</sup>Pharmaceutical Sciences, Washington State University, Pullman, WA.

We have previously shown that exposure of mice to the Ah receptor (AhR) ligand 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) prior to infection with influenza A virus results in 4-fold higher levels of IFN $\gamma$  in the lung and decreases survival to an otherwise non-lethal infection. Using Ah receptor (AhR)-deficient mice, we show here that the AhR mediates the elevated IFN $\gamma$  levels in the lungs of infected mice. We also demonstrate that exposure to other AhR ligands, (polychlorinated biphenyl (PCB) 126, PCB 129 and tetrachloroazobenzene) enhances pulmonary IFN $\gamma$  levels in infected mice. These findings are significant because excessive IFN $\gamma$  production is associated with enhanced inflammation and severe tissue damage in many model systems. In addition to increasing pulmonary IFN $\gamma$  levels, exposure to TCDD alters the cellular source of this cytokine in the lung by elevating IFN $\gamma$  production by macrophages and neutrophils. In fact, we show here that the majority of the excess IFN $\gamma$  in the lungs of TCDD-treated mice comes from alveolar macrophages. Furthermore, elevated IFN $\gamma$  levels correlate with an increase in iNOS in the lungs of TCDD-treated mice. The de-regulated levels of IFN $\gamma$  and iNOS likely contribute to the pulmonary inflammation and decreased survival of TCDD-treated, virus-infected mice via a nitric oxide-dependent mechanism. Given that chronic inflammatory diseases of the lower respiratory tract are on the rise worldwide, and that high levels of both IFN $\gamma$  and iNOS have been associated with the pathology of these diseases, our data suggest that environmental exposure to AhR ligands may contribute to the development of these disorders. Thus, determining the mechanism that drives the elevated IFN $\gamma$  and iNOS levels in the lung will further our understanding of the causal relationship between activation of the AhR, dysregulated immune responses to viral infections, and these chronic inflammatory diseases.

INCREASED NUMBERS OF NEUTROPHILS IN TCDD-TREATED MICE INFECTED WITH INFLUENZA A VIRUS ARE CAUSED BY AN AH RECEPTOR-MEDIATED MECHANISM THAT IS LIKELY SPECIFIC TO THE LUNG.

S. Teske<sup>1</sup>, A. A. Bohn<sup>2</sup> and B. Lawrence<sup>1,2</sup>. <sup>1</sup>Pharmacology/Toxicology Graduate Program, Washington State University, Pullman, WA and <sup>2</sup>Department of Veterinary Clinical Sciences, Washington State University, Pullman, WA.

Increased numbers of neutrophils at the site of antigen challenge constitute one of the immunomodulatory effects of exposure to the aryl hydrocarbon receptor (AhR) ligand 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD). For example, exposure to TCDD doubles the number of neutrophils in the lungs of influenza virus-infected mice. Using AhR-deficient mice, we show here that the AhR mediates this increase in neutrophil number. Furthermore, *in vivo* depletion of neutrophils improves host resistance to influenza virus, indicating that the excessive pulmonary neutrophilia is detrimental to the host. We have previously shown that exposure to TCDD does not enhance neutrophil chemoattractants, up-regulate adhesion molecules on neutrophils, or delay neutrophil apoptosis in the lungs of infected mice. In this study we examined two alternative mechanisms by which AhR activation could result in excess neutrophils in the lung. First, we determined the number of neutrophils in the bone marrow and spleen, the primary sites of neutrophil production. Our results show that treatment with TCDD did not increase neutrophil numbers in these organs, suggesting that the elevated neutrophilia is specific to the lung. Second, we tested whether AhR activation increases lung injury and vascular permeability in infected mice. Lung lavage fluid lactate dehydrogenase, protein levels, and lung wet-to-dry weight ratios were not altered by exposure to TCDD, which indicates that excess neutrophilia is not due to increased lung injury and concomitant influx of neutrophils. In contrast to the lack of a direct effect on neutrophils or injury to the lung, we show that exposure to TCDD specifically enhances CYP1A1 levels in Clara cells, Type II pneumocytes and lung endothelial cells. Thus, our data suggest that lung epithelial/endothelial cells constitute potential targets for AhR-mediated deregulation of pulmonary inflammation.

$\Delta$ 9-TETRAHYDROCANNABINOL ALTERS HOST RESISTANCE TO INFLUENZA A/PR/8 INFECTION IN C57BL/6 MICE.

J. P. Buchweitz<sup>1,3</sup>, N. E. Kaminski<sup>1,3</sup> and J. R. Harkema<sup>2</sup>. <sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI, <sup>2</sup>Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI and <sup>3</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

The present study was designed to examine whether THC treatment decreases host resistance to influenza infection in the mouse. Mice were treated by oral gavage with 50 mg/kg THC or vehicle [corn oil (CO)] for 5 consecutive days and on Day

3 were infected by intranasal instillation with 50 plaque forming units (pfu) influenza virus A/PR/8 (PR8) or its respective vehicle, saline. Mice were sacrificed on Days 3, 7, 10, 15 and 21 post-infection (PI). Using real-time RT-PCR, changes in mRNA levels from apical and cardiac right lung lobes were determined for IL-4, IFN- $\gamma$ , and TNF- $\alpha$ . IL-4 mRNA was not detected in any of the treatment groups on any of the days. IFN- $\gamma$  and TNF- $\alpha$ , however, were significantly increased in CO/PR8 treated mice on Days 7 and 10 PI with a marked attenuation observed on Day 7 PI for IFN- $\gamma$  in the THC/PR8 treatment group, but not TNF- $\alpha$ . Cytometric bead array analysis revealed an increase in circulating serum IFN- $\gamma$  and TNF- $\alpha$  on Day 7 PI in mice treated with CO/PR8 that was attenuated by THC treatment. Treatment of mice with PR8 resulted in airway epithelial cell exfoliation on Day 3 PI with regeneration observed on Days 7 and 10 PI, followed by mucous cell metaplasia (MCM) on Days 15 and 21 PI. There is a trend toward increased alveolitis on Day 10 PI and MCM on Day 15 PI in lungs from THC/PR8 treated mice. Using image analysis and standard morphometric techniques, airway epithelial cell densities of intraepithelial mucosubstances (Vs) were determined on AB/PAS stained sections obtained from the left lung lobes. Sections from PR8 treated mice for Days 15 and 21 PI were characterized by viral-induced MCM with a trend toward increased Vs in sections from THC/PR8 treated mice. Collectively, these studies suggest that THC exacerbated the pathogenesis of influenza infection by altering host immunity. (Supported by NIH grant DA07908 and the MSU Foundation).

EXPOSURE TO THC, A MARIJUANA CANNABINOID, INDUCES ALTERATIONS IN TH1/TH2 CYTOKINE PROFILE RESULTING IN SUPPRESSION OF IMMUNITY AND INCREASED SUSCEPTIBILITY TO BREAST CANCER.

R. McKallip<sup>1</sup>, P. S. Nagarkatti<sup>2</sup> and M. Nagarkatti<sup>1</sup>. <sup>1</sup>Department Micro/Immunol, VCU/MCV, Richmond, VA and <sup>2</sup>Pharmacology and Toxicology, VCU/MCV, Richmond, VA.

In the current study, we tested the central hypothesis that exposure to THC can lead to enhanced growth of tumors that express low to undetectable levels of cannabinoid receptors by specifically suppressing the anti-tumor immune response. We demonstrated that the human breast cancer cell lines MCF-7 and MDA-MB-231 and the mouse mammary carcinoma, 4T1, express low to undetectable levels of CB1 and CB2 and that these cells are resistant to THC-induced cytotoxicity. Furthermore, exposure of mice to THC led to significantly elevated 4T1 tumor growth and metastasis due to inhibition of the specific anti-tumor immune response *in vivo*. The suppression of the anti-tumor immune response was mediated primarily through CB2 as opposed to CB1 expression on immune cells. Furthermore, exposure of mice to THC led to increased production of IL-4 and IL-10, suggesting that THC may specifically suppress the cell-mediated Th1 response by skewing the immune system to a Th2 response. This possibility was further supported by microarray data demonstrating the upregulation of a number of Th2-related genes and the downregulation of a number of Th1-related genes following exposure to THC. Finally, injection of anti-IL-4 and anti-IL-10 mAbs led to a partial reversal of the THC-induced suppression of the immune response to 4T1. Such findings suggest that marijuana exposure either recreationally or medicinally may increase the susceptibility to and/or incidence of breast cancer as well as other cancers that are resistant to THC-induced apoptosis. Supported by NIH grants (R01DA016545, R21DA014885, R01ES09098, R01AI053703, R01HL058641, R01AI058300, K12DA14041 and P50DA05274), The American Cancer Society (IRG-100036) and The Jeffress Memorial Trust Fund (J-741).

IMMUNE FUNCTIONAL AND HISTOPATHOLOGICAL ALTERATIONS FOLLOWING EXPOSURE IN FEMALE B6C3F1 MICE TO THE WIDELY USED VEHICLE ELMIRON®

K. L. White Jr.<sup>1</sup>, A. Nyska<sup>2</sup>, R. D. Brown<sup>1</sup>, D. L. Musgrave<sup>1</sup>, T. L. Guo<sup>1</sup> and D. R. Germolec<sup>2</sup>. <sup>1</sup>Virginia Commonwealth University, Richmond, VA and <sup>2</sup>NIEHS, Research Triangle Park, NC.

Elmiron is the trade name for  $\beta$ -cyclodextrin ( $\beta$ -CD), a cyclic polymer of 8- $\beta$ -1, 4-linked glucopyranosyl units, which is used in food and pharmaceutical preparations. Elmiron solutions have also been used as the vehicle for numerous toxicological studies, including studies evaluating various contaminants found in drinking water. Recent studies conducted by the National Toxicology Program have demonstrated that exposure of rats and mice to Elmiron induced infiltration of vacuolated histiocytes into multiple tissues, including the lymph nodes and spleen. Transmission electron microscopy identified these vacuoles as lysosomal structures that exhibited a variety of contents. Additional studies were conducted to determine if Elmiron altered immune function or pathology when administered to female B6C3F1 mice by gavage. Mice received doses of 0, 63, 125, 250, 500, and 1, 000 mg/kg for 28 days by gavage. An increase in liver weight was noted at the two

highest doses. With the exception of an increase in reticulocyte numbers, hematological parameters were not affected. The antibody forming cell response to sheep erythrocytes was not altered by Elmiron administration. Evaluation of the functional activity of the mononuclear phagocytic system demonstrated a slight decrease in vascular half-life of sheep erythrocytes and a significant increase in the percent uptake by the liver in the high dose animals. At histopathology, a slight to moderate presence of vacuolated histiocytes were noted in the spleen and mesenteric lymph nodes. These studies demonstrate that the extensively used vehicle Elmiron when administered at doses of 1000 mg/kg or greater may alter function and histopathology of macrophages in mice, consistent to effects reported in rat (Supported by the NIEHS Contract ES 05454).

#### INTERACTIONS OF MERCURY WITH LIVER-STAGE RESPONSES TO MALARIA INFECTION.

J. F. Nyland<sup>1</sup>, A. Lima<sup>1</sup>, G. Mouton<sup>2</sup>, K. West<sup>3</sup>, E. Zavala<sup>1</sup> and E. Silbergeld<sup>1</sup>.  
<sup>1</sup>EHS & MMI, Johns Hopkins, Baltimore, MD, <sup>2</sup>Grambling State, Grambling, LA and <sup>3</sup>University Hosp of West Indies, Kingston, Jamaica.

Malaria, a life-threatening parasitic disease transmitted by mosquitoes, has re-emerged in Amazonia over the past two decades. Among the many factors proposed for this re-emergence are changes in population distribution, failures of vector control and pharmacologic management, as well as local and global environmental changes including the widespread use of mercury (Hg) for gold extraction. Our previous studies with BALB/c mice have shown that pretreatment with Hg impairs host resistance to subsequent infection by sporozoites of the murine-specific *Plasmodium yoelii*. Hg also decreased production of nitric oxide by splenocytes, and down-regulated expression of both IFN-gamma and nitric oxide synthase. These effects appeared to involve hepatic mechanisms, since Hg did not affect parasitemia following infection with blood stage plasmodia. In addition, we reported that Hg pretreatment failed to prevent parasitemia in animals immunized twice with irradiated sporozoites. In these studies we explored early responses at the liver stage of infection in BALB/c mice pretreated with Hg by studying liver-stage infection and cytokine levels in animals pretreated with Hg and infected with *P. yoelii* sporozoites. At 40 hours following infection, Hg pretreatment unexpectedly decreased plasmodia in liver, detected by measurement of a plasmodial 18S rRNA sequence in the liver (specific for liver stages of *P. yoelii* parasites). However, at this time, in Hg treated mice, levels of IFN-gamma and IL-6 protein were reduced in spleen homogenates, and mRNA levels of these cytokines were reduced in liver. We also examined plasmodia in liver after a single immunization with irradiated sporozoites, followed one week later by infection with live sporozoites. In this model, we found no effect of Hg on early liver-stage immunity. These results indicate that Hg can affect early hepatic responses to malaria infection but that these effects may not predict the interactions of Hg with acquisition of immunity (defined by parasitemia).

#### THE EFFECTS OF CIGARETTE SMOKE EXPOSURE AND PREGNANCY ON INNATE AND ADAPTIVE IMMUNE RESPONSES IN B6C3F1 MICE.

E. M. Vancza, S. P. Ng and J. T. Zelikoff. New York University School of Medicine, Tuxedo, NY.

It is well-known that cigarette smoke (CS) exposure *in utero* negatively affects the development and viability of the offspring, causing a host of defects including lower birth weight, nicotine-related neurological problems and alterations in immune function. Despite this, 20-30% of women in the United States still smoke. Although adult smokers experience some immunosuppression, the relationship between CS and the immune response has not been extensively examined for pregnant women. This study investigates the role of pregnancy on CS-induced immune modulation by examining innate and adaptive immunity in pregnant and non-pregnant B6C3F1 mice. Following inhalation of mainstream CS for 5d/wk (4hr/d from gestational d5 to parturition for the dams), inflammation was assessed via differential counts of bronchoalveolar lavage fluid and blood. Effects on tumor surveillance were evaluated *in vivo* by tumor challenge with cultured lymphoma cells and *ex vivo* by examination of cytotoxic T lymphocyte (CTL) activity. While no significant differences in lung inflammation were observed between the groups (i.e., air and CS or dams and virgins), pregnancy modulated the response to transplanted tumor cells in CS-exposed mice; tumor incidence in the smoke-exposed dams was 53.8%, while 87.5% of the exposed virgins demonstrated tumors. Furthermore, CTL activity measured in the spleens of both groups of females appeared higher in CS-exposed dams than in their virgin counterparts. These findings suggest that pregnancy may actually protect against the immunosuppressive effect of CS. Moreover, results begin to provide insight on the link between the immune response in smoking mothers and some of the adverse health outcomes affecting their offspring. Philip Morris Foundation Inc.

#### SMOKING DURING PREGNANCY REDUCES IMMUNE TUMOR SURVEILLANCE MECHANISMS IN THE OFFSPRING: A TOXICOLOGICAL MODEL.

S. P. Ng<sup>1</sup>, A. E. Silverstone<sup>2</sup>, Z. Lai<sup>2</sup> and J. T. Zelikoff<sup>1</sup>. <sup>1</sup>Nelson Institute of Environmental Medicine, New York University School of Medicine, Tuxedo, NY and <sup>2</sup>Department of Microbiology & Immunology, SUNY Upstate Medical University, Syracuse, NY.

Accumulating epidemiologic evidence suggests that prenatal exposure to intact cigarette smoke increases the incidence of cancer in the offspring. A study was proposed to examine the effects and underlying mechanisms of prenatal exposure to mainstream cigarette smoke (MCS) on offspring resistance to tumor challenge and surveillance mechanisms critical for the recognition and destruction of developing neoplasms. Pregnant B<sub>6</sub>C<sub>3</sub>F<sub>1</sub> mice were exposed by whole body inhalation to MCS for 5 d/wk (4 hr/d from gestational d5 to parturition) and smoke-induced effects on offspring host resistance to transplanted tumors, body/organ weight, natural killer cell and cytotoxic T-lymphocyte (CTL) activity, lymphoproliferation, cytokine levels, immune cell subpopulations and lymphoid organ histology were examined. At a concentration of smoke equivalent to smoking 2-3 packs of cigarettes, prenatally-exposed male offspring challenged at 5-wk of age with EL4 lymphoma cells demonstrated a >2-fold increase in tumor incidence (relative to age-/gender-matched air-exposed offspring). Furthermore, CTL activity in the smoke-exposed 5- and 10-wk-old male pups was significantly lower than the age-/gender-matched controls. Prenatal exposure to cigarette smoke also reduced (compared to age-/gender-matched controls) mitogen-stimulated T-lymphocyte proliferation in the 3-wk-old male offspring; circulating numbers of white blood cells and lymphocytes were increased in the smoke-exposed offspring. No effects were observed on body/organ weight, cytokine levels or immune cell subpopulations. Results demonstrate that exposure of pregnant mice to a relatively low dose of MCS decreases offspring resistance against nascent tumors and persistently reduces immune functions associated with tumor surveillance. This study suggests that children of mothers who smoke during pregnancy have a greater risk of developing tumors in later life. Supported by Philip Morris Foundation Inc.

#### GESTATIONAL EXPOSURE TO PFOS SUPPRESSES IMMUNOLOGICAL FUNCTION IN F1 MICE.

D. E. Keil<sup>1</sup>, T. Mehlman<sup>1</sup>, L. Butterworth<sup>1</sup> and M. M. Peden-Adams<sup>2</sup>.  
<sup>1</sup>Analytical Sciences Branch, NIOSH, Morgantown, WV and <sup>2</sup>Department of Pediatrics, Medical University of South Carolina, Charleston, SC.

Perfluorinated hydrocarbons have been manufactured for over 40 years and have numerous applications in industry. This group of compounds has recently generated much interest as common metabolites (i.e., perfluorooctane sulfonate (PFOS); perfluorooctanoic acid (PFOA)) are found to be persistent in the environment, have been detected in blood samples of both wildlife and humans, and appear to have a common mechanism of action. Studies show that these perfluorinated compounds cause peroxisomal proliferation, hepatomegaly, altered steroidogenesis, and body weight decreases that are associated with a wasting syndrome; however, effects on immune function have not been extensively assessed. This study examined the immunotoxicological effects of PFOS on the developing immune system should exposure occur during pregnancy. Therefore, C57BL/6N pregnant dams (mated with C3H/HeJ males) were orally exposed with 0, 0.1, 1.0 or 5.0 mg/kg of PFOS during each day of gestation. F1 offspring were evaluated for immunological alterations at 4 and 8 weeks of age. In general, there were no treatment effects on body, spleen, or thymus mass, and limited effects on kidney and liver mass. Corresponding flow cytometric analysis of CD4/CD8 lymphocytic subpopulations in the thymus and spleen were not altered in 4- or 8-week F1 mice. However, assessment of functional immunological parameters at 8-weeks of age revealed functional deficits. Natural killer cell activity was dose-dependently suppressed in both male and female F1 adults, whereas IgM plaque forming cell (PFC) responses were only suppressed in male F1 adults. Our data indicate that prenatal exposure to PFOS can suppress functional immunological responses that are evident at adulthood, with increased vulnerability exhibited in the male F1 offspring.

#### CHANGES IN THE OVINE HYPOTHALAMIC-PITUITARY-ADRENAL AXIS DURING PREGNANCY AND LACTATION FOLLOWING CHALLENGE WITH ESCHERICHIA COLI LIPOPOLYSACCHARIDE.

L. C. Kabaroff<sup>1</sup>, N. Karrow<sup>1</sup> and H. Boermans<sup>2</sup>. <sup>1</sup>Animal and Poultry Science, University of Guelph, Guelph, ON, Canada and <sup>2</sup>Toxicology, University of Guelph, Guelph, ON, Canada.

Lipopolysaccharide (LPS) is a gram-negative bacterial membrane component that is known to induce a systemic inflammatory response through the activation of blood monocytes and hepatic kupffer cells. These cells secrete the pro-inflamm-

tory cytokines IL-1 and 6, and TNF- $\alpha$ , which subsequently induce the hypothalamic-pituitary-adrenal axis (HPAA) to release cortisol, an anti-inflammatory hormone that assists in the regulation of the inflammatory response. We hypothesize that the ovine HPAA is attenuated in response to inflammatory stressors (LPS) during pregnancy and lactation and that this attenuation could potentially increase susceptibility to, and recovery from various bacterial induced inflammatory diseases such as mastitis and metritis. Initial studies were designed to determine various levels of HPAA activation at different LPS concentrations (0, 200, 400, 600 ng/kg) by measuring serum cortisol concentrations over time in ewes after i.v. challenge. This showed a maximal cortisol response in the 400ng/kg dose group, which was then used in the follow-up studies involving LPS challenge of ewes at different stages of pregnancy and lactation to assess whether or not the HPAA is attenuated in response to inflammatory stress. From these results we show that the HPAA is not attenuated in response to an inflammatory stressor, in fact there seems to be hyper-responsiveness of cortisol secretion over the duration of pregnancy. Unexpectedly, we also observed the thermogenic response to LPS was attenuated during early pregnancy.

#### 884

#### TETRACHLORODIBENZO-P-DIOXIN (TCDD) INHIBITS DIFFERENTIATION AND INCREASES APOPTOTIC CELL DEATH OF PRECURSOR T CELLS IN THE FETAL MOUSE THYMUS.

E. Besteman, K. Zimmerman, B. Smith and S. Holladay. *Virginia Tech, Blacksburg, VA.*

TCDD causes thymic atrophy as well as alterations in thymocyte maturity in mice. Fetal mice appear to be highly sensitive to the immunotoxic effects of TCDD when it is administered during thymic development, between gestational days (gd) 10 to 18. Multiple mechanisms for thymic hypopcellularity have been suggested, including increased thymocyte apoptosis, a maturation arrest of thymocyte development, and decreased seeding of the thymus by hematopoietic progenitors. Treatment of pregnant C57BL/6 mice in these experiments with doses of 5 or 10  $\mu$ g/kg TCDD on gd 14 and 16 resulted in both decreased thymic cellularity as well as increased percentages of less mature CD4 $^+$ CD8 $^+$  thymocytes when examined on gd 18. The marker 7-AAD showed a decrease in viable thymocytes from TCDD-treated fetal mice, and a dose-related increase of thymocytes in early apoptosis. Relative to control, thymocytes from the 5 and 10  $\mu$ g/kg TCDD exposure groups displayed 1.92% and 5.32% respective increases in early apoptotic cells. Increases in apoptotic cells were primarily noted in the CD4 $^+$ CD8 $^+$  phenotype. As apoptotic cells are rapidly cleared from the thymus, these data support thymocyte apoptosis as contributing to fetal thymic atrophy after TCDD exposure. Histopathologic evaluation of the thymi demonstrated a decrease in organ size, an increase in pyknotic cells, disruption of organ architecture with a loss of distinction between cortical and medullary regions, and a decrease in cortical size in the TCDD treated feti. A decrease in thymocyte density was noted in all regions, but was marked in the cortical zones. A decrease in the frequency of mitoses in the epithelial, cortical, and medullary regions was also noted after TCDD treatment. These findings support TCDD's effects on the fetal thymus in causing thymic atrophy and increasing thymocyte apoptosis. The disruption in architecture, decreased cortical size, decreased thymocyte density, and decreased frequency of mitoses suggests a chemical effect on thymocyte maturation/proliferation as well.

#### POST-NATAL EXPOSURE OF THE RAT TO CYCLOSPORINE DOES NOT RESULT IN PROLONGED IMPAIRMENT OF THE IMMUNE SYSTEM.

J. Descotes<sup>1</sup>, G. Ravel<sup>2</sup>, F. Horand<sup>2</sup> and P. C. Barrow<sup>2</sup>. <sup>1</sup>*Poison Center, Lyon, France* and <sup>2</sup>*MDS Pharmacology Services, Saint Germain s/ L'Arbresle, France.*

Cyclosporine (CY) is an immunosuppressive drug widely used to prevent graft rejection in young patients. This study was performed to investigate the possible effects of post-natal exposure to CY on the development of the immune system in the Sprague-Dawley rat. 20 male and 20 female rat pups were given CY by the oral route at the dose level of 10 mg/kg/day from 4 days of age through to 28 days of age. An equal number of control pups received the vehicle (olive oil). Each dam raised 4 treated and 4 control pups. Immune tests, including blood and spleen lymphocyte subset determinations, a T-dependent antibody response to sheep red blood cells, a humoral immune response to KLH, and total IgG and IgM assays, were performed in various sub-groups of rats at intervals up to the age of 10 weeks. Lymphoid organs from different sub-groups of rats were weighed and submitted to histopathology at 2, 3, 4, 6 and 10 weeks of age. The 6-week post-treatment follow-up period was included to allow the detection of any persistent functional defects in the absence of the confounding influences of direct immune modulation. The period of exposure in the rat was intended to cover the developmental stages that occur in the human from late fetal development through to late infancy. The treated juvenile rats showed severe immune depression during exposure to CY, but recovered full immune function after cessation of treatment. These results did not suggest a developmental immunotoxic potential of CY following post-natal exposure in the rat.

#### EFFECT OF TRIBUTYLTIN CHLORIDE ON NATURAL IMMUNODEFENCES IN THE F1 GENERATION IN MICE.

Y. Sugita-Konishi<sup>1</sup>, K. Kimura<sup>2</sup>, K. Kobayashi<sup>1</sup>, M. Tsunoda<sup>3</sup> and Y. Suzuki<sup>2</sup>.

<sup>1</sup>*Division of Microbiology, National Institute of Health Sciences, Tokyo, Japan,*

<sup>2</sup>*Department of Veterinary Sciences, Azabu University, Sagamihara, Japan and*

<sup>3</sup>*Department of Preventive Medicine and Public Health, Kitazato University, School of Medicine, Sagamihara, Japan.*

Tributyltin (TBT) accumulated in edible fish or shellfish is suspected of having immunotoxic effects on animals. In terms of studies on the toxicity of TBT, little information is available about immunotoxicity in offspring exposed to low dose of TBT during lactation, especially about the effects on host resistance to bacteria. Thus, in this study, we investigated the effect of TBT on the natural immunodefense in offspring breast-fed by dams exposed to low doses of TBT using *in vivo* and *in vitro* experiments with *Escherichia coli* K-12 (*E. coli* K-12), a non-pathogenic bacterium. Pregnant C57BL/6 mice were given water containing 0, 15 or 50 ppm of TBT from parturition to weaning. For an *in vivo* infection experiment, offspring were i.p. inoculated with *E. coli* K-12 at weaning time, and the bacterial clearance from the peritoneal cavity and spleen was examined. For an *in vitro* experiment, to evaluate the effect of TBT on the natural immunity that plays an important role in the early stage of infection, the anti-bacterial functions of neutrophils and macrophages in peritoneal cavity, such as binding, phagocytic and killing activities, were examined. The infection experiment demonstrated that the bacterial clearance was significantly depressed in F1 breast-fed by dams exposed to 15 ppm (15 ppm F1) but not in F1 breast-fed by dams exposed to 50 ppm. The *in vitro* experiment revealed that the killing activity of neutrophils was significantly decreased in 15 ppm F1, supporting the result of the infection experiment. These results suggest that TBT impairs natural immunodefenses in the F1 generation through breast milk. We propose that it is necessary to accumulate additional information about the effect of low dose of TBT on host resistance to bacterial infection in offspring and that such maternal toxicity should be taken into account the risk assessment of TBT.

#### ALTERED SPLENOCYTE FUNCTIONS IN FOURTEEN-MONTH OLD MICE PRENATALLY EXPOSED TO DIETHYLSТИLBESTROL.

R. M. Gogal<sup>1,2</sup>, J. Feneaux<sup>1</sup>, D. Lindsay<sup>1</sup>, C. Hardy<sup>1</sup>, D. Ward<sup>1</sup>, G. Saunders<sup>1</sup> and S. Ahmed<sup>1</sup>. <sup>1</sup>*Biomedical Sciences and Pathobiology, Va Tech, Blacksburg, VA* and <sup>2</sup>*Biomedical Sciences, Via Virginia College of Osteopathic medicine, Blacksburg, VA.*

An excellent example of a fetal basis of adult disease is the linkage of *in utero* exposure to diethylstilbestrol (DES) and the manifestation of a variety of reproductive disorders and possibly immune-related illness in adults. While the long-term adverse consequences of prenatal DES-exposure on reproductive disorders are well known, there is a paucity of data with regards to immune outcome. We hypothesize that prenatal DES-exposure imprints on the immune system altering the response to subsequent exposure of DES in adult mice. To test this hypothesis, C57BL/6 mice were prenatally exposed to DES or vehicle only (oil) at one-year of age and alterations in the immune system examined. Female DES-exposed mice (DESprenatal/DESadult) had higher serum levels of interferon-gamma (IFNg) in response to administration of *Toxoplasma gondii* soluble antigens compared to female controls, which received oil during prenatal life (Oilprenatal/DESadult). Splenic lymphocytes from female DESprenatal/DESadult mice, when activated with Concanavalin-A (Con-A), also secreted higher levels of IFNg compared to female controls (Oilprenatal/DESadult) when examined at 14-months of age. This increase in IFNg in prenatal DES-exposed mice is not due to enhanced numbers of splenocytes or increased relative percentages of CD4 or CD8 cells. Con-A-activated T-cells from female DESprenatal/DESadult had increased expression of the co-stimulatory molecule, CD28. The above immune changes were not evident in the males prenatally exposed to DES. Further, prenatal DES exposure did not induce autoimmunity in non-autoimmune C57BL/6 mice. Overall, these results provide provocative evidence that prenatal DES exposure has long-term immune consequences as demonstrated by altered immune capabilities, which become evident following a secondary exposure to DES in adult life.

#### 888

#### T-CELL MEDIATED IMMUNITY IN ADULT SPRAGUE-DAWLEY RATS IMPLANTED WITH DEPLETED URANIUM.

L. B. Healey<sup>1</sup>, J. M. Rutkiewicz<sup>1</sup>, S. R. Lohrke<sup>2</sup>, D. P. Arfsten<sup>2</sup> and K. A. Grasman<sup>1</sup>. <sup>1</sup>*Wright State University, Dayton, OH* and <sup>2</sup>*Naval Health Research Center Environmental Health Effects Laboratory, Wright-Patterson AFB, OH.*

The density and tensile strength of depleted uranium (DU) make it ideal for projectiles used to penetrate armored vehicles and hardened bunkers. As exposure to heavy metals and radiation can impact reproductive, neurological, and immunological health, embedded DU shrapnel, which is radioactive and can dissolve and relocate to other tissues, may be cause for concern. This study, which is part of a multi-generational experiment, assessed the effects of embedded DU on thymic

development and T-cell function in adult Sprague-Dawley (SD) rats. Nine-week-old rats were implanted with 4, 8, or 12 DU pellets in the gastrocnemius muscle. Tantalum steel (Ta) pellets were used to bring each rat's pellet burden to 12. Only females were treated with 4 or 8 DU pellets. Rats implanted with 12 Ta pellets and untreated rats were used as negative controls. Thirty weeks post surgery rats were twice immunized (2 weeks apart) with  $2 \times 10^8$  sheep red blood cells (SRBC). Six days after the second immunization,  $1 \times 10^8$  SRBC was injected into the footpad to stimulate a delayed type hypersensitivity (DTH) response. Swelling was measured 24 h later. Upon necropsy, the thymus was evaluated for mass and thymocyte cellularity. No significant differences in the DTH response were found between control and DU groups. Thymic mass and total thymocyte numbers showed no differences between DU groups and controls for males. In females the non-surgery control had greater relative thymic mass and thymocyte counts than the DU treated groups and the Ta implanted control. Thymocyte viability did not differ among groups. In another part of this study, cyclophosphamide treatment significantly suppressed thymic mass, cellularity, and DTH response in younger adult rats, demonstrating the sensitivity of these assays for detecting immunosuppression. In conclusion, the doses of DU used in this study did not alter thymic mass, thymocyte cellularity, or T-cell mediated DTH response in 42-week-old SD rats following 33 weeks of exposure.

IMMUNE FUNCTION IN ADULT RATS EXPOSED TO DBT IN DRINKING WATER.

J. DeWitt<sup>1</sup>, C. Copeland<sup>2</sup> and R. Luebke<sup>2</sup>. <sup>1</sup>*Curriculum in Toxicology, UNC, Chapel Hill, NC* and <sup>2</sup>*NHEERL/ETD/ITB, USEPA, Research Triangle Park, NC*.

Organotins are used commercially as agricultural pesticides, antifouling agents and stabilizers for polyvinyl chloride (PVC) pipe. Mono- and di-substituted methyl and butyltins, used in PVC pipe production, are of concern to the USEPA as they leach from supply pipes into drinking water and have been reported to cause multisystem toxicity. As part of an ongoing study to evaluate immunotoxic effects of organotins, we assessed immune function after dibutyltin dichloride (DBT) exposure. Individually housed adult male and female Sprague-Dawley rats were given drinking water containing 0, 10 or 25 mg/L of DBT (final concentration) in 0.5% Alkamuls for 28 days. Water bottles were changed and water consumption was monitored twice weekly. Body weights (BW) were recorded weekly. Delayed-type hypersensitivity (DTH), primary and secondary antibody responses to sheep red blood cells, and natural killer (NK) cell activity were evaluated in separate groups on day 29. DBT consumption had no significant effect on BW although water consumption was significantly decreased in both sexes at 25 mg DBT/L, especially during the first two weeks. DTH response and NK cell activity were similar across all groups regardless of dose. Although IgM responses were similar in all groups, IgG responses were significantly elevated in males consuming 25 mg DBT/L compared to controls. Organotins are immunotoxic in adult and pre-weanling rats and although these data did not suppress the adult immune responses we examined, the elevated IgG responses we observed were similar to an enhanced antibody response observed by Smialowicz, et al. (1989, 1990) in F344 rats exposed to tributyltin oxide. This enhancement is not consistent with other studies that have demonstrated suppressed or no changes in antibody responses. Therefore, this study illustrates that the immunotoxic effects of organotins may be related to the age of the animal, exposure duration, timing of immunization, rat strain, and/or individual organotins. This abstract does not reflect EPA policy and was supported by UNC/EPA Cooperative Training Agreement CT829472.

IN VIVO AND IN VITRO IMMUNOSUPPRESSIVE EFFECTS OF 1, 2:5, 6-DIBENZANTHACENE IN FEMALE BALB/C MICE.

C. Jin<sup>1</sup>, T. Jeon<sup>1</sup>, S. Lee<sup>1</sup>, S. Hyun<sup>1</sup>, D. Lee<sup>1</sup>, G. Kim<sup>1</sup>, I. Jun<sup>1</sup>, E. Lee<sup>1</sup>, H. Jeong<sup>2</sup> and T. Jeong<sup>1</sup>. <sup>1</sup>*College of Pharmacy, Yeungnam University, Kyungsan, South Korea* and <sup>2</sup>*College of Pharmacy, Chosun University, Gwangju, South Korea*.

Although polycyclic aromatic hydrocarbons (PAHs) have been known to suppress immune responses, few studies have addressed the immunotoxicity of 1, 2:5, 6-dibenzanthracene (DA). In this study, we investigated the immunosuppression by DA, both *in vivo* and *in vitro*, in female BALB/c mice. To assess the effects of DA on humoral immunity as splenic antibody response to sheep red blood cells (SRBCs), DA was given a single dose or once daily for 7 consecutive days po with 30, 60 and 120  $\mu$ moles/kg. Acute oral administration of DA induced activities of hepatic ethoxresorufin *O*-deethylase and pentoxresorufin *O*-depentylase. In addition DA reduced the number of antibody forming cells (AFCs) in a dose-dependent manner. Subacute treatment with DA caused weight decreases in spleen and thymus. Interestingly, subacute DA inhibited the hepatic activity of methoxresorufin *O*-demethylase. The number of AFCs was dramatically decreased by DA in a dose-dependent manner. In a subsequent study, mice were subacutely exposed to same doses of DA without an immunization with SRBCs, followed by splenic and

thymic lymphocyte phenotypings using a flow cytometry and *ex vivo* mitogen-stimulated proliferation. DA exposed mice exhibited reduced splenic and thymic cellularity, decreased numbers of total T cells, CD4<sup>+</sup> cells and CD8<sup>+</sup> cells in spleen and immature CD4<sup>+</sup>CD8<sup>+</sup> cells, CD4<sup>+</sup>CD8<sup>-</sup> cells and CD8<sup>+</sup>CD4<sup>-</sup> cells in thymus. The number of CD4<sup>+</sup> IL-2<sup>+</sup> cells was reduced about 16%, 13% and 33%, following exposure of mice to 30, 60 and 120  $\mu$ moles/kg of DA, respectively. In *ex vivo* lymphocyte proliferation assay, DA inhibited splenocyte proliferation by LPS and Con A. These results demonstrated that DA-induced immunosuppression might be mediated, at least in part, through the IL-2 production, and caused by mechanisms associated with metabolic processes. (Supported by a grant from Korea Food and Drug Administration and a grant from KOSEF, Korea).

EVALUATION OF THE IMMUNOMODULATORY EFFECTS OF DIBENZ(A, H)ANTHRACENE IN ADULT FEMALE B6C3F1MICE.

D. M. Hernandez, W. Auttachaoat, T. L. Guo and K. L. White Jr. *Virginia Commonwealth University, Richmond, VA*.

Dibenz(a, h)anthracene (DBA) is an environmental contaminant classified on EPA's priority pollutant list. It is a polycyclic aromatic hydrocarbon formed by the incomplete combustion of carbon-containing compounds. For example, it has been identified in auto exhaust and cigarette smoke. The objective of this study was to evaluate the immunomodulatory effects of DBA in adult female B6C3F1 mice. Mice were exposed subcutaneously to DBA in corn oil (158, 500, 1580, and 5000  $\mu$ g/kg) daily for 28 days. Several quantitative measures and functional assays, e.g. the IgM antibody forming cell (AFC) response to the T-dependent antigen, sheep red blood cells, natural killer cell (NK) activity, anti-CD3 antibody-mediated proliferation, mixed leukocyte response (MLR), delayed type hypersensitivity (DTH) response and phenotypic analysis, were employed to evaluate humoral, innate and cell-mediated immunity. A dose-dependent decrease ranging from 45% to 100% in both total activity (AFC/Spleen) and specific activity (AFC/106 splenocytes) was observed with the three highest doses reaching the level of statistical significance. For NK activity, MLR and anti-CD3 antibody-mediated proliferation, a significant decrease of 36%, 27%, and 75% was observed at the highest dose level, respectively. The DTH response to the antigen, *Candida albicans*, was less sensitive to detect the immunosuppressive effect of DBA, and significant decreases were only observed when the dose reached the level of 40 mg/kg. The results of these studies indicate that DBA is a potent suppressor of a variety of immune functions at low exposure levels with the humoral immunity as the most sensitive. (Supported in part by the NIEHS Contract ES 05454).

CYTOCHROME P450 1B1 (CYP1B1) IS REQUIRED FOR 7, 12-DIMETHYLBENZ(A)- ANTHRACENE (DMBA) INDUCED SPLEEN CELL IMMUNOTOXICITY IN C57BL/6N MICE.

J. Gao, S. W. Burchiel, F. T. Lauer and S. Dunaway. *College of Pharmacy Toxicology Program, The University of New Mexico, Albuquerque, NM*.

7, 12-Dimethylbenz(a)anthracene (DMBA) is a potent carcinogen that induces immunosuppression of both humoral and cell-mediated immunity in mice and other species. Previous studies have shown that CYP1B1 is required for bone marrow toxicity produced by DMBA in mice. Therefore, the purpose for this series of studies was to determine whether CYP1B1 was required for spleen cell immunotoxicity. Female C57BL/6N wild-type and CYP1B1 knockout (-/-) mice were treated with 0, 17, 50, or 150 mg/kg (cumulative dose) DMBA in corn oil by oral gavage once a day for 5 days. Several immunotoxicological assays were used to assess the effects of DMBA on systemic immunity. These included the *in vitro* T-dependent antibody response to sheep red blood cells (SRBC) measured using a direct plaque forming cell (PFC) assay, T and B cell mitogenesis induced by Con A and LPS, and nonspecific cell-mediated immunity was evaluated using an NK cytotoxicity assay. In addition, lymphocyte subpopulations were measured by flow cytometry using specific cell surface markers. Following 5 days of DMBA treatment, the body weights and spleen cell surface markers of the wild-type and CYP1B1 -/- mice showed no significant changes. A decrease in NK activity was found at the 50 mg/kg DMBA dose in wild-type mice, but not in the CYP1B1 -/- mice. The SRBC PFC response demonstrated that the IgM antibody response was suppressed by DMBA in wild-type mice in a dose-dependent manner (significant at 50 and 150 mg/kg). However, there were no changes in the SRBC PFC responses in any DMBA test group in the CYP1B1 -/- mice. Similarly, while DMBA suppressed B and T cell mitogenesis at the 50 and 150 mg/kg dose levels in C57BL/6N wild type mice, no effect was seen in CYP1B1 -/- mice. Thus, CYP1B1 appears to be critical for the immunosuppression of DMBA in mice, suggesting a role for bioreactive metabolites in the spleen cell immunotoxicity produced by DMBA. Supported by ROI ES05495 and P30 ES012072

NONCOPLANAR PCB-INDUCED IMMUNOTOXICITY  
IN A FISH MODEL IS NOT AHR-MEDIATED.

J. T. Zelikoff and J. Duffy. Department of Environmental Medicine, New York University School of Medicine, Tuxedo, NY.

Binding to, and activation of, the aryl hydrocarbon receptor (AhR) is well-defined and believed to be a pre-requisite for polychlorinated biphenyl (PCB)-induced toxicity, including immunotoxicity. In recent years studies have emerged in which noncoplanar PCB congeners have been shown to alter both innate and cell-mediated immune parameters in mammals. The objective of this study was to determine the impact of a noncoplanar (PCB 153) and coplanar (PCB 126) PCB congener on the immune response and to investigate an AhR-independent mechanism of PCB-induced immunotoxicity using a laboratory fish model. Bluegill sunfish, injected intraperitoneally (i.p.) with either 0.01 or 1.0  $\mu$ g PCB 126/g BW or 5.0 or 50.0  $\mu$ g PCB 153/g BW, were sacrificed after 3, 7, 14 or 21 d and hepatic CYP1A induction, phagocyte-mediated superoxide ( $O_2^-$ ) production and T- and B-lymphocyte proliferation were measured. Results demonstrated that while PCB 126 significantly increased hepatic CYP1A induction at all post-injection time points, immune parameters were unaffected by exposure. Conversely, in the absence of CYP1A induction, treatment of fish with 50.0  $\mu$ g PCB 153/g BW suppressed T- and B-lymphoproliferation for up to 7 d and increased phagocyte-mediated extracellular  $O_2^-$  production at 3 d post-injection. Based upon these results, studies were initiated to examine the role of the neuroimmune axis, specifically the serotonergic component, as a potential mechanism of PCB-induced immunotoxicity. Preliminary studies using parachlorophenylalanine (a specific inhibitor of the rate-limiting enzyme in serotonin [5-HT] synthesis, tryptophan hydroxylase) to determine if 5-HT is important for mounting an immune response have demonstrated that similar to that observed for other fish and mammals, 5-HT is important for regulating immune function in bluegill. Studies are ongoing to determine how exposure to PCB impacts this neuroimmune balance. Hudson River Foundation Graduate Fellowship and USACEHR No. DAMD 17-99-9011.

## METALLOTHIONEIN INFLUENCES ON IMMUNE CAPACITY IN METAL-STRESSED SYSTEMS.

K. Zaffuto, D. Unfricht, E. Canpolat, G. Jin, N. Hadjout, X. Yin and M. A. Lynes. Molecular and Cell Biology, University of Connecticut, Storrs, CT, CT.

Metallothionein (MT) is a small molecular weight thiol rich protein. This protein associated thiols confer to MT its capacity to protect against heavy metal toxicity and oxidative stress. Moreover, MT also alters the immune response. Studies conducted in our laboratory have shown that MT plays a immunosuppressive role in an adaptive immune response. Antibody responses to T-dependent antigens are decreased when antigen is injected concurrently with MT. Similarly, challenging Mt-1/Mt-2 null mice with T-dependent antigen, or challenging in the presence of anti-MT antibody result in increased antibody levels. In this report, we examine the effects of MT gene dose on the inflammatory process. C57BL/6J (WT), B6-Mt-1 transgenic (B6-TGN) and B6-Mt-1/Mt-2 null (B6-KO) mice were injected with sterile thioglycollate. Inflammatory peritoneal cells were harvested at 4 and 24 hours and examined for GR-1 and CD11b expression by flow cytometry. Simultaneously, the livers were also harvested, and MT levels were measured by ELISA using a monoclonal anti-MT antibody (UC1MT). The total number of inflammatory cells responding to TG stimulus does not differ amongst the three strains at 4 and 24 hours after TG injection. However, the expression of CD11b did vary according to MT gene dose. Liver MT increased in proportion to MT gene dose at 4 hours, persisted at 24 hours in proportion to MT gene dose. *In vitro* treatment with H2O2 also illuminated differences in oxidant management and anti-oxidant enzymes (catalase and superoxide dismutase) between the three strains. Alteration in available MT may alter both intrinsic and inflammatory environments, which in turn would alter the expression of oxidant-sensitive molecules such as CD11b. These studies suggest that MT gene dose and MT protein levels play a complex but important role in management of immune and inflammatory processes. Supported by NIEHS ES07408 and NIEHS ES25490.

THE PARADOXICAL EFFECTS OF LEAD IN IFN $\gamma$ KNOCKOUT (KO) BALB/C MICE.

D. Gao, J. Kasten-Jolly and D. A. Lawrence. Wadsworth Center, Albany, NY.

Lead (Pb) exposure enhances IL-4 and inhibits IFN $\gamma$  production in wild type (WT) BALB/c mice. Here, we examined Pb effects on immunity in IFN $\gamma$ KO mice. WT and IFN $\gamma$ KO BALB/c mice (2-4 mon-old) were i.p. injected with PbCl<sub>2</sub> (50  $\mu$ g/100  $\mu$ L saline) 3x/wk for 3 wk beginning on day 1. Mice were immunized i.p. with KLH (100  $\mu$ g) at day 7 and day 14. Blood was collected at day 21; KLH delayed-type hypersensitivity (DTH) was performed at day 35. After DTH assessment, splenocytes (SPL) or popliteal lymph node cells (PLN) were assayed *in vitro* for cytokine production. Other mice were immunized with DNFB and assessed on

day 5 for contact hypersensitivity (CHS) after 24 hr. Pb significantly increased IgG1 anti-KLH levels in WT mice ( $30.3 \pm 13.2 \mu$ g/mL) compared to the controls ( $16.8 \pm 8.6 \mu$ g/mL); IgG2a anti-KLH levels also were increased by Pb. In addition, total IgE level was increased, but not IgE anti-KLH. In IFN KO mice, the IgG1 and IgG2a anti-KLH and total IgE levels were significantly lower than those of WT mice. Surprisingly, Pb significantly enhanced IgG1 and IgG2a anti-KLH and total IgE levels in the IFN KO mice. However, unlike with WT mice, Pb caused a greater percent increase of IgG2a than IgG1 anti-KLH, indicating enhanced Th1 immunity. Pb also enhanced the KLH DTH response in WT mice (control,  $0.22 \pm 0.1$  mm; Pb,  $0.41 \pm 0.09$  mm). Not surprisingly, minimal KLH DTH occurred in IFN KO mice ( $0.06 \pm 0.04$  mm); however, Pb induced a strong KLH DTH ( $0.32 \pm 0.1$  mm). In these mice, IL-4, IL-5 and IL-10, but not THF, IL-2 and IL-12, were increased in SPL and PLN supernatants. In contrast to KLH, DNFB CHS was detected in all groups, and Pb only slightly enhanced CHS. As with previous findings, Pb enhances Th2 responses in WT mice; however, Pb promoted type-1 immunity in the IFN KO mice, and enhanced KLH DTH > DNFB CHS, which is more CD8 T cell dependent. Supported by NIH grant ES11135.

## ROLE OF COPPER CHELATION, ALTERATION OF RED-OX BALANCE, AND STRESS MEDIATORS IN MODULATION OF CYTOKINE RESPONSES BY SODIUM METHYLDITHIOCARBAMATE.

S. B. Pruitt, C. L. Schwab, Q. Zheng and R. Fan. Cell. Biol. & Anatomy, LSU Health Sciences Center, Shreveport, LA.

Sodium methylthiocarbamate (Metam Sodium, SMD) is the third most abundantly used conventional pesticide in the US. In this study, potential mechanisms by which SMD alters LPS-induced cytokine production in the peritoneal cavity of mice were examined. On the basis of the chemistry of SMD or preliminary data presented here, three mechanisms were selected for evaluation. They were evaluated by administration of 1) SMD or an equivalent amount of SMD-copper chelation complex to female B6C3F1 mice, 2) by administration of N-acetyl cysteine (NAC), which increases the amount of reduced glutathione (GSH) prior to SMD, and 3) by administration of a glucocorticoid antagonist (RU 486) and a beta-adrenergic antagonist (nadolol) prior to SMD to prevent the actions of important stress mediators. The combination of RU 486 and nadolol partly and significantly prevented the SMD-induced reduction of peritoneal IL-12 production in LPS-treated mice. In contrast, NAC exacerbated both the decreased production of IL-12 and the increase of IL-10 caused by SMD. The copper complex of SMD caused a greater increase in IL-10 than SMD, but it caused no suppression of IL-12, in contrast with SMD, which significantly suppressed IL-12. In addition, the effects of the major breakdown product of SMD, methyl isothiocyanate (MITC) on production of IL-12 and IL-10 were examined. MITC (at an equimolar dosage compared to SMD) caused a similar suppression of LPS-induced IL-12 and a greater increase in IL-10 in the peritoneal lavage fluid. These results indicate that all three of the hypothesized mechanisms of SMD action are probably involved in the dysregulation of TLR4-mediated cytokine production. However, MITC does not chelate copper and cannot act as a reducing agent (whereas SMD can), and it may act by an independent mechanism, such as formation of adducts with signaling proteins. This work was supported by NIH grant ES09158.

## SODIUM METHYLDITHIOCARBAMATE SUPPRESSES INNATE IMMUNITY: ROLE OF TLR SIGNALING AND CYTOKINE PRODUCTION.

C. L. Schwab, Q. Zheng, R. Fan and S. B. Pruitt. Cell. Biol. & Anatomy, LSU Health Sciences Center, Shreveport, LA.

Sodium methylthiocarbamate (Metam Sodium, SMD) is the third most abundantly used conventional pesticide in the US. The study described here was done to determine if SMD acts to inhibit innate immunity induced through Toll-like receptors (TLR) and if inhibition of TLR signaling could be one of the mechanisms for this effect. Female B6C3F1 mice were treated with SMD (200 or 300 mg/kg, in water by oral gavage) 30 min before administration of lipopolysaccharide (LPS, 60 micro g/mouse, iv). Three hr later, cytokine concentrations in peritoneal lavage fluid, cellular lysates of peritoneal macrophages, and serum were determined using ELISA kits. In separate sets of mice treated in the same manner, signaling parameters in peritoneal macrophages were analyzed by Western blot or BioRad multiplex bead array 30 or 90 min after LPS. Cytokine mRNA in the same cells was analyzed by RNase protection assay. Finally, resistance to infection was assessed by administration of an LD40-LD100 dose of indigenous Escherichia coli. The results demonstrate that SMD decreased the induction of IL-12 in serum, peritoneal fluid, and macrophage lysates and increased the induction of IL-10 in the same samples. Changes in mRNA for these cytokines were similar to the changes in protein. This was associated with decreased activation of kinases late in the TLR4 signaling pathway (p38, JNK, and ERK), but not early in the pathway (IRAK-1). Activation of

AP-1 transcription factor was significantly inhibited, but the translocation of the p65 component of NF-kappaB to the nucleus was not inhibited. Resistance of mice to *E. coli* peritonitis was decreased significantly as indicated by lower survival times and decreased rates of survival. These results indicate that SMD is a potent modulator of TLR signaling and cytokine production, and it suppresses innate resistance to *E. coli*. An experiment with specific kinase inhibitors suggests that inhibition of TLR signaling may be the mechanism by which SMD modulates cytokine expression. This work was supported by NIH grant ES09158.

IDENTIFICATION OF BIOMARKERS FOR DRUG-INDUCED STRESS: COMPARISON OF MOUSE AND RAT MODELS.

P. Hebert<sup>1</sup>, S. B. Pruitt<sup>1</sup>, J. M. LaPointe<sup>2</sup> and T. T. Kawabata<sup>2</sup>. <sup>1</sup>*Cell. Biol. & Anatomy, LSU Health Sciences Center, Shreveport, LA* and <sup>2</sup>*Safety Sciences, Pfizer, Inc., Groton, CT.*

Biomarkers for stress are needed to determine if signs of immunotoxicity that are detected in routine safety testing are caused by a non-specific stress response rather than direct immunotoxicity. The objective of this study was to compare the stress response in female (Sprague-Dawley) rats to that observed previously in female (B6C3F1) mice. Oral administration of ethanol at 5 g/kg in rats increased serum corticosterone levels from 1-12 hr after dosing and yielded an area under the corticosterone concentration vs. time curve (AUC) of 3328 ng/ml\*hr. Administration of ethanol at 5 g/kg in mice yields an AUC value of 1033 ng/ml\*hr, and dose of 6 g/kg yields an AUC value of 2239 ng/ml\*hr. In mice, ethanol at 6 g/kg significantly decreases the expression MHC class II proteins on cells in the spleen 24 hr after dosing. However, the larger stress response (corticosterone AUC) induced by ethanol in rats did not cause significant changes in MHC class II expression in the spleen or on B cells in the blood. The percentage of blood neutrophils was increased significantly in both species, but the increase was greater in mice than rats. The results for exogenous corticosterone administration were similar. The corticosterone AUC value for rats given one dose of corticosterone at 20 mg/kg was 1380 ng/ml\*hr and the value for rats given 30 mg/kg was 2852 ng/ml\*hr. The corticosterone AUC value for mice given corticosterone at 18 mg/kg was 3268 ng/ml\*hr. Neither dosage in rats affected MHC class II expression in the spleen or the blood, whereas significant decreases in MHC class II occurred in mice. At 24 hr, there was a small, significant decrease in thymus cellularity in mice, but not in rats. There was an increase in blood neutrophils in rats and a larger increase in mice. Thus, several immune parameters that are sensitive to corticosterone and ethanol-induced stress in mice are less sensitive in a rat strain commonly used in pre-clinical testing. ROLE OF CORTICOSTERONE IN STRESS-MEDIATED SUPPRESSION OF TUMOR RESISTANCE.

J. Adams, S. B. Pruitt and P. Hebert. *Cell. Biol. & Anatomy, LSU Health Sciences Center, Shreveport, LA.*

Natural killer (NK) cells are involved in resistance to metastatic tumors. Many types of stress, including that induced by chemicals, reduce NK cell function. These experiments were performed to test the hypothesis that corticosterone (Cort), a hormone released during stress, exogenously administered to mimic an active stress response, is involved in NK cell-mediated resistance to metastatic tumors. Additionally, ethanol (EtOH), which increases Cort levels, was used as a model of chemically-induced stress. EtOH decreased ex-vivo NK cell killing of YAC-1 cells in Fischer-344 (F-344) rats, as measured by Cr-release assay. In one experiment, lytic units (LU) were  $29.0 \pm 1.13$ ,  $22.66 \pm 0.41$ , and  $12.97 \pm 0.44$  (mean  $\pm$  SEM) for naive, vehicle and oral EtOH groups (5g/kg), respectively (significance between naive and vehicle groups was  $p < 0.01$ , whereas, that between the EtOH and either naive or vehicle was  $p < 0.001$ ,  $n=3$ ). In the other experiment, LU were  $10.12 \pm 1.18$  and  $5.22 \pm 0.67$  for vehicle and EtOH groups ( $p < 0.01$ ,  $n=4$ ). *In vivo* NK cell function was evaluated by injecting MADB106 cells into F344 or Sprague-Dawley (SD) rats receiving Cort (20 mg/kg, or vehicle), or SD rats treated with EtOH (or vehicle). After two weeks, lung tumor nodules were counted. SD rats treated with Cort developed  $19.0 \pm 1.8$  lung tumors, and those treated with vehicle had  $8.6 \pm 1.1$  ( $p < 0.001$ ,  $n=4-5$ ). SD rats treated with EtOH had  $28.0 \pm 8.8$  tumors, and vehicle-treated animals had  $1.0 \pm 0.77$  ( $p < 0.01$ ,  $n=4-5$ ). F344 rats treated with Cort developed  $31 \pm 1.5$  lung tumors while vehicle animals had only  $20 \pm 1.5$  ( $p < 0.0001$ ,  $n=3-5$ ). These results indicate that both EtOH and exogenous Cort significantly reduce the ability of NK cells to kill target cells, and this has implications with regard to decreased resistance to metastatic tumors. They also suggest a role for Cort in this process. Next, we will further evaluate Cort involvement by blocking Cort activity or synthesis to confirm its involvement in this type of stress-induced decrease in NK cell mediated immunity. This work was supported by the Office of Multicultural Affairs, LSUHSC-S.

INVESTIGATION OF HABITUATION OR TOLERANCE IN THE STRESS RESPONSE AND IMMUNOMODULATORY ACTIONS OF ETHANOL.

Q. Zheng, C. L. Schwab, R. Fan and S. B. Pruitt. *Cell. Biol. & Anatomy, LSU Health Sciences Center, Shreveport, LA.*

Acute administration of ethanol (EtOH) suppresses a number of immune parameters, and some of these effects are mediated by the vigorous stress response induced by EtOH. Some reports indicate that chronic EtOH administration in a liquid diet or in drinking water does not induce a stress response. However, there is uncertainty as to whether these models or a large dose of EtOH once a day would be more representative of the drinking patterns of alcohol-dependent persons. In the present study, the effects of daily administration of EtOH (4, 5, 6, and 7 g/kg by gavage) for 28 days were compared to the effects of a single dose of EtOH at the same dosages, as determined in previously published studies. In both cases, serum corticosterone concentrations were measured at 2, 4, 6, 8, and 12 hr after EtOH and immune parameters were measured 12 hr after EtOH. After the first dose of EtOH, there was a significant increase in corticosterone, which persisted for 8 hr. However, after the 28th daily dose, the increase in corticosterone was minimal and only persisted for 1 hr. As expected, immune parameters known to be suppressed by stress responses, such as the expression of MHC II on B cells and the lymphocyte to neutrophil ratio in the blood in the blood were affected less after 28 days of dosing than after a single dose. However, parameters for which suppression is not primarily mediated by the stress response, such as natural killer cell activity in the spleen, were affected to a greater extent after 28 days of dosing than after a single dose. These results demonstrate that mice become habituated (or tolerant) to the stress-inducing effects of EtOH but not to other immunotoxic mechanisms. This work was supported by NIH grants AA09505 and ES09158.

ACUTE AND CHRONIC EFFECTS OF ETHANOL ON MACROPHAGES.

Q. Dai and S. B. Pruitt. *Cell. Biol. & Anatomy, LSU Health Sciences Center, Shreveport, LA.*

Alcohol consumption is a risk factor for infections. There is evidence for different effects of chronic alcohol drinking versus binge drinking on the outcome of patients with infections and/or cardiovascular diseases. Previous study results in our lab have demonstrated that acute ethanol (EtOH) interferes with the innate immune response. However, it is not clear whether chronic ethanol has the same effect. The purpose of the present study is to investigate the mechanisms by which chronic and acute ethanol affect LPS-induced cytokine production and TLR4 signaling. Mice or RAW264.7 cells were treated with lipopolysaccharide (LPS), which induces cytokine production through TLR4. Some groups of mice received acute EtOH by our binge drinking model and/or chronic EtOH at 20% (wt/vol) in the drinking water as the sole liquid source for 4 weeks. For cell culture, ethanol was directly added to the medium acutely or for 24/48 hours. The results demonstrate different effects of chronic ethanol versus acute ethanol on LPS-induced cytokine production *in vivo* as well as *in vitro*. Chronic EtOH induces over-production of cytokines in mice or RAW264.7 cells stimulated with LPS. Mice or RAW 264.7 cells previously exposed to chronic EtOH treatment became resistant to the acute suppressive effect of EtOH. EtOH, at least in part, has a direct effect on LPS-induced TNF-alpha production *in vivo*. These results indicate that acute and chronic EtOH act by different mechanisms to modify TNF-alpha expression. An initial experiment indicates that acute EtOH may act in the *in vitro* system by disrupting lipid rafts, which are known to be involved in TLR4 signaling. It is not known if this is also the case for chronic EtOH, but we speculate that chronic EtOH may induce membrane adaptations that prevent the effects of acute EtOH on lipid raft structure. Considering that septic shock is the number one cause of death in intensive care units and cardiovascular disease is a common cause of death in the US, these observations may have practical significance. This work was funded by NIH grants R01 AA009505 and R01 ES09158.

EVALUATION OF FLOW CYTOMETRIC ENDPOINTS FOR THE LYMPH NODE PROLIFERATION ASSAY (LNPA).

J. L. Weaver and D. Broud. *DAPR, USFDA, Silver Spring, MD.*

The LNPA is being developed for use in detection of the potential for systemically administered drugs to cause clinical hypersensitivity reactions. This method, modified from the local lymph node assay, uses *in vivo* uptake of 3H-thymidine in the superficial cervical lymph node as the endpoint. The research reported here was performed to determine whether changes in lymphocyte subpopulation numbers or cell surface marker expression could be used as a non-radioactive endpoint in the LNPA. Groups of BALB/c mice were injected s.c. with saline or test drugs for three days, rested for two days, and sacrificed. The drugs tested were: assay control: strep-

tozotocin; negative - phenobarbital, metformin; positive - nevirapine, abacavir, lamotrigine, ofloxacin, zomepirac, clonidine, procainamide, and sulfamethoxazole. Leukocytes from draining lymph nodes and peripheral blood were analyzed for changes in cell surface proteins using flow cytometry. These markers were initially measured in lymph node cells: sIgE, IgA, CD45R/B220, CD4, CD8, CD25, TcR-beta, CD62L, CD44, CD71, CD54, CD86. In the lymph nodes, changes were seen in cell numbers only with streptozotocin, lamotrigine, abacavir and nevirapine. Changes in the percent of B220+ cells were seen with nevirapine, and lamotrigine. Alterations among T-cell populations were observed with nevirapine, lamotrigine, and abacavir with changes in proportions of CD4, CD8 and CD62L populations. Significant changes in absolute numbers among T-cell populations were seen only with streptozotocin and nevirapine, due to the larger variability in lymph node cell counts. No changes in CD25, CD44, CD71, CD54, or CD86 were seen with any drug. Changes in percentages of cells in peripheral blood were also seen following treatment with abacavir, lamotrigine, nevirapine, and ofloxacin. The expression of CD62L was increased only with nevirapine treatment. The presence of the alterations in expression of cell surface proteins and in the proportions of cells in both lymph nodes and peripheral blood are in general agreement with the results of the <sup>3</sup>H-thymidine-uptake results.

### ASSESSMENT OF EARLY IMMUNOLOGICAL PARAMETERS IN THE POPLITEAL LYMPH NODE ASSAY TO DETECT IMMUNOMODULATING DRUGS.

R. Pieters<sup>1</sup>, M. Aalbers<sup>1</sup>, R. Bleumink<sup>1</sup>, L. Boon<sup>2</sup> and S. Nierkens<sup>1</sup>.

<sup>1</sup>Immunotoxicology, Institute for Risk Assessment Sciences, Utrecht, Netherlands and <sup>2</sup>Bioceros BV, Utrecht, Netherlands.

Some drugs have the ability to induce immune-mediated drug hypersensitivity reactions in susceptible individuals. Validated predictive screening tools to evaluate these undesired side-effects are presently unavailable. The popliteal lymph node assay (PLNA) with reporter antigens (RA) is a promising candidate for this purpose. The present study was designed to provide valuable mechanistic information on the very early induction phase of drug-induced type 1 and type 2 immune reactions in the PLNA. In addition, we evaluated the use of potential predictive readouts in this assay. The anti-rheumatic drug D-Penicillamine (D-Pen) induced a type 2 response, characterized by an early influx of dendritic cells (DC) and B cells that expressed CD40, CD54, and CD86, but no CD80. First DC, but later B cells appeared to function as APC and plasma cells produced IgG1 in the presence of IL-4. Streptozotocin (STZ; chemotherapeutic drug) induced a type 1 response, showing an increase in activated CD8 cells (high expression of CD25 and CD69) and macrophages, accompanied by high concentrations of IFN- $\gamma$  and IL-12 from day 2 after exposure. CD40 expression was absent, but CD54, CD80, and CD86 were present predominantly on non-B APC, presumably macrophages. Apparently, these type 1- and type 2-inducing drugs produce drug-specific patterns of immune adjuvanting factors that stimulate very different, time-dependent profiles of cells, cytokine production, and expression of costimulatory molecules very shortly after the initial exposure to drugs. The parameters obtained with the PLNA provide information about the immunological mechanisms in the early induction phase of drug-induced hypersensitivity and may be useful in the development of an appropriate screening test to predict the allergenic potential of drugs in a preclinical phase.

### INVESTIGATING THE MECHANISM OF NEVIRAPINE-INDUCED SKIN LESIONS IN THE FEMALE BROWN NORWAY RAT.

M. Popovic, J. M. Shenton and J. P. Uetrecht. *Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada.*

Nevirapine, a non-nucleoside reverse transcriptase inhibitor, often results in a severe idiosyncratic rash in patients. We previously found that nevirapine can cause a skin rash in Brown Norway (BN) female rats. The skin rash is immune-mediated because sensitivity can be transferred from a sensitized animal to a naïve animal with spleen cells. We set out to further characterize this novel animal model. In studies addressing the role of various leukocytes, we treated BN female rats for 5, 8 or 22 days. After primary exposure, followed by a month of a drug-free period, several rats were re-exposed to nevirapine for either 1 or 9 days. Upon completion of each treatment period, we used flow cytometry analysis to determine the change in cell populations present in the rat spleens, auricular and mesenteric lymph nodes (ALN, MLNs). Numbers of CD4/T cells decreased in the spleen, ALNs and MLNs, while CD8/T cell numbers increased in the ALNs and MLNs on primary and in the spleen on the secondary exposure. Activated T cells, B cells and macrophages were observed in the spleen, MLNs and ALNs. B cells and macrophages also expressed MHC II, CD80 and CD86 surface receptors. Low dose treatment for 2 weeks or co-treatment with tacrolimus led to tolerance to a dose that would otherwise lead to a rash. We suspected that this was immune tolerance, but both treatments also led to lower concentrations of nevirapine so it could be metabolic tolerance. However, when the tacrolimus co-treated rats were exposed

to aminobenzotriazole, a known P450 inhibitor, drug plasma levels were higher than previously observed in the sick animals, without making rats sick. This indicated the potential immune nature of tolerance, which when further investigated appeared to be long term, as final rechallenge of animals with nevirapine for 2 weeks, resulted in only 1 out of 6 animals developing the skin rash. These studies further characterize the mechanism of nevirapine-induced skin rash. (This research was supported by a grant from the Canadian Institutes of Health Research).

Current evidence suggests that drug-induced liver injury is often caused by an allergic response (drug-induced allergic hepatitis, DIAH) induced by hepatic drug-protein adducts. The relatively low incidence of these reactions has led us to hypothesize that tolerogenic mechanisms prevent DIAH from occurring in most people. Here we present evidence for the existence of one of these regulatory pathways. When wild type and highly susceptible IL-4/-IL-10/- mice were treated with 300 mg/kg or 80 mg/kg of APAP, respectively, liver injury was concomitant with an influx of lymphocytes, macrophages, and granulocytes. Histological and flow cytometric analyses of the lymphoid organs (thymus, spleen, and lymph nodes) revealed that APAP treatment induced lymphocytolysis in both the T- and B-cell zone areas that was attributed in part to apoptosis. No signs of lymphocytolysis were apparent in the absence of significant hepatotoxicity. The decrease in cells in the lymphoid organs was associated with an increase of mononuclear cells infiltrating the liver. Following APAP treatment, the levels of IL-2, TGF-beta, IL-12, and IL-6 mRNA were decreased in liver mononuclear cells, suggesting that the infiltrating cells may not be capable of mounting an immune response. These findings suggest that the widespread lymphocytolysis following a hepatotoxic dose of APAP may inhibit an adaptive immune response to APAP adducts, thereby accounting for the lack of APAP-induced hypersensitivity reactions in most patients.

### ANTIBODIES AGAINST CYP2E1 AFTER EXPOSURE TO 1, 1, 1-TRIFLUOROETHANE AND 1, 1, 1, 2-TETRAFLUOROETHANE.

S. Gunnare<sup>1</sup>, M. Vidali<sup>2</sup>, E. Albano<sup>2</sup> and G. Johansson<sup>1</sup>. <sup>1</sup>Work Environment Toxicology, Karolinska Institutet, Stockholm, Sweden and <sup>2</sup>Department of Medical Sciences, University of Piedmont, Novara, Italy.

Hydrofluorocarbons (HFC) are used as substitutes for the ozone depleting chlorofluorocarbons, e.g. for refrigeration. Associations between high exposure to refrigerants and pain in joints and influenza-like symptoms have been shown for refrigeration mechanics. These symptoms may be signs of autoimmune reactions. Exposure to similar substances (e.g. trichloroethylene, vinyl chloride and the anaesthetic halothane) has previously been associated with autoimmune diseases. The HFCs are metabolised by Cytochrome P450 2E1 (CYP2E1). Our hypothesis is that trifluoroacetaldehyde formed during metabolism binds to CYP2E1. If trifluoroacetyl-CYP2E1 is seen as non-self, antibodies against the adduct and/or against CYP2E1 may be produced. Antibodies against CYP2E1 have been found in humans accidentally exposed to hydrochlorofluorocarbons, a group of substances similar to the HFCs. The aim of this pilot study was to determine if experimental and/or occupational exposure to HFCs generates measurable increases in antiCYP2E1 titres. Healthy, male refrigeration mechanics were exposed to 500 ppm 1, 1, 1-trifluoroethane (n=9) and 1, 1, 1, 2-tetrafluoroethane (n=10) at two different occasions in an exposure chamber. Plasma sampled 22 hours post exposure was screened for antibodies against CYP2E1 with enzyme-linked immunosorbent assay. The titres were compared to titres from an unexposed group of controls (n=10). The study was approved by the Regional Ethical Committee at Karolinska Institutet. There was no difference in antibody level between the exposed subjects and the unexposed controls. However, since only healthy subjects were allowed to participate, sensitive individuals may have been excluded from the study. Also, the experimental and occupational exposure levels may have been too low to generate measurable autoimmune reactions. In conclusion, antibodies against CYP2E1 could not be detected in healthy refrigeration mechanics experimentally and occupationally exposed to HFCs.

## 907

### POTENTIAL AUTOIMMUNITY OF RECOMBINANT MOUSE IL-2 AS A CANCER THERAPEUTIC AGENT IN TUMOR-BEARING BALB/C MICE.

H. Kim, Y. Cho, J. H. Eom, J. Gil, J. Lee and K. Park. *Toxicology, National Institute for Toxicological Research, Seoul, South Korea. Sponsor: Y. Heo.*

Recombinant interleukin-2 (IL-2) has been developed to augment the immune response against cancer since IL-2 not only stimulates T lymphocytes but also enhances natural killer (NK) cell activity. In order to evaluate the immunological

safety of recombinant mouse IL-2 (rmIL-2) in cancer therapy, renal cell carcinoma was established in the flank by s.c. injection of renca cell line. Tumor-bearing BALB/c mice were treated i.p. injections with  $2 \times 10^5$  IU rmIL-2. Even though the tumor size was diminished, there were not significant recovery of body and relative lymphoid organ weights including thymic atrophy in rmIL-2 immunotherapy. On the one hand, emergence of autoantibodies (ANA, anti-dsDNA, and anti-histone) in blood was measured after rmIL-2 treatment. The results showed that the levels of ANA and anti-dsDNA did not significantly changed, but the level of anti-histone was increased significantly owing to rmIL-2 therapy. Distribution ratios of T cell subsets in thymus were analysed using flow cytometry. Without regard to dosage of rmIL-2, the ratio of CD3+CD4-CD8- T cells was increased in accordance with survival of solid tumor but that of CD4+CD8+ T cells was decreased dramatically. There was no effect in case of therapy with recombinant human IL-2 in tumor-bearing BALB/c mice model. These results indicate rmIL-2 immunotherapy is to induce the autoimmune potential, and the anti-histone measurement as a biomarker of autoimmunity is useful in cancer immunotherapy.

## 908

### SILICA FAILS TO INDUCE FIBROSIS IN SCAVENGER RECEPTOR DEFICIENT MICE.

C. A. Beamer and A. Holian. *Center for Environmental Health Sciences, University of Montana, Missoula, MT.*

The role of the class A scavenger receptor (SR-A) has been well studied with regards to recognition and internalization of various environmental particles; however, its link to the downstream events of inflammation and fibrosis in the lung are not well understood. In the current study, SR-A-deficient mice were used to investigate the role of SR-A on the development of inflammation and fibrosis in the murine lung *in vivo*. Consistent with current models, histopathology from 129Sv wild-type mice exposed to silica revealed typical focal lesions, interstitial thickening with increased connective tissue matrix, and cell infiltrate into air space. In contrast, SR-A deficient mice exhibited little to no deposition of collagen, yet demonstrated enhanced accumulation of inflammatory cells. This increase in inflammatory cells in SR-A -/- lungs was determined to be largely composed of neutrophils. Results also demonstrated that wild-type and SR-A -/- AM possess the ability to recognize and uptake crystalline silica, although this response is attenuated in SR-A -/- AM. These results suggest that SR-A plays a role in the initiating events of silicosis, and is important to the resolution of inflammatory cells. Furthermore, because SR-A deficient mice fail to develop fibrosis following 6 months silica exposure, these results indicate that the function of SR-A is critical to the development of fibrosis.

## 909

### COMPARISON OF CHLORDECON AND ESTROGEN EFFECTS ON PHENOTYPIC MARKERS ON IMMUNOCYTES.

F. Wang<sup>1,2</sup>, S. M. Roberts<sup>1,3</sup> and E. S. Sobel<sup>2</sup>. <sup>1</sup>*Depts of Pharmacology and Therapeutics, University of Florida, Gainesville, FL*, <sup>2</sup>*College of Medicine, University of Florida, Gainesville, FL* and <sup>3</sup>*Physiological Sciences, University of Florida, Gainesville, FL*.

Both chlordecone and estrogen accelerate the development of systemic lupus erythematosus (SLE) in female (NZBxNZW)F1 (NZB/WF1) mice. It has been hypothesized that chlordecone and estrogen influence autoimmunity in NZB/WF1 mice through a common mode of action; that is, that chlordecone acts as an estrogen mimic. Doses of chlordecone that shorten the time to onset of SLE are generally too low to produce significant estrogenic effects as assessed through classical uterine hypertrophy measurements. However, low doses of chlordecone might nonetheless produce estrogen-like effects on immunocytes. This was tested in experiments in which ovariectomized NZB/WF1 mice were treated with 17-beta estradiol (0.025mg/kg/day) or chlordecone (0.5 and 2.5mg/kg/day) using sustained-release pellets implanted subcutaneously. Control mice received pellets with matrix only. Flow cytometric analysis after five weeks of treatment found that estrogen treatment resulted in an altered distribution of B cell subsets, with a decrease in immature transitional CD21loCD24hi T1 and an increase in CD21hiCD24lo marginal zone B cells ( $p < 0.01$  by ANOVA). Chlordecone treatment had little effect on B cell subsets. Estrogen increased the expression of the germinal center marker CXCR5 ( $p < 0.05$ ) on B cells and the percent of mature splenic CD19-CD138+ plasma cells ( $p < 0.01$ ), a trend seen only weakly with chlordecone treatment. Also, estrogen treatment decreased CD4 and CD8 T-cell populations ( $p < 0.01$ ) and CD11b+ dendritic cells ( $p < 0.05$ ), while chlordecone treatment caused a moderate dose-dependent decrease of T cells, but had no effect on dendritic cells. On the other hand, chlordecone, but not estrogen, increased the level of MHC class II expression on splenic B cells ( $p < 0.05$ ). These results indicate that low doses of chlordecone, relevant to effects on autoimmunity, affect lymphocyte populations, but the pattern of changes is different from that produced by estrogen. Supported by ES07375 from NIH.

## 910

### ADAPTATION OF THE SYSTEMIC LUPUS ERYTHREMOTOSUS PRONE (NZB X NZW)F1 MOUSE STRAIN FOR AUTOIMMUNE TOXICOLOGY EVALUATION.

S. P. Keegan, K. L. Nadwodny, B. A. Speal, D. J. Herzyk and J. M. Soos. *Safety Assessment, GlaxoSmithKline, King of Prussia, PA.*

Evaluation of unintended immunostimulation that can lead to autoimmune disease is very challenging to address in both preclinical and clinical studies. In absence of established methods for immunotoxicology evaluation, the systemic lupus erythematosus (SLE) model in (NZBxNZW)F1 mice was used for adaptation of a model of autoimmunity. (NZBxNZW)F1 mice are genetically prone to spontaneously develop autoimmune disease similar to SLE in humans and disease in this strain is characterized by development of anti-DNA antibodies, proteinuria and glomerulonephritis. We monitored female (NZBxNZW)F1 mice from 18 to 36 weeks of age for single stranded and double stranded DNA antibodies at bi-weekly intervals, proteinuria at weekly intervals and glomerulonephritis at 20, 28, 32 and 36 weeks of age. Detection of specific levels of anti-DNA antibodies and proteinuria indicated end stage development of disease in this study. The correlation of these two primary endpoints enabled us to adapt this model for earlier disease detection and enhanced ethical treatment of animals. In a separate study comparing SLE prone (NZBxNZW)F1 mice with the SLE resistant strains BALB/c and CD-1, female mice were immunized with keyhole limpet hemocyanin (KLH) in Complete Freund's Adjuvant at 8, 16 and 24 weeks of age. Ten days post immunization *ex vivo* splenocyte proliferation and cytokine production in response to KLH was evaluated. (NZBxNZW)F1 exhibited overall reduced antigen specific proliferation compared to BALB/c and CD-1. (NZBxNZW)F1 also produced less IFN- $\gamma$  and more IL-10 and KC at young age that did not increase over time like that observed for the other two strains tested. The adaptation of this SLE model and identification of a distinct profile of immune responses in (NZBxNZW) F1 mice can provide a new approach to autoimmune toxicology evaluation of immunomodulatory drugs in development.

## 911

### ASBESTOS-INDUCED AUTOIMMUNITY IN C57BL/6 MICE.

J. C. Pfau, J. Sentissi, R. Thompson and C. MacKenzie. *Ctr for Environ Health Sciences/Biomed Pharmacology Sciences, University of Montana, Missoula, MT.*

Environmental impacts on autoimmunity have significant public health implications. Epidemiological studies have shown associations between exposure to airborne silicates, such as crystalline silica or asbestos, and autoimmunity, but the etiology remains unclear. A mouse model is needed to explore mechanisms of asbestos-associated autoimmunity. In order to determine whether asbestos could lead to autoimmune responses in mice, female C57Bl/6 mice were instilled intratracheally with tremolite asbestos, wollastonite, or saline. Serum samples were collected via saphenous vein bleeds and urine was checked for protein bi-weekly for 7 months, at which time tissue and serum samples were taken following sacrifice. Tremolite, but neither wollastonite nor saline, led to cellular infiltrations and fibrosis, as measured by histology and Lucifer yellow staining. By 26 weeks, the tremolite-instilled animals had a significantly higher frequency of positive anti-nuclear antibody (ANA) tests compared to wollastonite and saline groups. Of those positive ANAs, most showed homogeneous or combined homogeneous/specckled patterns on HEp-2 cells, and tested positive for antibodies to dsDNA by ELISA. Although no glomerulonephritis was apparent according to proteinuria tests, immune complex deposition was demonstrated in the kidneys of tremolite-instilled mice. There was an overall decrease in the mean IgG serum concentration in tremolite-instilled mice. Flow cytometry demonstrated a significant decrease in the percentage of CD25 T suppressor cells and an increase in the percentage of B1a B cells in the cervical lymph nodes of the tremolite-instilled mice, consistent with changes seen in autoimmune-prone mice. These data demonstrate that tremolite asbestos led to lung fibrosis as well as immunologic changes consistent with the development of autoimmunity. This study demonstrates a murine model of asbestos-induced autoimmunity, which can be used to elucidate the mechanisms leading to these responses. This work was supported by CDC Grant #CCR822091-01 and COBRE Grant #RR-017670.

## 912

### IMMUNOTOXICITY OF DICHLOROACETYL CHLORIDE AND DICHLOROACETIC ANHYDRIDE IN FEMALE MRL +/- MICE.

G. Ansari, P. Cai, M. F. Khan and B. S. Kaphalia. *pathology, UTMB, Galveston, TX.*

Dichloroacetyl chloride (DCAC), one of the trichloroethene metabolites, is known to induce/accelerate autoimmune response in female autoimmune-prone MRL +/- mice. DCAC is proposed to acylate proteins resulting in formation of neoantigens that can lead to an autoimmune response. Similar acylation of proteins is expected

to occur by dichloroacetic anhydride (DCAA). Therefore, to evaluate the mechanism of neoantigen formation, we compared the immunotoxicity of DCAC and DCAA. Female MRL  $+/+$  mice (5 weeks old) were intraperitoneally treated (twice/week) with 0.2 mmol/kg of DCAC or DCAA in corn oil for 6 weeks and overall immune response was evaluated in serum samples. Total IgG, its isotypes and IgM were quantified by using radial immunodiffusion, IgE was determined by ESLIA. Total IgG and IgG1 were increased in DCAC (IgG 177% and IgG1 272%) and DCAA-treated (IgG 124% and IgG1 142%) mice as compared to controls. No changes were observed in IgG2a, IgG2b, and IgG3 levels in all groups. The IgM in DCAC and DCAA groups were decreased as compared to controls. IgE was significantly increased in DCAC-treated (200%) group as compared to controls and DCAA group. Our study shows that DCAC and DCAA elicit similar immune responses, DCAC being more pronounced apparently due to its greater acylating potential.

**913**

#### IMMUNOTOXICITY OF OLEIC ACID ANILIDE AND ITS HYDROLYSIS PRODUCTS IN FEMALE MRL $+/+$ MICE.

P. Cai, M. F. Khan, B. S. Kaphalia and G. S. Ansari. *Pathology, UTMB, Galveston, TX.*

An epidemic of a multi-systemic disease, known as the toxic oil syndrome (TOS), was caused by edible oil denatured with 2% aniline. Oleic acid anilide (OAA) has been suggested as one of the most likely etiologic agents responsible for TOS based upon their presence in TOS-related oils. The aim of this study was to evaluate the immune response of OAA and its hydrolysis products (aniline and oleic acid). We treated female autoimmune-prone MRL  $+/+$  mice with equimolar doses of OAA, aniline or oleic acid (0.8mmol/kg), i.p., twice a week for 6 weeks. The immunoglobulins IgE, IgG and its isotypes IgG1, IgG2a, IgG2b, and IgG3 were analyzed in the serum. Also, serum levels of cytokines including G-CSF, MIP-1a, IL-4, IL-6, IL-12 P40/P70, IL-13 were analyzed by cytokine arrays and cytokine protein multiplex immunoassay. Exposure to OAA and oleic acid caused significant increases in IgG, IgG1, IgG2a and IgG2b levels as compared to aniline and control groups, whereas IgG3 value increased only in OAA-treated mice. The IgE levels in OAA (637 ng/ml), aniline (568 ng/ml) and oleic acid (473 ng/ml) groups were significantly higher than the controls (219 ng/ml). Among cytokines, only G-CSF increased in aniline (110 pg/ml) and OAA (84 pg/ml) treated groups vs. control (57 pg/ml), while decreased in oleic acid (24 pg/ml) treated group. These studies provide a complex picture, which supports the contention that OAA and/or its hydrolysis products cause perturbation in the immune response and this could be one of the potential mechanisms leading to autoimmune-type of symptoms observed in TOS-related cases.

#### A RESPIRATORY SAFETY PHARMACOLOGY ASSESSMENT OF HYDROCODONE BITARTRATE AND NALTREXONE HYDROCHLORIDE.

K. Hew<sup>1</sup>, S. Mason<sup>2</sup> and H. Penton<sup>2</sup>. <sup>1</sup>*Safety Assessment, Purdue Pharmacology L.P., Ardsley, NY* and <sup>2</sup>*Safety Pharmacology, CTBR Bio-Research Inc., Senneville, NY.*

The effects of hydrocodone bitartrate and hydrocodone bitartrate + naltrexone hydrochloride on the respiratory function of the albino rat were investigated in this study. Male Cr:CD®(SD)IGS BR VAF/Plus® rats were administered a single oral gavage dose of hydrocodone bitartrate at 0, 125, 250, 500, 600 or 1200 mg/kg body weight, or a combination of hydrocodone bitartrate/naltrexone hydrochloride at 125/1.5625, 250/3.125, 500/6.25, 600/7.5 or 1200/15 mg/kg body weight, at a fixed ratio for each component of 80:1. Following dose administration, surviving animals were placed in 'head out' plethysmographs to for assessment of respiratory parameters. Administration of hydrocodone bitartrate alone resulted in 11 deaths at doses ranging from 125 to 1200 mg/kg. When hydrocodone bitartrate was administered in combination with naltrexone hydrochloride, there were only 2 compound-related deaths at the high dose of 1200/15 mg/kg, indicating that naltrexone hydrochloride had an antagonistic effect on the action of hydrocodone bitartrate. Oral administration of hydrocodone bitartrate alone also resulted in a dose-related decrease in respiratory rate in these rats at  $\geq 125$  mg/kg beginning at 15 minutes post-dose. This change was similar to the respiratory depressant effect seen following administration of morphine in an earlier safety pharmacology study. When hydrocodone bitartrate was administered concurrently with naltrexone hydrochloride, the effect on respiratory rate was less pronounced and of a shorter duration than that seen in the hydrocodone-treated animals. These results show that naltrexone hydrochloride has a protective effect on the action of hydrocodone bitartrate. The presence of naltrexone hydrochloride increased the viability and alleviated the respiratory depression effect of hydrocodone bitartrate in the hydrocodone-treated animals, indicating that the combination of hydrocodone bitartrate and naltrexone hydrochloride ameliorate the toxic effects of hydrocodone bitartrate.

#### PARTICLE OVERLOAD IN RAT LUNG FOLLOWING INHALATION TO A POORLY SOLUBLE COMPOUND.

S. Holt<sup>1</sup>, M. Pino<sup>1</sup>, N. Barlow<sup>1</sup>, E. Orton<sup>2</sup> and T. M. Monticello<sup>1</sup>. <sup>1</sup>*Drug Safety & Evaluation, Sanofi-Aventis, Bridgewater, NJ* and <sup>2</sup>*GPD/Pharmaceutical Sciences, Sanofi-Aventis, Bridgewater, NJ.*

Inhalation of poorly soluble particles induces a range of toxicological responses in the lung as a result of particle overload, which is reported as a rodent specific event. Cmpd AVE, an interleukin-4 expression inhibitor, is a highly insoluble compound being evaluated for the treatment of asthma. As part of a preclinical safety program, a 13-week inhalation toxicity study was conducted in rats using a dry powder formulation of micronized crystalline Cmpd AVE (monohydrate) blended in lactose. Rats were exposed to ambient air (air control), lactose monohydrate powder (vehicle control) or Cmpd AVE in lactose at 0.5, 5 or 50 mg/kg/day by aerosol via nose-only inhalation exposure for 4 hours/day for 13 weeks (high dose equates to a 70 mg/g lung burden). Indices of toxicity, including histopathology endpoints, were evaluated at the end of the 13-week exposure period. Treatment-related microscopic changes were observed in the lungs and tracheobronchial and mediastinal lymph nodes at 5 and 50 mg/kg/day, and were consistent with particle overload. Microscopic lung changes consisted of increased numbers of hypertrophied alveolar macrophages containing birefringent crystalline material (interpreted as Cmpd AVE) and hyperplasia/hypertrophy of alveolar type II epithelial cells; the amount of accumulated material and associated tissue reaction was dose-related. Macrophage aggregates containing crystalline material were also present in the regional lymph nodes at 50 mg/kg/day. Raman microprobe imaging confirmed the macrophage material as Cmpd AVE. In a 14-day rat inhalation study conducted at similar doses, crystalline material in the respiratory tract was not observed. Results of the 13-week study indicate that prolonged inhalation exposure to a poorly soluble compound can induce particle overload in the rat. The human safety relevance of this rat lung change is not known.

#### ALTERED SUSCEPTIBILITY TO 1-NITRONAPHTHALENE OF RAT NASAL MUCOSA AFTER CHRONIC OZONE EXPOSURE.

M. G. Lee<sup>1</sup>, A. M. Wheelock<sup>2</sup>, M. V. Fanucchi<sup>1</sup>, A. R. Buckpitt<sup>2</sup> and C. G. Plopper<sup>1</sup>. <sup>1</sup>*VM:APC, UC Davis, Davis, CA* and <sup>2</sup>*VM:MB, UC Davis, Davis, CA.*

1-Nitronaphthalene (1-NN) and ozone are ubiquitous, cytotoxic air pollutants. Increased rates of photochemical formation of nitroarenes from naphthalene have been observed in irradiated air as the concentration of ozone increases. Previous studies have shown that 1-NN toxicity in the lung is considerably higher in the ozone-treated rats compared to corresponding filtered air-treated rats. The present study was designed 1) to evaluate acute injury from 1-NN in the nasal mucosa of rats, and 2) to determine whether previous long-term exposure to ozone would alter the susceptibility of the nasal mucosa to 1-NN. Adult male Sprague-Dawley rats were exposed to filtered air or 0.8 ppm ozone for 8 hour per day for 90 days (night time exposure). On the 91st day, rats were treated with 0, 12.5, or 50 mg/kg 1-NN by intraperitoneal injection. Following filtered air, 1-NN treatment resulted in injury in the nasal mucosa of rats at the 50 mg/kg dose. In general, 1-NN injury was not cell-type specific. The nasal transitional epithelium (NTE) sustained the most inflammation and injury. Goblet cells in respiratory epithelium were unaltered. In ozone-exposed, corn oil-treated rats had prominent, wide-spread mucous cell metaplasia and an occasional hyperplasia occurred only in the NTE. In ozone-exposed rats, the NTE showed less injury from 1-NN. Chronic ozone exposure did not appear to alter susceptibility to 1-NN-induced injury in the nasal regions other than the NTE. We conclude that the nasal mucosa of rats is a target of systemic 1-NN, and previous ozone exposure markedly lessens the severity of injury in the NTE where the histologic changes induced by ozone-exposure preexist. This study suggests that mucous cell metaplasia may be an adaptive/protective cellular response which is capable of protecting the nasal mucosa from toxic insults. #### QUANTITATION OF AIRWAY SPECIFIC GENE EXPRESSION OF ENDOTHELIN-1 AND IT'S RECEPTORS DURING NAPHTHALENE INJURY AND REPAIR IN THE ADULT MOUSE LUNG.

G. L. Baker, K. L. Sutherland, C. D. Brown, C. G. Plopper and L. S. Van Winkle. *VM: APC, UC Davis, Davis, CA.*

The potential for airway repair following acute injury may be a key factor in the initiation or exacerbation of a number of xenobiotic induced lung diseases. Endothelins have important regulatory roles in normal tissues and diseases as potent vasoconstrictors / bronchoconstrictors and are mitogens for epithelial cells and other lung cells. Previous work by our laboratory has demonstrated that ET-1 protein is elevated during the proliferative phase of bronchiolar injury and repair and

that addition of ET-1 to mouse bronchioles *in vitro* stimulates epithelial cell proliferation. In this study we used a well-defined model of bronchiolar injury and repair in which acute Clara cell injury is produced in mice by the bioactivated toxicant, naphthalene. Measurements of airway specific gene expression of endothelin-1 and the Type A or B endothelin receptors (ET-1, ETR-A and ETR-B) were determined using real time RT-PCR at 6 hrs, 1, 2, 4, 7, 14, and 21 days following naphthalene injury. We found airway RNA expression for ET-1, ETR-A and ETR-B remained unchanged one day following treatment. Two days following treatment airway RNA expression decreased two to five fold and did not return to control levels by 21 days after treatment. Previous studies with this model have demonstrated that two days following treatment is when maximal airway epithelial cell proliferation occurs. Therefore, it is likely that these expression changes represent part of the mechanism involved in attenuating the cell proliferation that occurs following airway injury. It is particularly interesting is that expression levels of ET-1, ETR-A and ETR-B do not return to control levels 21 days following injury, as airway epithelial repair is complete 14 and 21 days following injury. How these sustained expression decreases will impact future injury and repair is unknown. Supported by NIEHS 04311, 05707 and by California TRDRP grants 6KT-0306, 11RT-0258.

PROTEOMIC CHARACTERIZATION OF BRONCHOALVEOLAR LAVAGE FLUID (BALF), LUNG, AND SERUM IN A MOUSE EMPHYSEMA MODEL INDUCED BY ELASTASE.

J. N. Adkins<sup>1</sup>, R. C. Barry<sup>1</sup>, M. E. Monroe<sup>1</sup>, R. D. Smith<sup>1</sup>, K. Lee<sup>2</sup> and J. G. Pounds<sup>1</sup>. <sup>1</sup>Battelle, Pacific Northwest National Laboratory, Richland, WA and <sup>2</sup>Battelle, Toxicology Northwest Division, Richland, WA.

The purpose of this study was to characterize gene expression changes in the lung associated with elastase-induced emphysema in mice. Male C57BL/6 mice were administered porcine pancreatic elastase (0 or 37.5 U/Kg BW) by intra-tracheal instillation. Groups of control or treated mice (n = 6) were sacrificed at one or four weeks after dosing. Anatomical pathology and lung morphometry were used to evaluate the induction of emphysema. BALF, lung tissue, and serum were digested with trypsin. BALF was analyzed by cLC-FTICR-MS using the Accurate Mass and Time tag strategy; lung tissue and serum were digested and analyzed by cLC-MS/MS. The group's mean ion current for each BALF protein was used as a measure of abundance for each of the 491 proteins identified. 106 proteins were up-regulated by elastase treatment after 4 wk; 28 of these were up- and 5 down-regulated at 1 wk. 28 proteins were down regulated after 4 wk; 1 of these was up- and 6 down-regulated at 1 wk. The content of albumin in BALF was not altered, suggesting that the blood-air barrier was not significantly damaged by the elastase treatment. Proteins consistently up regulated include meltrin alpha (ADAM 12), which interacts with growth factors; surfactant pulmonary associate protein; glutathione S-transferase mu; glutathione peroxidase 1; and apolipoprotein A. Proteins down-regulated included glutathione S-transferase alpha 3; peroxiredoxin 5; and several members of the alcohol and aldehyde dehydrogenase families. 17 proteins identified as hypothetical from RIKEN cDNA were differentially abundant at 1 wk, but not 4 wk. These proteins represent a knowledge gap for understanding pulmonary function. Further analysis of this dataset, and integration with pulmonary gene profiles and metabolomic datasets from the same study, will lead to a better understanding of the elastase-induced emphysema model in mice. CHARACTERIZATION OF ELASTASE-INDUCED EMPHYSEMA IN MOUSE LUNG PER HISTOPATHOLOGY, MORPHOMETRY, AND BRONCHOALVEOLAR LAVAGE (BAL) MEASUREMENTS.

K. M. Lee<sup>1</sup>, Q. Meng<sup>1</sup>, R. A. Renne<sup>1</sup>, K. M. Gideon<sup>1</sup>, S. J. Harbo<sup>1</sup>, J. T. Pierce<sup>1</sup>, L. A. Wisse<sup>1</sup> and J. G. Pounds<sup>2</sup>. <sup>1</sup>Battelle Toxicology NW, Richland, WA and <sup>2</sup>Pacific Northwest National Laboratories, Richland, WA.

An intra-tracheal instillation of elastase induces specific lung damage, mimicking pulmonary emphysema. However the induction regimen and characterization criteria vary among investigators, making common usage of the model difficult. The objective of this project was to establish definitive pulmonary emphysema in mice as a prototype animal model. Young C57BL/6 mice were subjected to intra-tracheal instillation of porcine pancreatic elastase (37.5 U/kg BW) or saline at ~0.07mL (6 mice/dose/timepoint). A group of mice was sacrificed at 1 or 4 wk postdosing and BAL was performed on isolated lung with PBS. The supernatant from the first two washes (BALF) were analyzed for LDH, NAG, protein, and cytokines. Cell pellets from all 6 washes were used for cytological evaluation. Another group was necropsied at 1 and 4 wk postdosing and lungs were preserved and processed for light microscopy. Lung morphometry was performed using Image Pro® Plus. There were no mortality or body weight effects throughout 4 weeks. Mild or moderate alveolar emphysema was present in all dosed mice by 1 week. Multifocal lesions were pre-

dominantly subpleural and most frequently involved the diaphragmatic lobe. This was accompanied by significant increase in mean linear intercept and lung volume. A mixed inflammatory cell infiltrate (macrophages, granulocytes, and lymphocytes) was present surrounding or adjacent to areas of emphysema. Alveolar emphysema was present at 4 weeks but less severe than at 1 week postdosing. BAL macrophage counts were significantly elevated in the dosed mice at both times. BALF NAG concentration increased significantly in the dosed group at 1 week, while BALF IL1 $\beta$  and IFN- $\gamma$  concentrations were significantly decreased at 4 weeks. In summary, the current elastase regimen produced consistent, reliable and quantifiable lung damage in mice that was sustained up to 4 weeks postdosing without notable in-life toxicity. THE USE OF LUNG MECHANICS FOR THE PHENOTYPING OF LUNG RESPONSES TO CIGARETTE SMOKE EXPOSURE IN MICE.

M. G. Cosio<sup>2</sup> and T. F. Schueller<sup>1</sup>. <sup>1</sup>SCIREQ Inc., Montreal, QC, Canada and <sup>2</sup>Meakins-Christie Labs, McGill University, Montreal, QC, Canada. Sponsor: N. Sponsor.

Cigarette smoke exposure in mice produces airspace enlargement resembling emphysema, and the mouse has become an acceptable model for the study of the human disease. Genetic predisposition is an important determinant for the development of emphysema in humans, thus we reasoned that the availability of resistant and susceptible mice strains for the development of emphysema would be important for the study of genetic determinants in mice which could then apply to the human disease. We exposed 7 strains of mice, 6 animals and 6 controls per strain, to 2 cigarettes a day utilizing a nose only exposure apparatus during 6 months. At the end of the exposure all animals underwent lung mechanics measurements (elastance and P-V curves) while alive and anesthetized utilizing the flexiVent (SCIREQ Inc., Montreal, Canada). Animals were then sacrificed, the lungs dissected and prepared for histology. Based in the results of the mean linear intercept (Lm) and the lung mechanics we identified 3 groups of susceptibility for the development of emphysema: NZW- resistant, no Lm increase and no changes in elastance; C57BL6, A/J, SJL- mildly susceptible, Lm increase but no changes in elastance; Pallid and AKR-susceptible, increased Lm and decrease in elastance. BAL/c strain developed marked increase in elastance and decreases in Lm found to be secondary to diffuse lung fibrosis. In conclusion lung mechanics measurements in mice are essential for a proper phenotyping of emphysema. Based in these findings we have identified a resistant strain, NZW and a susceptible AKR for the development of emphysema. Furthermore using lung mechanics we have identified a strain which could become a model for lung fibrosis.

EVALUATION OF RELATIVE CONTRIBUTIONS OF VAPOR PHASE AND PARTICULAR MATTER TO THE TOTAL CYTOTOXICITY OF CIGARETTE SMOKE.

R. Meng, M. Clark, K. Hitchman and L. Wisse. Battelle, Richland, WA. Sponsor: K. Lee.

The purpose of this study was to evaluate the relative contribution of vapor phase and particular matter to the total cytotoxicity of cigarette smoke. Smoke was generated from research cigarettes 2R4F, US Burley, and Brazilian Flue cured cigarettes using an AMESA smoke generation system, diluted with clean air to achieve target wet total particulate matter (WTPM) concentration, and then directed to cell media containers placed within an incubator maintained at 37°C. Cytotoxicity of whole cigarette smoke or vapor phase was measured using the neutral red cytotoxicity assay in BALB/c 3T3 cells. Two experiments were performed for each cigarette and four doses (three cultures/dose) were used in each experiment. The exposure duration was one hour and the neutral red cytotoxicity assay was performed 24 hours after exposure. Dose-response curve fitting and LC<sub>50</sub> calculation for relative cell survival data were performed using the CalcuSyn program. Dose-related decrease in cell survival was observed in all three cigarettes for both whole smoke and vapor phase. The mean LC<sub>50</sub> for vapor phase were 39.3, 72.2, and 94.1 µg/L (WTPM), for 2R4F, Brazilian flue cured, and US Burley cigarettes, respectively. The mean LC<sub>50</sub> for whole smoke were 30.9, 58.0, and 90.7 µg/L (WTPM), for 2R4F, Brazilian flue cured, and US Burley cigarettes, respectively. Vapor phase contributed from 65 to 99% of total toxicity of cigarette smoke in the doses studied in these three cigarettes. The ratios of mean LC<sub>50</sub> for whole smoke versus vapor were 78.6, 80.3, and 96.4%, for 2R4F, Brazilian flue cured, and US Burley cigarettes, respectively. These results indicate that the neutral red cytotoxicity assay protocol used in current study is suitable to evaluate the cytotoxic effects of vapor phase or whole cigarette smoke, and vapor phase is the dominant factor in determining the cytotoxicity of cigarette smoke. ## LUNG INFLAMMATION IN RATS AFTER ACUTE EXPOSURE TO CIGARETTE SMOKE.

P. Vanschaewijck<sup>1</sup>, E. Van Miert<sup>1</sup> and B. Friedrichs<sup>2</sup>. <sup>1</sup>PHILIP MORRIS Research Laboratories boba, Leuven, Belgium and <sup>2</sup>PHILIP MORRIS Research Laboratories GmbH, Cologne, Germany. Sponsor: H. Haussmann.

We have reported (SOT, 2004) that acute exposure of rats to cigarette mainstream smoke induces changes in inflammatory mediators in bronchoalveolar lavage fluid (BALF). Here, we investigate how the changes in inflammatory mediators are reflected in changes in BALF neutrophils after acute and subchronic exposure to cigarette mainstream whole smoke (WS), gas-phase depleted particulate phase (PP), and gas phase (GP). Sprague-Dawley rats (8/group) were exposed to smoke from University of Kentucky filtered reference cigarettes. Acute exposure was 2 x 1 hour to WS and PP at concentrations of 0 (sham) to 1200  $\mu$ g total particulate matter (TPM)/l, or to equivalent concentrations for GP; subchronic exposure was 2 x 1 h/day for 35 days to WS at 500 and 750  $\mu$ g TPM/l, PP at 750  $\mu$ g TPM/l and an equivalent concentration for GP. Inflammatory mediators (IL-1 $\beta$ , CINC-1, CINC-3, MCP-1, fractalkine) and free lung cells (FLC) were quantified in BALF (flow cytometry) and respiratory parameters were measured (plethysmography). Acute exposure to WS and PP resulted in a concentration-related increase of inflammatory mediators. GP had no effect. Effects of PP were more pronounced than WS. At 1200  $\mu$ g TPM/l, FLC consisted of 16% neutrophils in the WS-group, 25% in PP and 2% in GP (sham: 2%). After subchronic exposure, neutrophils were concentration-dependently increased. At 750  $\mu$ g TPM/l, neutrophils were 20% higher after PP than after WS; GP was equal to sham. A reduction of 40% in respiratory minute volume was found during exposure to WS and GP; for PP, no reduction was seen. This indicates that PP-exposed rats took up more TPM, which causes the inflammatory changes, than rats exposed to WS. Effects after acute exposure were qualitatively the same as those observed after subchronic exposure. Acute inhalation exposure of rats may be a useful short-term *in vivo* assay for the evaluation of the inflammatory effects of cigarette smoke.

## FOCAL PROLIFERATIVE LESIONS IN A/J MOUSE LUNG FOLLOWING 5-MONTH EXPOSURE TO CIGARETTE MAINSTREAM SMOKE.

J. T. Hamm<sup>1</sup>, S. Yee<sup>1</sup>, N. Rajendran<sup>2</sup>, R. L. Morrissey<sup>3</sup> and M. Misra<sup>1</sup>. <sup>1</sup>Lorillard Tobacco Company, Greensboro, NC, <sup>2</sup>IIT Research Institute, Chicago, IL and <sup>3</sup>PAI, Chicago, IL. Sponsor: C. Smith.

Incidence and multiplicity of grossly-observed and microscopic alterations of the respiratory tract of nose-only, mainstream smoke-exposed A/J mice (50, 200 or 400 mg total particulate matter/m<sup>3</sup> from 2R4F cigarettes; 3 hr/d, 5 d/wk for 5 months) was compared with filtered air controls. Animals were necropsied at the end of exposure (5 months) or allowed to recover for an additional 4 or 7 months (9 or 12 months from initiation of exposure). Lungs were visually inspected for tumors at all necropsies and examined histopathologically at 9 and 12 months. At 5 months no tumors were recorded. At 9 months the incidence of visual tumors was similar for all groups whereas multiplicity was significantly increased in the mid-dose smoke group (0.90 versus 0.55 for controls). At 12 months, multiplicity was increased over the 9-month necropsy, but there were no dose-related trends in multiplicity or incidence. Histopathological examination of the lung revealed increased numbers of proliferative lesions and identified the presence of focal hyperplasia. At 9 months, the multiplicity of focal lung lesions was 1.4 in controls but was decreased by smoke exposure and averaged 1.0 for all smoke-exposed groups. At 9 months, the percentage of focal hyperplasia decreased with increasing smoke concentration from 62.5% to 36.4% to 16.7% for the 50, 200 and 400 mg/m<sup>3</sup> exposures respectively, compared to controls (71.4%). At 12 months the high-dose smoke exposure group had increased multiplicity of 2.3 lesions compared with 1.6 among controls and the percentage of hyperplastic lesions was similar between groups. Microscopic examination of the lung increased the number of lesions recorded and identified focal hyperplastic lesions. In addition, smoke exposure was associated with a shift from predominately focal hyperplasia in control animals to adenomas in smoke-exposed animals at the 9-month time point.

## INFLUENCE OF SUB-CHRONIC CIGARETTE SMOKE EXPOSURE ON THE PROGRESSION OF MYOCARDIAL HYPERTROPHY IN SPONTANEOUSLY HYPERTENSIVE RATS (SHR).

K. von Holt<sup>1</sup>, K. Schlueter<sup>2</sup>, S. Ruf<sup>2</sup>, K. Meurrens<sup>3</sup> and R. Schleef<sup>4</sup>. <sup>1</sup>PHILIP MORRIS Research Laboratories GmbH, Cologne, Germany, <sup>2</sup>Justus-Liebig-University, Giessen, Germany and <sup>3</sup>PHILIP MORRIS Research Laboratories boba, Leuven, Belgium. Sponsor: H. Haussmann.

In search of an experimental model for cardiac risk by smoking we exposed 8-week-old male SHR to cigarette mainstream smoke (MS) from the Kentucky Reference Cigarette 2R4F (450  $\mu$ g total particulate matter/l) or to fresh air (sham) for 30, 60,
